16. List examples of health promotion topics for older adulthood.

KEY TERMS

activity theory, 375	dementia, 380	kyphosis, 372	presbyopia, 372
adult day care, 368	disengagement theory, 375	long-term memory, 378	recent memory, 378
ageism, 365	dyspnea, 373	osteoporosis, 372	sarcopenia, 371
Alzheimer's disease (AD), 367	e-health, 376	pathologic fractures, 372	sensory memory, 378
assisted living, 367	geriatrics, 366	perception, 377	short-term memory, 378
cataracts, 372	gerontology, 366	presbycusis, 372	
continuity theory, 375	hypothermia, 379		

INTRODUCTION

According to a United Nations report, the current world population is 7.2 billion with a projected increase of 1 billion in 12 years, with the ultimate population of 9.6 billion by the year 2050 (UN News Centre, 2013). The world's population of people ages 65 and older is projected to increase from 524 million in 2010 to 1.5 billion in 2050. In the United States, the population ages 65 and older will more than double, from 43.1 million in 2012 to 92 million in 2060 (U.S. Census Bureau, 2012). This increase has been termed the "graying of America." Because the population will be older and greater in number in the coming years, overall U.S. health care costs are projected to increase 25% by 2030 (Tabloski, 2014, p. 12). The magazine *U.S. News and World Report* (2012) describes the American population ages 65 and older to be soaring. The states with the greatest population of older Americans are Florida, West Virginia, Maine, Pennsylvania, and Iowa.

CHARACTERISTICS OF OLDER ADULTS IN THE UNITED STATES

Older adults represent an increasingly diverse population in the United States. A review of the major characteristics of the older population includes demographic, socioeconomic, ethnicity, and health characteristics.

Demographics

At one time, all individuals over the age of 65 were considered old. With advancements in disease control, living conditions, and health technology, people are living longer. A 65-year-old American woman may expect to live another 19.2 years, and a 65-year-old American man may expect to reach the age of 82.8 years (U.S. Department of Health and Human Services [USDHHS], 2012). People 85 years and older are the fastest growing of all age groups in the country, numbering 5.5 million in 2010, but projected to reach 19 million by the year 2050 (Federal Interagency Forum on Aging-Related Statistics [FIFAS], 2012). Older adults are as heterogeneous as any other age group that spans 40 years or more. The categories of older adults established by Eliopoulos (2014) include the young-old, ages 60 to 74 years; the old-old, ages 75 to 100 years; and centenarians, older than 100 years. Each of these groups has a distinct set of interests and health care needs.

Baby boomers is a term used to describe the people born from 1946 to 1964 that represented a large increase in the U.S. birthrate. Starting in 2011 (and through 2030) they began to enter their senior years with better education, higher household incomes, and very active lifestyles compared to previous generations of seniors. They tend to be informed consumers of health care and may research information on the Internet prior to seeing a health care provider (Eliopoulos, 2014; Miller, 2012) (Figure 23-1 ■).

Figure 23–1 ■ Older adults are the fastest growing group of computer users.

Socioeconomic

Socioeconomic characteristics such as gender, marital status, education, income, and living arrangements vary among the young-old and old-old groups (Miller, 2012). The 2010 census data revealed that 22 million women are 65 years or older. The male population is slightly lower at 17 million (U.S. Census Bureau, 2011). Women outnumber men because they have a longer life expectancy than men. In addition, women are more likely than men to be widowed, and older men have higher remarriage rates.

The level of education can affect the socioeconomic status of the older adult. Higher education is usually associated with higher incomes. According to Miller (2012), educational levels for older adults are gradually increasing as indicated by the increasing percentage rates of people 65 years and older who have completed high school. However, there is significant variation among racial and ethnic groups. In previous decades, older adults were the most economically disadvantaged group. However, the current trend is that older adults are doing better economically. Older women over the age of 75 years are more economically disadvantaged than men of the same age. Widowed women and those living alone are the largest group of elderly living in poverty (Miller, 2012, p. 12).

Living arrangements of older adults are linked not only to income, but also to health status. Most live in a variety of community settings with only 4% living in nursing homes. Older men are more likely to live with a spouse as compared to older women who are more likely to live alone. Living arrangements vary by race and ethnicity. Asian men and women are more likely to live with relatives other than a spouse. White women, Black women, and Black men are more likely to live alone (FIFAS, 2012).

Ethnicity

The growing population of older adults consists primarily of increasing numbers of minorities. When projecting to 2050, the higher proportion of the older White population will continue. However, the non-White older population is expected to increase with older Hispanics being the fastest growing subpopulation group. It is estimated that the older Hispanic population will grow from 3 million in 2010 to 17.5 million in 2050 (FIFAS, 2012). These numbers emphasize the importance of nurses being culturally sensitive and competent. See Table 23–1 for a comparison of the older adult population growth.

TABLE 23–1

Comparison of Older Population for 2010 Census and Projected Older Population for 2050 Census by Ethnicity

Ethnicity	2010	2050 Projection
White	32,243,428	51,771,738
Black	3,322,859	9,942,696
Asian	1,318,961	7,434,131
Hispanic	2,857,619	17,514,734
American Indian/ Alaskan Natives	200,323	645,537
Hawaiian/Pacific Islander	33,235	170,040

From "Projected Future Growth of the Older Population: By Race and Hispanic Origin, Persons 65 and Over," U. S. Department of Health and Human Services, 2010b. Retrieved from http://www.aoa.gov/AoARoot/Aging_Statistics/future_growth/future_growth.aspx.

Health

Chronic health problems and disabilities increase as age increases. However, disease is *not* a normal outcome of aging. In 2012, 44% of noninstitutionalized older Americans rated their health as excellent or very good. Although there was little difference between health status ratings for gender, there were cultural differences. Whites (447%) and Asians (33%) rated health as excellent or very good compared to African Americans (25.8%), American Indian/Alaska Natives (29%), and Hispanics (29.7%), who did not rate their health as excellent/very good (USDHHS, 2012). Nurses need to be aware that promoting health and wellness and assessing and promoting functional abilities for activities of daily living (ADLs) continue to be valid and important for 65-year-old clients who have 16 to 19 more years to enjoy life. In fact, *Healthy People 2020* includes new objectives for older adults such as reducing the proportion of older adults who have moderate to severe functional limitations and increasing the proportion of older adults with one or more chronic health conditions who report confidence in managing their conditions (USDHHS, 2010a).

ATTITUDES TOWARD AGING

Because of the increase in numbers, nurses will be caring for older adults at some point. It is important for nurses to be aware of their own values and attitudes toward aging, and examine whether myths or stereotypes influence those attitudes.

Ageism

American society values youth. See Culturally Responsive Care to see how different cultures view older adults. The term **ageism** is used to describe negative attitudes toward aging or older adults (Mauk, 2014, p. 10). Ageism is discrimination based solely on age. Popham, Kennison, and Bradley (2011) found that young adults distanced themselves from older adults to shield themselves from being aware of their own mortality. These individuals engaged in activities that made them feel strong, increased their energy, and diminished their vulnerability. Lun's (2010) research revealed that students who were exposed to the older population through frequency and quality of interactions were positively influenced and were more likely to make careers of elder care.

Culturally Responsive Care

PATIENT-CENTERED CARE

How Different Cultures View Older Adults

Many cultures have a deep respect for older adults, viewing them as wise, experienced, and knowledgeable. The following are examples of how some cultures view their elders.

BLACK/AFRICAN AMERICAN

- Older adults are respected, obeyed, and considered a source of wisdom.
- To survive to old age is often considered an accomplishment reflecting personal strength, resourcefulness, and faith.
- Grandparents, especially grandmothers, are often very involved in the support and care of their grandchildren.

HISPANIC/LATINO

- Older adults are held in high esteem.
- Old age is viewed as a positive time in the life of the older adult.
- Care for older adults is provided by the extended family. Children are expected to care for their elderly parents.

NATIVE AMERICAN

- Traditionally, elders are respected for their wisdom, experience, and knowledge.
- Older adults, regardless of tribe, assume significant roles as teachers and caretakers of the young.

CHINESE

- Traditional Chinese values place the family and society over the individual. Many American-born Chinese may not be as traditional but still hold values of respect for elders and authority.
- The oldest son has obligations toward the family and is expected to respect and care for parents.

- The tradition of “filial piety” is the value of total respect for the family, especially the elders. This respect for elders was advocated by Confucius, the famous Chinese philosopher and many Chinese and Chinese American families choose to follow these ancient principles.

VIETNAMESE

- Older adults are highly respected in Vietnamese society. They are considered the carriers of tradition, knowledge, and wisdom. Age is considered an asset, not a liability.
- Elderly grandparents and parents stay with the family for support and care.
- Older adults may prepare meals and care for grandchildren if both the husband and wife work.
- In Vietnam, older adults are the leaders and decision makers in the family and often sought for advice. When these elders move to the United States, they can become socially and culturally isolated for many reasons (inability to speak English, seniority, lack of training for work). In contrast, the younger family members may become more Americanized and may behave in ways their elders do not approve. This can create tension in families where older adults feel ignored and not respected.

KOREAN

- Traditional Koreans value filial piety and respect for older adults.
- Children are taught to respect older adults whether they are right or wrong.
- Children are expected to take care of their parents in old age.
- Two important family holidays that are celebrated with feasts include the 60th birthday and the 70th birthday.

Evidence-Based Practice Do Attitudes on Aging Affect Well-Being?

EVIDENCE-BASED PRACTICE

Mock and Eibach (2011) conducted a 10-year longitudinal study on attitudes toward aging. They hypothesized that attitudes toward aging affect the psychological well-being of older adults. If older clients felt they were old, then they possessed negative views on aging. Clients who possessed favorable attitudes about aging possessed more positive feelings about the aging process. The researchers conducted interviews with older adults on the subjects of subjective age, favorability of aging attitudes, well-being, demographics, and analyses. In the area of subjective age, clients were asked if they felt their chronological age. If participants felt older than their chronological age, then they possessed negative attitudes about aging. Participants who felt less than their chronological age possessed

positive attitudes toward aging. In this study 85% of the participants felt younger than their chronological age. Twenty percent felt their quality of life was higher than it had been in their 20s. Individuals who were married had an improved quality of life. If participants felt their health was good, they possessed a greater positive attitude. People's attitudes toward aging have an impact on their attitudes toward the aging process.

IMPLICATIONS

The outcome of an older client's care will be affected by the client's attitudes toward age. If a client has a positive attitude, the recovery time and related outcomes may be enhanced.

Myths and Stereotypes

Ageism contributes to the development of negative stereotypes about older adults. Stereotypes occur when younger people do not understand or identify with older adults as unique human beings. Instead, they generalize undesirable characteristics (e.g., senile, old fashioned, unproductive, inflexible) to all older adults. Many negative attitudes about aging are based on myths and incorrect information regarding growing old. An older client only experiences loss of memory related to the onset of a neurological disease. Most causes of disability are related to the adverse effects of many drugs such as pain medications. Disease processes also increase the client's risk of developing disabling conditions. For example, diabetes mellitus can result in loss of feeling in the extremities, diminished kidney function, and loss of vision. As a result, it is important for nurses to provide accurate information about aging. This has been found to be an effective intervention for

reducing negative stereotypes and improving attitudes about aging (Miller, 2012, p. 8).

GERONTOLOGICAL NURSING

The older adult population is characterized by unique and diverse individuals who may require a variety of health care professionals to meet their health care needs. **Gerontology** is a term used to define the study of aging and older adults. Gerontology is multidisciplinary and is a specialized area within various disciplines such as nursing, psychology, and social work. **Geriatrics** is associated with the medical care (e.g., diseases and disabilities) of older adults.

Development

Gerontological nursing involves advocating for the health of older adults at all levels of prevention (Mauk, 2014). In the 1960s,

gerontological nursing became a subspecialty of nursing. In the 1980s, gerontological nursing leaders stated that most practicing nurses did not have sufficient knowledge about gerontology. This prompted discussion of how to prepare nurses for gerontological nursing. Since the late 1990s, the nursing profession has recognized the importance of preparing all practicing nurses with basic gerontological knowledge. As a result, schools of nursing provide classes or courses about nursing care of older clients. Practicing gerontological nurses can obtain gerontological nursing certification through the American Nurses Association. Advanced practice in gerontological nursing requires a master's degree in nursing, of which there are two options: the gerontological clinical nurse specialist and the gerontological nurse practitioner.

Roles

The gerontological nurse has many roles: provider of care, teacher, manager, advocate, and research consumer. As a provider of care, the nurse gives direct care to older adults in a variety of settings. The teaching of gerontological nurses often focuses on modifiable risk factors (e.g., healthy diet, physical activity, stress management). Gerontological nurse managers balance the concerns of the older client and family, as well as the concerns of nurses and other interdisciplinary team members. As an advocate, the gerontological nurse empowers older adults by helping them remain independent and strengthen their autonomy and decision-making ability. Being a research consumer requires nurses to read the latest professional literature for evidence-based practice to improve the quality of nursing care for older clients.

CARE SETTINGS FOR OLDER ADULTS

Gerontological nurses practice in many settings. Older adults are the primary users of health care services that range from acute care facilities to rehabilitation, long-term care, and the community (Eliopoulos, 2014). Regardless of the setting, older adults require health assessment and promotion.

Acute Care Facilities

Older adults are the majority of clients cared for in acute care. Platts-Mills, Leacock, Cabanas, Shofer, and McLean (2010) studied the use of emergency services by the elderly. They found that 60% of clients ages 85 years and older utilize emergency medical services (EMS) for transportation to the emergency department. As the population of elderly steadily increases, it is important that EMS professionals be adequately trained by the health care team to improve the care provided to the nation's oldest clients.

Nurses in an acute care setting focus on protecting the health of the older adult, with the goal of the older adult returning to his or her prior level of independence. Examples include the following:

- Preventing nosocomial infections (e.g., urinary tract infections, pneumonia).
- Preventing therapy-related problems (e.g., confusion, sleeplessness, dehydration, decreased nutrition).
- Treating the health problem that resulted in the older adult's admission plus assessing for potential undiagnosed health problems (e.g., depression, drug and/or alcohol abuse).
- Preventing complications (e.g., decubitus ulcer).

Older adults often perceive that hospitalization could change their ability to be autonomous and independent. As a result, nurses need to assess the older adult's stage or perception of need for control and autonomy during hospitalization and his or her fears and hopes about being discharged from the hospital setting.

Long-Term Care Facilities

Long-term care is the provision of health care and personal care assistance to clients who have a chronic disease or disability (Li & Jensen, 2011). Long-term care facilities are also known as nursing facilities. Nursing facility is a new term that includes providers of care who are certified by Medicare and institutions previously referred to as intermediate care. The primary difference between institutions is the care offered, and the level of care provided to the client (Pratt, 2010, p. 70). In the long-term care setting or nursing facilities, the individual is referred to as a resident. Care includes many different levels of care. These may include assisted living, intermediate care, skilled care, and Alzheimer's units. Older adults who do not feel safe living alone or require additional help with ADLs may desire **assisted living**. They usually have their own apartment. The assisted living facility provides meals, weekly activities, and a pleasant environment to socialize with other residents. Some assisted living units are part of a larger facility. When residents require additional assistance, they may enter intermediate care. Residents of intermediate care are no longer able to live independently. This level of care provides 24-hour nursing oversight to protect the client from injury and increase the client's quality of life (Pratt, 2010, pp. 18–19).

Skilled care units or skilled nursing facilities (SNFs) are designed to provide for the needs of clients whose acuity levels require a higher level of nursing care. Gerontological nurses working in SNFs often care for clients who require tube feedings, intravenous therapy, chronic wound therapy, and mechanical ventilators.

Many long-term care facilities offer specialized units for clients with **Alzheimer's disease (AD)**. AD is characterized by progressive dementia, memory loss, and inability to care for oneself. Gerontological nurses working in AD units have specialized knowledge and help family members understand and cope with the disease process affecting their loved one.

Hospice

Gerontological nurses may also work in hospice and care for dying clients and their families. The majority of hospice clients are older adults. Hospice requires a great deal of patience, expertise, understanding, interdisciplinary communication, and compassion skills on the part of gerontological nurses. The goal of hospice care is to provide the client with pain management and with psychosocial and spiritual care through the dying process (End-of-Life Nursing Education Consortium Core Curriculum, 2013).

Rehabilitation

Gerontological rehabilitation nursing combines expertise in gerontological nursing with rehabilitation concepts and practice. Nurses working in gerontological rehabilitation often care for older adults with chronic illnesses and long-term functional limitations (e.g., orthopedic surgery, stroke, or amputation). This rehabilitative care may be found in several settings: acute care hospitals, subacute or transitional care centers, and long-term care facilities. The nurse is

an important member of the interdisciplinary rehabilitation team. The role of the nurse is often as a health care coordinator, manager, and counselor for older adults and their families. For example, nurses monitor the client's health care, assist with ADLs, and assist older adults to regain and maintain the highest level of function and independence possible while preventing complications and enhancing quality of life (Mauk, 2014, p. 12).

Community

Gerontological nurses provide nursing care in many types of community settings. Nurses often assess the older client's needs and then try to match the need with a community resource. Examples of the different community areas in which gerontological nurses practice include the following:

- **Home health care.** Home care is designed for those who are homebound due to the severity of illness or disability. The Medicare

guidelines describe these clients as homebound and unable to leave the home without a considerable amount of effort. Services are provided by a primary care provider and require skilled or rehabilitation nursing. Research has shown that providing home health services to older adults prevents hospital readmissions (Miller, 2012).

- **Nurse-run clinics.** These clinics focus on managing chronic illness. Nurses follow up with either telephone contacts or home visits within a week after discharge from a hospital. Again, this often helps decrease hospital readmissions.
- **Adult day care.** The older adult may receive **adult day care** where the focus is on social activities and health care (Figure 23–2 ■). The level of nursing care can vary (e.g., bathing, medication administration, wound dressing). Family caregivers who may need to work during the day or need some respite from the continual care often use these services. This is an alternative to institutionalizing an older adult.

PHYSIOLOGICAL AGING

In the past half-century, scientists have proposed numerous theories of why people age. More recently, as both the absolute number and the population percentage of older adults increase, there is renewed interest in why and how people age and what factors affect the physical, psychological, and functional status of older persons. This interest has resulted in the development of additional theories about the aging process. There are many different theories of aging in the biological, psychological, and social sciences. Three nursing theories of aging have been developed in the past 20 years. Miller (2012) developed the functional consequences theory in 1990. Functional consequences are age-related changes, actions that have placed the client at risk for illness or injury, and risk factors for disease. The nurse should design interventions that promote safety and improve the client's quality of life. In 2002 Haight, Barba, Courts and Tesh's theory of thriving asserted that nurses must intervene to promote the older adult's growth and development. The third theory is a middle-range theory. It is the nursing theory of successful aging developed by Flood. Flood (2005) defined successful aging as the "cumulative physiologic and functional alterations associated with the passage of time" (p. 36). The client experiences spiritual connections and a sense of meaning and worth. Nurses must target interventions for the older adult in the promotion of mental, physical, and spiritual health through the aging process. Mauk (2014) asserted that nursing theories on aging lack all holistic elements that influence aging. Nurses must be aware of a client's socioeconomic resources. It is important for future theoretical development to address the client's cultural, spiritual, geographic, psychosocial, physiological, and environmental elements that are influential in the age-related process (Mauk, 2014, p. 88). Examples of theories for explaining physical aging include wear-and-tear, endocrine, free-radical, genetic, cross-linking, and immunologic theories. Table 23–2 describes the various biological theories of aging.

At this point, it is helpful to distinguish between normal or usual aging (the typical aging course with concomitant diseases and disabilities) and successful aging (the aging course without disease). Arthritis, heart disease, cancer, and diabetes are leading causes of disability or death in the United States. The health care costs to treat chronic diseases in the older American population greater than age 65 years total 95%. This is five times higher than the cost of health care for individuals under the age of 65. The current treatment of older adults with multiple chronic illnesses totals 66% of the U.S. health care budget (Centers for Disease Control and Prevention, 2013).

As a person ages, many physical changes occur; some are visible, some are not. In general, lean body mass is reduced, fat tissue increases, and bone mass decreases. Extracellular fluid remains constant; however, intracellular fluid decreases and leads to reduced total body fluid. Thus, older adults are at risk for developing dehydration. Table 23–3 provides a summary of the normal physical changes associated with aging.

Integument

Obvious changes occur in the integumentary system (skin, hair, nails) with age. The skin becomes drier, less elastic, and more fragile, making the older person more susceptible to skin tears and shearing injuries. The hair loses color, the fingernails and toenails become thickened and brittle, and in women over age 60, facial hair increases.

Responses to these changes vary among individuals and cultures. For example, one person may feel distinguished with gray hair, whereas another may feel embarrassed or depressed, interpreting gray hair as a sign of losing one's youth.

These integumentary changes accompany progressive losses of subcutaneous fat and muscle tissue, muscle atrophy, and loss of elastic fiber, resulting in a "double" chin, sagging of eyelids and earlobes, and wrinkling of skin, especially in areas exposed to sun. Bony

TABLE 23–2 Common Biological Theories of Aging

Theory Type	Hypotheses
Wear-and-tear theory	Proposes that humans, like automobiles, have vital parts that run down with time, leading to aging and death.
	Proposes that the faster an organism lives, the quicker it dies.
	Proposes that cells wear out through exposure to internal and external stressors, including trauma, chemicals, and buildup of natural wastes.
Endocrine theory	Proposes that events occurring in the hypothalamus and pituitary are responsible for changes in hormone production and response that result in the organism's decline.
Free-radical theory	Proposes that unstable free radicals (groups of atoms) result from the oxidation of organic materials, such as carbohydrates and proteins. These radicals cause biochemical changes in the cells, and the cells cannot regenerate themselves.
Genetic theory	Proposes that the organism is genetically programmed for a predetermined number of cell divisions, after which the cells/organism dies.
	Proposes that when damage to the protein synthesis occurs, faulty proteins will be synthesized and will gradually accumulate, causing a progressive decline in the organism.
Cross-linking theory	Proposes that the irreversible aging of proteins such as collagen is responsible for the ultimate failure of tissues and organs.
	Proposes that as cells age, chemical reactions create strong bonds, or cross-linkages, between proteins. These bonds cause loss of elasticity, stiffness, and eventual loss of function.
Immunologic theory	Proposes that the immune system becomes less effective with age, resulting in reduced resistance to infectious disease and viruses.
	Proposes that a decrease in immune function may result in an increase in autoimmune responses, causing the body to produce antibodies that attack itself.

TABLE 23–3 Normal Physical Changes Associated with Aging

Physical Changes	Rationale
INTEGUMENTARY	
Increased skin dryness	Decrease in sebaceous gland activity and tissue fluid
Increased skin pallor	Decreased vascularity
Increased skin fragility	Reduced thickness and vascularity of the dermis; loss of subcutaneous fat
Progressive wrinkling and sagging of the skin	Loss of skin elasticity, increased dryness, and decreased subcutaneous fat
Brown “age spots” (lentigo senilis) on exposed body parts (e.g., face, hands, arms)	Clustering of melanocytes (pigment-producing cells)
Decreased perspiration	Reduced number and function of sweat glands
Thinning and graying of scalp, pubic, and axillary hair	Progressive loss of pigment cells from the hair bulbs
Slower nail growth and increased thickening with ridges	Increased calcium deposition
NEUROMUSCULAR	
Decreased speed and power of skeletal muscle contractions	Decrease in muscle fibers
Slowed reaction time	Diminished conduction speed of nerve fibers and decreased muscle tone
Loss of height (stature)	Atrophy of intervertebral disks, increased flexion at hips and knees
Loss of bone mass	Bone reabsorption outpaces bone reformation
Joint stiffness	Drying and loss of elasticity in joint cartilage
Impaired balance	Decreased muscle strength, reaction time, and coordination, change in center of gravity
Greater difficulty in complex learning and abstraction	Fewer cells in cerebral cortex
SENSORY/PERCEPTUAL	
Loss of visual acuity	Degeneration leading to lens opacity (cataracts), thickening, and inelasticity (presbyopia)
Increased sensitivity to glare and decreased ability to adjust to darkness	Changes in the ciliary muscles; rigid pupil sphincter; decrease in pupil size
Partial or complete glossy white circle around the periphery of the cornea (arcus senilis)	Fatty deposits
Progressive loss of hearing (presbycusis)	Changes in the structures and nerve tissues in the inner ear; thickening of the eardrum
Decreased sense of taste, especially the sweet sensations at the tip of the tongue	Decreased number of taste buds in the tongue because of tongue atrophy
Decreased sense of smell	Atrophy of the olfactory bulb at the base of the brain (responsible for smell perception)
Increased threshold for sensations of pain, touch, and temperature	Possible nerve conduction and neuron changes
PULMONARY	
Decreased ability to expel foreign or accumulated matter	Decreased elasticity and ciliary activity
Decreased lung expansion, less effective exhalation, reduced vital capacity, and increased residual volume	Weakened thoracic muscles; calcification of costal cartilage, making the rib cage more rigid with increased anterior-posterior diameter; dilation from inelasticity of alveoli
Difficult, short, heavy, rapid breathing (dyspnea) following intense exercise	Diminished delivery and diffusion of oxygen to the tissues to repay the normal oxygen debt because of exertion or changes in both respiratory and vascular tissues
CARDIOVASCULAR	
Reduced cardiac output and stroke volume, particularly during increased activity or unusual demands; may result in shortness of breath on exertion and pooling of blood in the extremities	Increased rigidity and thickness of heart valves (hence, decreased filling/emptying abilities); decreased contractile strength
Reduced elasticity and increased rigidity of arteries	Increased calcium deposits in the muscular layer
Increase in diastolic and systolic blood pressure	Inelasticity of systemic arteries and increased peripheral resistance
Orthostatic hypertension	Reduced sensitivity of the blood pressure–regulating baroreceptors

TABLE 23–3 Normal Physical Changes Associated with Aging—*continued*

Physical Changes	Rationale
GASTROINTESTINAL	
Delayed swallowing time	Alterations in the swallowing mechanism
Increased tendency for indigestion	Gradual decrease in digestive enzymes, reduction in gastric acid production, and slower absorption rate
Increased tendency for constipation	Decreased muscle tone of the intestines; decreased peristalsis; decreased free body fluid
URINARY	
Reduced filtering ability of the kidney and impaired renal function	Decreased number of functioning nephrons (basic functional units of the kidney) and arteriosclerotic changes in blood flow
Less effective concentration of urine	Decreased tubular function
Urinary urgency and urinary frequency	Enlarged prostate gland in men; weakened muscles supporting the bladder or weakness of the urinary sphincter in women
Tendency for nocturnal frequency and retention of residual urine	Decreased bladder capacity and tone
GENITALS	
Prostate enlargement (benign) in men	Exact mechanism is unclear; possible endocrine changes
Multiple changes in women (shrinkage and atrophy of the vulva, cervix, uterus, fallopian tubes, and ovaries; reduction in secretions; and changes in vaginal flora)	Diminished secretion of female hormones and more alkaline vaginal pH
Increased time to sexual arousal	Changes in blood supply to penis, clitoris
Decreased firmness of erection, increased refractory period (men)	Changes in blood supply
Decreased vaginal lubrication and elasticity (women)	Loss of estrogen effects
IMMUNOLOGIC	
Decreased immune response; lowered resistance to infections	T cells less responsive to antigens; B cells produce fewer antibodies
Poor response to immunization	
Decreased stress response	
ENDOCRINE	
Increased insulin resistance	Immune system changes may precipitate insulin resistance
Decreased thyroid function	Unclear mechanism

prominences may become visible. In older women, the breasts become less firm and may sag. Loss of subcutaneous fat also decreases older adults' tolerance of cold.

Health promotion teaching about skin care for older adults can include the following:

- Maintaining healthy skin:
 - Ensure optimal nutrition.
 - Maintain adequate hydration.
 - Prevent skin dryness by using emollient lotions after bathing or showering, when the skin is still moist.
 - Avoid skin products that contain perfume or alcohol.
 - Assess the frequency of bathing/showering.
- Avoiding sun damage:
 - Use sun-screening lotions with a sun protection factor (SPF) of 15 or higher.
 - Wear wide-brimmed hats, sun visors, and sunglasses when exposed to the sun.
 - Observe for any skin changes (e.g., new lesions, change in mole size or color) and seek medical evaluation.

- Preventing skin injury:
 - Do not use strong detergent to launder clothes.
 - Avoid rough texture in clothing.
 - Avoid highly starched linens.
 - Use soft washcloths, towels, and bed linens.

Neuromuscular

With aging comes a gradual reduction in the speed and power of skeletal or voluntary muscle contractions and sustained muscular effort. Exercise can strengthen weakened muscles, and up to about age 50 the skeletal muscles can increase in bulk and density. **Sarcopenia** is a syndrome that results in muscle weakness leading to diminished independence and contributes to the client's decreased ability to perform ADLs. Alva, Camacho, Velaquez, and Lazarevich (2013) conducted a study of elderly woman in Mexico City. They found that women with sarcopenia had a higher prevalence of being undernourished. The anthropometric measurements of these women were lower, particularly in the calf region. Chien, Kuo, and Wu (2010) compared the physical activity, muscle strength, cardiopulmonary

fitness, and physical disability in clients ages 65 years and older. They found that cardiopulmonary fitness was decreased in clients with sarcopenia. Muscle endurance also diminishes with age, resulting in muscle fatigue after short periods of exercise. There is substantial evidence, however, that muscles in the older adult can be strengthened through exercise and training, with resulting improvements in functional status.

The person's reaction time slows with age. Reaction time can be delayed further by decreased muscle tone as a result of diminished physical activity. Older adults compensate for this reaction difference by being exceptionally cautious, for instance, in their driving habits, which exasperates some impatient younger drivers.

Loss in overall stature occurs with age. This can be exaggerated by muscular weakness resulting in a stooping posture and **kyphosis** (humpback of the upper spine). Imbalance in the rates of absorption and formation of bone tissue occurs with aging, so that older adults have more porous and fragile bones than do younger adults, making older adults prone to serious fractures. **Osteoporosis**, a pathologic decrease in bone density that is more common in older than younger adults, may lead to spontaneous (i.e., without a fall or other trauma to the bone) fractures that are called **pathologic fractures**. Osteoporosis occurs more frequently in people with insufficient intake of dietary calcium, in women after menopause, in Caucasians and Asians, and in people who are immobilized or physically inactive. Often considered a woman's disease, it is important to remember that osteoporosis also affects men (Eliopoulos, 2014; Mosekilde, Vestergaard, & Rejnmark, 2013). Osteoporosis occurs in both women and men with fractures of the proximal femur, proximal humerus, or forearm. The client may have low bone mineral density in the lumbar spine and hip. Testosterone increases longitudinal and appositional bone growth in children. Estrogen produces epiphyseal closure. As the male ages, testosterone and estradiol levels decrease. The risk of fracture in male clients is associated with the declining estradiol levels (Mosekilde et al., 2013).

Joints and their supporting structures change with age. Decreased elasticity, strength, and hydration of the tendons and ligaments make movement stiffer and more restricted. Stiffness is aggravated by inactivity; for example, if a person sits too long, the joints become stiff, and the person has difficulty standing and walking. These changes may be compounded by osteoarthritis. A continual program of physical activity and proper nutrition will slow bone density loss and decrease muscle atrophy and stiffness (Figure 23-3 ■).

As indicated, these age-related changes may affect the mobility and safety of the older adult. For example, decreased muscle strength, decreased balance, and osteoporosis put the older adult at risk for falls and fractures. For health promotion, the nurse assesses the musculoskeletal functioning of the older adult and identifies any risk factors that may contribute to falls or the ability of the older adult to perform ADLs. Health promotion interventions often include providing information about the risk factors for osteoporosis and the importance of adequate intake of calcium and vitamin D.

Sensory-Perceptual

Each of the five senses becomes less efficient in older adulthood. Changes in vision associated with aging include the obvious changes around the eye, such as the shrunken appearance of the eyes due to loss of orbital fat, the slowed blink reflex, and diminished eyelid muscle tone. Other changes result in decreased visual acuity, less power of

Figure 23-3 ■ A regular program of exercise is important for maintaining joint mobility and muscle tone. mezzotint/Shutterstock.

adaptation to darkness and dim light, and decreased accommodation to near and far objects. Loss of peripheral vision, atrophy of lacrimal glands resulting in dry eyes, and difficulty in discriminating similar colors, especially blues, greens, and purples, also occur.

Presbyopia, the inability to focus or accommodate due to a loss of flexibility of the lens, causes decreased near vision. This process generally starts around age 40. Visual acuity lessens gradually after age 50 and more rapidly after age 70 (Miller, 2012).

By the age of 80, nearly all older adults have some lens opacity (**cataracts**) that reduces visual acuity and causes glare to be a problem. In addition to cataracts, three other conditions result in visual impairment and blindness: age-related macular degeneration (ARMD), glaucoma, and diabetic retinopathy (Miller, 2012). It is important for the nurse to promote health by informing older clients that they should schedule routine eye examinations to maintain and protect their vision. Also, wearing sunglasses will help avoid the damaging effect of ultraviolet light.

The loss of hearing ability related to aging, called **presbycusis**, affects people over age 65. Gradual loss of hearing is more common among men than women, perhaps because men are more frequently in noisy work environments. Hearing loss is greater in the higher frequencies than the lower. Thus older adults with hearing loss usually

Evidence-Based Practice Do the Characteristics of Sleep Affect All Causes of Mortality in the Elderly Hispanic Population?

EVIDENCE-BASED PRACTICE

Howery, Peek, Raji, Ray, and Ottenbacher (2012) conducted a cross-sectional study utilizing the Hispanic Established Epidemiological Studies of the Elderly. This was a population-based study of 3,050 Hispanic clients age 65 or older living in five southwestern states. The researchers noted that older adults have increased difficulty in staying asleep. They noted that a considerable amount of research had been done on the duration of sleep the older adult experiences, but little on the individuals' quality of sleep. This evidence-based practice study investigated the association between self-reported sleep problems and the mortality of older Mexican Americans. The

study confirmed that alterations in health, symptoms of depression, and sleep difficulties such as trouble falling asleep, waking up several times during the night, difficulty staying asleep, or waking up feeling tired were associated with the greatest mortality risk in the Mexican American population.

IMPLICATIONS

It is important for nurses to assess each older client to determine the amount of sleep and the sleep patterns they experience. Clients who awaken frequently at night are at risk for falls due to changes in blood pressure or feelings of fatigue.

hear speakers with low, distinct voices best. Hard consonants (e.g., *k*, *d*, *t*) and long vowel sounds (e.g., *ay*, *ee*) are more easily recognized, and sibilant sounds (e.g., *s*, *th*, *f*) are the most difficult to hear. Older adults may have more difficulty compensating for hearing loss than the young, who pay closer attention to the lip movements of the speaker.

If family members notice communication problems or social withdrawal, the nurse should provide health promotion teaching by suggesting a referral for hearing screening. Also, the older adult's ears should be checked for impacted earwax. If hearing has diminished, assistive listening devices are available and the nurse can provide information to the older adult and family. To help avoid increased hearing loss, inform the older adult to use ear protection devices when working in or around activities that produce loud noise.

Older people have a poorer sense of taste and smell and are less stimulated by food than the young. It is common for the sense of smell to decline more than the sense of taste. These changes significantly affect appetite in the older adult, contributing to poor nutrition. Decreased or absent sense of smell and taste also add to the health hazard of increased salt usage and safety issues (e.g., being unable to smell a gas leak). It is important for the nurse to teach the older client and family about the safety issues involved with a decreased sense of taste and smell and what strategies can be implemented to promote the older adult's safety (e.g., dating and labeling foods, using smoke alarms).

Loss of skin receptors takes place gradually, producing an increased threshold for sensations of pain, touch, and temperature. The older person may not be able to distinguish hot from cold or the intensity of heat. Stimuli causing severe pain in a younger person may cause only minor sensation or pressure in older adults. This places the older adult at higher risk for burns and other injuries. Again, it is important for the nurse to teach about the involved safety risks and subsequent interventions (e.g., setting the temperature of the water heater to 110°F to prevent scalding).

Pulmonary

Respiratory efficiency declines with age. Tidal volume (the measurement of air moved in and out during normal respiration) remains the same. However, the older adult has a decreased vital capacity. This means the older adult is unable to compensate for increased oxygen need by significantly increasing the amount of air inspired. **Dyspnea** (difficult breathing) often occurs with physically demanding activities, such as running for a bus or carrying heavy parcels upstairs. A greater volume of residual air is left in the lungs after expiration, and the capacity to cough efficiently decreases because of weaker

expiratory muscles. Mucous secretions tend to collect more readily in the respiratory tree. Thus susceptibility to respiratory infections increases in older adults.

Health promotion teaching includes information about the following:

- Cessation of smoking, if appropriate
- Preventing respiratory infections by washing hands
- Ensuring that influenza and pneumonia vaccinations are up to date.

Cardiovascular

The working capacity of the heart diminishes with age. This is particularly evident when increased demands are made on the heart, such as during periods of exercise or emotional stress. The heart rate at normal rest may decrease with age. However, the heart rate of the older person is slower to respond to stress and slower to return to normal after periods of physical activity.

Changes in the arteries occur concurrently. Reduced arterial elasticity may result in diminished blood supply to, for instance, the legs and the brain, resulting in pain on exertion in the calf muscles and dizziness, respectively. In addition, there may be a delay in the circulatory adjustments required when a person quickly stands up from a lying or sitting position. The delay results in an abrupt drop in systolic blood pressure known as *orthostatic hypotension*.

For blood pressure measurements, it is not unusual to have a slight increase in the systolic pressure while the diastolic pressure remains the same. For many years, isolated systolic hypertension was considered to be "normal" in older adults, and was frequently not treated. Newer evidence indicates that a systolic pressure at or greater than 140 mmHg is as problematic in older adults as in younger ones, and should be as aggressively treated with antihypertensive agents, diet, and exercise. Obese older adults with hypertension will have pathophysiological changes affecting the heart, blood vessels, and kidneys. Damage to the renal system with comorbid cardiovascular disease increases the client's risk of death (Aronow et al., 2011; Porth, 2011). The older adult population must be educated on lifestyle modifications such as a reduced-fat diet, smoking cessation, stress reduction, limited salt intake, and exercise. The reduction in blood pressure will preserve kidney function and reduce heart disease and stroke risk.

Health promotion activities are aimed at detecting and reducing risks for cardiovascular disease. To detect risks, blood pressure and cholesterol levels should be checked annually and more frequently with abnormal results. To reduce risks of cardiovascular disease, the

nurse should inform the older adult about the importance of the following: smoking cessation (if applicable), maintaining ideal body weight, exercising daily, avoiding foods high in sodium and fat and eating fruits and vegetables, and discussing the use of low-dose aspirin therapy with the primary care provider (Miller, 2012).

Gastrointestinal

Age-related changes in the gastrointestinal system include the following:

- Periodontal disease can lead to tooth loss. With age, tooth enamel becomes harder and more brittle, making teeth more susceptible to fractures. The root of the tooth shrinks and the gingiva retracts. The bones that support the teeth decrease in density and height, all leading to tooth loss.
- Reduced production of saliva may lead to xerostomia (dry mouth) and make the oral mucosa more susceptible to infection.
- Decreased esophageal motility can slow the esophageal emptying process.
- Stomach motility and emptying time are decreased. Also, a higher pH of the stomach contributes to increased incidence of gastric irritation in the older adult.
- The production of intrinsic factor (protein needed to make vitamin B₁₂) is decreased, leading to pernicious anemia.
- Intestinal absorption, motility, and blood flow are decreased.

Health promotion teaching for older adults includes effective oral hygiene and preventive dental care (e.g., semiannual teeth cleaning). Nutrition is important including appropriate diet and sufficient fluid intake. Maintenance of a regular bowel routine is helpful, and screening for colorectal cancer is important (e.g., annual fecal occult blood test, sigmoidoscopy every 5 years, and colonoscopy every 10 years) (Miller, 2012, p. 552).

Urinary

The excretory function of the kidney diminishes with age, but usually not significantly below normal levels unless a disease process intervenes. The kidney's filtering abilities may also be impaired; thus waste products may be filtered and excreted more slowly. For this reason, the nurse should be aware of whether medications that are administered are excreted via the kidney or liver. Drugs that are metabolized predominantly in the kidney may accumulate in the older adult, and the nurse should watch for signs of toxicity.

More noticeable changes are those related to the bladder. Complaints of urinary urgency and urinary frequency are common. The capacity of the bladder and its ability to completely empty diminish with age. Many older adults need to void during the night (nocturia) and may experience retention of residual urine, predisposing them to bladder infections.

Although older adults are susceptible to urinary incontinence (UI) because of changes in the kidney and bladder, UI is *never* normal. The nurse must promptly investigate UI, particularly when of new onset. Urinary incontinence has many ill effects on older adults, including social isolation, falls, and skin breakdown.

The nurse can teach the following health promotion activities for good urinary function:

- Drink sufficient fluids daily (e.g., 8 to 10 glasses of noncaffeinated liquid).

- Drink fluids even if not thirsty. (The thirst mechanism in older adults is diminished.)
- Avoid foods that can irritate the bladder (e.g., sugar, caffeine, alcohol, chocolate, artificial sweeteners, and spicy and acidic foods).
- Practice pelvic muscle exercises to stop or control stress incontinence.

The nurse should explain that incontinence is not a normal change related to aging.

Genitals

Degenerative changes in the gonads are gradual in men. Production of testosterone continues, and the testes can produce sperm well into old age although there is a gradual decrease in the number of sperm produced. In women the degenerative changes in the ovaries are noticed by the cessation of menses in middle age during the menopause.

Changes in the gonads of older women result from diminished secretion of the ovarian hormones. Some changes, such as the shrinking of the uterus and ovaries, go unnoticed. Other changes are obvious. The breasts atrophy, and lubricating vaginal secretions are reduced. Reduced natural lubrication may be the cause of painful intercourse, which may be addressed through the use of water-soluble lubricants.

The older man will notice several age-related changes in his sexual response and performance, but it is important for both the client and nurse to know that sexual response and performance should be present in the older adult. There is a decline in sexual hormones with a more gradual decline in the male than the female (Tabloski, 2014). For both men and women, the major age-related change in sexual response is timing. It takes longer to become sexually aroused, longer to complete intercourse, and longer before sexual arousal can occur again. In general, the older man's libido may decrease, but not disappear. If an older man reports a loss in sexual interest, the nurse should be as concerned as when a younger man reports a loss of interest in sexual activity. Older men achieve an erection that is less firm than in younger men, but still capable of penetration. Ejaculation may take longer to occur, and the older man may have difficulty anticipating or delaying ejaculation. During orgasm the urethral contractions are decreased and there is a decrease in seminal fluid and lessened force of ejaculation (Tabloski, 2014).

The risk of erectile dysfunction (ED) increases with each decade of age (Tabloski, 2014). The many possible causes of ED include atherosclerosis, diabetes, hypertension, medications, and psychological factors. Various treatment options are available such as oral medication, vacuum pump devices, penile implants, and drugs injected into the penis. Oral medication is the first line of therapy used if there are no contraindications to the drug. Viagra® (sildenafil), Levitra® (vardenafil), and Cialis® (tadalafil) are the three oral medications used for ED.

Older women also experience changes in their sexual responses. Sexual dysfunction in older women is related to vaginal dryness, vaginal bleeding with intercourse, reduced sexual response, and inability to experience sexual arousal (Simon, 2011). The clitoris remains an important part of orgasm, but may become irritated more easily because the clitoral hood is less protective than in younger women. During orgasm, the uterus will contract less frequently, but the contractions remain vigorous, and orgasm is as intense as in younger women.

The nurse needs excellent communication skills when providing health education about sexual function to the older adult. It is important to avoid the use of medical terminology. A quiet private

room to discuss sensitive issues related to sexuality is essential. Older adults are fully capable of enjoying sexual activity. If they experience problems with sexual function, they are encouraged to seek professional advice from their primary care provider or other appropriate health care professional (Miller, 2012).

Psychosocial Aging

A number of theories have attempted to explain psychosocial aging. These theories focus on behavior and attitude changes during the aging process. One of the earliest, **disengagement theory**, developed in the early 1960s proposed that aging involves mutual withdrawal (disengagement) between the older person and others in the older person's environment (Tabloski, 2014). It has been widely criticized for the assumption that disengagement is appropriate for the older adult. According to Havighurst's **activity theory** (1972), the best way to age is to stay active physically and mentally. The **continuity theory** proposes that people maintain their values, habits, and behavior in old age. A person who is accustomed to having people around will continue to do so, and the person who prefers not to be involved with others is more likely to disengage (Tabloski, 2014). This theory accounts for the great variety of behavior seen in older people.

According to Erikson, the developmental task at this time is ego integrity versus despair. People who attain ego integrity view life with a sense of wholeness and derive satisfaction from past accomplishments. They view death as an acceptable completion of life. People who develop integrity accept "one's one and only life cycle" (Erikson, 1963, p. 263). By contrast, people who despair often believe they have made poor choices during life and wish they could live life over.

Acknowledging that the "young-old" and "old-old" differ not only in physical characteristics but also in psychosocial responses, many people have difficulty with Erikson's singular developmental task. Peck (1968) proposed the following three developmental tasks of the older adult in contrast to Erikson's task of ego integrity versus despair:

1. Ego differentiation versus work-role preoccupation
2. Body transcendence versus body preoccupation
3. Ego transcendence versus ego preoccupation.

For details about these tasks, see Chapter 20 ∞. See Box 23–1 for additional themes of the older adult.

Retirement

The ability to retire at the age of 65 is becoming increasingly more challenging for older adults based on the changes within the U.S. labor force. Economic risk has risen in the past several years. Today's seniors may lack the assets needed to retire. Complicating this situation are rising health care costs and inadequate monthly income to meet the needs of seniors (Polivka, 2013). Older adults may find that their retirement income has not kept up with inflation. They may need to continue working to meet medical, insurance, and housing costs.

Retirement can be a time when projects or recreational activities deferred for a long time can be pursued, or it can be a difficult time of adjustment. Either way, retirement requires a process of adaptation (Figure 23–4 ■). Retired people are no longer governed by an alarm clock and can get up when they please. The enjoyment of staying up later is another luxury. Physical activity is often a measure of how a person's health and wellness are judged. Those who are accustomed

BOX 23–1 Developmental Tasks of the Older Adult

60 TO 75 YEARS

- Adjusting to decreasing physical strength and health
- Adjusting to retirement and lower fixed income
- Adjusting to the death of parents, spouses, and friends
- Adjusting to new relationships with adult children
- Adjusting to leisure time
- Adjusting to slower physical and cognitive responses
- Keeping active and involved
- Making satisfying living arrangements as aging progresses

75 YEARS AND OLDER

- Adapting to living alone
- Safeguarding physical and mental health
- Adjusting to the possibility of moving into a nursing home
- Remaining in touch with other family members
- Finding meaning in life
- Adjusting to one's own death

to activity find many outlets, including jobs, community projects, travel, volunteer services, intellectual or recreational pursuits, or hobbies (Figure 23–5 ■). Research in gerontological exercise physiology indicates that maintenance of a physically active lifestyle delays or improves age change associated with cardiovascular, respiratory, and musculoskeletal function. Physical inactivity, on the other hand, is

Figure 23–5 ■ Retirement provides time for enjoying hobbies.
bikeriderlondon/Shutterstock.

a risk factor for many chronic diseases experienced by older adults, including obesity, diabetes, cardiovascular, and respiratory diseases (Ebersole, Hess, Touhy, Jett, & Luggen, 2012, p. 201).

The lifestyle of later years is to a large degree formulated in youth. People who attempt suddenly to refocus and enrich their lives at retirement usually have difficulty. Those who learned early in life to live well-balanced and fulfilling lives are generally more successful in retirement. The woman who has been concerned only with the accomplishments of her children or the man who has been concerned only with the paycheck and his job status can be left with a feeling of emptiness when children leave and the job no longer exists. The later years can foster a sense of integrity and continuity, or they can be years of despair.

E-HEALTH

In retirement, seniors may take a class to learn to use a computer or they may retire having already learned computer skills. The term **e-health** is used to describe the use of technology in the delivery of health care and health information. Seniors have been the fastest growing age group using the Internet. They are now ranked as the fastest growing users of social media. The use of social networking sites by seniors has increased 150% according to a Princeton Survey

reported by U.S. News and World Report (2013). Searches on the Internet also include a variety of topics that often include health care or disease information. Blogs and online discussions are utilized by seniors to search for information related to living with chronic disease and answers to health-related questions (Mauk, 2014).

Economic Change

The financial needs of older adults vary considerably. Although most need less money for clothing, entertainment, and work, and although some own their homes outright, costs continue to rise, making it difficult for some to manage. Food and medical costs alone are often a financial burden. Adequate financial resources enable the older person to remain independent.

Problems with income are often related to low retirement benefits, lack of pension plans for many workers, and the increased length of the retirement years. Older members of minority groups and women often have greater financial problems than older Whites (Eliopoulos, 2014). Older women of all ages usually have lower incomes than men, and the oldest women may be the poorest.

Nurses should be aware of the costs of health care. For example, while assisting a client to plan a diet, the nurse must consider which foods the client can afford to buy. The nurse or the client can request the primary care provider to order lower priced medications, or assist the older client to apply for medication assistance programs operated by pharmaceutical companies. In addition, the supplies used in a client's care should be as economical as possible.

Grandparenting

Grandparents traditionally provide gifts, money, and other forms of support (e.g., babysitting) for younger family members. They also provide a sense of continuity, family heritage, rituals, and folklore (Giger, 2013). However, the rate of grandparents being the primary caregiver for their grandchildren is increasing. The major reasons for grandparents raising grandchildren include substance abuse, incarceration, teen pregnancy, emotional problems, and parental death. The terms used to describe families in which grandparents serve as the parents are kinship families, grandfamilies, or skipped-generation families. These families provide the primary care of the child or children. In some instances, the grandparent may be required to protect the child from the parent. This is needed in the case of abuse or a client's mental illness (Cooper, 2012).

While loving their grandchildren, the grandparents often experience stress, anxiety, financial hardships, and potential deteriorating health. For example, they must cope with their own chronic health problems while caring for their grandchildren. It is important for nurses to assess and help maintain the health of the grandparents.

Relocation

During late adulthood, many people experience relocation. A variety of factors may lead to this decision. The house or apartment may be too large or too expensive. The work involved in maintaining the house may become burdensome or impossible for an older person or couple. Some older adults with decreased mobility desire living arrangements that are all on one floor or need more accessible bathroom facilities.

Making the decision to move is stressful. Moving to an apartment may mean leaving the comfort of the family home and the neighbors and friends of several decades. Some older adults need to move nearer to their children for general support and supervision. For many, this decision is difficult and stressful. For others, relocation is voluntary. The person may be seeking a more moderate climate with better recreational facilities geared to a more leisurely lifestyle. Adjustment will be much easier for the older adult making a voluntary move.

More living choices and options are available for the older adult today. Depending on their needs, examples include the following:

- **Assisted living.** This is a facility that meets the needs of the older person (e.g., wide doorways, grab bars in the bathroom, a call light). Various degrees of personal care assistance may be provided.
- **Adult day care.** The older adult who lives at home can attend a day care center that provides health and social services to the older person. While the older adult is at day care, the caregiver has a respite from the daily care tasks.
- **Adult foster care and group homes.** These programs offer services to individuals who can care for themselves but require some form of supervision for safety purposes.

Some older adults, however, must relocate to long-term care facilities or nursing homes. The decision to enter a nursing home is frequently made when older adults can no longer care for themselves, often because of problems of mobility and memory impairment. The facilities in nursing homes differ in many ways and offer varying degrees of independence to the residents. All provide meals but vary in providing other services, such as assistance with hygiene and dressing, physical therapy or exercise, recreational activities, transportation services, and medical and nursing supervision.

Nurses in hospitals should find out whether a client is being discharged to a nursing home or to a private home. Nursing homes require appropriate information to provide for continuity of care. Clients returning home, however, may require the assistance of a home care nurse.

Maintaining Independence and Self-Esteem

Most older Americans thrive on independence. It is important to them to be able to look after themselves even if they have to struggle to do so. Although it may be difficult for younger family members to watch an older person completing tasks in a slow, determined way, older adults need this sense of accomplishment. Children might notice that the aging father or mother with failing vision cannot keep the kitchen as clean as before. The aging parent may be slower and less meticulous in carpentry tasks or gardening. To maintain the older adult's sense of self-respect, nurses and family members need to encourage them to do as much as possible for themselves, provided that safety is maintained. Many young people, including nurses, mistakenly think that they are being helpful to older adults when they take over for them and do the job much faster and more efficiently.

Nurses need to acknowledge the older adult's ability to think, reason, and make decisions. Most older adults are willing to listen to suggestions and advice, but they do not want to be ordered around.

The nurse can support a decision by an older adult even if eventually the decision is reversed because of failing health.

Older adults appreciate the same thoughtfulness, consideration, and acceptance of their abilities as younger people do. There is as much diversity among older adults as there is in any other population group, and the nurse should be just as wary of stereotyping them as with stereotyping any other group. The values and standards held by older people need to be accepted, whether they are related to ethical, religious, or household matters. For example, the nurse should respect an older person's decision to hang the laundry outside rather than to use a dryer, or to cook on a conventional stove rather than in a microwave oven.

Facing Death and Grieving

Well-adjusted aging couples usually thrive on companionship. Many couples rely increasingly on their partners for this company and may have few outside friends. Great bonds of affection and closeness can develop during this period of aging together and nurturing each other. When a mate dies, the remaining partner inevitably experiences feelings of loss, emptiness, and loneliness. Many are capable of living alone and can manage to do so; however, reliance on younger family members may increase as age advances and ill health occurs. Some widows and widowers remarry, particularly the latter because most widowers are less inclined than widows to maintain a household. More women than men face bereavement and solitude because women usually live longer (FIFAS, 2012). Older adults are often reminded of the brevity of life by the death of friends. It is a time when they review their life with happiness or regret. Feelings of serenity or guilt and inadequacy can arise. Survivor coping ability improves when the person is aware that death and bereavement can lead to growth (Ebersole et al., 2012). This coping can result from the anticipatory grief related to the premature detachment from the person who is dying. It is the goal of the gerontological nurse to support those who are grieving. See Chapter 43  for a discussion about facing death.

Nurses help clients who are alone a great deal to adjust to their living arrangements or lifestyle so that they have more companionship. Moving to a retirement home that has other people in similar circumstances and organized social activities is one example. Many communities provide social centers for older adults, for example, drop-in centers or community centers that offer day trips for seniors. Nurses refer clients to services and encourage them to obtain companionship.

COGNITIVE ABILITIES AND AGING

Piaget's phases of cognitive development end with the formal operations phase. However, considerable research on cognitive abilities and aging is currently being conducted. Intellectual capacity includes perception, cognitive agility, memory, and learning.

Perception

Perception, or the ability to interpret the environment, depends on the acuteness of the senses. If the aging person's senses are impaired, the ability to perceive the environment and react appropriately is diminished. Changes in the nervous system may also affect perceptual capacity.

Changes in cognitive structures occur as a person ages. The brain loses mass with aging. In addition, blood flow to the brain decreases, the meninges thicken, and brain metabolism slows. As yet, little is known about the effect of these physical changes on the cognitive functioning of the older adult. Lifelong mental activity, particularly verbal activity, helps the older adult retain a high level of cognitive function and helps maintain long-term memory.

Cognitive Agility

In older adults, changes in cognitive abilities are more often a difference in speed than in ability. Overall the older adult maintains intelligence, problem solving, judgment, creativity, and other well-practiced cognitive skills. Intellectual loss generally reflects a disease process such as atherosclerosis, which causes the blood vessels to narrow and diminishes perfusion of nutrients to the brain. Most older adults do not experience cognitive impairments. Dementia affects 2.4 to 5.5 million Americans. Mild cognitive impairment is different from dementia since the client is able to perform ADLs independently (Lin, O'Connor, Rossom, Perdue, & Eckstrom, 2013). It is important to note, that memory impairment is more prevalent in persons over age 85 than persons between the ages of 65 and 69. Cognitive impairment that interferes with normal life is not considered part of normal aging. A decline in intellectual abilities that interferes with social or occupational functions should always be regarded as abnormal. Family members should be advised to seek prompt medical evaluation.

Memory

Memory is also a component of intellectual capacity that involves the following steps:

1. Momentary perception of stimuli from the environment referred to as **sensory memory**.
2. Storage in **short-term memory** (information held in the brain for immediate use or what one has in mind at a given moment). An example of this type of memory is when you call information for a telephone number and remember the number only for the brief time needed to dial the number. Short-term memory also deals with activities or the recent past of minutes to a few hours that is often referred to as **recent memory**.
3. Encoding during which the information leaves short-term memory and enters **long-term memory**, the repository for information stored for periods longer than 72 hours and usually weeks and years. Memories of childhood friends, teachers, and events are stored in long-term memory. Older people who remember the flowers in their wedding bouquet or the names of the boys on their dance card are drawing from long-term memory.

In older adults, retrieval of information from long-term memory can be slower, especially if the information is not frequently used. Most age-related differences, however, occur in short-term memory. Older adults tend to forget the recent past. This forgetfulness can be improved by the use of memory aids, making notes or lists, and placing objects in consistent locations.

Learning

Older people need additional time for learning, largely because of the problem of retrieving information. Motivation is also

important. Older adults have more difficulty than younger ones in learning information they do not consider meaningful; therefore, the nurse should be particularly careful to discover what is meaningful to the older adult before attempting client education. See Chapter 27 ∞.

MORAL REASONING

Much of the theoretical and empirical work related to moral development in older adults was conducted in the 1980s, and few current studies can be found. According to Kohlberg (1984), moral development is completed in the early adult years. Kohlberg hypothesized that an older person at the preconventional level obeys rules to avoid pain and the displeasure of others. At stage 1, a person defines good and bad in relation to self, whereas older people at stage 2 may act to meet another's needs as well as their own. Older adults at the conventional level follow society's rules of conduct in response to the expectations of others. Pratt, Diessner, Pratt, Hunsberger, and Pancer (1996) found that moral reasoning does not decline in old age.

Gilligan (1982), however, challenged Kohlberg's stages as not being applicable to women. She developed a theory of moral reasoning based on the concept of caring. She believed that women base moral judgments on connectedness to others and the value of relationships, while Kohlberg based his stages on concepts of justice, objectivity, and preservation of rights. Subsequent research has demonstrated that men and women make moral decisions differently, and represent Kohlberg (men) and Gilligan (women) along gender lines. Older adults, however, begin to make moral decisions that are consistent with *both* Kohlberg and Gilligan (Pinch & Parsons, 1997). Older men consider relationships, as well as justice, in moral decisions, and older women add justice to the factors they consider in moral situations.

The value and belief patterns that are important to older adults may be different from those held by younger people because they developed during a time that was very different from today. Cultural background, life experiences, gender, religion, and socioeconomic status all influence one's values. The nurse must identify and consider the specific values of the older client when nursing care is planned.

SPIRITUALITY AND AGING

Older adults can contemplate new religious and philosophical views and try to understand ideas missed previously or interpreted differently. The older person may derive a sense of worth by sharing experiences or views. In contrast, the older adult who has not matured spiritually may feel impoverishment or despair as the drive for economic and professional success lessens.

Many older adults take their faith and religious practice very seriously, and display a high level of spirituality. It would be a mistake, however, to assume that religiosity increases with age. Today's older adults grew up in a time when religion was much more important than it is for younger people today. The continuing participation in religious practices provides an inner strength that enhances coping. Nurses should support the practice of religion by providing time to pray and assisting the older adult in attendance at church services (Eliopoulos, 2014). Many older people have strong religious

convictions and continue to attend religious meetings or services. Involvement in religion often helps the older adult to resolve issues related to the meaning of life, to adversity, or to good fortune. Religion may also be an important coping resource, leading to enhanced well-being. The “old-old” person who cannot attend formal services often continues religious participation in a more private manner. Assisting the older person to participate in religious and spiritual practices is an important nursing responsibility.

HEALTH PROBLEMS

Health problems that older adults may experience include injuries, chronic disabling disease such as hypertension and arthritis, drug abuse and misuse, alcoholism, dementia, and mistreatment. Leading causes of death in people ages 65 and over are heart disease, cancer, cerebrovascular disease (stroke), lower respiratory disease, pneumonia/influenza, and diabetes mellitus (FIFAS, 2012).

Injuries

Injury prevention is a major concern for older people. Falls are a leading cause of morbidity and mortality among older adults (Edelman & Mandle, 2010, p. 635). Because vision is limited, reflexes are slowed, and bones are brittle, caution is required in climbing stairs, driving a car, and even walking. Driving, particularly night driving, requires caution because accommodation of the eye to light is impaired and peripheral vision is diminished. Older people need to learn to turn the head before changing lanes and should not rely on side vision, for example, when crossing a street. Driving in fog or other hazardous conditions should be avoided.

Fires are a hazard for the older adult with a failing memory. Older adults may forget that the iron or stove is left on or may not extinguish a cigarette completely. Because of reduced sensitivity to pain and heat, care must be taken to prevent burns when the person bathes or uses heating devices.

Many older adults suffer and die each year from hypothermia. **Hypothermia** is a body temperature below normal. A lowered metabolism and loss of normal insulation from thinning subcutaneous tissue decrease the older client's ability to retain heat. The older adult who spends time outdoors in cold weather or who does not turn on the heat in the home is at significant risk for hypothermia.

Nurses can help older adults make the home environment safe by identifying and correcting specific hazards; for example, installing handrails on staircases. The nurse teaches the importance of taking only prescribed medications and contacting a health professional at the first indication of intolerance to them.

Individuals with AD or other types of dementia experience increasing safety needs as their condition deteriorates. Judgment becomes impaired as the disease progresses, and some environmental modification is needed to help the older adult remain safe. Some of these are keeping poisons and medications out of reach (preferably locked up), taking knobs off kitchen stoves to prevent burns and fires, and putting special locks on doors for individuals who tend to wander. Attention should be given to these potential problems whether the client lives at home or is in a health facility.

Guidelines for injury prevention for the older adult are detailed in Chapter 32 ∞.

Chronic Disabling Illness

Many older adults function well within the community without impairments; others are afflicted with one or more chronic illnesses that may seriously impair their functioning. Examples of these are arthritis, osteoporosis, heart disease, stroke, obstructive lung disease, hearing and visual alterations, and cognitive dysfunctions. In addition, acute illnesses such as pneumonia and fractures and trauma from falls, motor vehicle crashes, or other incidents may create chronic health problems. Chronic illness brings many changes to the client and the family members. The client, for example, may need increasing help with the ADLs of ambulation, feeding, hygiene, and so on; health care expenses often escalate and may become an economic concern; family roles may need to be altered; and family members may need to change their lifestyle to meet caregiving needs.

Drug Abuse and Misuse

Older adults take an average of 31.1 prescriptions per year (Mauk, 2014, p. 419). Added to this, older adults may purchase over-the-counter (OTC) drugs to remedy common discomforts related to aging, such as constipation, sleep disturbance, and joint pain. During the past few years, the use of vitamins, food supplements, and herbal remedies has increased. These agents fall under the category of OTC drugs and are often not reported by clients as part of their medicine regimen. An accurate assessment should include a listing of all these agents. Many of these agents have not had adequate testing for effectiveness, side effects, or interactions with other medications.

The complexities involved in the self-administration of medication may lead to a variety of misuse situations, including taking too much or too little medication, combining alcohol and medication, combining prescribed medications with OTC drugs causing increased risk for drug interactions and adverse events, taking medications at the wrong time, or taking someone else's medication. Other potential misuse situations occur when more than one primary care provider prescribes medications and the client fails to tell each primary care provider what has been previously prescribed.

Additionally, the pharmacodynamics of drugs are altered in older adults. The variations in absorption, distribution, metabolism, and excretion of drugs are related to physiological changes associated with aging. These variations are discussed in Chapter 35 ∞.

Most older adults living independently in the community take their medications with no supervision. Therefore, education about medications is important for safe medication-taking behaviors. The following strategies, taught by the nurse, can promote safe medication use by the older adult:

- Write a list of all the medications you are taking, including OTC drugs and herbal supplements. Include any medication allergies on the list. Keep the list current and carry it in your purse or billfold.
- Know the reason you are taking each medication. Ask your primary care practitioner the reason for any new medication.
- Consider using a “pill organizer” system to help you remember to take your medications. This is helpful if you have many medications to take each day.
- Ask your pharmacist for easy-to-open containers if you have difficulty opening the medications.

- If possible, obtain all medications from the same pharmacy. This allows the pharmacist to monitor for drug duplications and interactions.

Alcoholism

There are two types of older alcoholics: those who began drinking alcohol in their youth and those who began excessive alcohol use later in life to help them cope with the changes and problems of their older years. Approximately one third of older alcoholics are late-onset drinkers (after age 60) and that number includes a higher number of women (Ebersole et al., 2012, p. 357).

Chronic drinking has major effects on all body systems, causes progressive liver and kidney damage, damages the stomach and related organs, and slows mental response, frequently leading to injuries and death. Alcohol interacts with various drugs, altering the normal effect of the medication on the body. Some medications have an increased effect when taken with alcohol (e.g., anticoagulants and narcotics), whereas the action of other medications (e.g., antibiotics) is inhibited. For the older adult who has a chronic illness and takes many medications, the combination of drugs and alcohol can lead to serious drug overdose.

Clients with alcoholism should not be stereotyped or prejudged by the nurse. Rather, they should be accepted, listened to, and offered help. The nurse should assess the number and type of alcoholic beverages consumed as well as the pattern and frequency of consumption. It is important for the nurse to discuss any medications the client is taking and review the side effects and interaction effects of alcohol and medication. The role of the nurse is to act as a client advocate and facilitate the treatment of the drinking problem in addition to the prevention of possible complications.

Dementia

Dementia is a progressive loss of cognitive function. It is critical that dementia be differentiated from delirium, which is an acute and reversible syndrome. Both may be characterized by changes in memory, judgment, language, mathematic calculation, abstract reasoning, and problem-solving ability. The most common causes of *delirium* are infection, medications, and dehydration. The most common type of *dementia* is Alzheimer's disease (AD), of which the cause is unknown.

The course of this disease is slow and insidious, affecting about 5 million people in the United States. Unless a prevention or cure is found, it is estimated that 16 million Americans will have AD by the year 2050 (Alzheimer's Association, 2013).

The symptoms of AD vary from client to client. The most prominent symptoms are cognitive dysfunctions, including decline in memory, learning, attention, judgment, orientation, and language skills. The symptoms are progressive, leading to a steady decline in cognitive and physical abilities, lasting between 7 and 15 years, and ending in death. In the last stage, the client requires total assistance, is unable to communicate, is incontinent, and is often unable to walk. There is no cure or specific treatment for AD. Several drugs have been developed, but none has been shown consistently to reverse the progression of the disease.

It is estimated that about 1 million people with AD are cared for in the home. The burden of care is frequently on women—wives and daughters—who are themselves aging. AD is devastating for the families and caregivers of its victims. Caregivers may experience physical and emotional exhaustion while rendering continuous care to their loved one. Caregiving is complicated when the client no longer recognizes family members or close friends. The nurse's responsibility is to provide supportive nursing care, accurate information, and referral assistance when placement in a nursing care facility is deemed necessary. Help by the nurse in facilitating the provision of respite services may also be very helpful to the caregiver. Ongoing nursing assessment of both the client and the caregiver is important, especially as the client's condition deteriorates.

Mistreatment of Older Adults

Approximately 1 to 2 million Americans over the age of 65 have been abused, neglected, or exploited by someone on whom they depend for protection and care (National Council on Child Abuse & Family Violence, 2014). Mistreatment of older adults may affect either gender. However, the victims most often are women over 75 years of age who are physically or mentally impaired and dependent for care on the abuser. The abuse may be physical, psychological, or emotional in nature. Sexual abuse, financial abuse, violation of human or civil rights, and active or passive neglect have also been documented.

DRUG CAPSULE

Parasympathomimetic or Cholinesterase Inhibitor donepezil (Aricept)

THE CLIENT WITH ALZHEIMER'S DISEASE

Cholinesterase inhibitors improve cholinergic function by inhibiting acetylcholinesterase, thus increasing the amount of acetylcholine in the brain.

In normal brain function, acetylcholine is an essential neurotransmitter and plays an important role in cognitive function, including memory storage and retrieval (Frandsen & Pennington, 2014).

Cholinesterase inhibitors do not alter AD but may stabilize the older client at the current level of dementia and/or lessen symptoms for a short period of time (e.g., average of 6 months).

NURSING RESPONSIBILITIES

- Assess cognitive ability of the client.
- Monitor heart rate because bradycardia may occur.

CLIENT AND FAMILY TEACHING

- Explain that donepezil may cause dizziness and the client may want to take the medication in the evening before going to bed.
- Teach that the medication can be taken with or without food.
- Emphasize the importance of taking the medication every day. A missed dose should be skipped, and the client should return to the regular schedule the next day.
- Explain that the medication is started at a lower dose with a gradual increase in dosage. Higher doses may not increase the effects but may increase the side effects (gastrointestinal disturbance, sleep disturbance, and sedation).

Note: Prior to administering any medication, review all aspects with a current drug handbook or other reliable source.

When mistreatment involves physical neglect, victims may suffer from dehydration, malnutrition, and oversedation. The victim may be deprived of necessary articles, such as glasses, hearing aids, or walkers. Psychologically, the person may suffer verbal assaults, threats, humiliation, or harassment. Abuse may also include failure to provide appropriate medications or medical treatment, isolation, unreasonable confinement, lack of privacy, an unsafe environment, and involuntary servitude. Some are financially exploited by relatives who steal from them or misuse their property or funds. Others are beaten and even raped by family members. Most victims experience two or more forms of abuse.

Abuse or neglect of older adults may occur in private homes, senior citizens' homes, nursing homes, hospitals, and long-term care facilities. Many of the abusers are either sons or daughters; others include spouses, relatives (grandchildren, siblings, nieces, and nephews), and in some instances health care providers.

Older adults at home may fail to report abuse or neglect for many reasons. They may be ashamed to admit that their children have mistreated them or fear retaliation if they seek help. They may fear being sent to an institution. They frequently lack financial resources or lack the mental capacity to be aware of abuse or neglect and to report the situation. Examples of crimes are assault and financial abuse of an older person who is physically or mentally incompetent and has no trustworthy friend or relative to help. In some instances, nurses can intervene by educating caregivers about the needs of older adults and available resources to provide increased home support. They should also report the situation to the appropriate person in the health care agency.

Nurses should be familiar with the laws of their particular state regarding the reporting of suspected or known abuse. The legally competent adult cannot be forced, however, to leave the abusive situation and in many cases may decide to stay. If the client is not legally competent, court proceedings to attain guardianship can be initiated.

HEALTH ASSESSMENT AND PROMOTION

Assessment guidelines for the development of the older adult are shown in the accompanying Developmental Assessment Guidelines. Assessment activities include measurement of weight, height, and vital signs; observation of the skin for hydration status or presence of lesions; examination of visual acuity using the Snellen chart; examination of hearing acuity using the Weber and Rinne tests (see Chapter 30 ∞); and questions about the following:

- Usual dietary pattern
- Bowel or urinary elimination problems
- Activity, exercise, and sleep patterns
- Family and social activities and interests
- Reading, writing, or problem-solving difficulties
- Adjustment to retirement or the loss of a partner.

Health care professionals should also be alert for these signs:

- Symptoms of depression
- Risk factors for suicide
- Signs of abnormal bereavement
- Changes in cognitive function
- Medications that increase risk of falls
- Signs of physical abuse or neglect
- Skin lesions (malignant and peripheral)
- Tooth decay, gingivitis, loose teeth
- Peripheral arterial disease.

Older adults are usually concerned about their health and interested in information and behavioral strategies directed toward improving it. The nurse may wish to discuss some or all of the health promotion topics outlined in Box 23–2. These topics are discussed in detail in subsequent chapters throughout this text.

Developmental Assessment Guidelines

The Older Adult

In these three developmental areas, does the older adult do the following?

PHYSICAL DEVELOPMENT

- Adjust to physiological changes (e.g., appearance, sensory-perceptual, musculoskeletal, neurologic, cardiovascular).
- Adapt lifestyle to diminishing energy and ability.
- Maintain vital signs (especially blood pressure) within normal range for age and gender.

PSYCHOSOCIAL DEVELOPMENT

- Manage retirement years in a satisfying manner.
- Participate in social and leisure activities.
- Have a social network of friends and support people.

- View life as worthwhile.
- Have high self-esteem.
- Gain support from value system and/or spiritual philosophy.
- Accept and adjust to the death of significant others.

DEVELOPMENT IN ACTIVITIES OF DAILY LIVING

- Exhibit healthy practices in nutrition, exercise, recreation, sleep patterns, and personal habits.
- Have the ability to care for self or to secure appropriate help with ADLs.
- Have satisfactory living arrangements and income to meet changing needs.

BOX 23-2 Health Promotion Guidelines for Older Adults**HEALTH TESTS AND SCREENING**

- Total cholesterol and high-density lipoprotein measurement every 3 to 5 years until age 75
- Aspirin, 81 mg, daily, if in high-risk group
- Diabetes mellitus screen every 3 years, if in high-risk group
- Smoking cessation
- Screening mammogram every 1 to 2 years (women)
- Clinical breast exam annually (women)
- Pap smear annually if there is a history of risk factors (exposed to diethylstilbestrol [DES] before birth, weakened immune system from HIV infection, organ transplant, chemotherapy, or chronic steroid use), abnormal smears or previous hysterectomy for malignancy (American Cancer Society, 2012)
- Women 65 years and older who have had normal cervical results should not be tested for cervical cancer. Women with a history of a serious cervical pre-cancer should continue to be tested at least 20 years after the diagnosis, even if testing continues past age 65 (American Cancer Society, 2013).
- Annual digital rectal exam
- Annual prostate-specific antigen (PSA)
- Annual fecal occult blood test (FOBT)
- Sigmoidoscopy every 5 years; colonoscopy every 10 years
- Visual acuity screen annually
- Hearing screen annually
- Depression screen periodically
- Family violence screen periodically
- Height and weight measurements annually
- Sexually transmitted infection testing, if in high-risk group
- Annual flu vaccine if over age 65 or in high-risk group
- Pneumococcal vaccine at age 65 and every 10 years thereafter
- Single dose of shingles vaccine for adults 60 years of age or older
- Tetanus booster every 10 years

SAFETY

- Home safety measures to prevent falls, fire, burns, scalds, and electrocution
- Working smoke detectors and carbon monoxide detectors in the home
- Motor vehicle safety reinforcement, especially when driving at night
- Older driver skills evaluation (some states require for license renewal)
- Precautions to prevent pedestrian accidents

NUTRITION AND EXERCISE

- Importance of a well-balanced diet with fewer calories to accommodate lower metabolic rate and decreased physical activity
- Importance of sufficient amounts of vitamin D and calcium to prevent osteoporosis
- Nutritional and exercise factors that may lead to cardiovascular disease (e.g., obesity, cholesterol and fat intake, lack of exercise)
- Importance of 30 minutes of moderate physical activity daily; 20 minutes of vigorous physical activity three times per week

ELIMINATION

- Importance of adequate roughage in the diet, adequate exercise, and at least six 8-ounce glasses of fluid daily to prevent constipation

SOCIAL INTERACTIONS

- Encouraging intellectual and recreational pursuits
- Encouraging personal relationships that promote discussion of feelings, concerns, and fears
- Assessment of risk factors for maltreatment
- Availability of social community centers and programs for seniors

**Critical Thinking Checkpoint**

Alice Green, a 78-year-old female, has had a bone density scan as part of a regular physical exam and has been told that she has severe osteoporosis. Her primary care provider has ordered a new experimental medication that is supposed to maintain bone mass in clients with osteoporosis. She lives alone in her own home and is able to perform ADLs independently.

1. How would you define osteoporosis to Mrs. Green?
2. What risk factors related to osteoporosis should be included in an assessment of Mrs. Green?

3. Which of the risk factors are modifiable or can be altered by a change in lifestyle?
4. What medication teaching is essential when a client is taking medications to increase or maintain bone mass in osteoporosis?
5. What preventive measures should be taught to decrease risks of fractures and to maintain bone mass?

See Critical Thinking Possibilities on student resource website.

Chapter 23 Review

CHAPTER HIGHLIGHTS

- The older adult population is steadily growing and projected to outnumber young people by the middle of the 21st century.
- Older adults are categorized into young-old (60 to 74 years), old-old (75 to 100 years), and centenarians (over 100 years).
- Older adults represent a diverse population in the United States. For example, women outnumber men, older Hispanics are the

fastest growing subpopulation group, and the majority of older adults rate their health as good.

- It is important for nurses to be aware of their own values and attitudes toward aging to avoid ageism, and to examine whether myths or stereotypes influence their personal attitudes and beliefs.

- The gerontological nurse has many roles: provider of care, teacher, manager, advocate, and research consumer.
- Older adults are primary users of health care services in different types of care settings, including acute care, rehabilitation, long-term care, and the community. Regardless of the setting, the older adult requires health assessment and health promotion.
- Several theories have been proposed to account for the biological aging process: wear-and-tear, endocrine, free-radical, genetic, cross-linking, and immunologic theories.
- Older adults experience many physical changes associated with aging. All body systems undergo change: integumentary, neuromuscular, sensory-perceptual, pulmonary, cardiovascular, gastrointestinal, and genitourinary.
- Psychosocial theories about aging include the disengagement, activity, and continuity theories.
- The older adult has to adjust to possible psychosocial changes, including retirement (which necessitates financial and social adjustments), grandparenting, relocation, increasing dependence on others, and coping with losses and death.
- The cognitive abilities of the healthy older adult undergo some changes in perception, cognitive agility, memory, and learning.
- In the realm of moral reasoning, most older adults begin to blend concepts of justice and caring relationships into their moral decision making.
- Many older adults take their faith and religious practice seriously and display a high level of spirituality.
- Health problems of older adults include injuries, chronic disabling illness, drug abuse and misuse, alcoholism, dementia, and mistreatment.
- Health promotion information for all adults needs to include positive health practices that can promote health and wellness. These include (a) recommended physical, visual, hearing, and dental assessments; (b) screenings for cardiovascular disease and tuberculosis; (c) breast and testicular self-examinations; (d) immunizations; (e) Papanicolaou smears for some older women; (f) safety precautions to prevent injuries; (g) the importance of appropriate nutrition and exercise; and (h) the importance of measures to prevent constipation.

TEST YOUR KNOWLEDGE

- The nurse provides care for an older adult whose husband died 8 months ago. Which of the following behaviors indicates that the client is experiencing effective coping? Select all that apply.
 - Shows the nurse photographs of her family.
 - Refuses to keep her beauty appointments.
 - Visits her husband's grave every 2 weeks.
 - Attends church on a regular basis.
 - Increases her consumption of alcohol.
- A nurse in a long-term care facility is caring for several older adults with noticeable hearing losses. Which is the best way for the nurse to communicate with these clients?
 - Speak slowly using the proper volume and as few words as possible.
 - Write the information using large lettering.
 - Speak in a low and distinct voice tone.
 - Have the client increase the volume in the hearing aid.
- The nurse observes that an 85-year-old man at an adult day care center fondly shares stories about traveling on the "orphan trains" and his subsequent adoption. Following a behavioral assessment, the nurse should perform which interventions?
 - Refer him for a geriatric psychiatric evaluation.
 - Listen and ask him questions about his life.
 - Distract him and change the conversation.
 - Involve him in more social activities.
- The home health nurse evaluates an older adult for depression. The client's daughter is present and comments, "I don't see the need for this evaluation. Aren't all older people depressed?" Which is the nurse's best initial response?
 - "How many losses has your mother had?"
 - "Your mother looks so depressed."
 - "How long has she been depressed?"
 - "Depression is not a normal part of aging."
- While being admitted to a rehabilitation unit, an 82-year-old woman mentions to the nurse that she "has trouble holding her water," adding "if I could have that tube back in me like I had in the hospital, I wouldn't have so many accidents." What is the nurse's best response?
 - "Don't worry, the staff will bring plenty of pads to keep you dry."
 - "I'll put the tube back in you so you will stay dry."
 - "Tell me more about your problem."
 - "Just call the staff and we'll help you to the bathroom in time."
- The nurse notices that when an 80-year-old man rises from a seated position, the client uses both arms to push himself up, and also "rocks" back and forth before finally standing. What is the most appropriate nursing intervention for this client?
 - Suggest a referral to physical therapy for strengthening exercises.
 - Request a waist restraint to remind the client not to stand by himself.
 - Praise the client for his attempts to remain independent.
 - Assist the client to rise by grasping both his shoulders and pulling forward.
- A healthy 78-year-old woman who is considering marriage to a healthy 79-year-old neighbor tells the nurse that she wonders if they will be able to have sexual intercourse. Which is the nurse's most appropriate response?
 - "Sexual activity may be too demanding for your heart."
 - "Older women maintain sexual function, but most older men are impotent."
 - "Most older people are not interested in sexual activity."
 - "Both of you may have slower responses to sexual stimulation."

8. The client complains of having difficulty clearly seeing the words in the newspaper unless he holds the newspaper an arm's length away. The nurse uses which terminology to document this assessment?
1. Presbycusis
 2. Xerostomia
 3. Presbyopia
 4. Presbyesophagus
9. The nursing student is planning care for an older adult who had a total knee replacement yesterday evening. Which nursing intervention would be *most* appropriate?
1. Ask the client how much of his bath he can independently perform.
 2. Ask the client if he has any questions regarding discharge from the hospital.
 3. Tell the client that he needs to decide when he wants his medications.
 4. Tell the client that he needs to rest and will be given a complete bed bath.
10. A 76-year-old woman with dementia lives in an assisted living facility and often asks, "When will my sister come to visit me this afternoon?" The sister passed away last year. Which is the best response from the nurse?
1. "This is so sad. I'm sorry to tell you but your sister died last year."
 2. "She won't be coming to visit today."
 3. "I understand you want her to visit you. Where did you and your sister grow up?"
 4. "Wait and see if she comes to visit today."

See Answers to Test Your Knowledge in Appendix A.

READINGS AND REFERENCES

Suggested Readings

- Baumbusch, J., Dahle, S., & Phinney, A. (2012). Nursing students' knowledge and beliefs about care of the older adults in a shifting context of nursing education. *Journal of Advanced Nursing*, 68, 2550–2558. doi:10.1111/j.1365-2648.2012.05958.x
This article was a study of improvements in students' knowledge of nursing care delivered to older adults. The students completed an introductory course that integrated both adult and older adult content. Upon completion of the course the students' knowledge and beliefs were positively influenced.
- Neidrick, T. J., Fick, D. M., & Loeb, S. J. (2012). Physical activity promotion in primary care targeting the older adult. *Journal of the American Academy of Nurse Practitioners*, 24, 405–416. doi:10.1111/j.1745-7599.2012.00703.x
This study identified and examined literature that focused on the physical activity that is provided in primary care settings. The study revealed that activity interventions implemented in the primary care setting yielded short-term activity increases. The authors concluded that activity orders should be provided in primary care settings.
- Rolison, J. J., Hewson, P. J., Hellier, E., & Husband, P. (2012). Risk of fatal fall injury in older adult drivers, passengers, and pedestrians. *Journal of the American Geriatrics Society*, 60, 1504–1508. doi:10.1111/j.1532-5415.2012.04059.x
This article compared the risk of fatal injury in elderly road users with younger road users. The risk of fatal injury was higher for older drivers, passengers, and pedestrians.

24 Promoting Family Health

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Describe the functions of the family.
2. Describe different types of families.
3. Identify theoretical frameworks used in family health promotion.
4. Identify the components of a family health assessment.
5. Identify common risk factors for family health problems.
6. Develop nursing diagnoses, outcomes, and interventions pertaining to family functioning.

KEY TERMS

family, 386

genogram, 389

nuclear family, 386

extended family, 386

family-centered nursing, 386

INTRODUCTION

Nurses assess and plan health care for three types of clients: the individual, the family, and the community. The beliefs and values of each person and the support he or she receives come in large part from the family and are reinforced by the community. Thus, an understanding of family dynamics and the context of the community assists the nurse in planning care. When a family is the client, the nurse determines the health status of the family and its individual members, the level of family functioning, family interaction patterns, and family strengths and weaknesses.

FAMILY HEALTH

The **family** is a basic unit of society. It consists of those individuals, male or female, youth or adult, legally or not legally related, genetically or not genetically related, who are considered by the others to represent their significant people. In the nursing profession, interest in the family unit and its impact on the health, values, and productivity of individual family members is expressed by **family-centered nursing**: nursing that considers the health of the family as a unit in addition to the health of individual family members.

Functions of the Family

The economic resources needed by the family are secured by adult members. The family protects the physical health of its members by providing adequate nutrition and health care services. Nutritional and lifestyle practices of the family also directly affect the developing health attitudes and lifestyle practices of the children.

In addition to providing an environment conducive to physical growth and health, the family creates an atmosphere that influences the cognitive and the psychosocial growth of its members. Children and adults in healthy, functional families receive support, understanding, and encouragement as they progress through predictable developmental stages, as they move in or out of the family unit, and as they establish new family units. In families where members are physically and emotionally nurtured, individuals are challenged to achieve their potential in the family unit. As individual needs are met, family

members are able to reach out to others in the family and the community, and to society.

Families from different cultures are an integral part of North America's rich heritage. Each family has values and beliefs that are unique to their culture of origin and that shape the family's structure, methods of interaction, health care practices, and coping mechanisms. These factors interact to influence the health of families. Families of a particular culture may cluster to form mutual support systems and to preserve their heritage; however, this practice may isolate them from the larger society (Figure 24–1 ■).

Becoming acculturated is a slow, stressful process of learning the language and customs of a new country. Children in cultural clusters often have greater contact with the world around them than do adults; through school, children become more proficient in a new language and more comfortable with new customs and behaviors. Sometimes children create conflict in the family when they bring home new ideas and values. For more information about cultural aspects of health of individuals and families, see Chapter 18 ∞.

Types of Families in Today's Society

Families consist of individuals (structure) and their responsibilities within the family (roles). Government data are grouped by types of **households**: married couples with children, married couples without children, other family households (single-parent families), men living alone, women living alone, and other nonfamily households. A family structure of parents and their offspring is known as the **nuclear family**. The relatives of nuclear families, such as grandparents or aunts and uncles, compose the **extended family**. In some families, members of the extended family live with the nuclear family. Although members of the extended family may live in different areas, they may be a source of emotional or financial support for the family.

Some families live in houses, some in apartments; some live in urban areas, some in rural towns; and some are homeless. Annually, the U.S. Conference of Mayors publishes a *Hunger and Homelessness Survey*. It contains the results of surveys from 25 cities across the country. In 2012 it reported that 60% of the cities in the survey

Figure 24-1 ■ Cultural separation.
Gunter Marx © Dorling Kindersley.

had documented an increase in the homeless population. Homeless families increased by 8% according to the survey. The lack of affordable housing for families has been established as the key reason for this increase.

TRADITIONAL FAMILY

The traditional family is viewed as an independent unit in which both parents reside in the home with their children, the mother often assuming the nurturing role and the father providing the necessary economic resources. In today's society both males and females are less bound to traditional role patterns. For example, fathers are more likely to be involved with the household chores, their children, and family life (Figure 24-2 ■). The U.S. Census Bureau (2012b) reported 24.7 million fathers in married-couple families, 176,000 of whom were stay-at-home fathers (caring for 332,000 children) in 2011. The percentage of families with their own children living in the home had been dropping as the baby boomer generation aged. However, the economic downturn of the late 2000s has modified that trend. According to the U.S. Census Bureau, in 2011, 59% of men and 50% of women ages 25 to 34 years old resided in their parents' home. In 2005 it was 53% and 46%, respectively.

TWO-CAREER FAMILY

In two-career (or dual-career) families, both partners are employed. They may or may not have children. Two-career families have steadily increased since the 1960s because of increased career opportunities for women, a desire to increase their standard of living, and economic necessity. Finding good-quality, affordable child care is one of the greatest stresses faced by working parents.

SINGLE-PARENT FAMILY

From 1970 on the number of single-parent households had been increasing. However, recent statistics show that single-parent households have stabilized at 9% (U.S. Census Bureau, 2012a). Twenty-eight percent of children in the United States live in single-parent households. The Asian population has the smallest percentage of single-parent households. The largest ethnic group representing single-parent families are African Americans at 55%. There are many reasons for single parenthood, including death of a spouse, separation, divorce, birth of a child to an unmarried woman, or adoption of a child by a single man or woman. The birthrate among unmarried

Figure 24-2 ■ Role patterns within traditional families are changing.
Flynn Larsen/Cultura/Riser/Getty Images.

women is approximately 21% of all births (U.S. Census Bureau, 2012c). The stresses of single parenthood are many: child care concerns, financial concerns, role overload and fatigue in managing daily tasks, and social isolation.

ADOLESCENT FAMILY

Birthrates among teenagers peaked in 1991 and have decreased progressively since then with a slight increase in 2006. From 2007 to 2011 the teen birthrate has declined by 25%. This decrease was noted among all races. Teen births per 1,000 females ages 15–19 years were highest among Hispanic teens at 49.6% followed by non-Hispanic Blacks at 47.3%, American Indian/Alaska Native at 36.1%, and non-Hispanic White women at 21.7%. The lowest percentage is that of Asian and Pacific Islanders at 10.2%. On average this is down 1% for racial group since 2010 (U.S. Department of Health and Human Services, 2013). These young parents are often developmentally, physically, emotionally, and financially ill prepared to undertake the responsibility of parenthood. Adolescent pregnancies frequently interrupt or stop formal education. Children born to an adolescent are often at greater risk for health and social problems, and they have few role models to assist in breaking out of the cycle of poverty.

FOSTER FAMILY

Children who can no longer live with their birth parents may require placement with a family that has agreed to include them temporarily.

The legal agreement between the foster family and the court to care for the child includes the expectations of the foster parents and the financial compensation they will receive. A family (with or without their own children) may house more than one foster child at a time or different children over many years. Hopefully, at some time the fostered child can return to the birth parent(s) or be legally and permanently adopted by other parents.

BLENDING FAMILY

Existing family units who join together to form new families are known as *blended* or *step families*. There are no official statistics on the number of blended families, but a commonly accepted view is that about one of every three Americans is a member of a stepfamily. Family integration requires time and effort. Stresses occur as blended families become acquainted with each other, respect differences, and establish new patterns of behavior. When blended families with children form following the divorce or death of a parent, adjustment can be particularly challenged by the normal processes of grief and loss (see Chapter 43 ∞).

INTRAGENERATIONAL FAMILY

In some cultures, and as people live longer, more than two generations may live together. Children may continue to live with their parents even after having their own children, or the grandparents may move in with their grown children's families after some years of living apart. In other situations, a generation is skipped or missing; in 23% of the situations in which grandparents live with and care for their grandchildren, the children's parents are not a part of this family. For 2011 the U.S. Census Bureau (2012a) reported a 64% increase in the number of children living with a grandparent since 1991. Of these grandparents 8% are living in poverty. Many life events and choices can lead to this type of family.

COHABITING FAMILY

Cohabiting (or communal) families consist of unrelated individuals or families who live under one roof. Reasons for cohabiting may be a need for companionship, a desire to achieve a sense of family, testing a relationship or commitment, or sharing expenses and household management. Cohabiting families illustrate the flexibility and creativity of the family unit in adapting to individual challenges and changing societal needs.

GAY AND LESBIAN FAMILY

Homosexual adults form gay and lesbian families based on the same goals of caring and commitment seen in heterosexual relationships. In addition, the structure of gay and lesbian families is as diverse as that of heterosexual families, including stepfamilies and single-parent families. Children raised in these family units develop sex role orientations and behaviors similar to children in the general population.

Legal issues for same-sex couples are significant and constantly changing. *Domestic partner* policies extend the same rights and privileges to the partner of a nonmarried employee of the same or opposite gender as would be offered to spouses. California Family Code Section 297–297.5 defines domestic partners as “two adults who have chosen to share one another's lives in an intimate and committed relationship of mutual caring.” Numerous state and federal regulations have been introduced in the United States to either allow or prohibit same-sex marriages or civil unions. It can be a challenge for the nurse to keep current on how such legislation affects health care issues such as insurance coverage and the right to consent for health care.

SINGLE ADULTS LIVING ALONE

Individuals who live by themselves represent a significant portion of today's society—about 30%. In younger adults 18 to 34 years of age, there is little variation in the percentages between males and females. However, among all adults living alone, 10.4% are men ages 65 years and older, and 25.2% are women ages 65 years and older (U.S. Census Bureau, 2012a). Singles include young self-supporting adults who have recently left the nuclear family as well as older adults living alone. Young adults typically move in and out of living situations and may have membership in family households, nonfamily households, and living alone categories at several different times. Older adults may find themselves single through divorce, separation, or the death of a spouse but generally remain living alone for the remainder of their lives.

APPLYING THEORETICAL FRAMEWORKS TO FAMILIES

Theoretical frameworks provide the nurse with a context or structure from which to view health and health promotion for families across the life span. Nurses generally use a combination of theoretical frameworks in promoting the health of individuals and families. Two major theoretical frameworks that nurses use in promoting the health of families are systems theory and structural–functional theory.

Systems Theory

Systems theory was introduced in Chapter 16 ∞. Nurses are increasingly using systems theory to understand not only biological systems but also systems in families, communities, and nursing and health care. Family system members are interdependent, working toward specific purposes and goals. Families, as open systems, are continually interacting with and influenced by other systems in the community. Boundaries regulate the input from other systems that interact with the family system; they also regulate output from the family system to the community or to society. Boundaries protect the family from the demands and influences of other systems. Healthy families are likely to welcome input from the outside, encourage individual members to adapt beliefs and practices to meet the changing demands of society, seek out health care information, and use community resources.

Using systems theory for health promotion of the family, the nurse considers how each element of the system affects the others. For example, if a child is seriously injured in a home accident, other siblings may feel left out of the considerable attention devoted to the child, a parent may withdraw if there are feelings of guilt for not preventing the accident, and other family members may be recruited to assist with finances or chores while the nuclear family focuses on the injured child. The nurse will facilitate a care plan that includes diagnoses and problems affecting the different components of the family system.

Structural–Functional Theory

The structural–functional theory, as the name implies, focuses on family structure and function. The structural component of the theory addresses the membership of the family and the relationships among family members. Intrafamily relationships are complex because of the numerous relationships that exist within the family structure—mother–daughter, brother–sister, spouse–partner, and so on. These relationships are constantly evolving as children mature and leave the family nest and adults age and become more dependent on others to meet their daily needs.

The functional aspect of the theory examines the effects of intra-family relationships on the family system, as well as their effects on other systems. Some of the main functions of the family include developing a sense of family purpose and affiliation, adding and socializing new members, and providing and distributing care and services to members. A healthy family organizes its members and resources in meeting family goals; it functions in harmony, working toward shared goals.

Using this theory to examine the case described earlier in which one child in a family is seriously injured, the nurse considers how the family is structured. The members of the family are parents and more than one child plus extended family, but we do not know exactly how they communicate. Who is the decision maker and in which directions do communication occur? Then, how is the family functioning? In this case, the most important functional aspects are likely to be the economic and emotional stability of the family members. The nurse will facilitate a care plan that includes diagnoses and problems from the perspective of stabilizing or enhancing the family structure and function during this episode of disruption.

●○○ NURSING MANAGEMENT

Assessing

The purpose of family assessment is to determine the level of family functioning, clarify family interaction patterns, identify family strengths and weaknesses, and describe the health status of the family and its individual members. Also important are family living patterns, including communication, child rearing, coping strategies, and health practices. Family assessment gives an overview of the family process and helps the nurse identify areas that need further investigation (Box 24-1). Nurses carry out a detailed assessment in specific target areas as they become more acquainted with the family and begin to understand family needs and strengths more fully. In planning interventions, nurses need to focus not only on problems but also on family strengths and resources as part of the nursing care plan.

The assessment begins with a complete health history. The nurse focuses first on the family unit and then on the individuals in that family. The health history is one of the most effective ways of identifying existing or potential health problems. The history is followed by physical assessment of family members.

Employment of a genogram will help the nurse visualize how all family members are genetically related to each other and to grasp how patterns of chronic conditions are present within the family unit. A **genogram** is composed of visual representations of gender and lines of birth descent through the generations (Figure 24-3 ■). If further evaluation is indicated, a referral is made to the appropriate health care professional.

The nurse should also develop an ecomap for family members individually and as a group to document the family unit's energy expenditures within the community setting. An **ecomap** provides a visualization of how the family unit interacts with the external community environment such as schools, religious commitments, occupational duties, and recreational pursuits (Figure 24-4 ■). When the focus is on health, the appraisal includes information on lifestyle behaviors and health beliefs. The nurse uses data from the health appraisal to formulate a health profile. The health profile provides the data necessary to determine wellness or to establish a nursing diagnosis and to plan appropriate nursing interventions to promote optimal health through lifestyle modification.

Health Beliefs

To promote health, the nurse must understand the health beliefs of individuals and families. Health beliefs may reflect a lack of information or misinformation about health or disease. They may also include folklore and practices from different cultures. Because of the many advances in medicine and health care during the past few decades, clients may have outdated information about health, illness, treatment, and prevention. The nurse is frequently in a position to give information or correct misconceptions. This function is an

BOX 24-1 Family Assessment Guide

FAMILY STRUCTURE

- Size and type: nuclear, extended, or other type of family
- Age and gender of family members

FAMILY ROLES AND FUNCTIONS

- Family members working outside the home; type of work and satisfaction with it
- Household roles and responsibilities and how tasks are distributed
- Ways child-rearing responsibilities are shared
- Major decision maker and methods of decision making
- Family members' satisfaction with roles, the way tasks are divided, and the way decisions are made

PHYSICAL HEALTH STATUS

- Current physical health status of each member
- Perceptions of own and other family members' health
- Preventive health practices (e.g., status of immunizations, oral hygiene practices, regularity of visual examinations)
- Previous acute illnesses and presence of chronic conditions of any member
- Screening for and knowledge of any genetic disorders
- Routine health care, when and why primary care provider last seen

INTERACTION PATTERNS

- Ways of expressing affection, love, sorrow, anger, and so on
- Most significant family member in person's life
- Openness of communication with all family members

FAMILY VALUES

- Cultural and religious orientations; degree to which cultural practices are followed
- Use of leisure time and whether leisure time is shared with total family unit
- Family's view of education, teachers, and the school system
- Health values: how much emphasis is put on exercise, diet, preventive health care

COPING RESOURCES

- Degree of emotional support offered to one another
- Availability of support people and affiliations outside the family (e.g., friends, church memberships)
- Sources of stress
- Methods of handling stressful situations and conflicting goals of family members
- Financial ability to meet current and future needs

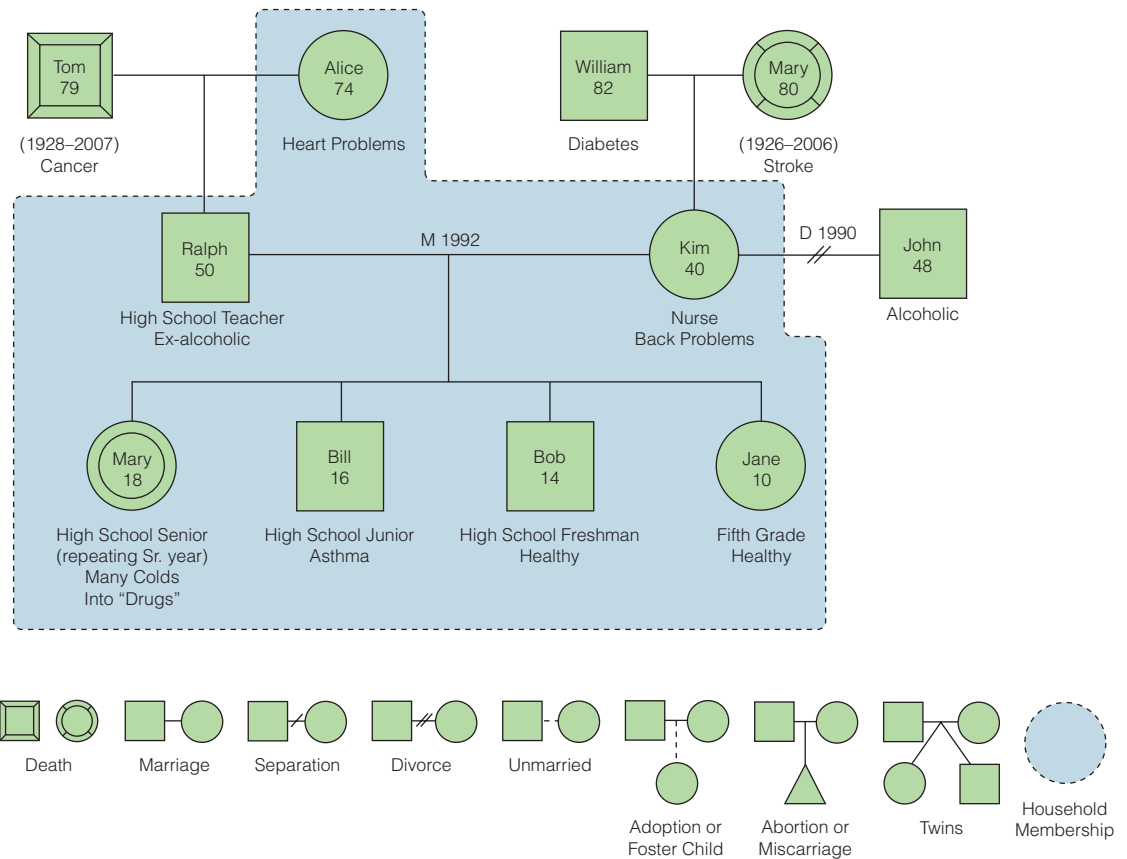

Figure 24-3 ■ Example of a family genogram with accompanying legend (symbols used in genograms).

important component of the nursing care plan. For additional information on health beliefs, see Chapter 17.

Family Communication Patterns

The effectiveness of family communication determines the family’s ability to function as a cooperative, growth-producing unit. Messages are constantly being communicated among family members, both verbally and nonverbally. The information transmitted influences how members work together, fulfill their assigned roles in the family, incorporate family values, and develop skills to function in society. Intrafamily communication plays a significant role in the development of self-esteem, which is necessary for the growth of personality.

Families that communicate effectively transmit messages clearly. Members are free to express their feelings without fear of jeopardizing their standing in the family. Family members support one another and have the ability to listen, empathize, and reach out to one another in times of crisis. When the needs of family members are met, they are more able to reach out to meet the needs of others in society.

When patterns of communication among family members are dysfunctional, messages are often communicated unclearly. Verbal communication may be incongruent with nonverbal messages. Power struggles may be evidenced by hostility, anger, or silence. Members may be cautious in expressing their feelings because they cannot predict how others in the family will respond. When family communication is impaired, the growth of individual members is stunted. Members often turn to other systems to seek personal validation and gratification.

The nurse needs to observe intrafamily communication patterns closely. Nurses should pay special attention to who does the

talking for the family, which members are silent, how disagreements are handled, and how well the members listen to one another and encourage the participation of others. Nonverbal communication is important because it gives valuable clues about what people are feeling.

Family Coping Mechanisms

Family coping mechanisms are the behaviors families use to deal with stress or changes imposed from either within or without. The use of coping mechanisms can be viewed as an active method of problem solving developed to meet life’s challenges. The coping mechanisms families and individuals develop reflect their individual resourcefulness. Families may use coping patterns rather consistently over time or may change their coping strategies when new demands are made on the family. The success of a family largely depends on how well it copes with the stresses it experiences.

Nurses working with families realize the importance of assessing coping mechanisms as a way of determining how families relate to stress. Also important are the resources available to the family. Internal resources, such as knowledge, skills, effective communication patterns, and a sense of mutuality and purpose within the family, assist in the problem-solving process. In addition, external support systems promote coping and adaptation. These external systems may be extended family, friends, religious affiliations, health care professionals, or social services. The development of social support systems is particularly valuable today because many families, due to stress, mobility, or poverty, are isolated from the resources that would traditionally have helped them cope.

Figure 24-4 ■ Example of a family ecomap. Many more components may be added to the map.

Family Violence

The incidence of family violence has increased in recent years. Statistics are not accurate, because many cases remain unreported. Family violence includes abuse between intimate partners, child abuse, and elder abuse, and may include physical, mental, and verbal abuse, as well as neglect. Early symptoms are evident in burns, cuts, fractures, and even death. Other manifestations often seen are depression, alcohol and substance abuse, and suicide attempts. Nurses should be alert to the symptoms of family violence and act appropriately to report it and obtain resources for the family. In most circumstances, laws require that the nurse report suspected abuse.

Risk for Health Problems

Risk assessment helps the nurse identify individuals and groups at higher risk than the general population of developing specific health problems, such as stroke, diabetes, and lung cancer. The vulnerability of family units to health problems may be based on the maturity level of individual family members, hereditary or genetic factors, sex, or ethnicity, sociologic factors, and lifestyle practices.

Maturity Factors

Families with members at both ends of the age continuum are at risk of developing health problems. Families entering childbearing and child-rearing phases experience many changes in roles, responsibilities, and expectations. The many, often conflicting, demands on the family cause stress and fatigue, which may impede the growth of individual family members and the functioning of the group as a unit. Adolescent

mothers, because of their developmental level and lack of knowledge about parenthood, and single-parent families, because of role overload experienced by the head of the household, are more likely to develop health problems. Older adults may feel a lack of purpose and decreased self-esteem. These feelings in turn reduce their motivation to engage in health-promoting behaviors, such as exercise or community and family involvement. Adults who simultaneously help care for their own parents and their children may have particular challenges.

Hereditary Factors

Individuals born into families with a history of certain diseases, such as diabetes or cardiovascular disease, are at greater risk of developing these conditions. A detailed family health history, including genetically transmitted disorders, is crucial to the identification of individuals and families at risk. These data are used to monitor the health of individual family members and to recommend health practices that reduce risk, minimize consequences, or postpone development of genetically related conditions.

Sex or Ethnicity

Some family units or family members may be at risk of developing a disease because of sex or ethnicity. Males, for example, are at greater risk of having cardiovascular disease at an earlier age than females, and females are at greater risk of developing osteoporosis, particularly after menopause. Although it is sometimes difficult to separate genetic factors from cultural factors, certain risk factors seem to be related to ethnicity. Sickle cell disease, for example, is a hereditary disease limited to

people of African descent, and Tay-Sachs is a neurodegenerative disease that occurs primarily in descendants of Eastern European Jews.

Sociologic Factors

Poverty is a major problem that affects not only the family but also the community and society. Poverty is a real concern among the rising number of single-parent families. As the number of these families increases, poverty will affect a large number of growing children.

When ill, the poor are likely to put off seeking services until the illness reaches an advanced state and requires longer or more complex treatment. Although the health of the people of industrialized nations has improved significantly during the past century, this progress has not benefited all segments of society, particularly the poor. Those affected by homelessness and violence experience similar challenges.

Lifestyle Practices

Many diseases are preventable, the effects of some diseases can be minimized, or the onset of disease can be delayed through lifestyle modifications. Certain cancers, cardiovascular disease, adult-onset diabetes, and tooth decay are among the lifestyle diseases. The incidence of lung cancer, for example, would be greatly reduced if people stopped smoking. Good nutrition, dental hygiene, and use of fluoride—in the water supply, in toothpaste, as a topical application, or as supplements—have been shown to reduce dental decay or caries, one of America's most prevalent health problems. Many diseases can be prevented through immunizations such as rubella, pertussis, and hepatitis B. Most of these are given in childhood but can be given to adults who have not developed immunity. See Chapter 31 ∞ for details regarding immunization schedules. Other important lifestyle considerations are exercise, stress management, and sleep.

Today health professionals have the knowledge to prevent or minimize the effects of some of the main causes of disease, disability, and death. The challenge is to disseminate information about prevention and to motivate families to make lifestyle changes prior to the onset of illness.

Diagnosing and Planning

Data gathered during a family assessment may lead to the following NANDA International (Herdman & Kamitsuru, 2014) nursing diagnoses:

- **Caregiver Role Strain:** difficulty in performing family caregiver role
- **Disabled Family Coping:** behavior of significant individual (family member or other primary individual) that disables his or her capacities and the client's capacities to effectively address tasks essential to either individual's adaptation to the health challenge
- **Dysfunctional Family Processes:** psychosocial, spiritual, and physiological functions of the family unit are chronically disorganized,

which leads to conflict, denial or problems, resistance to change, ineffective problem solving, and a series of self-perpetuating crises

- **Impaired Home Maintenance:** inability to independently maintain a safe growth-promoting immediate environment
- **Impaired Parenting:** inability of the primary caretaker to create, maintain, or regain an environment that promotes the optimum growth and development of the child
- **Interrupted Family Processes:** change in family relationships and/or functioning
- **Readiness for Enhanced Family Coping:** effective management of adaptive tasks by family member involved with the client's health challenge, who now exhibits desire and readiness for enhanced health and growth in regard to self and in relation to the client.

Being sensitive to cultural differences is important during assessment and when planning care. Knowing who makes most of the decisions in the family, especially health care decisions, helps the nurse know to whom to direct questions in order to obtain information and to whom to give instructions. The extended family unit is found in many cultures and there may be a difference in health beliefs and health practices within the family. Older members of the family may use their traditional practices, whereas younger members may have had more exposure to modern practices. Building a trusting relationship with these families is the first step toward planning care that is more effective by being able to talk to the family members about their beliefs and practices.

Nurses need to focus on assisting the family to plan realistic goals/outcomes and strategies that enhance family functioning, such as improving communication skills, identifying and utilizing support systems, and developing and rehearsing parenting skills. Anticipatory guidance may assist well-functioning families in preparing for predictable developmental transitions that occur in the life of families.

The Family Experiencing a Health Crisis

Illness of a family member is a crisis that affects the entire family system. The family is disrupted as members abandon their usual activities and focus their energy on restoring family equilibrium. Roles and responsibilities previously assumed by the ill family member are delegated to other family members, or those functions may remain undone for the duration of the illness. The family experiences anxiety because members are concerned about the sick individual and the resolution of the illness. This anxiety is compounded by additional responsibilities when there is less time or motivation to complete the normal tasks of daily living. See Box 24–2 for some factors that determine the impact of illness on the family unit.

The family's ability to deal with the stress of illness depends on the members' coping skills. Families with good communication skills

Evidence-Based Practice Why Is It Vital to Provide the Client's Family Caregivers with the Essential Knowledge to Care for the Client?

EVIDENCE-BASED PRACTICE

Angelo, Egan, and Reid (2013) conducted a study of 17 community palliative care teams to ascertain the information that should be provided to family caregivers. The researchers conducted three focus groups to determine what information should be included when designing an educational program for caregivers. As ideas were addressed the team discussed and prioritized them. The study resulted in three themes to be included when educating family caregivers. The family caregivers must be taught to care for themselves

physically, emotionally, and spiritually. The caregivers must also be taught about what to expect as the client's health declines and how to care for the client.

IMPLICATIONS

Providing education to meet the needs of the client and family caregivers will enhance end-of-life outcomes for the client and family. It will also increase caregiver empowerment.

BOX 24-2 Factors That Determine the Impact of Illness on the Family

- The nature of the illness, which can range from minor to life threatening
- The duration of the illness, which ranges from short term to long term
- The residual effects of the illness, including none to permanent disability
- The meaning of the illness to the family and its significance to family systems
- The financial impact of the illness, which is influenced by factors such as insurance and ability of the ill member to return to work
- The effect of the illness on future family functioning (for instance, previous patterns may be restored or new patterns may be established)

are better able to discuss how they feel about the illness and how it affects family functioning. They can plan for the future and are flexible in adapting these plans as the situation changes. An established social support network provides strength, encouragement, and services to the family during the illness. During health crises, families need to realize that it is a strength, not a sign of weakness, to turn to others for support. Nurses can be part of the support system for families, or they can identify other sources of support in the community.

During a crisis, families are often drawn together by a common purpose. In this time of closeness, family members have the opportunity to reaffirm personal and family values and their commitment to one another. Indeed, illness may provide a unique opportunity for family growth.

The Nurse's Role with Families Experiencing Illness

Nurses committed to family-centered care involve both the ill individual and the family in the nursing process. Through their interaction with families, nurses can give support and information. Nurses make sure that not only the individual but also each family member understands the health condition, its management, and the effect of these two factors on family functioning. The nurse also assesses the family's readiness and ability to provide continued care and supervision at home when warranted. After carefully planned instruction and practice, families are given an opportunity to demonstrate their ability to provide care under the supportive guidance of the nurse. When the care indicated is beyond the capability of the family, nurses work with families to identify available resources that are socially and financially acceptable.

Critical Thinking Checkpoint

Linda is a young mother of three children who has developed a severe arthritic condition that has affected her ability to work and adequately care for her family. Her illness has created a financial hardship for the family and has strained their roles. Linda and her husband have custody of their children from previous marriages as well as a daughter of their own. They are reluctant to seek assistance from outside sources because they fear interference from their ex-spouses with regard to their children.

In helping families reintegrate the ill person into the home, nurses use data gathered during family assessment to identify family resources and deficits. By formulating mutually acceptable goals for reintegration, nurses help families cope with the realities of the illness and the changes it may have brought about, which may include new roles and functions of family members or the need to provide continued medical care to the ill or recovering person. Working together, nurses and families can create environments that restore or reorganize family functioning during illness and throughout the recovery process.

Death of a Family Member

The death of a family member often has a profound effect on the family. After the death, families may need counseling to deal with their feelings and to talk about the person who died. Individual members experience a sense of loss. They grieve for the lost person, and they grieve for the family the way that it once was. Family disorganization may occur. The structure of the family is altered, and this change may in turn affect how it functions as a unit. Members may also want to talk about their fears and hopes for the future. At this time, families often derive comfort from their religious beliefs and their spiritual advisers. Support groups are also available for families experiencing the pain of death. This painful blow takes time to heal. However, as the family begins to recover, a new sense of normalcy develops, the family reintegrates its roles and functions, and it comes to grips with the reality of the situation.

It is often difficult for nurses to deal with grieving families because the nurses also feel the loss and may feel inadequate in knowing what to say or do. By understanding the effect death has on families, nurses can help families resolve their grief and move ahead with life. (See Chapter 43  for a discussion of loss and grieving.)

Implementing and Evaluating

Nursing interventions are based on the medical diagnoses, nursing diagnoses, and selected goals or outcomes. In evaluating the success of the family care plan, the nurse assesses for the presence of the indicators identified for the chosen outcomes. If the indicators are present, it is likely that the outcome has been achieved. If the indicators or outcomes are partially or not met, all aspects of the family situation must be reexamined: Have the intervention activities been carried out? Are the indicators and outcomes appropriate? Is the nursing diagnosis proper? Has the medical condition or diagnosis changed?

Recognition of individual and family strengths helps to maintain wellness and directs behavior in crisis situations. If a plan of care has to be modified to be more effective, these strengths should be identified and utilized.

1. What aspects of Linda's physical problem must the nurse be concerned about as they relate to the other issues occurring in Linda's life?
2. Explain why Linda's family is considered to be in a health crisis when only Linda is experiencing an illness.
3. What are the advantages or disadvantages of facing illness as a member of a family as opposed to individually?
4. Describe Linda's family from the perspective of general systems theory.

See Critical Thinking Possibilities on student resource website.

Chapter 24 Review

CHAPTER HIGHLIGHTS

- The family is the basic unit of society.
- Family-centered nursing addresses the health of the family as a unit, as well as the health of family members.
- In today's society, many types of families exist: traditional, two-career, single-parent, those headed by one or more adolescent parents, foster, blended, intragenerational, cohabiting, and gay and lesbian families. In addition, many single adults live alone.
- Theoretical frameworks provide the nurse with a structure for viewing the health promotion of families across the life span.
- The purpose of family assessment is to determine the level of family functioning, clarify family interaction patterns, identify family strengths and weaknesses, and describe the health status of the family and its individual members.
- Information on how family members are genetically related is gathered via a genogram. An ecomap allows the nurse to see where the family's energy is being expended.
- Families at risk for health problems may be considered based on individual family members' maturity levels, presence of hereditary factors, sex or ethnicity, sociologic factors, and lifestyle practices.
- Nursing diagnoses that relate to family health needs and problems include *Caregiver Role Strain*, *Disabled Family Coping*, *Dysfunctional Family Processes*, *Impaired Home Maintenance*, *Impaired Parenting*, *Interrupted Family Processes*, and *Readiness for Enhanced Family Coping*.

TEST YOUR KNOWLEDGE

1. Because a severely injured middle-aged client informed the nurse that he did not have any immediate family members, the nurse contacted extended family members. Which of the following is most representative of extended family members?
 1. Grandparents, aunts, and uncles
 2. Parents and spouse
 3. Children who no longer live at home
 4. Roommates and close family friends
2. Examine Figures 24–3 and 24–4 on pages 390–391. Based on the information in these two diagrams, which family member is at greatest risk for developing a health problem?
 1. Alice
 2. Bill
 3. Kim
 4. Mary
3. What should a nurse instruct a client who identifies “the family” as two college roommates, a dog, and a cat when completing a family health history form?
 1. Include all information about blood relatives and the animals and roommates that might influence his health.
 2. Include only information about genetic/hereditary and environmental illnesses of blood relatives.
 3. Leave the area blank since the client does not live with blood relatives.
 4. Use the client's own judgment in completing the area since the physical exam is more important than the history.
4. A visual representation of family members by sex, age, health status, and lines of relationships through the generations is referred to as a _____.
5. To assess the impact of illness on the family as a unit, it is essential for the nurse to assess which factors? Select all that apply.
 1. The duration of the illness
 2. The meaning of the illness to the family and its significance to family systems
 3. The coping mechanisms used by other families with similar illnesses
 4. The financial impact of the illness (including factors such as insurance and ability of the ill member to work)
 5. The incidence of the illness in the community at large
6. An adult child brings a parent to an agency with signs and symptoms of potential fluid retention (e.g., high blood pressure, swollen feet) possibly related to excessive sodium intake. Further nursing assessment indicates inadequate food storage and preparation techniques in the home. Which would be the most appropriate nursing diagnosis?
 1. *Readiness for Enhanced Family Coping*
 2. *Disabled Family Coping*
 3. *Impaired Parenting*
 4. *Caregiver Role Strain*
7. Prior to finalizing a family-oriented nursing care plan and implementing interventions, it is essential for the nurse to perform which of the following?
 1. Meet with all family members simultaneously.
 2. Confirm that the family health insurance covers all family members.
 3. Establish a trusting relationship with the family as a group.
 4. Complete a thorough history and physical examination of each family member.

8. Nurses often utilize systems theory to assess family units. Which example illustrates a family unit that does NOT meet the criteria of a well-functioning system?
1. The family members allow input from outside the family unit.
 2. The family members are interdependent.
 3. Each member's personal boundaries are well defined.
 4. The primary activities of each member focus on personal purposes.
9. What is a primary function of a family?
1. Provide everything each member wants.
 2. Provide an environment that supports growth of individuals.
 3. Ensure that the members are accepted into society.
 4. Ensure that family resources are not shared with the broader community.
10. Which family risk factor for developing a health problem is of highest priority for the nurse to address?
1. Family members' ages of 4, 13, 38, 42, and 75 place them in many different developmental stages.
 2. There is a history of adult-onset diabetes on the 42-year-old father's side.
 3. The primary wage earner for a family of five has recently been let go from the job and lost health insurance.
 4. The family members are primarily sedentary and no one engages in physical exercise for more than 1 hour each week.

Grant, R., Gracy, D., Goldsmith, G., Shapiro, A., & Redlener, I. E. (2013). Twenty-five years of child and family homelessness: Where are we now? *American Journal of Public Health, 103*(52), E1–E10. doi:10.2105/AJPH.2013.301618
Since the 1980s homelessness among families has been documented as a significant public health problem in the United States. This article reviewed journal articles, news reports, and government reports addressing homelessness in the United States. Homelessness is more prevalent in poor and low-income families. The rate of mental illness and the use of illegal substances are contributing factors for homelessness. Government support by subsidizing shelter-based services such as vouchers for rent will decrease the financial burden on families and promote health.

Meeting the Standards

This unit provides an overview of the concepts of growth and development, focusing on health promotion across the life span and within the family. In order for nurses to deliver developmentally appropriate care, we must be knowledgeable about normal growth and development and the age-specific risks faced by individuals in each stage of development. Knowledge of growth and development provides a framework for health assessment and health promotion across the life span. An understanding of the role of the family in the client's life, as well as how the family impacts health beliefs, will improve the nurse's care of the individual.

In the case described below, the family is coping with an illness of one member that impacts all members in unique ways based on their developmental stages and tasks. The nurse acts to provide support, resources, and coping strategies to help each member meet his or her developmental needs.

CLIENT: Carmelita AGE: 76 CURRENT MEDICAL DIAGNOSIS: Alzheimer's Disease

Medical History: Carmelita is a healthy Latino woman of Colombian descent. She was diagnosed with Alzheimer's disease 5 years ago and is now in stage II. She is usually unable to identify her daughter and son-in-law, and wanders frequently, requiring constant watching. She is unable to sleep most nights, and takes naps periodically throughout the day. Her daughter reports that she is easily upset and will scream and strike out when frustrated. She has no other health problems and is very active, enjoying walking with her daughter or grandchildren around the neighborhood or to the local park. Lately however, her grandchildren have found it difficult to control her behavior during walks, and are reluctant to be alone with her.

Personal and Social History: Carmelita lives with her daughter and son-in-law and their five children ages 19, 15, 10, 5, and 2 years of age. Her husband of 43 years died 4 years ago and Carmelita was unable to live independently. She used to speak some English

but is increasingly only able to communicate in Spanish. The family lives in a single-family home with three bedrooms. Four children have to share a room while the oldest child, a boy, sleeps on a couch in the basement in order to provide the client with her own room. They tried having one of the girls share Carmelita's room, but her late night sleeplessness and wandering was interfering with the girl's sleep. Carmelita's daughter admits to feeling tired all of the time as well as often feeling pulled in many different directions when her children and her mother need her attention or help at the same time. Carmelita often calls her son-in-law by her husband's name, making him uncomfortable caring for her. The family has considered moving Carmelita into a long-term care facility, but her daughter promised her shortly after diagnosis that she would take care of her mother for as long as necessary. Now she cannot bring herself to break her promise.

Questions

American Nurses Association Standard of Practice #5B is Health Teaching and Health Promotion: *The nurse employs strategies to promote health and a safe environment by using health promotion and health teaching methods appropriate to the situation and the health care consumer's values, beliefs, health practices, developmental level, learning needs, readiness and ability to learn, language preference, spirituality, culture, and socioeconomic status.*

1. What health promotion teaching would you provide this family?
2. What recommendations would you make to each family member to promote health based on each member's current developmental level?
3. How will Carmelita's condition impact her own development and health promotion needs?

American Nurses Association Standard of Practice #14

is Professional Practice Evaluation: *The nurse provides age-appropriate and developmentally appropriate care in a culturally and ethnically sensitive manner.*

4. The nurse assesses that Carmelita's condition is likely to have what impact on the developmental tasks of the other members of her family?
5. The nurse anticipates that Carmelita's condition is likely to have what impact on the health of the family, both physically and psychologically?

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Discuss the meaning of caring.
2. Identify nursing theories that focus on caring.
3. Analyze the importance of different types of knowledge in nursing.
4. Describe how nurses demonstrate caring in practice.
5. Evaluate the importance of self-care for the professional nurse.
6. Identify the value of reflective practice in nursing.

KEY TERMS

aesthetic knowing, 401

caring practice, 398
empirical knowing, 401

ethical knowing, 401
personal knowing, 401

reflection, 406

INTRODUCTION

In this age of technologic competence and efficiency, the knowledge and skills embedded in caring practices are often overlooked. Technology does not negate caring; in fact, the isolation that may accompany technology makes the significance of caring all the more important (Diener & Hobbs, 2012). Caring is a dimension of human relating, and often referred to as the art of nursing. Smith (2013) proposes that nursing cannot exist without caring. Caring is central to all helping professions, and enables people to create meaning in their lives. **Caring** is sharing deep and genuine concern about the welfare of another person.

PROFESSIONALIZATION OF CARING

Caring practice involves connection, mutual recognition, and involvement between nurse and client. Consider the following examples of caring, emerging from nursing situations:

- A client experiencing postoperative pain is given medication to control her symptoms, and then the nurse talks quietly and holds her hand for a few minutes as the pain resolves. The nurse's presence, in itself, provides comfort for the client.
- After the student nurse washes the hair of an older woman who is immobilized and applies her makeup, she helps the woman into a wheelchair to greet her daughter and grandchildren. The woman is extremely grateful and her sense of dignity is enhanced by this personal care.

Just as clients benefit from caring practices, the nurses involved in these situations experience caring through knowing that they have made a difference in their clients' lives. Consider, for example, one student nurse's feeling of gratitude that she had been able to help a young mother with breast-feeding: "I liked that feeling of having helped someone. A young mother had troubles starting breast-feeding. . . . And then, all of a sudden you can suggest a way of doing it. She is so happy and everything worked for me. You get this feeling that you have done something important. You've helped someone

today and you were able to cope with the situation" (Pedersen & Sivonen, 2012, p. 842).

When nurses feel free to concentrate their attention on others, they can make a positive difference to clients. The ability to give clients focused attention means leaving the egocentric self behind. Students of nursing can develop this ability by studying the meaning of caring in nursing.

Caring as "Helping the Other Grow"

Milton Mayeroff (1990), a noted philosopher, has proposed that to care for another person is to help him grow and actualize himself. Caring is a process that develops over time, resulting in a deepening and transformation of the relationship. Recognizing the other as having potential and the need to grow, the caregiver does not impose direction, but allows the direction of the other person's growth to help determine how to respond.

Mayeroff (1990) defines major ingredients of caring that provide structure and further description of this process: (a) *knowing* means understanding the other's needs and how to respond to these needs; (b) *alternating rhythms* signifies moving back and forth between the immediate and long-term meanings of behavior, considering the past; (c) *patience* enables the other to grow in his own way and time; (d) *honesty* includes awareness and openness to one's own feelings and a genuineness in caring for the other; (e) *trust* involves letting go, to allow the other to grow in his own way and own time; (f) *humility* means acknowledging that there is always more to learn, and that learning may come from any source; (g) *hope* is belief in the possibilities of the other's growth; and (h) *courage* is the sense of going into the unknown, informed by insight from past experiences.

Mayeroff (1990) proposes that the caring process has benefits for the one giving care. By helping the other person grow, the caregiver moves toward self-actualization. By caring and being cared for, each person "finds his place" in the world. By serving others through caring, individuals live the meaning of their own lives.

NURSING THEORIES ON CARING

The focus of any professional discipline is derived from its belief and value system, the nature of its service, and its area of knowledge development. Caring is at the heart of nursing's identity; indeed, the root of the word *nursing* means “nurturance” or “care” (Smith, 2013). Nurse scholars have reviewed the literature, conducted research, and analyzed nurses' experiences, resulting in the development of theories and models of caring. These theories and models are grounded in humanism and the idea that caring is the basis for human science. Each theory develops different aspects of caring, describing how caring is unique in nursing. Several nursing theorists focus on caring: Leininger, Ray, Roach, Boykin and Schoenhofer, Watson, and Swanson.

Culture Care Diversity and Universality (Leininger)

Based on studies in nursing and anthropology, Leininger notes that caring, as nurturing behavior, has been present throughout history and is one of the most critical factors in helping people maintain or regain health. Leininger emphasizes care as a “distinct, dominant, unifying, and central focus of nursing” (George, 2011, p. 406). Her theory of culture care diversity and universality is based on the assumption that nurses must understand different cultures in order to function effectively.

Transcultural nursing focuses on both the differences and similarities among individuals in diverse cultures. Although cultures have different ways of caring for others, certain universal behaviors are seen among all cultures of the world. To provide care that is congruent with cultural values, beliefs, and practices, the nurse must understand these differences and similarities. To understand the care desired by clients, the nurse requires knowledge of the culture and local language. When nursing care fails to be reasonably congruent with the client's beliefs, lifeways, and values, signs of conflict, non-compliance, and stress may arise.

Culturally congruent care involves three action–decision care approaches: (1) preservation of the client's familiar lifeways, (2) accommodations that help clients adapt to or negotiate for satisfying care, and (3) repatterning nursing care to help the client move toward wellness. Leininger holds that creative nursing approaches incorporating the above activities are needed to make care both meaningful and helpful to clients. She further defines caring as “assistive, supportive, and enabling experiences or ideas towards others with evident or anticipated needs, to ameliorate or improve a human condition or lifeway” (George, 2011, p. 406).

Theory of Bureaucratic Caring (Ray)

Ray's theory of bureaucratic caring focuses on caring in organizations (e.g., hospitals) as cultures. The theory suggests that caring in nursing is contextual and is influenced by the organizational structure. In Ray's research (Coffman, 2010), the meaning of caring varied in the emergency department, intensive care unit, oncology unit, and other areas of the hospital. For example, an intensive care unit had a dominant value of technologic caring (i.e., monitors, ventilators, treatments, and pharmacotherapeutics), and an oncology unit had a value of a more intimate, spiritual caring (i.e., family focused, comforting, compassionate). Furthermore, the meaning of caring was further influenced by the role and position a person held. Staff nurses valued

caring in terms of its relatedness to clients, whereas administrators valued caring as more system related, such as safeguarding the economic well-being of the hospital (Coffman, 2010).

As depicted in Figure 25–1 ■, spiritual-ethical caring influences each aspect of the bureaucratic system (technologic, physical, legal, political, economic, social-cultural, and educational). Each of these aspects is different, but they make up a whole bureaucratic system (e.g., a hospital). Nurses influence client care by making choices about each of these aspects. Nurses make these choices with the interest of the client at heart and use ethical principles as the foundation for the basis of professional decision making. According to Ray's theory, “Spiritual-ethical caring for nursing does not question whether or not to care in complex systems, but intimates how sincere deliberations and ultimately the facilitation of choices for the good of others can or should be accomplished” (Coffman, 2010, p. 123).

Caring, the Human Mode of Being (Roach)

Roach (2013) focuses on caring as a philosophical concept and proposes that caring is the human mode of being. All individuals are caring, and develop their caring abilities by being true to self, being real, and being who they truly are. Thus, caring is not unique to nursing.

Roach (2013) visualizes caring to be unique in nursing however, because caring is the center of all attributes she uses to describe nursing. Roach defines these attributes as the six C's of caring: compassion, competence, confidence, conscience, commitment, and comportment. See Box 25–1 for definitions of each characteristic. The six C's are used as a broad framework, suggesting categories of behavior that describe professional caring. Each category reflects specific values and includes virtuous actions by which a nurse can demonstrate caring.

BOX 25–1 The Six C's of Caring in Nursing

COMPASSION

Awareness of one's relationship to others, sharing their joys, sorrows, pain, and accomplishments. Participation in the experience of another.

COMPETENCE

Having the “knowledge, judgment, skills, energy, experience and motivation required to respond adequately to the demands of one's professional responsibilities” (Roach, 2013, p. 172).

CONFIDENCE

Comfort with self, client, and others that allows one to build trusting relationships.

CONSCIENCE

Morals, ethics, and an informed sense of right and wrong. Awareness of personal responsibility.

COMMITMENT

The deliberate choice to act in accordance with one's desires as well as obligations, resulting in investment of self in a task or cause.

COMPORTEMEN

Appropriate bearing, demeanor, dress, and language that are in harmony with a caring presence. Presenting oneself as someone who respects others and demands respect.

From “Caring: The Human Mode of Being,” by M. S. Roach, 2013. In M. Smith, M. Turkel, & Z. Wolf, *Caring in nursing classics: An essential resource* (pp. 165–179), New York, NY: Springer.

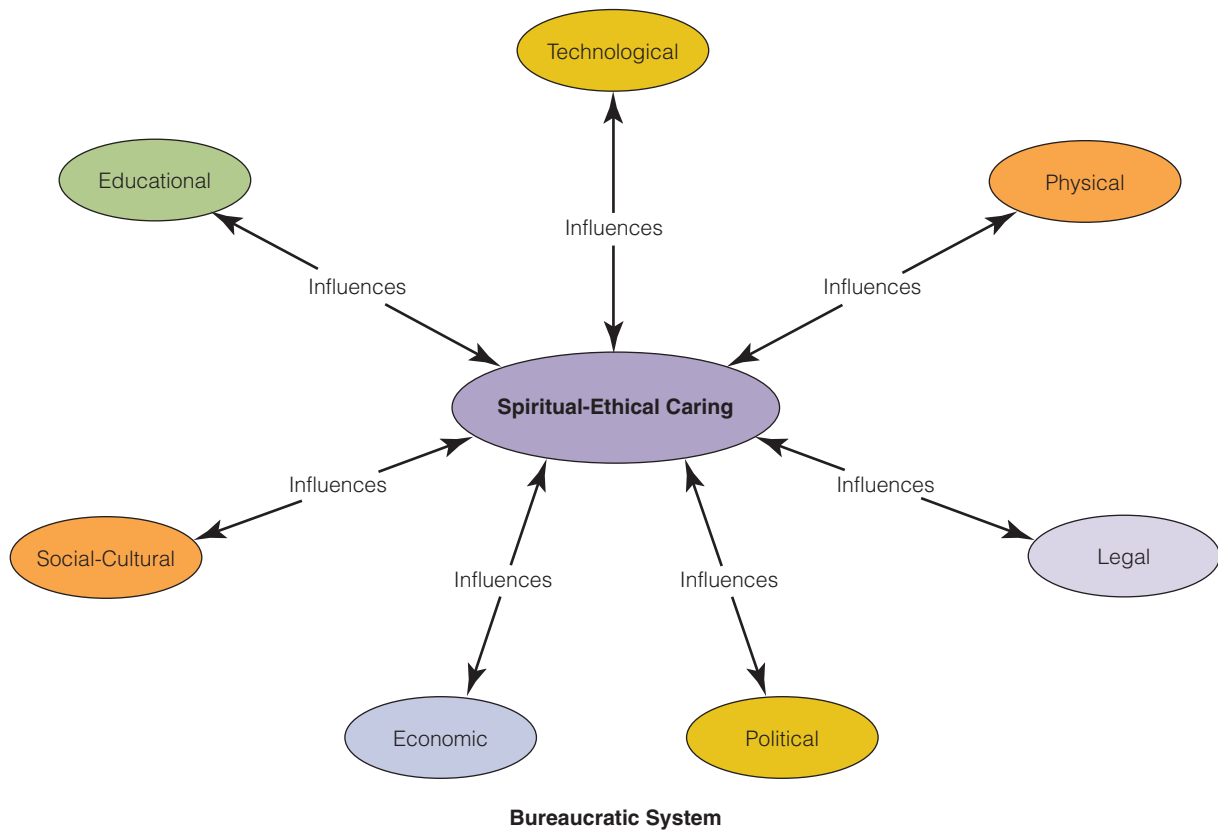

Figure 25-1 ■ Concept map reflecting the theory of bureaucratic caring.

Nursing as Caring (Boykin and Schoenhofer)

Boykin and Schoenhofer suggest that the purpose of the discipline and profession of nursing is to know people and nurture them as individuals living and growing in caring (Purnell, 2010). Respect for people as caring individuals and respect for what matters to them are assumptions underlying the theory of nursing as caring. Similar to Roach’s idea that all individuals are caring, Boykin and Schoenhofer emphasize the importance of the nurse knowing self as a caring person. Maintaining this approach may be difficult in practice environments, which may depersonalize the nurse and view nursing care only as tasks that need to be completed. However, caring is a lifetime process, lived moment to moment by the nurse and constantly unfolding. Through knowing self as a caring person, the nurse can be authentic to self, freeing oneself to truly be with others. This awareness of self allows the nurse to authentically care for others in nursing practice.

From the perspective of the theory of nursing as caring, the nurse approaches each client as a caring person, whole and complete in the moment. The idea of wholeness includes the understanding that people are not perfect, but constantly growing and changing. By living nursing as caring, the nurse establishes a mutual relationship of trust and respect with the client. Through fully appreciating the life-world of others, the nurse energizes self and others to grow as caring individuals.

Theory of Human Care (Watson)

Watson’s theory of human care views caring as the essence and the moral ideal of nursing. Human care is the basis for nursing’s role in society; indeed, nursing’s contribution to society lies in its moral

commitment to human care. Nursing as human care goes beyond the realm of ethics (Jesse, 2010). Assumptions of Watson’s theory and nursing interventions related to human care, or her carative factors, are presented in Chapter 3 ∞.

Watson emphasizes nursing’s commitment to care of the whole person as well as a concern for the health of individuals and groups (Box 25-2). The nurse and client are coparticipants in the client’s movement toward health and wholeness. This human connection is labeled transpersonal human caring, through which the nurse enters into the experience of the client, and the client can enter into the nurse’s experience. By identifying with each other, the nurse and client gain self-knowledge and, in doing so, keep alive his or her common humanity and avoid reducing the other to an object.

BOX 25-2 Social and Ethical Responsibilities of Nurses in Relation to Caring

- The nurse must care for the self in order to care for others.
- Nurses must remain committed to human care ideals.
- Cultivation of a higher/deeper self and a higher consciousness leads to caring.
- Human care can only be demonstrated through interpersonal relationships.
- Honoring the connectedness of all (unitary consciousness) leads to transpersonal caring-healing.
- Education and practice systems must be based on human values and concern for the welfare of others.

From “Watson’s Philosophy and Theory of Transpersonal Caring,” by D. E. Jesse, 2010. In M. Alligood & A. Tomey (Eds.), *Nursing theorists and their work* (7th ed., pp. 91–112), St. Louis, MO: Mosby.

Watson emphasizes that the practice of nursing is both transpersonal and metaphysical. While the nurse maintains professional objectivity as a scientist, scholar, clinician, and moral agent, the nurse is also subjectively engaged in the interpersonal relationship with the client. Within the actual caring situation, each person (nurse and client) seeks a sense of harmony within the mind, body, and soul, thereby actualizing the real self. This transpersonal contact has the potential to touch the higher, spiritual sense of self, or the soul. Such contact, which touches the soul, has the power to generate the self-healing process.

Theory of Caring (Swanson)

Swanson defines caring as “a nurturing way of relating to a valued ‘other,’ toward whom one feels a personal sense of commitment and responsibility” (Wojnar, 2010, p. 743). An assumption of her theory is that a client’s well-being should be enhanced through the caring of a nurse who understands the common human responses to a specific health problem. The theory focuses on caring processes as nursing interventions. Swanson’s theory was developed through interactions with parents at the time of pregnancy, miscarriage, and birth. The five caring processes are described in Table 25–1. These processes provide guidance to nurses who work with pregnant and postpartum clients. Further research will test the applicability of these caring dimensions to other client populations.

TABLE 25–1

Caring Processes from Swanson’s Theory of Caring

Process and Definition	Subdimensions
KNOWING Striving to understand an event as it has meaning in the life of the other	Avoiding assumptions Centering on the one cared for Assessing thoroughly Seeing cues Engaging the self of both
BEING WITH Being emotionally present to the other	Being there Conveying ability Sharing feelings Not burdening
DOING FOR Doing for the other as he/she would do for the self if it were at all possible	Comforting Anticipating Performing competently/skillfully Protecting Preserving dignity
ENABLING Facilitating the other’s passage through life transitions and unfamiliar events	Informing/explaining Supporting/allowing Focusing Generating alternatives/thinking it through Validating/giving feedback
MAINTAINING BELIEF Sustaining faith in the other’s capacity to get through an event or transition and face a future with meaning	Believing in/holding in esteem Maintaining a hope-filled attitude Offering realistic optimism “Going the distance”

From “The Theory of Caring,” by D. Wojnar. In M. Alligood & A. Tomey (Eds.), 2010, *Nursing theorists and their work* (7th ed., p. 743). St. Louis, MO: Mosby.

TYPES OF KNOWLEDGE IN NURSING

Nursing involves different types of knowledge that are integrated to guide nursing practice. Nurses require scientific competence (empirical knowledge), therapeutic use of self (personal knowing), moral/ethical awareness (ethical knowing), and creative action (aesthetic knowing). These four types of knowledge were identified by Carper (2009) from her observations of nurses’ activities. An understanding of each type of knowledge is important for the student of nursing because only by integrating all ways of knowing can the nurse develop a professional practice. Figure 25–2 ■ illustrates the interconnection of these different types of knowledge.

Empirical Knowing: The Science of Nursing

Knowledge about the empirical world is systematically organized into laws and theories for the purpose of describing, explaining, and predicting phenomena of special concern to the discipline of nursing. **Empirical knowing** ranges from factual, observable phenomena (e.g., anatomy, physiology, chemistry) to theoretical analysis (e.g., developmental theory, adaptation theory).

Personal Knowing: The Therapeutic Use of Self

Personal knowledge is concerned with the knowing, encountering, and actualizing of the concrete, individual self. Because nursing is an interpersonal process, the nurse’s view of self, as well as the client, is a critical factor in the therapeutic relationship. The nurse is aware of his or her own attitudes and behavior and views the client as a unique individual who is free to choose and create her or his own life. **Personal knowing** promotes wholeness and integrity in the personal encounter, achieves engagement rather than detachment, and denies the manipulative or impersonal approach.

Ethical Knowing: The Moral Component

Goals of nursing include the conservation of life, alleviation of suffering, and promotion of health. **Ethical knowing** focuses on “matters of obligation or what ought to be done” (Carper, 2009, p. 382), and goes beyond simply observing the nursing code of ethics. Nursing care involves a series of deliberate actions or choices that are subject to the judgment of right or wrong. Occasionally, the principles and norms that guide choices may be in conflict. The more sensitive and knowledgeable the nurse is to these issues, the more “ethical” the nurse will be.

Aesthetic Knowing: The Art of Nursing

Aesthetic knowing is the art of nursing and is expressed by the individual nurse through his or her creativity and style in meeting the needs of clients. The nurse uses aesthetic knowing to provide care that is both effective and satisfying. Empathy, compassion, holism, and sensitivity are important modes in the aesthetic pattern of knowing.

Developing Ways of Knowing

The methods for developing each type of knowledge are unique (Chinn & Kramer, 2011). The methods that are required for developing one pattern cannot be used to develop knowledge within

Figure 25-2 ■ The four ways of knowing.

another pattern. For example, personal knowing is developed through critical reflection on one's own actions and feelings in practice. Empirical knowing is gained from studying scientific models and theories and from making objective observations. Ethical knowing involves confronting and resolving conflicting values and beliefs. Aesthetic knowing arises from a deep appreciation of the uniqueness of each individual and the meanings that individual ascribes to a given situation. The nurse who practices effectively is able to integrate all types of knowledge to understand situations more holistically.

CARING ENCOUNTERS

How does a nurse demonstrate caring? Given similar situations, why is one nurse judged to be “caring” while another is said to be “uncaring”? Nurse theorists and researchers have studied this question and identified caring attributes and behaviors. Consider, for example, Roach's six C's, Watson's carative factors (Chapter 3 ∞), and Swanson's structure of caring (see Table 25-1). Because caring is contextual, a nursing approach used with a client in one situation may be ineffective in another. Caring responses are as varied as clients' needs, environmental resources, and nurses' imaginations. When clients perceive the encounter to be caring, their sense of dignity and self-worth is increased, and feelings of connectedness are expressed. Common caring patterns include knowing the client, nursing presence, empowering the client, compassion, and competence.

Knowing the Client

Caring attends to the totality of the client's experience. The nurse asks: Who is this person? What is the client's history? Needs? Desires? Dreams? Spiritual beliefs? Who loves and cares for this person at home? Where is home and what resources are there? What does this person need today, from me, right now? Can this person tell me what is needed? Personal knowledge of the client is a key in the caring relationship between nurse and client. The nurse aims to know who the client is, in his or her *uniqueness*. This knowledge is gained by observing and talking with the client and family while using effective listening and communication skills. The nurse cannot remain detached, but must be actively engaged with the client.

Take, for example, an older client experiencing postoperative pain after removal of a cancerous prostate. The nurse assesses the client's pain, using an appropriate pain scale. The client's positioning, hygiene, amount of rest, and other physiological variables are assessed for their effect on pain. In addition, a multitude of other factors affect the client's perception of pain. Is this surgery likely to cure the cancer, or is it primarily palliative? The meaning of the diagnosis and surgery to this client affects his pain experience. The nurse discovers that this man lost his wife to cancer 2 years ago. His daughter, at the bedside, is his primary support. The nurse discusses with his daughter how she can make her father more comfortable.

Knowing the client and family ultimately involves the nurse and client in a caring transaction. By attending broadly to personal, ethical, aesthetic, and empirical knowledge, the nurse understands events

as they have meaning in the life of the client. The nurse's *knowing the client* ultimately increases the possibilities for therapeutic interventions to be perceived as relevant.

Nursing Presence

Caring in nursing always takes place in a relationship. Mutuality within this relationship involves a partnership between the nurse and client. Watson describes the transpersonal caring relationship, in which the nurse enters into the life space of another person (Jesse, 2010). Establishment of a caring relationship depends on a moral commitment by the nurse and the nurse's ability to assess and realize another person's state of being. As nurses and students increase their self-awareness and commitment to nursing, the ability to be authentically present to the other grows (see Box 25–2).

Healing presence requires an openness and consciousness of the self and the client. The nurse must create some space for awareness by being truly present and focused on the moment. The nurse is aware of his or her own thoughts and feelings, while also aware of an interconnectedness with the client. Authentic presence involves empathy and openness to positive or negative feelings, nonpossessive warmth, a relaxed posture, and facial expressions that are congruent with other communications (Jesse, 2010).

Swanson's category *being with* (see Table 25–1) provides a description of nursing presence. By being emotionally present to the client and family, the nurse conveys that they and their experiences matter. Being present is a way of sharing in the meanings, feelings, and lived experiences of the client. Physical presence is combined with the promise of availability, especially during a time of need. This may be as simple as responding promptly to a call bell on a hospital unit or as complex as sitting with a parent who has just lost a child in a neonatal intensive care unit. Figure 25–3 ■ shows nurses and student nurses participating in a healing presence ceremony where they formally dedicate or rededicate themselves to nursing and the importance of healing presence in nursing.

Empowering the Client

Through knowing the client and engaging in a mutual relationship, the nurse is able to identify and build on client/family strengths. This empowering relationship includes mutual respect, trust, and

Figure 25–3 ■ Students and faculty dedicate themselves to nursing in a healing presence ceremony.
sherrilyn.coffman@nsc.edu.

confidence in the other's abilities and motives. According to Swanson (Wojnar, 2010), the caring behavior of *enabling* is defined as "facilitating the other's passage through life transitions and unfamiliar events" (p. 743). Enabling also includes coaching, informing, explaining, supporting, assisting, guiding, focusing, and validating. There are times when enabling involves substitutive care (doing for the client who is unable to do for oneself), but doing no more than is needed at the time. At other times, enabling involves providing an environment in which the client can function safely and effectively. The nurse should remain mindful of professional boundaries and responsibilities to avoid enabling pathologic or undesirable choices by the client. The goal is always to promote healthy growth and development.

Nurses both *advocate for* (verb) and are *advocates* (noun) for clients and families. Through advocacy, nurses are champions for their clients. They empower clients and families through activities that enhance well-being, understanding, and self-care.

Compassion

Universally, clients equate compassion with caring. The caring nurse is described as warm and empathetic, compassionate and concerned. To demonstrate empathy, the nurse must be able to identify with the client, appreciating the pain and discomfort of illness, or imagine "walking in his shoes" in regard to some part of the client's life experience.

Like empathy, compassion involves participating in the client's experience, with sensitivity to the person's pain or discomfort, and a willingness to share in their experience. Compassion is given as part of the caring relationship, as the nurse shares the client's joys, sorrows, pain, and accomplishments. Compassion requires courage and openness, as the nurse experiences his or her own humanness and interconnectedness with the client (Boykin & Schoenhofer, 2013). Compassion is a gift from the heart, rather than an advanced skill or technique.

Attention to spiritual needs is part of compassionate care particularly in the face of death and bereavement. The nurse is aware that spiritual and religious beliefs are important coping mechanisms in dealing with issues of mortality (see Chapter 41 ∞). The nurse does not impose his or her own spiritual beliefs, but rather assists the client and family in drawing on their own beliefs as spiritual resources.

Comfort is often associated with compassionate care and many nursing interventions are carried out to provide comfort. For example, bathing, positioning, talking, touching, and listening are often performed to increase the client's comfort level. Just like pain or discomfort, comfort is subjective and is defined as "whatever the client says it is," based on the individual's perceptions. Despite this subjectivity, comfort care is often the basis for nursing in settings ranging from intensive care to hospice, and serves as a motivator for nursing interventions. Nurses are challenged to be creative and innovative, basing interventions on knowledge of the client's preferences, in order to provide comfort care.

Competence

The competent nurse employs the necessary knowledge, judgment, skills, and motivation to respond adequately to the client's needs. Just as competence without compassion is cold and inhumane,

compassion without competence is meaningless and dangerous. The competent nurse, as described by Roach (2013), understands the client's condition, treatment, and associated care. The nurse is able to provide the necessary care while guiding the client and family through the process. The nurse's abilities to assess, plan, implement, and evaluate a plan of care are focused on meeting the client and family needs. Practice of these skills requires a high level of cognitive, affective, technical, and administrative skills.

MAINTAINING CARING PRACTICE

The concept of caring for self seems almost foreign to many nurses and students of nursing because of the professional emphasis on meeting others' needs. Yet, as nurses take on multiple commitments to family, work, school, and community, they risk exhaustion, burnout, and stress. Obstacles to self-care may be professional, related to the demands of a particular work setting, or may be personal, such as poor health habits or unrealistic expectations of self. (See Chapter 42 ∞ for more information on stress and coping.) Despite these challenges, it is imperative that nurses attend to their own needs, because caring for self is central to caring for others.

Caring for Self

Mayeroff (1990) describes caring for self as helping oneself grow and actualize one's possibilities. Self-care, when defined as responding to one's own needs to grow, is the opposite of the self-complacency that often accompanies egocentricity. Caring for self means taking the time to nurture oneself. This involves initiating and maintaining behaviors that promote healthy living and well-being. Although different activities may be helpful to different people, some examples of these activities include:

- A healthy lifestyle (e.g., nutrition, activity and exercise, recreation)
- Mind–body therapies (e.g., guided imagery, meditation, yoga).

Self-care focuses on care of the self in the deepest sense. Self-awareness and self-esteem are intimately connected to self-care. Each person is unique and possesses individual strengths and weaknesses. Self-care practices are intentionally created by the self and vigilantly maintained. This is a lifelong unfolding process, leading to wholeness that comes from and contributes to self-esteem. In its code of ethics, the American Holistic Nurses Association (2012) states that “the nurse has a responsibility to model health care behaviors. Holistic nurses strive to achieve harmony in their own lives and assist others striving to do the same.” Individuals with high self-esteem can critically problem solve and tackle obstacles more effectively. Self-care practices build self-esteem, leading to feelings of comfort and accomplishment.

A HEALTHY LIFESTYLE

Everyone needs to pay attention to nutrition and exercise, and to avoid unhealthy lifestyle practices. Key words for a healthy lifestyle are *balance* and *moderation*. These lifestyle practices are supplemented by regular physical examinations and health screenings.

NUTRITION Healthy eating is important for everyone. A nutritionally balanced eating plan provides energy, builds endurance to carry out daily activities, and reduces the risk for certain health

Figure 25–4 ■ Regular exercise is an effective self-care practice. Ariel Skelley/Blend Images/Corbis.

problems. Healthy eating means learning to make good choices in the foods eaten, preparing foods appropriately, and eating in moderation. It is important to select a variety of foods, to eat regular meals, and to eat the correct amount to maintain a healthy weight. Determining a healthy weight depends on several factors, including age, activity level, and the presence of weight-related medical problems such as high blood pressure. Dietary guidelines and standards for a healthy diet are included in Chapter 47 ∞.

ACTIVITY AND EXERCISE Exercise is recognized as a lifetime endeavor that is essential for energetic, active, and healthy living (Figure 25–4 ■). The benefits of exercise have been linked to many physiological and psychological responses, from a reduced feeling of stress to an increased sense of well-being. Exercise strengthens the heart, lungs, and blood vessels to prevent heart disease, keeps the joints flexible, and helps many people deal with sad or unhappy feelings. For individuals who are overweight, exercise has the added benefit of burning calories, resulting in weight loss or maintenance. American Heart Association (2013) guidelines recommend that healthy adults, ages 18 to 65 years, engage in the following activities to promote and maintain health:

- At least 30 minutes of moderate-intensity aerobic activity at least 5 days per week for a total of 150 minutes
OR
- At least 25 minutes of vigorous aerobic activity at least 3 days per week for a total of 75 minutes; or a combination of the two
AND
- Moderate to high intensity muscle-strengthening activity at least 2 or more days per week for additional health benefits.

Nurses participate in activities that call for knowledge to prevent self-injuries. Self-care practices are based on competence and compliance with use of assistive devices, such as the different types of hydraulic lifts, and assistive transfer equipment. An in-depth discussion of these devices is included in Chapter 44 ∞.

RECREATION Self-care also includes taking time to do the things that bring joy and stimulate creativity. Nurses need to reward themselves, to experience spontaneity, and even to take downtime or time to do nothing. Defending the right to this time may take courage and conviction in the face of others' demands. “Twelve Things You

BOX 25-3 Twelve Things You Would Love to Do

We often put off doing the simple things that bring us joy and happiness. Make a list of 12 things you would love to do after reviewing the list on the left. Post your list where you can see it. Resolve to carry out one activity by a specified time. Enjoy!

Some Ideas	Your List
1. Go out for ice cream.	1. _____
2. Take a nap.	2. _____
3. Dance a samba.	3. _____
4. Make a campfire.	4. _____
5. Roast marshmallows.	5. _____
6. Ride a bike.	6. _____
7. Shop for new shoes.	7. _____
8. Watch a favorite movie.	8. _____
9. Rearrange your furniture.	9. _____
10. Take a ceramics class.	10. _____
11. Read a mystery novel.	11. _____
12. Walk in the park.	12. _____

Would Love to Do” in Box 25-3 is intended to help a person recapture a sense of joy, fun, and self-reward.

AVOIDING UNHEALTHY PATTERNS Part of staying healthy is avoiding unhealthy life patterns. This means avoiding activities or thought patterns that contribute to negative health outcomes. Negative thinking can create a stress response with all its physiological, mental, and emotional outcomes. It is not what happens, but how events are perceived, that determines an individual's reaction. Practices such as identifying negative feelings, refocusing on the positive, and using humor are helpful to avert the stress response by changing thought patterns. Using positive affirmations, as listed in Box 25-4, can lead to greater self-esteem and control self-doubt. It is also important to avoid destructive lifestyle choices such as smoking, abuse of alcohol or drugs, and misuse of medications.

MIND-BODY THERAPIES

The interconnectedness of the mind and body is the basis for the complementary therapies. Imagery, meditation, storytelling, music therapy, and yoga are examples of complementary therapies that bring balance to thoughts and emotions. Practice of one or more mind-body therapies is an effective self-care strategy to help restore

BOX 25-4 Positive Affirmations

Begin the day with positive statements about how you want to think and act:

- I am a person of worth and goodness.
- I am happy to be alive.
- I am in the right place at the right time.
- I am prepared to do a good job today.
- I am surrounded by people that I love, who love me.
- I am doing what brings me joy.
- This is an opportunity to grow.

peace and balance. More in-depth information on different types of complementary therapies is included in Chapter 19 ∞.

GUIDED IMAGERY Imagery is a mind-body intervention that uses the power of the imagination as a therapeutic tool. Imagery is used to promote relaxation, decrease anxiety, and enhance psychological or spiritual insight. Through forming mental images of an object, event, or situation, the individual can reframe negative responses into positive images, enhancing healing and emotional well-being.

MEDITATION Through quieting the mind and focusing it on the present, meditation assists the individual in releasing fears, worries, and doubts. The technique involves both relaxation and focused attention. Guidelines for mindful meditation include choosing a quiet space, sitting comfortably, achieving progressive relaxation through deep breathing, and focusing attention on breathing or a mental image.

STORYTELLING As expressions of human consciousness, stories help individuals gain a greater understanding of life. Stories communicate life experience and are often shared with clients and others to inspire and comfort. The language of stories allows nurses to begin to understand the deeper meaning of clinical situations. Stories are also a mechanism to deal with stress and move toward wholeness.

SELF-CARE ALERT

Haigh and Hardy (2011) explored storytelling in nursing education. They found that students develop greater sensitivity to client situations and increased ability to analyze clinical events when sharing stories with other students and faculty. Internet discussion boards facilitated this process.

What stories have you told or listened to lately:

- That focused on clients' conditions during shift report?
- About challenges in the work setting?
- To analyze ethically difficult cases?
- To understand cultural differences?
- Regarding stressful client care situations?

MUSIC THERAPY Using music as therapy includes listening, singing, rhythm, and body movement. Quiet, soothing music is often used to induce relaxation. Active rhythms can awaken feelings of power and control. Familiar music allows the listener to recall past events or feelings. Music can also serve as an effective distraction technique. Each person's likes and dislikes are taken into account in order to achieve the desired emotional response.

YOGA The practice of yoga unites the body, mind, and spirit (Figure 25-5 ■). Through daily practice of the various postures and breathing practices of yoga, an individual can achieve increased balance and flexibility, mental alertness, and calmness. The bending, stretching, and holding properties of the postures help to relax and tone the muscles and improve function of the internal organs. Breath control is designed to still the mind and enhance awareness. Eliopoulos (2010) sums up the goal of yoga: to “create balance between movement and stillness, which is said to be the state of a healthy body” (p. 350).

Figure 25–5 ■ Yoga is a mind–body self-care strategy to help restore peace and balance.
Russell Saur © Dorling Kindersley.

Reflection on Practice

Critical thinking, self-analysis, and reflection are required in order to learn from one’s experience. The student develops as a practitioner by thinking about how values and standards guide practical experience. **Reflection** is thinking from a critical point of view, analyzing why one acted in a certain way, and assessing the results of one’s actions. To develop oneself as a caring practitioner, reflection on practice must be personal and meaningful.

Rischer (2011) developed a clinical reflection activity that is an application of Swanson’s caring processes (see Table 25–1 earlier). The five subdimensions of Swanson’s knowing process are listed on this reflection tool (Box 25–5). Students write in their own words how they would implement the caring intervention(s) for each subdivision of the knowing process followed by an evaluation of how the client responded to the caring intervention.

Reflective practice is a method of self-examination that involves thinking back over what happened in a nursing situation. It involves the whole person, including one’s emotions. Reflective practice includes becoming aware of how one feels about oneself and recognizing how one thinks and acts.

Reflective practice requires discipline, action, openness, and trust. It is a form of self-evaluation. Reflective journaling, as a tool for learning, is usually shared with a mentor or teacher, who works in partnership with the student. A framework, such as the one in Box 25–6, provides structure for the journaling process. Writing reflections in a journal provides a space for the student to look at and acknowledge the deeper self. Guidance from a mentor or teacher can help the student view a nursing situation from many different perspectives. It helps the student find meaning in the event,

BOX 25–5 Developing a Plan of Intentional Caring: Knowing the Client

Aspects of Knowing	Caring Interventions That I Will Implement in My Nursing Care	Evaluation (Client Response to My Interventions)
1. Avoiding assumptions		
2. Centering on the one cared for		
3. Assessing thoroughly		
4. Seeking cues		
5. Engaging of self

BOX 25–6 A Framework for Reflective Journaling

Using a framework is especially helpful to the beginner who is establishing the process of reflection. The framework listed below includes suggestions from several different models on reflection, and can be further developed by the individual practitioner. The goal of any reflective framework is to encourage description and self-awareness as well as critical thinking and analysis.

- 1. What happened?** Describe the situation or event, including who was involved and the associated events. Avoid making judgments; simply describe.
- 2. What did you do and think?** Describe your role in the situation, what you did, and your thoughts at the time. Again, focus on description only.
- 3. What did it mean?** Analyze the meaning of the event to those involved. How did the environment or context of the event influence the participants? Bring in ideas from outside of the experience to enlighten and compare.
- 4. How do you evaluate the situation?** What was good or bad about the experience, in light of your own values and feelings?
- 5. What did you learn?** What conclusions did you reach about the situation, in a general sense? More specifically, what did you learn about yourself and your own way of working?
- 6. Now what?** What are you going to do differently (or the same) based on what you learned from this experience? Where can you get more information to improve your understanding and approach to practice?

understand and learn through it, and emerge at a higher level of understanding.

Box 25–7 provides an example of a beginning nursing student’s experience. See how it compares to your own. Think about the questions and use them for your own reflection.

BOX 25-7 Nursing Student Reflection Checkpoint

Debbie started nursing school in September, and by October felt overwhelmed by the amount of reading and studying that was required. Her anxiety level began to rise, but at the same time, she became more aware of her feelings and reactions to situations. In her nursing courses she was studying nursing as caring, and in the clinical setting she focused on applying these ideas in her practice with clients. She was surprised how genuinely her clients responded to a kind word of encouragement, the attention of personal care, and her concern for their well-being. Her clients' responses boosted her confidence and motivated her to learn more about their conditions and needs.

Each week Debbie analyzed and described the clinical situations encountered in practice in a reflective journal. Through reflecting on her clinical experiences and feedback from her clinical instructor, she was able to identify her personal strengths and areas for growth. She began to think about how she could better organize her study schedule, plan time with her family, and provide the same level of caring for herself that she desired to give her clients.

1. Being in nursing school is often an overwhelming experience. Can you relate to Debbie's situation?
2. As you study caring in nursing, what ideas interest you most? How have you implemented these ideas in your own practice as a student nurse?
3. According to Carper's four ways of knowing, give examples of how you practiced each of these ways of knowing in your care of clients.
4. What value do you see in keeping a reflective journal? As you reflect on practice situations, have you written down your thoughts?
5. What changes can you make in your weekly schedule, to be more efficient with studying and also plan time for self-care?
6. What self-care activities would be most helpful to you right now? Changes in diet? Scheduled exercise or recreation? Meditation, yoga, or another mind-body therapy?
7. Do you have unhealthy patterns, such as smoking or negative thinking, that you need to work on? Develop an action plan to change these behaviors.

Evidence-Based Practice How Do Student Nurses' Experiences in Clinical Practice and Reflection on Practice Help Them Develop Ethical Caring?
EVIDENCE-BASED PRACTICE

Each student enters nursing school with an inherent capacity to care for others, which is professionalized through classroom, laboratory, and clinical experiences. Pedersen and Sivonen (2012) conducted a phenomenologic research study to gain a deeper understanding of how student nurses' experiences in clinical practice and reflection on practice helped them develop ethical caring. An assumption of the study was that students already possess caring competencies, which are strengthened and developed in clinical practice situations. The study sample consisted of 21 female and 3 male nursing students, ages 20 to 39, of different educational levels and ethnic backgrounds. Students were interviewed individually or in groups, with questions focusing on caring for vulnerable and suffering clients, ethical problems in practice, and inner reactions and motivations. The study was approved by an ethics committee in Finland. Tape-recorded interviews were transcribed and reviewed by the researchers. The findings consisted of three themes:

1. *Theme 1: Two states of vulnerability.* In reaction to the vulnerability and suffering of clients, students' own vulnerability was triggered. Students felt overwhelmed, a feeling which was experienced either as (a) a weakness, which caused the students to suffer, or (b) as a strength that challenged the students to develop new ways to deal with client suffering. When students focused on their own suffering, rather than on the client's choices and behaviors, the students' vulnerability became a weakness. When students engaged in further self-reflection and continued to pay attention to the client, their vulnerability became a source of ethical and professional development.
2. *Theme 2: Making a difference and providing loving care.* Students whose focus remained on the client received feedback from the client that strengthened their perception of

themselves as professionals. Students' helping behaviors were reinforced by the positive changes they saw in their clients. One student commented, "Having tried again and again has increased my self-confidence, and it's been very important for my development. Now I know that I'm able to do it" (p. 843). Another student stated, "Loving care—it isn't something you give out of a sense of duty. . . . It is something you want to give. . . . The clients can sense that. . . . They open up more and become more trustful and it becomes much easier to help them" (p. 843).

3. *Theme 3: Ethical development at risk of decline.* Inevitably, nursing students' ideals were challenged in the real world of clinical practice. There was a risk that students would compromise their ethical practices. One student described time constraints: "I wanted to be there and talk with him, but I was constrained by the time. I couldn't give as much of myself as I wanted. It wasn't possible." When students encountered a lack of caring by staff, they often limited their own behavior, or provided care when they were alone with the client. Students were more likely to be overwhelmed by their own vulnerability if they found that their ideals conflicted with those of uncaring staff.

IMPLICATIONS

The authors concluded that students develop the courage to use their innate ethical caring competencies in nursing practice through exposure to suffering clients, interacting with different role models in a caring environment, and being aware of and reflecting on their own feelings. Students can move from a state of being overwhelmed by their vulnerability to developing professional approaches that alleviate suffering by focusing on the client, maintaining self-awareness, and reflecting on the meaning of situations.

Critical Thinking Checkpoint

After morning report, the nurse, Megan, approaches Robbie James, a 10-year-old boy lying quietly in his hospital bed. She introduces herself and writes her name on the white board in the room, so that when Robbie's mother arrives, she will know the name of Robbie's nurse. Megan's client assignment today consists of four acutely ill children of different ages. As Megan makes her initial rounds, she assesses the immediate needs of each child and begins to prioritize her nursing activities.

Megan has her own needs. She is tired from the night before when her own daughter was up late with coughing and fever. She is comfortable with her arrangements for child care, however, and is able to focus on her care of the clients on the pediatric unit.

When Megan returns with intravenous morphine, Robbie barely speaks, a pinched look of discomfort on his face. Using the FACES pain scale, Robbie has identified his pain as the "worst possible pain." This is his first day postop after surgery for a ruptured appendix, and he has a nasogastric (NG) tube in place, draining to wall suction. Megan administers the medication according to unit protocol and continues her assessment. She checks patency and placement of the NG tube and measures Robbie's vital signs.

Megan notes a "walking chart" on the wall beside Robbie's bed. The walking chart includes spaces to place a sticker each time Robbie walks in the hall. Robbie knows that after three stickers, he can

choose a prize from the treasure box. Before Megan leaves the room, she suggests to Robbie, "When you feel better from this medicine, I'll help you walk, and we'll put another sticker on that chart!"

1. Describe which aspect of the nurse's approach relates to each of the following six C's of caring in nursing as outlined by Roach: compassion, competence, confidence, conscience, commitment, and comportment.
2. In analyzing this case study and reflecting on the four ways of knowing (e.g., personal, empirical, aesthetic, and ethical), describe how each type of knowing prepared the nurse, Megan, for her caring approach.
3. In the theory of bureaucratic caring, Ray suggests that different aspects of the hospital system influence the choice making of the nurse. Describe how each of the following aspects influences the nurse's care:
 - Spiritual-ethical caring
 - Physical
 - Technologic
 - Social-cultural
 - Educational
 - Legal

See Critical Thinking Possibilities on student resource website.

Chapter 25 Review

CHAPTER HIGHLIGHTS

- Caring practice involves connection, mutual recognition, and involvement between nurse and client. Caring is central to nursing practice.
- To care for another person is to help the person grow and actualize himself or herself. By helping the other grow, the caregiver moves toward self-actualization. Caring behaviors described by Mayeroff include knowing, alternating rhythms, patience, honesty, trust, humility, hope, and courage.
- Various theorists have focused on caring as the essence of nursing. Each theory develops different aspects of caring, describing how caring is unique in nursing.
- Nursing involves different types of knowledge that are integrated to guide nursing practice. Empirical knowing includes scientific

competence, personal knowing focuses on the self, ethical knowing requires moral/ethical awareness, and aesthetic knowing is the creative art of nursing.

- Caring encounters are influenced by the diversity of human responses. Common caring patterns include knowing the client, nursing presence, empowering the client, compassion, and competence.
- Caring for self is central to caring for others. Nurse self-care includes a healthy lifestyle (e.g., nutrition, activity and exercise, recreation) and mind–body therapies (e.g., guided imagery, meditation, yoga).
- The student nurse matures as a practitioner by reflecting on practice. Through reflection, nurses can grow and participate more fully in caring-healing relationships.

TEST YOUR KNOWLEDGE

1. Which example best illustrates the principle of knowing the client?
 1. The nurse provides a back rub to help the client relax, and then makes the bed with clean linen.
 2. The nurse listens as the client describes how he has been caring for his diabetes at home.
 3. The nurse administers a piggyback antibiotic for a client with pneumonia.
 4. The nurse collects a urine specimen to send to the lab, and explains to the client the reason for the test.
2. The nurse teaches a client with diabetes how to make decisions about insulin management after discharge. This teaching most clearly reflects which caring activity?
 1. Empowering the client
 2. Compassion
 3. Knowing the client
 4. Nursing presence

3. Mayeroff described allowing the other to grow in his own way and time. This behavior most clearly reflects which major ingredient of caring?
 1. Humility
 2. Knowing
 3. Patience
 4. Courage
4. Leininger's theory, culture care diversity and universality, would provide the best framework for assessing which nursing situation?
 1. The Indonesian parents of an infant prefer to use hot/cold therapies to prevent seizures so they withhold the prescribed seizure medication (phenobarbital).
 2. Staff nurses on a hospital unit discuss how to reorganize client care to provide more continuity of staff with clients.
 3. Nurses in a community agency search for learning resources about intravenous therapy in the home setting.
 4. A nurse manager explores ways to assist new nursing graduates to develop clinical skills on the hospital unit.
5. In a reflective journal, a nursing student writes this statement about a comatose client on the hospice unit: "The Do-Not-Resuscitate order was not on the chart, and none of the nurses knew what measures should be taken if the client stopped breathing." This statement most clearly reflects which of the four ways of knowing?
 1. Empirical
 2. Personal
 3. Ethical
 4. Aesthetic
6. The nurse sits with the client and holds the client's hand as his pain decreases. This situation is an example of which caring practice?
 1. Nursing presence
 2. Assessment
 3. Knowing the client
 4. Empowering
7. Which nursing theory is depicted by a model with spiritual-ethical caring in the center, surrounded by technologic, physical, legal, political, economic, social-cultural, and educational systems?
 1. Nursing as caring
 2. Theory of bureaucratic caring
 3. Caring, the human mode of being
 4. Theory of human care
8. The nursing student reviews the pathophysiology of myocardial infarction in preparation for the next day's clinical experience. This activity is an example of which type of knowledge development?
 1. Empirical knowing
 2. Aesthetic knowing
 3. Personal knowing
 4. Ethical knowing
9. A nurse, sitting quietly in a chair, breathing deeply, and focusing on the mental image of a crystal is using which mind-body therapy?
 1. Storytelling
 2. Yoga
 3. Music therapy
 4. Meditation
10. A 40-year-old client who comes to the clinic for a routine physical exam asks the nurse how much exercise is most recommended for a healthy lifestyle. Which answer is most appropriate?
 1. Moderate activity for 10 minutes daily
 2. Moderate activity for 20 minutes two to three times a week
 3. Vigorous activity for 25 minutes three days a week
 4. Vigorous activity for 30 minutes daily

See Answers to Test Your Knowledge in Appendix A.

26 Communicating

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Describe the components of the communication process.
2. Discuss the various aspects that nurses need to consider when using the different forms of communication.
3. Describe factors influencing the communication process.
4. Compare and contrast therapeutic communication techniques that facilitate communication and focus on client concerns.
5. Recognize barriers to communication.
6. Describe the four phases of the helping relationship.
7. Discuss characteristics of an effectively functioning group.
8. Identify types of groups helpful in promoting health and comfort.
9. Discuss how nurses use communication skills in each phase of the nursing process.
10. State why effective communication is imperative among health professionals.
11. Describe the following disruptive behaviors and how they affect the health care environment and client safety: incivility, lateral violence, and bullying.
12. Discuss the differences between nurse and physician communication and how to address these differences.
13. Differentiate the major characteristics of assertive and nonassertive communication.

INTRODUCTION

Communication is a critical skill for nursing. It is the process by which humans meet their survival needs, build relationships, and experience emotions. In nursing, communication is a dynamic process used to gather assessment data, to teach and persuade, and to express caring and comfort. It is an integral part of the helping relationship.

COMMUNICATING

The term *communication* has various meanings, depending on the context in which it is used. To some, communication is the interchange of information between two or more people; in other words, the exchange of ideas or thoughts. This kind of communication uses methods such as talking and listening or writing and reading. However, painting, dancing, and storytelling are also methods of communication. In addition, thoughts are expressed to others not only by spoken or written words but also by gestures or body actions.

Communication may have a more personal connotation than the interchange of ideas or thoughts. It can be a transmission of feelings or a more personal and social interaction between people. Frequently, one member of a couple comments that the other is not communicating. Some teenagers complain about a generation gap—being unable to communicate with understanding or feeling to a parent or authority figure. Sometimes a client may say that a nurse is efficient but lacking in something called *bedside manner*. For the

purpose of this text, **communication** is any means of exchanging information or feelings between two or more people. It is a basic component of human relationships, including nursing.

The intent of any communication is to obtain a response. Thus, communication is a process. It has two main purposes: to influence others and to gain information. Communication can be described as helpful or unhelpful. The former encourages a sharing of information, thoughts, or feelings between two or more people. The latter hinders or blocks the transfer of information and feelings.

Nurses who communicate effectively are better able to collect assessment data, initiate interventions, evaluate outcomes of interventions, initiate change that promotes health, and prevent the safety and legal problems associated with nursing practice. The communication process is built on a trusting relationship with a client and support people. Effective communication is essential for the establishment of a nurse–client relationship.

Communication can occur on an intrapersonal level within a single individual as well as on interpersonal and group levels. Intrapersonal communication is the communication that you have with yourself; another name is *self-talk*. Both the sender and the receiver of a message usually engage in self-talk. It involves thinking about the message before it is sent, while it is being sent, and after it is sent, and it occurs constantly. Consequently, intrapersonal communication can interfere with a person's ability to hear a message as the sender intended (Figure 26–1 ■).

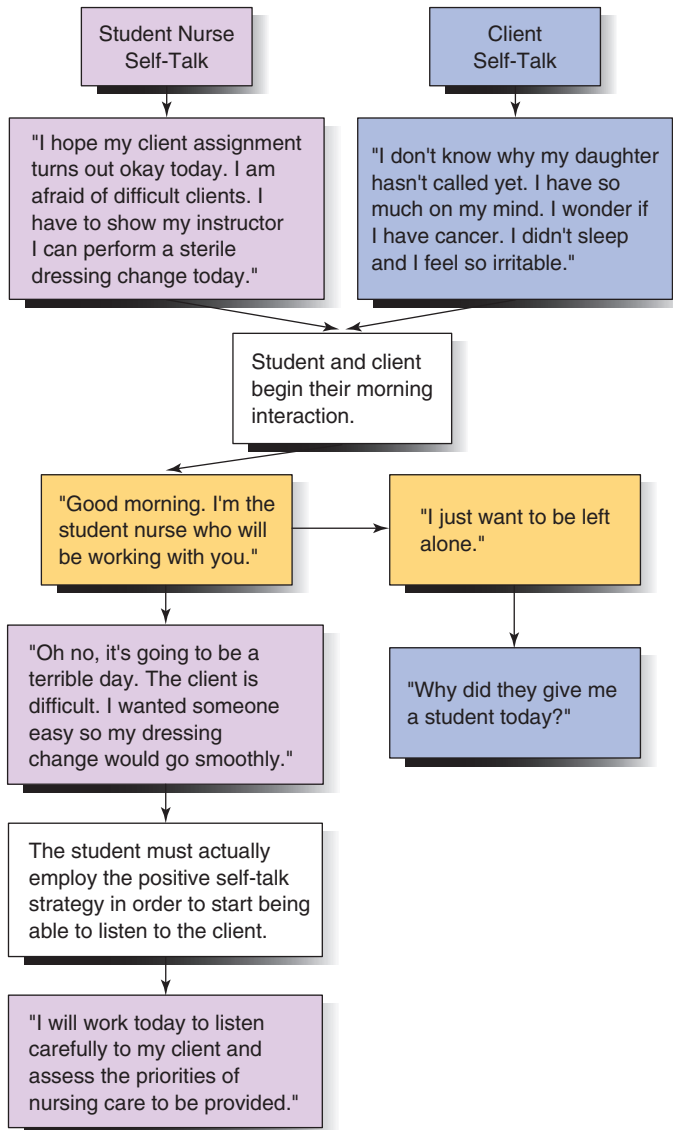

Figure 26-1 ■ Student nurse self-talk.

The Communication Process

Face-to-face communication involves a sender, a message, a receiver, and a response, or feedback (Figure 26-2 ■). In its simplest form, communication is a two-way process involving the sending and the receiving of a message. Because the intent of communication is to elicit a response, the process is ongoing; the receiver of the message

Figure 26-2 ■ The communication process. The dashed arrows indicate intrapersonal communication (self-talk). The solid lines indicate interpersonal communication.

then becomes the sender of a response, and the original sender then becomes the receiver.

SENDER

The *sender*, a person or group who wishes to communicate a message to another, can be considered the *source-encoder*. This term suggests that the person or group sending the message must have an idea or reason for communicating (source) and must put the idea or feeling into a form that can be transmitted. **Encoding** involves the selection of specific signs or symbols (codes) to transmit the message, such as which language and words to use, how to arrange the words, and what tone of voice and gestures to use. For example, if the receiver speaks English, the sender usually selects English words. If the message is “Mr. Johnson, you have to wait another hour for your pain medication,” the tone of voice selected and a shake of the head can reinforce it. The nurse must not only deal with dialects and foreign languages but also cope with two language levels—the layperson’s and the health professional’s.

MESSAGE

The second component of the communication process is the *message* itself—what is actually said or written, the body language that accompanies the words, and how the message is transmitted. The method used to convey the message can target any of the receiver’s senses. It is important for the method to be appropriate for the message, and it should help make the intent of the message clearer.

For example, talking face to face with a person may be more effective in some instances than telephoning or writing a message. Recording messages on tape or communicating by radio or television may be more appropriate for larger audiences. Written communication is often appropriate for long explanations or for a communication that needs to be preserved. The nonverbal channel of touch is often highly effective (Figure 26-3 ■).

RECEIVER

The *receiver*, the third component of the communication process, is the listener, who must listen, observe, and attend. This person is the *decoder*, who must perceive what the sender intended (interpretation). Perception uses all the senses to receive verbal and nonverbal messages. To **decode** means to relate the message perceived to the receiver’s storehouse of knowledge and experience and to sort out the meaning of the message. Whether the message is decoded accurately by the receiver, according to the sender’s intent, depends

Figure 26-3 ■ Appropriate forms of touch can communicate caring. Cultura Tim MacPherson/Getty Images.

largely on their similarities in knowledge and experience and socio-cultural background. If the meaning of the decoded message matches the intent of the sender, then the communication has been effective. Ineffective communication occurs when the receiver misinterprets the sent message. For example, Mr. Johnson may perceive the message accurately—“No pain medication for another hour.” However, if experience has taught him that he can receive the pain medication early if a certain nurse is on duty, he will interpret the intent of the message differently.

RESPONSE

The fourth component of the communication process, the *response*, is the message that the receiver returns to the sender. It is also called **feedback**. Feedback can be either verbal, nonverbal, or both. Nonverbal examples are a nod of the head or a yawn. Either way, feedback allows the sender to correct or reword a message. In the case of Mr. Johnson, the receiver may appear irritated or say, “Well, the nurse on the other shift gives me my pain medication early if I need it.” The sender then knows the message was interpreted accurately. However, now the original sender becomes the receiver, who is required to decode and respond.

Modes of Communication

Communication is generally carried out in two different modes: verbal and nonverbal. **Verbal communication** uses the spoken or written word; **nonverbal communication** uses other forms, such as gestures or facial expressions, and touch. Although both kinds of communication occur concurrently, the majority of communication is nonverbal. Learning about nonverbal communication is important for nurses in developing effective communication patterns and relationships with clients. Another form of communication has evolved with technology—**electronic communication**. A common form of electronic communication is e-mail, in which an individual can send a message, by computer, to another person or group of people. Nurses need to know when it is and when it is not appropriate to use e-mail for communicating with clients.

VERBAL COMMUNICATION

Verbal communication is largely conscious because people choose the words they use. The words used vary among individuals according to culture, socioeconomic background, age, and education. As a result, countless possibilities exist for the way ideas are exchanged. An abundance of words can be used to form messages. In addition, a wide variety of feelings can be transmitted when people talk.

Nurses need to consider the following when choosing words to say or write: pace and intonation, simplicity, clarity and brevity, timing and relevance, adaptability, credibility, and humor.

PACE AND INTONATION The manner of speech, as in the rate or rhythm and tone, will modify the feeling and impact of a message. The tone of words can express enthusiasm, sadness, anger, or amusement. The rate of speech may indicate interest, anxiety, boredom, or fear. For example, speaking slowly and softly to an excited client may help calm the client.

SIMPLICITY Simplicity includes the use of commonly understood words, brevity, and completeness. Many complex technical terms become natural to nurses. However, laypersons often misunderstand these terms. Words such as *vasoconstriction* or *cholecystectomy*

are meaningful to the nurse and easy to use but are ill advised when communicating with clients. Nurses need to learn to select appropriate, understandable, and simple terms based on the age, knowledge, culture, and education of the client. For example, instead of saying to a client, “I will be catheterizing you for a urine analysis,” it may be more appropriate and understandable to say, “I need to get a sample of your urine, so I will collect it by putting a small tube into your bladder.” The latter statement is more likely to elicit a response from the client asking why it is needed and whether it will be uncomfortable, because the client understands the message being conveyed by the nurse.

CLARITY AND BREVITY A message that is direct and simple will be effective. Clarity is saying precisely what is meant, and brevity is using the fewest words necessary. The result is a message that is simple and clear. An aspect of this is congruence, or consistency, where the nurse’s behavior or nonverbal communication matches the words spoken. When the nurse tells the client, “I am interested in hearing what you have to say,” the nonverbal behavior would include the nurse facing the client, making eye contact, and leaning forward. The goal is to communicate clearly so that all aspects of a situation or circumstance are understood. To ensure clarity in communication, nurses also need to enunciate (pronounce) carefully.

TIMING AND RELEVANCE Nurses need to be aware of both relevance and timing when communicating with clients. No matter how clearly or simply words are stated or written, the timing needs to be appropriate to ensure that words are heard. Moreover, the messages need to relate to the person or to the person’s interests and concerns.

This involves sensitivity to the client’s needs and concerns. For example, a client who is fearful of the possibility of cancer may not hear the nurse’s explanations about the expected procedures before and after gallbladder surgery. In this situation it is better for the nurse first to encourage the client to express concerns, and then to deal with those concerns. The necessary explanations can be provided at another time when the client is better able to listen.

Another problem in timing is asking several questions at once. For example, a nurse enters a client’s room and says in one breath, “Good morning, Mrs. Brody. How are you this morning? Did you sleep well last night? Your husband is coming to see you before your surgery, isn’t he?” The client no doubt wonders which question to answer first, if any. A related pattern of poor timing is to ask a question and then not wait for an answer before making another comment. On the other hand, by allowing the client to respond to the social talk or chat, the nurse develops a rapport with the client that can help facilitate effective therapeutic communication.

ADAPTABILITY The nurse needs to alter spoken messages in accordance with behavioral cues from the client. This adjustment is referred to as *adaptability*. What the nurse says and how it is said must be individualized and carefully considered. This requires astute assessment and sensitivity on the part of the nurse. For example, a nurse who usually smiles, appears cheerful, and greets the client with an enthusiastic “Hi, Mrs. Brown!” notices that the client is not smiling and appears distressed. It is important for the nurse to then modify his or her tone of speech and express concern by facial expression while moving toward the client.

CREDIBILITY *Credibility* means worthiness of belief, trustworthiness, and reliability. Credibility may be the most important criterion of effective communication. Nurses foster credibility by being consistent, dependable, and honest. The nurse needs to be knowledgeable about what is being discussed and to have accurate information. Nurses should convey confidence and certainty in what they are saying, while being able to acknowledge their limitations (e.g., “I don’t know the answer to that, but I will find someone who does”).

HUMOR The use of humor can be a positive and powerful tool in the nurse–client relationship, but it must be used with care. Humor can be used to help clients adjust to difficult and painful situations. The physical act of laughter can be an emotional and physical release, reducing tension by providing a different perspective and promoting a sense of well-being.

When using humor, it is important to consider the client’s perception of what is considered humorous. Timing is also important to consider. Though humor and laughter can help reduce stress and anxiety, the feelings of the client need to be considered.

NONVERBAL COMMUNICATION

Nonverbal communication, sometimes called *body language*, includes gestures, body movements, use of touch, and physical appearance, including adornment. Nonverbal communication often tells others more about what a person is feeling than what is actually being said, because nonverbal behavior is controlled less consciously than verbal behavior (Figure 26–4 ■). Nonverbal communication either reinforces or contradicts what is said verbally. For example, if a nurse says to a client, “I’d be happy to sit here and talk to you for a while,” yet glances nervously at a watch every few seconds, the actions contradict the verbal message. The client is more likely to believe the nonverbal behavior, which conveys “I am very busy and need to leave.”

Observing and interpreting the client’s nonverbal behavior is an essential skill for nurses to develop. To observe nonverbal behavior efficiently requires a systematic assessment of the person’s overall physical appearance, posture, gait, facial expressions, and gestures. The nurse, however, needs to exercise caution in interpretation, always clarifying any observation with the client.

Clients who have altered thought processes, such as in schizophrenia or dementia, may experience times when expressing themselves verbally is difficult or impossible. During these times, the nurse needs to be able to interpret the feeling or emotion that the client is expressing nonverbally. An attentive nurse who clarifies observations very often portrays caring and acceptance to the client. This can be a beginning for establishing a trusting relationship between the nurse and the client, even in clients who have difficulty communicating appropriately.

Transculturally, nonverbal communication varies widely (Eubanks et al., 2010). Even for behaviors such as smiling and handshaking, cultures differ. For example, to many Hispanics smiling and handshaking are an integral part of an interaction and essential to establishing trust. The same behavior might be perceived by a Russian as insolent and frivolous.

The nurse cannot always be sure of the correct interpretation of feelings that are expressed nonverbally. The same feeling can be expressed nonverbally in more than one way, even within the same cultural group. For example, anger may be communicated by aggressive or excessive body motion, or it may be communicated by frozen stillness. In some cultures, a smile may be used to conceal anger.

A

B

Figure 26–4 ■ Nonverbal communication sometimes conveys meaning more effectively than words. *A*, The postures of these individuals indicate openness to communication. *B*, The listener’s posture and nonverbal demeanor suggest resistance to communication. *A*, Westend61/Getty Images; *B*, Steve Debonport/Getty Images.

Therefore, the interpretation of such observations requires validation with the client. For example, the nurse might say, “You look like you have been crying. Is something upsetting you?”

PERSONAL APPEARANCE Clothing and adornments can be sources of information about a person. Although choice of apparel is highly personal, it may convey social and financial status, culture,

religion, group association, and self-concept. Charms and amulets may be worn for decorative or for health protection purposes. When the symbolic meaning of an object is unfamiliar, the nurse can inquire about its significance, which may foster rapport with the client.

How a person dresses is often an indicator of how the person feels. People who are tired or ill may not have the energy or the desire to maintain their normal grooming. When a person known for immaculate grooming becomes careless about appearance, the nurse may suspect a loss of self-esteem or a physical illness. The nurse must validate these observed nonverbal data by asking the client. For acutely ill clients in hospital or home care settings, a change in grooming habits may signal that the client is feeling better. For example, a man may request a shave, or a woman may request a shampoo and some makeup.

POSTURE AND GAIT The ways people walk and carry themselves are often reliable indicators of self-concept, current mood, and health. Erect posture and an active, purposeful stride suggest a feeling of well-being. Slouched posture and a slow, shuffling gait suggest depression or physical discomfort. Tense posture and a rapid, determined gait suggest anxiety or anger. The posture of people when they are sitting or lying can also indicate feelings or mood. Again, the nurse clarifies the meaning of the observed behavior by describing to the client what the nurse sees and then asking what it means or whether the nurse's interpretation is correct. For example, "You look like it really hurts you to move. I'm wondering how your pain is and if you might need something to make you more comfortable?"

FACIAL EXPRESSION No part of the body is as expressive as the face (Figure 26-5 ■). Feelings of surprise, fear, anger, disgust, happiness, and sadness can be conveyed by facial expressions. Although the face may express the person's genuine emotions, it is also possible to control these muscles so the emotion expressed does not reflect what the person is feeling. When the message is not clear, it is important to get feedback to be sure of the intent of the expression. Many facial expressions convey a universal meaning. The smile expresses happiness. Contempt is conveyed by the mouth turned down, the head tilted back, and the eyes directed down the nose. No single expression can be interpreted accurately, however, without

Figure 26-5 ■ The nurse's facial expression communicates warmth and caring.
John Cowie/Getty Images.

considering other reinforcing physical cues, the setting in which it occurs, the expression of others in the same setting, and the cultural background of the client.

Nurses need to be aware of their own expressions and what they are communicating to others. Clients are quick to notice the nurse's facial expression, particularly when the client feels unsure or uncomfortable. The client who questions the nurse about a feared diagnostic result will watch whether the nurse maintains eye contact or looks away when answering. The client who has had disfiguring surgery will examine the nurse's face for signs of disgust. It is impossible to control all facial expression, but the nurse must learn to control expressions of feelings such as fear or disgust in some circumstances.

Eye contact is another essential element of facial communication. In many cultures, mutual eye contact acknowledges recognition of the other person and a willingness to maintain communication. Often a person initiates contact with another person with a glance, capturing the person's attention prior to communicating. A person who feels weak or defenseless often averts the eyes or avoids eye contact; the communication received may be too embarrassing or too dominating.

GESTURES Hand and body gestures may emphasize and clarify the spoken word, or they may occur without words to indicate a particular feeling or to give a sign. A father awaiting information about his daughter in surgery may wring his hands, tap his foot, pick at his nails, or pace back and forth. A gesture may more clearly indicate the size or shape of an object. A wave good-bye and the motioning of a visitor toward a chair are gestures that have relatively universal meanings. Some gestures, however, are culture specific. The Anglo American gesture meaning "shoo" or "go away" means "come here" or "come back" in some Asian cultures. In the Hmong culture it is considered rude to point at something with your toe.

For people with special communication problems, such as the deaf, the hands are invaluable in communication. Many people who are deaf learn sign language. Ill individuals who are unable to reply verbally can similarly devise a communication system using the hands. The client may be able to raise an index finger once for "yes" and twice for "no." Other signals can often be devised by the client and the nurse to denote other meanings.

ELECTRONIC COMMUNICATION

Computers are playing an increasing role in nursing practice. Many health care agencies are moving toward electronic medical records where nurses document their assessments and nursing care. Electronic mail (e-mail) can be used in health care facilities for many purposes: to schedule and confirm appointments, report normal lab results, conduct client education, and for follow-up with discharged clients.

E-MAIL E-mail is the most common form of electronic communication. It is important for the nurse to know the advantages and disadvantages of e-mail and also other guidelines to ensure client confidentiality.

ADVANTAGES E-mail has many positive advantages. It is a fast, efficient way to communicate and it is legible. It provides a record of the date and time of the message that was sent or received. Some health facilities provide information to their clients on how they can reach, via e-mail, specified staff members. This improves communication and continuity of client care. E-mail promises better access, and evidence has shown that clients and health care providers are willing to use Internet-based technologies (Dixon, 2010).

DISADVANTAGES One disadvantage or negative aspect of e-mail is concern by both clients and primary care providers regarding privacy, confidentiality, and potential misuse of information (Atherton, Sawmynaden, Meyer, & Car, 2012). Protection of client privacy remains an issue when transferring information electronically. The health care agency needs to have an e-mail encryption system to ensure security. An agency may have its own system or outsource it to an encryption service.

Another disadvantage is one of socioeconomic status. Not everyone has a computer, and even if people have access to computers at, say, a public library, not everyone has the necessary computer skills. E-mail may enhance communication with some clients but not all clients. Other forms of communication will be needed for clients who have limited abilities with speaking English, reading, writing, or using a computer.

OTHER GUIDELINES Agencies usually develop standards and guidelines for the use of e-mail in health care. Nurses need to know their agency's guidelines about what can be sent to clients by e-mail. The client usually signs an e-mail consent form. This form provides information about the risks of e-mail and authorizes the health agency to communicate with the client at a specified e-mail address.

Information sent to a client via e-mail is considered part of the client's medical record. Therefore, a copy of the e-mail needs to be put in the client's chart. E-mails, like other documentation in the client's record, may be used as evidence during litigation.

The use of e-mail can enhance effective relationships with clients. It is not, however, a substitute for effective verbal and nonverbal communication. Nurses need to use their professional judgment about what form of communication(s) will best meet their clients' health needs.

Factors Influencing the Communication Process

Many factors influence the communication process. Some of these are development, gender, values and perceptions, personal space, territoriality, roles and relationships, environment, congruence, interpersonal attitudes, and boundaries.

DEVELOPMENT

Language, psychosocial, and intellectual development move through stages across the life span. Knowledge of a client's developmental stage will allow the nurse to modify the message accordingly. The use of dolls and games coupled with simple language may help explain a procedure to an 8-year-old. With adolescents who have developed more abstract thinking skills, a more detailed explanation can be given, whereas a well-educated, middle-aged business executive may wish to have detailed technical information provided. Older clients are apt to have had a wider range of experiences with the health care system, which may influence their response or understanding. With aging also come changes in vision and hearing acuity that can affect nurse–client interactions.

GENDER

From an early age, females and males communicate differently. Girls tend to use language to seek confirmation, minimize differences, and establish intimacy. Boys use language to establish independence and negotiate status within a group. These differences can continue into

adulthood so that a man and a woman may interpret the same communication differently.

VALUES AND PERCEPTIONS

Values are the standards that influence behavior, and *perceptions* are the personal view of an event. Because each person has unique personality traits, values, and life experiences, each will perceive and interpret messages and experiences differently. For example, if the nurse draws the curtains around a crying woman and leaves her alone, the woman may interpret this as “The nurse thinks that I will upset others and that I shouldn't cry” or “The nurse respects my need to be alone.” It is important for the nurse to be aware of a client's values and to validate or correct perceptions to avoid creating barriers in the nurse–client relationship.

PERSONAL SPACE

Personal space is the distance people prefer in interactions with others. **Proxemics** is the study of distance between people in their interactions. Middle-class North Americans use definite distances in various interpersonal relationships, along with specific voice tones and body language. Communication thus alters in accordance with four distances, each with a close and a far phase. Beebe, Beebe, and Redmond (2014, p. 202) list the following examples:

1. **Intimate:** 0 to 1½ feet
2. **Personal:** 1½ to 4 feet
3. **Social:** 4 to 12 feet
4. **Public:** 12 feet and beyond.

Intimate distance communication is characterized by body contact, heightened sensations of body heat and smell, and vocalizations that are low. Vision is intense, is restricted to a small body part, and may be distorted. Nurses frequently use intimate distance. Examples include cuddling a baby, touching a client who is blind, positioning clients, observing an incision, and restraining a toddler for an injection.

It is a natural protective instinct for people to maintain a certain amount of space immediately around them, and the amount varies with individuals and cultures. When someone who wants to communicate steps into another person's personal space, the receiver unconsciously responds by stepping back a pace or two. In their therapeutic roles, nurses often are required to violate this personal space. However, it is important for them to be aware of when this will occur and to alert the client. In many instances, the nurse can respect (not come as close as) a person's intimate distance. In other instances, the nurse may come within intimate distance to communicate warmth and caring.

Personal distance is less overwhelming than intimate distance. Voice tones are moderate, and body heat and smell are noticed less. Physical contact such as a handshake or touching a shoulder is possible. More of the person is perceived at a personal distance, so that nonverbal behaviors such as body stance or full facial expressions are seen with less distortion. Much communication between nurses and clients occurs at this distance. Examples occur when nurses are sitting with a client, giving medications, or establishing an intravenous infusion. Communication at a close personal distance can convey involvement by facilitating the sharing of thoughts and feelings. On the other hand, it can also create tension if the distance encroaches on the other individual's personal space (Figure 26–6 ■). At the outer

LIFESPAN CONSIDERATIONS | Communication with Children

The ability to communicate is directly related to the development of thought processes, the presence of intact sensory and motor systems, and the extent and nature of an individual's opportunities to practice communication skills. As children grow, their communication abilities change markedly.

INFANTS

- Infants communicate nonverbally, often in response to body feelings rather than in a conscious effort to be expressive.
- Infants' perceptions are related to sensory stimuli, so a gentle voice is soothing, for example, while tension and anger around them create distress.

TODDLERS AND PRESCHOOLERS

- Toddlers and young children gain skills in both expressive (i.e., telling others what they feel, think, want, care about) and receptive (hearing and understanding what others are communicating to them) language.
- Allow time for them to complete verbalizing their thoughts without interruption.
- Provide a simple response to questions because they have short attention spans.
- Drawing a picture can provide another way for the child to communicate.

SCHOOL-AGE CHILDREN

- Talk to the child at his or her eye level to help decrease intimidation.
- Include the child in the conversation when communicating with the parents.

ADOLESCENTS

- Take time to build rapport with the adolescent.
- Use active listening skills.
- Project a nonjudgmental attitude and nonreactive behaviors, even when the adolescent makes disturbing remarks.

Nurses can use the following communication techniques to work effectively with children and their families:

- Play, the universal language, allows children to use other symbols, not just words, to express themselves.
- Nonverbal children may be able to use drawing, painting, and other art forms to communicate.
- Storytelling, in which the nurse and child take turns adding to a story or putting words to pictures, can help the child feel safer in expressing emotions and feelings.
- Word games that pose hypothetical situations or put the child in control, such as "What if . . . ?" "If you could . . .," "If a genie came and gave you a wish . . .," can help a child feel more powerful or explore ideas about how to manage the illness.
- Read books with a theme similar to the child's condition or problem, then discuss the meaning, characters, and feelings generated by the book. Movies or videos can also be used in this way.
- Writing can be used by older children to reflect on their situation, develop meaning, and gain a sense of control.

In all interactions with children, it is important to give them opportunities to be expressive, listen openly, and respond honestly, using words and concepts they understand.

Figure 26-6 ■ Personal space influences communication in social and professional interactions. Encroachment into another individual's personal space creates tension.

extreme of 4 feet, however, less involvement is expressed. Bantering and some social conversations usually take place at this distance.

Social distance is characterized by a clear visual perception of the whole person. Body heat and odor are imperceptible, eye contact is increased, and vocalizations are loud enough to be overheard by others. Communication is therefore more formal and is limited to seeing and hearing. The person may feel protected and out of reach for touch or personal sharing of thoughts or feelings. Social distance allows more activity and movement back and forth. It is expedient for communicating with several people at the same time or within a short

time. Examples occur when nurses make rounds or wave a greeting to someone. Social distance is important in accomplishing the business of the day. However, it is frequently misused. For example, the nurse who stands in the doorway and asks a client "How are you today?" will receive a more noncommittal reply than the nurse who moves to a personal distance to make the same inquiry.

Public distance requires loud, clear vocalizations with careful enunciation. Although the faces and forms of people are seen at public distance, individuality is lost. Instead, the perception is of the group of people or the community.

TERRITORIALITY

Territoriality is a concept of the space and things that an individual considers as belonging to the self. Territories marked off by people may be visible to others. For example, clients in a hospital often consider their territory as bounded by the curtains around the bed unit or by the walls of a private room. Health care workers must recognize this human tendency to claim territory. Clients often feel the need to defend their territory when it is invaded by others; for example, when a visitor or nurse removes a chair to use at another bed, the visitor has inadvertently violated the territoriality of the client whose chair was removed. Nurses need to obtain permission from clients to remove, rearrange, or borrow objects in their hospital area.

ROLES AND RELATIONSHIPS

The roles and the relationships between sender and receiver affect the communication process. Roles such as nursing student and instructor, client and primary care provider, or parent and child affect the content and responses in the communication process. Choice of

words, sentence structure, and tone of voice vary considerably from role to role. In addition, the specific relationship between the communicators is significant. The nurse who meets with a client for the first time communicates differently from the nurse who has previously developed a relationship with that client.

ENVIRONMENT

People usually communicate most effectively in a comfortable environment. Temperature extremes, excessive noise, and a poorly ventilated environment can all interfere with communication. Also, lack of privacy may interfere with a client's communication about matters the client considers private. For example, a client who is worried about the ability of his wife to care for him after discharge from the hospital may not wish to discuss this concern with a nurse within hearing of other clients in the room. Environmental distraction can impair and distort communication.

CONGRUENCE

In **congruent communication**, the verbal and nonverbal aspects of the message match. Clients more readily trust the nurse when they perceive the nurse's communication as congruent. This will also help to prevent miscommunication. Both nurse and client can easily determine if there is congruence between verbal expression and nonverbal expression. Nurses are taught to assess clients, but clients are often just as adept at reading a nurse's expression or body language. If there is an incongruence between verbal and nonverbal expression, the body language or nonverbal communication is usually the one with the true meaning. For example, when teaching a client how to care for a colostomy, the nurse might say, "You won't have any problem with this." However, if the nurse looks worried or disgusted while saying this, the client is less likely to trust the nurse's words.

INTERPERSONAL ATTITUDES

Attitudes convey beliefs, thoughts, and feelings about people and events. Attitudes are communicated convincingly and rapidly to others. Attitudes such as caring, warmth, respect, and acceptance facilitate communication, whereas condescension, lack of interest, and coldness inhibit communication.

Caring and *warmth* convey a feeling of emotional closeness, in contrast to an impersonal approach. Caring is more enduring and intense than warmth. It conveys deep and genuine concern for the person, whereas warmth conveys friendliness and consideration, shown by acts of smiling and attention to physical comforts. Caring involves giving feelings, thoughts, skill, and knowledge. It requires psychological energy and poses the risk of gaining little in return; yet by caring, people usually reap the benefits of greater communication and understanding.

Respect is an attitude that emphasizes the other person's worth and individuality. It conveys that the person's hopes and feelings are special and unique even though similar to others in many ways. People have a need to be different from—and at the same time similar to—others. Being too different can be isolating and threatening. A nurse conveys respect by listening with an open mind to what the other person is saying, even if the nurse disagrees. Nurses can learn new ways of approaching situations when they conscientiously listen to another person's perspective.

Health care providers may unknowingly use speech that they believe shows caring but the client perceives as demeaning or patronizing. This frequently happens in settings that provide health care to

older adults and/or individuals with obvious physical or mental disabilities. **Elderspeak** is a speech style similar to baby talk that gives the message of dependence and incompetence and is seen as patronizing by older adults (Morrow, 2013). It does not communicate respect. Many health care providers are not aware that they use elderspeak or that it can have negative meanings to the client. The characteristics of elderspeak include inappropriate terms of endearment (e.g., "honey," "grandma"), inappropriate plural pronoun use (e.g., "Are *we* ready for our bath"), tag questions (e.g., "You want to wear this dress"), and slow, loud speech (Cunningham & Williams, 2007, p. 46).

Acceptance emphasizes neither approval nor disapproval. The nurse willingly receives the client's honest feelings. An accepting attitude allows clients to express personal feelings freely and to be themselves. The nurse may need to restrict acceptance in situations where clients' behaviors are harmful to themselves or to others. Helping the client to find appropriate behaviors for feelings is often part of client teaching.

BOUNDARIES

Boundaries are defined by Boyd (2012) as "limits of individuals, objects, or relationships" (p. 113). For nurses, professional boundaries are crucial in the context of the nurse–client relationship. To keep clear boundaries, the nurse keeps the focus on the client and avoids sharing personal information or meeting his or her own needs through the nurse–client relationship. If the client seeks friendship with the nurse or a relationship outside the work environment, the nurse affirms his or her professional role and declines the invitation. Some indicators that boundary issues need to be addressed include gift-giving by the nurse or client, spending more time than necessary with a client, or the nurse believing only he or she understands the client (Boyd, 2012).

Web-based social networks such as Facebook, MySpace, and Twitter are experiencing increased usage. Unfortunately, online sites such as these have brought new hazards to nursing professionalism (Aylott, 2011). For example, many nurses believe that accepting a "friend" invitation from a client crosses professional boundaries and can be damaging to the therapeutic relationship (Tariman, 2010). Unprofessional uses of social networking tools are common; thus, the nurse needs to be diligent about not crossing nurse–client boundaries in an online setting. The American Nurses Association (ANA) Code of Ethics (2010) states that the nurse is responsible for maintaining professional boundaries in all encounters (p. 151). It is important to remember that the need for nurses to behave professionally is constant, even when not officially working or during their own personal, online time. Aylott (2011, p. 15) encourages nurses to reflect before publishing anything to a web-based social network site and to review the submission using the following PCA test:

- **Pause** and process (recognize potential for boundary crossing)
- **Choices** (evaluate the situation and options)
- **Act** accountably (professional conduct).

Therapeutic Communication

Therapeutic communication promotes understanding and can help establish a constructive relationship between the nurse and the client. Unlike a social relationship, where there may not be a specific purpose or direction, the therapeutic helping relationship is client and goal directed.

Nurses need to respond not only to the content of a client's verbal message but also to the feelings expressed. It is important to

understand how the client views the situation and feels about it before responding. The content of the client's communication is the words or thoughts, as distinct from the feelings. Sometimes people can convey a thought in words while their emotions contradict the words; that is, words and feelings are incongruent. For example, a client says, "I am glad he has left me; he was very cruel." However, the nurse observes that the client has tears in her eyes as she says this. To respond to the client's *words*, the nurse might simply rephrase, saying, "You are pleased that he has left you." To respond to the client's *feelings*, the nurse would need to acknowledge the tears in the client's eyes, saying, for example, "You seem saddened by all this." Such a response helps the client to focus on her feelings. In some instances, the nurse may need to know more about the client and her resources for coping with these feelings.

Sometimes clients need time to deal with their feelings. Strong emotions are often draining. People usually need to deal with feelings before they can cope with other matters, such as learning new skills or planning for the future. This is most evident in hospitals when clients learn that they have a terminal illness. Some require hours, days, or even weeks before they are ready to start other tasks. Some need only time to themselves, others need someone to listen, others need assistance identifying and verbalizing feelings, and others need assistance making decisions about future courses of action.

ATTENTIVE LISTENING

Attentive listening is listening actively and with mindfulness, using all the senses, and paying attention to what the client says, does, and feels as opposed to listening passively with just the ear. It is probably the most important technique in nursing and is basic to all other techniques. Attentive listening is an active process that requires energy and concentration. It involves paying attention to the total message, both verbal and nonverbal, and noting whether these communications are congruent. Attentive listening means absorbing both the content and the feeling the person is conveying, while putting aside your own judgments and ideas to really hear and focus on the client's needs. Attentive listening conveys an attitude of caring and interest, thereby encouraging the client to trust you, open up, and talk (Figure 26-7 ■).

Figure 26-7 ■ The nurse conveys attentive listening through a posture of involvement.
Fuse/Getty Images.

Attentive listening also involves listening for key themes in the communication. The nurse must be careful not to react quickly to the message. The nurse should not interrupt the speaker, and the nurse (the responder) should take time to think about the message before responding. As a listener, the nurse also should ask questions either to obtain additional information or to clarify. The message sender (i.e., the client) should decide when to close a conversation. When the nurse closes the conversation, the client may assume that the nurse considers the message unimportant. It is also important for nurses to be aware of their own biases. A message from a client that reflects different values or beliefs should not be discredited for that reason.

Kneisl and Trigoboff (2013) point out the following blocks to listening that may prevent the nurse from hearing what the client is saying and hinder therapeutic communication:

- Rehearsing—being too busy thinking about what you want to say
- Being concerned with yourself—the focus should be on the client
- Assuming—thinking that you know what the client “really means” without validation
- Judging—framing what you hear or see in terms of your judgment about the client as being immature, depressed, etc.
- Identifying—focusing on your own similar experiences, feelings, or beliefs
- Getting off track—changing the subject if you become uncomfortable, bored, or tired
- Filtering—tuning out or only hearing certain things (p. 197).

In summary, attentive listening is a highly developed skill, and it can be learned with practice. A nurse can communicate attentive listening to clients in various ways. Common responses are nodding the head, uttering “Uh huh” or “Mmm,” repeating the words that the client has used, or saying “I see what you mean.” Each nurse has characteristic ways of responding, and the nurse must take care not to sound insincere or phony.

VISIBLY TUNING IN

At times, your nonverbal behavior may be as important, or more important, than your words. Egan (2014) describes key nonverbal skills that can be used to visibly tune in to clients, which is an expression of empathy that tells “clients that you are with them, and it puts you in a position to listen carefully to their concerns” (p. 74). He reminds us that these skills of visibly tuning in can be learned; however, they will be phony if they are not driven by attitudes and values such as respect and empathy (p. 76). The five specific guidelines for visibly tuning in to clients are described in Box 26-1.

Therapeutic communication techniques facilitate communication and focus on the client's concerns (Table 26-1).

Barriers to Communication

Nurses need to recognize barriers or nontherapeutic responses to effective communication (Table 26-2). Failing to listen, improperly decoding the client's intended message, and placing the nurse's needs above the client's needs are major barriers to communication.

THE HELPING RELATIONSHIP

Nurse–client relationships are referred to by some as *interpersonal relationships*, by others as *therapeutic relationships*, and by still

BOX 26-1 Guidelines for Visibly Tuning in to Clients: Empathic Presence

Egan (2014) suggests specific nonverbal skills that a nurse can use to portray empathic presence through use of the acronym SOLER:

- **S:** Face the other person *squarely*. Adopt a posture that indicates involvement. This position says, “I am available to you.” Moving to the side lessens the degree of involvement.
- **O:** Adopt an *open* posture. The nondefensive position is one in which neither arms nor legs are crossed. It conveys that the person wishes to listen to what the other has to say.
- **L:** *Lean* toward the person. People move naturally toward one another when they want to say or hear something—by moving to the front of a class, by moving a chair nearer a friend, or by leaning across a table with arms propped in front. The nurse conveys involvement by leaning forward, closer to the client.
- **E:** Maintain good eye contact. In North American culture, mutual eye contact, preferably at the same level, recognizes the other person and denotes willingness to maintain communication. Eye contact neither glares at nor stares down another but

is natural. In other cultures, too much eye contact, especially with someone in a position of authority, is out of order (Egan, 2014, p. 78).

- **R:** Try to be relatively *relaxed* or natural. Total relaxation is not feasible when the nurse is listening with intensity, but the nurse can show relaxation by taking time to respond, allowing pauses as needed, balancing periods of tension with relaxation, and using gestures that are natural.

These five guidelines need to be adapted to the specific needs of clients in a given situation. For example, leaning forward may not be appropriate at the beginning of an interview. It may be reserved until a closer relationship grows between the nurse and the client. The same applies to eye contact, which is generally uninterrupted when the communicators are very involved in the interaction.

From *The Skilled Helper: A Problem-Management and Opportunity-Development Approach to Helping* (10th ed., pp. 77–78), by G. Egan, 2014, Belmont, CA: Brooks/Cole.

TABLE 26-1 Therapeutic Communication Techniques

Technique	Description	Examples
Using silence	Accepting pauses or silences that may extend for several seconds or minutes without interjecting any verbal response.	Sitting quietly (or walking with the client) and waiting attentively until the client is able to put thoughts and feelings into words.
Providing general leads	Using statements or questions that (a) encourage the client to verbalize, (b) choose a topic of conversation, and (c) facilitate continued verbalization.	“Can you tell me how it is for you?” “Perhaps you would like to talk about. . . .” “Would it help to discuss your feelings?” “Where would you like to begin?” “And then what?”
Being specific and tentative	Making statements that are specific rather than general, and tentative rather than absolute.	“Rate your pain on a scale of zero to ten.” (specific statement) “Are you in pain?” (general statement) “You seem unconcerned about your diabetes.” (tentative statement)
Using open-ended questions	Asking broad questions that lead or invite the client to explore (elaborate, clarify, describe, compare, or illustrate) thoughts or feelings. Open-ended questions specify only the topic to be discussed and invite answers that are longer than one or two words.	“I’d like to hear more about that.” “Tell me more. . . .” “How have you been feeling lately?” “What brought you to the hospital?” “What is your opinion?” “You said you were frightened yesterday. How do you feel now?”
Using touch	Providing appropriate forms of touch to reinforce caring feelings. Because tactile contacts vary considerably among individuals, families, and cultures, the nurse must be sensitive to the differences in attitudes and practices of clients and self.	Putting an arm over the client’s shoulder. Placing your hand over the client’s hand.
Restating or paraphrasing	Actively listening for the client’s basic message and then repeating those thoughts and/or feelings in similar words. This conveys that the nurse has listened and understood the client’s basic message and also offers clients a clearer idea of what they have said.	<i>Client:</i> “I couldn’t manage to eat any dinner last night—not even the dessert.” <i>Nurse:</i> “You had difficulty eating yesterday.” <i>Client:</i> “Yes, I was very upset after my family left.”

TABLE 26-1 Therapeutic Communication Techniques—*continued*

Technique	Description	Examples
Seeking clarification	A method of making the client's broad overall meaning of the message more understandable. It is used when paraphrasing is difficult or when the communication is rambling or garbled. To clarify the message, the nurse can restate the basic message or confess confusion and ask the client to repeat or restate the message. Nurses can also clarify their own message with statements.	"I'm puzzled." "I'm not sure I understand that." "Would you please say that again?" "Would you tell me more?" "I meant this rather than that." "I'm sorry that wasn't very clear. Let me try to explain another way."
Perception checking or seeking consensual validation	A method similar to clarifying that verifies the meaning of specific words rather than the overall meaning of a message.	<i>Client:</i> "My husband never gives me any presents." <i>Nurse:</i> "You mean he has never given you a present for your birthday or Christmas?" <i>Client:</i> "Well—not never. He does get me something for my birthday and Christmas, but he never thinks of giving me anything at any other time."
Offering self	Suggesting one's presence, interest, or wish to understand the client without making any demands or attaching conditions that the client must comply with to receive the nurse's attention.	"I'll stay with you until your daughter arrives." "We can sit here quietly for a while; we don't need to talk unless you would like to." "I'll help you to dress to go home, if you like."
Giving information	Providing, in a simple and direct manner, specific factual information the client may or may not request. When information is not known, the nurse states this and indicates who has it or when the nurse will obtain it.	"Your surgery is scheduled for 11 AM tomorrow." "You will feel a pulling sensation when the tube is removed from your abdomen." "I do not know the answer to that, but I will find out from Mrs. King, the nurse in charge."
Acknowledging	Giving recognition, in a nonjudgmental way, of a change in behavior, an effort the client has made, or a contribution to a communication. Acknowledgment may be with or without understanding, verbal or nonverbal.	"You trimmed your beard and mustache and washed your hair." "I notice you keep squinting your eyes. Are you having difficulty seeing?" "You walked twice as far today with your walker."
Clarifying time or sequence	Helping the client clarify an event, situation, or happening in relationship to time.	<i>Client:</i> "I vomited this morning." <i>Nurse:</i> "Was that after breakfast?" <i>Client:</i> "I feel that I have been asleep for weeks." <i>Nurse:</i> "You had your operation Monday, and today is Tuesday."
Presenting reality	Helping the client to differentiate the real from the unreal.	"That telephone ring came from the program on television." "Your magazine is here in the drawer. It has not been stolen."
Focusing	Helping the client expand on and develop a topic of importance. It is important for the nurse to wait until the client finishes stating the main concerns before attempting to focus. The focus may be an idea or a feeling; however, the nurse often emphasizes a feeling to help the client recognize an emotion disguised behind words.	<i>Client:</i> "My wife says she will look after me, but I don't think she can, what with the children to take care of, and they're always after her about something—clothes, homework, what's for dinner that night." <i>Nurse:</i> "Sounds like you are worried about how well she can manage."
Reflecting	Directing ideas, feelings, questions, or content back to clients to enable them to explore their own ideas and feelings about a situation.	<i>Client:</i> "What can I do?" <i>Nurse:</i> "What do you think would be helpful?" <i>Client:</i> "Do you think I should tell my husband?" <i>Nurse:</i> "You seem unsure about telling your husband."
Summarizing and planning	Stating the main points of a discussion to clarify the relevant points discussed. This technique is useful at the end of an interview or to review a health teaching session. It often acts as an introduction to future care planning.	"During the past half hour we have talked about. . . ." "Tomorrow afternoon we may explore this further." "In a few days I'll review what you have learned about the actions and effects of your insulin." "Tomorrow, I will look at your feeling journal."

TABLE 26–2 Barriers to Communication

Technique	Description	Examples
Stereotyping	Offering generalized and oversimplified beliefs about groups of people that are based on experiences too limited to be valid. These responses categorize clients and negate their uniqueness as individuals.	<p>“Two-year-olds are brats.”</p> <p>“Women are complainers.”</p> <p>“Men don’t cry.”</p> <p>“Most people don’t have any pain after this type of surgery.”</p>
Agreeing and disagreeing	Similar to judgmental responses, agreeing and disagreeing imply that the client is either right or wrong and that the nurse is in a position to judge this. These responses deter clients from thinking through their position and may cause a client to become defensive.	<p><i>Client:</i> “I don’t think Dr. Broad is a very good doctor. He doesn’t seem interested in his clients.”</p> <p><i>Nurse:</i> “Dr. Broad is head of the department of surgery and is an excellent surgeon.”</p>
Being defensive	Attempting to protect a person or health care services from negative comments. These responses prevent the client from expressing true concerns. The nurse is saying, “You have no right to complain.” Defensive responses protect the nurse from admitting weaknesses in the health care services, including personal weaknesses.	<p><i>Client:</i> “Those night nurses must just sit around and talk all night. They didn’t answer my light for over an hour.”</p> <p><i>Nurse:</i> “I’ll have you know we literally run around on nights. You’re not the only client, you know.”</p>
Challenging	Giving a response that makes clients prove their statement or point of view. These responses indicate that the nurse is failing to consider the client’s feelings, making the client feel it necessary to defend a position.	<p><i>Client:</i> “I felt nauseated after that red pill.”</p> <p><i>Nurse:</i> “Surely you don’t think I gave you the wrong pill?”</p> <p><i>Client:</i> “I feel as if I am dying.”</p> <p><i>Nurse:</i> “How can you feel that way when your pulse is 60?”</p> <p><i>Client:</i> “I believe my husband doesn’t love me.”</p> <p><i>Nurse:</i> “You can’t say that; why, he visits you every day.”</p>
Probing	Asking for information chiefly out of curiosity rather than with the intent to assist the client. These responses are considered prying and violate the client’s privacy. Asking “why” is often probing and places the client in a defensive position.	<p><i>Client:</i> “I was speeding along the street and didn’t see the stop sign.”</p> <p><i>Nurse:</i> “Why were you speeding?”</p> <p><i>Client:</i> “I didn’t ask the doctor when he was here.”</p> <p><i>Nurse:</i> “Why didn’t you?”</p>
Testing	Asking questions that make the client admit to something. These responses permit the client only limited answers and often meet the nurse’s need rather than the client’s.	<p>“Who do you think you are?” (forces people to admit their status is only that of client)</p> <p>“Do you think I am not busy?” (forces the client to admit that the nurse really is busy)</p>
Rejecting	Refusing to discuss certain topics with the client. These responses often make clients feel that the nurse is rejecting not only their communication but also the clients themselves.	<p>“I don’t want to discuss that. Let’s talk about. . . .”</p> <p>“Let’s discuss other areas of interest to you rather than the two problems you keep mentioning.”</p>
Changing topics and subjects	Directing the communication into areas of self-interest rather than considering the client’s concerns is often a self-protective response to a topic that causes anxiety. These responses imply that what the nurse considers important will be discussed and that clients should not discuss certain topics.	<p>“I can’t talk now. I’m on my way for coffee break.”</p> <p><i>Client:</i> “I’m separated from my wife. Do you think I should have sexual relations with another woman?”</p> <p><i>Nurse:</i> “I see that you’re 36 and that you like gardening. This sunshine is good for my roses. I have a beautiful rose garden.”</p>
Unwarranted reassurance	Using clichés or comforting statements of advice as a means to reassure the client. These responses block the fears, feelings, and other thoughts of the client.	<p>“You’ll feel better soon.”</p> <p>“I’m sure everything will turn out all right.”</p> <p>“Don’t worry.”</p>
Passing judgment	Giving opinions and approving or disapproving responses, moralizing, or implying one’s own values. These responses imply that the client must think as the nurse thinks, fostering client dependence.	<p>“That’s good (bad).”</p> <p>“You shouldn’t do that.”</p> <p>“That’s not good enough.”</p> <p>“What you did was wrong (right).”</p>
Giving common advice	Telling the client what to do. These responses deny the client’s right to be an equal partner. Note that giving expert rather than common advice is therapeutic.	<p><i>Client:</i> “Should I move from my home to a nursing home?”</p> <p><i>Nurse:</i> “If I were you, I’d go to a nursing home, where you’ll get your meals cooked for you.”</p>

others as **helping relationships**. Helping is a growth-facilitating process that strives to achieve three basic goals (Egan, 2014, pp. 9–12):

1. Help clients manage their problems in living more effectively and develop unused or underused opportunities more fully.
2. Help clients become better at helping themselves in their everyday lives.
3. Help clients develop an action-oriented prevention mentality in their lives.

A helping relationship may develop over weeks of working with a client, or within minutes. The keys to the helping relationship are (a) the development of trust and acceptance between the nurse and the client and (b) an underlying belief that the nurse cares about and wants to help the client.

The personal and professional characteristics of the nurse and the client influence the helping relationship. Age, gender, appearance, diagnosis, education, values, ethnic and cultural background, personality, expectations, and setting can all affect the development of the nurse–client relationship. Consideration of all these factors, combined with good communication skills and sincere interest in the client’s welfare, will enable the nurse to create a helping relationship. Characteristics of helping relationships are listed in Box 26–2.

Phases of the Helping Relationship

The helping relationship process can be described in terms of four sequential phases, each characterized by identifiable tasks and skills. The relationship must progress through the stages in succession because each builds on the one before. Nurses can identify the progress of a relationship by understanding these phases: preinteraction phase, introductory phase, working (maintaining) phase, and termination phase. Table 26–3 summarizes the tasks and skills required.

PREINTERACTION PHASE

The preinteraction phase is similar to the planning stage before an interview. In most situations, the nurse has information about the client before the first face-to-face meeting. Such information may include the client’s name, address, age, medical history, and/or social history. Planning for the initial visit may generate some anxious feelings in the nurse. If the nurse recognizes these feelings and identifies specific information to be discussed, positive outcomes can evolve.

INTRODUCTORY PHASE

The introductory phase, also referred to as the *orientation phase* or the *prehelping phase*, is important because it sets the tone for the

rest of the relationship. During this initial encounter, the client and the nurse closely observe each other and form judgments about the other’s behavior. The goal of the nurse in this phase is to develop trust and security within the nurse–client relationship (Boyd, 2012). Other important tasks of the introductory phase include getting to know each other and developing a degree of trust.

After introductions, the nurse may initially engage in some social interaction to put the client at ease. For example, the nurse and client may talk about what a nice day it is and what they would like to do if at home.

During the initial parts of the introductory phase, the client may display some resistive behaviors. *Resistive behaviors* are those that inhibit involvement, cooperation, or change. They may be due to difficulty in acknowledging the need for help and thus a dependent role, fear of exposing and facing feelings, anxiety about the discomfort involved in changing problem-causing behavior patterns, and fear or anxiety in response to the nurse’s approach, which may, in the client’s opinion, be inappropriate.

Resistive behaviors can be overcome by conveying a caring attitude, genuine interest in the client, and competence. These behaviors of the nurse also foster the development of trust in the relationship. Trust can be described as a reliance on someone without doubt or question, or the belief that the other person is capable of assisting in times of distress and in all likelihood will do so. To trust another person involves risk; clients become vulnerable when they share thoughts, feelings, and attitudes with the nurse. Trust, however, enables the client to express thoughts and feelings openly.

By the end of the introductory phase, clients should begin to:

- Develop trust in the nurse.
- View the nurse as a competent professional capable of helping.
- View the nurse as honest, open, and concerned about their welfare.
- Believe the nurse will try to understand and respect their cultural values and beliefs.
- Believe the nurse will respect client confidentiality.
- Feel comfortable talking with the nurse about feelings and other sensitive issues.
- Understand the purpose of the relationship and the roles.
- Feel that they are active participants in developing a mutually agreeable plan of care.

WORKING PHASE

During the working phase of a helping relationship, the nurse and the client begin to view each other as unique individuals. They begin to appreciate this uniqueness and care about each other. Caring is sharing deep and genuine concern about the welfare of another person. Once caring develops, the potential for empathy increases.

The working phase has two major stages: exploring and understanding thoughts and feelings, and facilitating and taking action. The nurse helps the client to explore thoughts, feelings, and actions and helps the client plan a program of action to meet preestablished goals.

EXPLORING AND UNDERSTANDING THOUGHTS AND FEELINGS The nurse must have the following skills for this phase of the helping relationship:

- **Empathetic listening and responding.** Nurses must listen attentively and communicate (respond) in ways that indicate they have listened to what was said and understand how the client feels. The nurse responds to content or feelings or both, as appropriate. The nurse’s

BOX 26–2

Characteristics of a Helping Relationship

A helping relationship:

- Is an intellectual and emotional bond between the nurse and the client and is focused on the client.
- Respects the client as an individual, including
 - Maximizing the client’s abilities to participate in decision making and treatments
 - Considering ethnic and cultural aspects
 - Considering family relationships and values.
- Respects client confidentiality.
- Focuses on the client’s well-being.
- Is based on mutual trust, respect, and acceptance.

TABLE 26–3 Tasks and Skills for Each Phase of the Helping Relationship

Phase	Tasks	Skills
PREINTERACTION PHASE	The nurse reviews pertinent assessment data and knowledge, considers potential areas of concern, and develops plans for interaction.	Organized data gathering; recognizing limitations and seeking assistance as required.
INTRODUCTORY PHASE		
1. Opening the relationship	Both client and nurse identify each other by name. When the nurse initiates the relationship, it is important to explain the nurse's role to give the client an idea of what to expect. When the client initiates the relationship, the nurse needs to help the client express concerns and reasons for seeking help. Vague, open-ended questions, such as "What's on your mind today?" are helpful at this stage.	A relaxed, attending attitude to put the client at ease. It is not easy for all clients to receive help.
2. Clarifying the problem	Because the client initially may not see the problem clearly, the nurse's major task is to help clarify the problem.	Attentive listening, paraphrasing, clarifying, and other effective communication techniques discussed in this chapter. A common error at this stage is to ask too many questions of the client. Instead focus on priorities.
3. Structuring and formulating the contract (obligations to be met by both the nurse and client)	Nurse and client develop a degree of trust and verbally agree about (a) location, frequency, and length of meetings; (b) overall purpose of the relationship; (c) how confidential material will be handled; (d) tasks to be accomplished; and (e) duration and indications for termination of the relationship.	Communication skills listed above and ability to overcome resistive behaviors if they occur.
WORKING PHASE	Nurse and client accomplish the tasks outlined in the introductory phase, enhance trust and rapport, and develop caring.	Listening and attending skills, empathy, respect, genuineness, concreteness, self-disclosure, and confrontation. Skills acquired by the client are nondescriptive listening and self-understanding.
1. Exploring and understanding thoughts and feelings	The nurse assists the client to explore thoughts and feelings and acquires an understanding of the client. The client explores thoughts and feelings associated with problems, develops the skill of listening, and gains insight into personal behavior.	
2. Facilitating and taking action	The nurse plans programs within the client's capabilities and considers long- and short-term goals. The client needs to learn to take risks (i.e., accept that either failure or success may be the outcome). The nurse needs to reinforce successes and help the client recognize failures realistically.	Decision-making and goal-setting skills. Also, for the nurse: reinforcement skills; for the client: risk taking.
TERMINATION PHASE	Nurse and client accept feelings of loss. The client accepts the end of the relationship without feelings of anxiety or dependence.	For the nurse: summarizing skills; for the client: ability to handle problems independently.

nonverbal behaviors are also important. Nonverbal behaviors indicating empathy include moderate head nodding, a steady gaze, moderate gesturing, and little activity or body movement. According to Boyd (2012), **empathy** is "the ability to experience, in the present, a situation as another did at some time in the past; the ability to put oneself in another person's circumstances and feelings" (p. 112). Empathetic listening focuses on a kind of "being with" clients to develop an understanding of them and their world. This understanding, however, must also be communicated effectively to the client in the form of an empathetic response. The end result of empathy is comforting and caring for the client and a helping, healing relationship.

- **Respect.** The nurse must show respect for the client's willingness to be available, desire to work with the client, and a manner that conveys the idea of taking the client's point of view seriously.

- **Genuineness.** Kneisl and Trigoboff (2013) describe genuineness as "the ability to be real or honest with another" (p. 195). To be effective, genuineness must be based on a solid relationship that is empathic and not phony. Phonyness can be expressed in a variety of ways, such as pretending to like someone when you do not or overstressing your professional role (e.g., I am the expert, the one with all the answers). Phonyness is incompatible with respect (Egan, 2014). The nurse who is genuine is more likely to help the client.
- **Concreteness.** The nurse must assist the client to be concrete and specific rather than to speak in generalities. When the client says, "I'm stupid and clumsy," the nurse narrows the topic to the specific by pointing out, "You tripped on the rug."
- **Confrontation.** The nurse points out discrepancies between thoughts, feelings, and actions that inhibit the client's self-understanding

or exploration of specific areas. This is done empathetically, not judgmentally.

During this first stage of the working phase, the intensity of interaction increases, and feelings such as anger, shame, or self-consciousness may be expressed. If the nurse is skilled in this stage and if the client is willing to pursue self-exploration, the outcome is a beginning understanding on the part of the client about behavior and feelings.

FACILITATING AND TAKING ACTION Ultimately the client must make decisions and take action to become more effective. The responsibility for action belongs to the client. The nurse, however, collaborates in these decisions, provides support, and may offer options or information.

TERMINATION PHASE

The termination phase of the relationship is often expected to be difficult and filled with ambivalence. However, if the previous phases have evolved effectively, the client generally has a positive outlook and feels able to handle problems independently. On the other hand, because caring attitudes have developed, it is natural to expect some feelings of loss, and each person needs to develop a way of saying good-bye.

Many methods can be used to terminate relationships. Summarizing or reviewing the process can produce a sense of accomplishment. This may include sharing reminiscences of how things were at the beginning of the relationship and comparing them to how they are now. It is also helpful for both the nurse and the client to express their feelings about termination openly and honestly. Thus termination discussions need to start in advance of the termination interview. This allows time for the client to adjust to independence. In some situations referrals are necessary, or it may be appropriate to offer an occasional standby meeting to give support as needed. Follow-up phone calls or e-mails are other interventions that ease the client's transition to independence.

Developing Helping Relationships

Whatever the practice setting, the nurse establishes some type of helping relationship in which mutual goals (outcomes) are set with the client or, if the client is unable to participate, with support people. Although special training in counseling techniques is advantageous, there are many ways of helping clients that do not require special training:

- Listen actively.
- Help to identify what the person is feeling. Often clients who are troubled are unable to identify or to label their feelings and consequently have difficulty working them out or talking about them. Responses such as “You seem angry about taking orders from your boss” or “You sound as if you’ve been lonely since your wife died” can help clients recognize what they are feeling and talk about it.
- Put yourself in the other person's shoes (i.e., empathize). Communicate to the client in a way that shows an understanding of the client's feelings and the behavior and experience underlying these feelings.
- Be honest. In effective relationships nurses honestly recognize any lack of knowledge by saying “I don't know the answer to that right now”; openly discuss their own discomfort by saying, for example, “I feel uncomfortable about this discussion”; and admit tactfully that problems do exist, for instance, when a client says “I'm a mess, aren't I?”

- Be genuine and credible. Clients will sense whether you are truly concerned.
- Use your ingenuity. There are always many courses of action to consider in handling problems. Whatever course is chosen needs to further the achievement of the client's goals (outcomes), be compatible with the client's value system, and offer the probability of success.
- Be aware of cultural differences that may affect meaning and understanding (see Chapter 18 ∞). To facilitate nurse–client interaction, recognize the language(s) and/or dialect(s) the client uses. Provide a bilingual interpreter as needed for clients who have limited English language skills.
- Maintain client confidentiality. To maintain the client's right to privacy, share information only with other health care professionals as needed for effective care and treatment.
- Know your role and your limitations. Every person has unique strengths and problems. When you feel unable to handle some problems, the client should be informed and referred to the appropriate health professional. Clarify functions and roles, specifically what is expected of the client, the nurse, and the primary care provider.

GROUP COMMUNICATION

People are born into a group (i.e., a family) and interact with others at all stages of life in various groups: peer groups, work groups, recreational groups, religious groups, and so on. A **group** is two or more people who have shared needs and goals, who take each other into account in their actions, and who thus are held together and set apart from others by virtue of their interactions. Groups exist to help people achieve goals (outcomes) that would be unattainable by individual effort alone. For example, groups can often solve problems more effectively than one person by pooling the ideas and expertise of several individuals; in addition, information can be disseminated to groups more quickly than to individuals.

Group Dynamics

The communication that takes place between members of any group is known as **group dynamics**. A number of interrelated factors and variables determine the manner of this communication. Each member of the group will have an effect on the group dynamics, based on their motivation for participating, their similarity to other group members, the maturity of the group members in expressing their feelings, and the goal of the group.

The unique dynamics of each group will influence its maturation or group process, as well as the effectiveness of the group. Three main functions are required for any group to be effective. It must maintain a degree of group unity or cohesion. It needs to develop and modify its structure to improve its effectiveness. Finally, it must accomplish its goals. The characteristics of an effectively functioning group are shown in Table 26–4.

Types of Health Care Groups

Nurses spend much of their professional life in a wide variety of groups, ranging from dyads (two-person groups) to large professional organizations. As a participant in a group, the nurse may be required to fulfill different roles: member or leader, teacher or learner, adviser or advisee, and so on.

TABLE 26–4 Comparative Features of Effective and Ineffective Groups

Factor	Effective Group	Ineffective Group
Atmosphere	Comfortable and relaxed; a working atmosphere in which people demonstrate their interest and involvement.	Tense; lacks privacy or voluntary commitment to the group.
Purpose	Goals, tasks, and outcomes are clarified, understood, and modified so that members of the group can commit themselves to purposes through cooperation.	Purposes are unclear, misunderstood, or imposed.
Leadership and member participation	Leadership is democratic with a shift in leadership from time to time depending on knowledge or experience.	Authoritarian; leader may dominate the group, or the members may defer unduly. Member participation is unequal, with some members dominating.
Communication	Open; ideas and feelings are encouraged.	Closed; only idea production is encouraged. Feelings are ignored. Members may have “hidden agendas” (personal goals at cross-purposes with group goals).
Decision making	By the group, although various decision-making procedures appropriate to the situation may be instituted.	By the highest authority in the group, or one or two strong members of the group, with minimal involvement by members. Disagreements are ignored.
Cohesion	Facilitated through valuing other group members, open expression of feelings, trust, and support.	Leader claims full credit for achievements. Comments are critical and focus on personal characteristics.
Conflict tolerance	The reasons for disagreements or conflicts are carefully examined, and the group seeks to resolve them.	Fear of conflict prevents decisions and growth.
Power	Determined by the members’ abilities and the information they possess. Power is shared.	Determined by position in the group. Obedience to authority is strong. The issue is who controls, based on individual emotional needs of members.
Problem solving	High; constructive criticism is frequent, frank, relatively comfortable, and oriented toward problem solving.	Low; criticism may be destructive, taking the form of either overt or covert personal attacks.
Creativity	Encouraged.	Discouraged.

Common types of health care groups include task groups, teaching groups, self-help groups, self-awareness/growth groups, therapy groups, and work-related social support groups. There are similarities and differences among the characteristics of these various types of groups and the nurse’s role.

TASK GROUPS

The task group is one of the most common types of work-related groups to which nurses belong. Examples are health care planning committees, nursing service committees, nursing team meetings, nursing care conference groups, and hospital staff meetings. The focus of such groups is the completion of a specific task, and the leader and/or members define the format at the beginning. The methods vary according to the task to be completed.

The leader of a task group, usually called the chairperson, must be accepted by the members as an appropriate leader and therefore should be an expert in the area of task emphasis. The chairperson’s role is to identify the specific task, clarify communication, and assist in expressing opinions and offering solutions. Committee members are generally selected in terms of their individual functional role and employment status, rather than in terms of their personal characteristics. The task often determines member participation. A target date for termination of the group is usually set in advance.

TEACHING GROUPS

The major purpose of teaching groups is to impart information to the participants. Examples of teaching groups include continuing

education and client health care groups. Numerous subjects are often handled via the group teaching format: childbirth techniques, birth control methods, effective parenting, nutrition, management of chronic illness such as diabetes, exercise for middle-aged and older adults, and instructions to family members about follow-up care for discharged clients. A nurse who leads a group in which the primary purpose is to teach or learn must be skilled in the teaching–learning process (see Chapter 27 ∞).

SELF-HELP GROUPS

A self-help group is a small, voluntary organization composed of individuals who share a similar health, social, or daily living problem. One of the central beliefs of the self-help movement is that people who experience a particular social or health problem have an understanding of that condition which those without it do not.

Self-help groups are available for a range of problems (e.g., stillbirth, parenting, pregnant adolescents, divorce, drug abuse, cancer, menopause, mental illness, diabetes, AIDS, women’s health, caregivers of older adults, and grief). Alcoholics Anonymous was the first self-help group. Positive aspects of self-help groups are outlined in Box 26–3.

The major functions of the nurse’s role in self-help groups include the following:

- Help clients form such groups by identifying key people who can act as facilitators.
- Share expertise with clients and help them gain appropriate knowledge and skills.

BOX 26-3 Positive Aspects of Self-Help Groups

- Members can experience almost instant kinship because the essence of the group is the idea that “you are not alone.”
- Members can talk about their feelings and listen to the concerns of others, knowing they all share this experience.
- The group atmosphere is generally one of acceptance, support, encouragement, and caring.
- Many members act as role models for newer members and can inspire them to attempt tasks they might consider impossible.
- The group provides the opportunity for people to help as well as to be helped—a critical component in restoring self-esteem after significant losses.

- Inform clients and support people about existing self-help groups available to them.
- Participate as a member of a self-help group when this is appropriate. The nurse’s role is that of a resource person, that is, of being “on tap, but not on top.”
- Help out in times of crisis.

SELF-AWARENESS AND GROWTH GROUPS

The purpose of self-awareness and growth groups is to develop or use interpersonal strengths. The overall aim is to improve the person’s functioning in the group to which they return, whether job, family, or community. From the beginning, broad goals are usually apparent, for example, to study communication patterns, group process, or problem solving. Because the focus of these groups is interpersonal concerns around current situations, the work of the group is oriented to reality testing with a here-and-now emphasis. Members are responsible for correcting inefficient patterns of relating and communicating with each other. They learn the group process through participation, involvement, and guided exercises.

THERAPY GROUPS

Therapy groups work toward self-understanding, more satisfactory ways of relating to or handling stress, and changing patterns of behavior toward health.

Members of a therapy group are chosen by health professionals after extensive selection interviews that consider the pattern of personalities, behaviors, needs, and identification of group therapy as the treatment of choice. Duration of therapy groups is not usually set. A termination date is usually mutually determined by the therapist and members.

WORK-RELATED SOCIAL SUPPORT GROUPS

Many nurses, for example, hospice, emergency, and acute care nurses, experience high levels of vocational stress. Various types of group support can buffer such stress. Group members who know about the work of others can encourage and challenge members to be more creative and enthusiastic about their work and to achieve more. For example, a nurse may help another team member consider alternative strategies for intervention. Members also can share the joys of success and the frustration of failure through active listening without giving advice or making judgments. This type of social support is best given outside of the work environment.

COMMUNICATION AND THE NURSING PROCESS

Communication is an integral part of the nursing process. Nurses use communication skills in each phase of the nursing process. Communication is also important when caring for clients who have communication problems. Communication skills are even more important when the client has sensory, language, or cognitive deficits.

●○○ NURSING MANAGEMENT**Assessing**

To assess the client’s communication abilities, the nurse determines communication impairments or barriers and communication style. Remember that culture may influence when and how a client speaks. Obviously, language varies according to age and development. With children, the nurse observes sounds, gestures, and vocabulary.

Impairments to Communication

Various barriers may alter a client’s ability to send, receive, or comprehend messages. These include language deficits, sensory deficits, cognitive impairments, structural deficits, and paralysis. The nurse must assess each to determine their presence.

Language Deficits

Determine the client’s primary language for communicating and whether a fluent interpreter is required. The language skills of some clients who use English as a second language may be inadequate to meet their needs.

Sensory Deficits

The ability to hear, see, feel, and smell are important adjuncts to communication. Deafness can significantly alter the message the client receives; impaired vision alters the ability to observe nonverbal behavior, such as a smile or a gesture; inability to feel and smell can impair the client’s abilities to report injuries or detect the smoke from a fire. For clients with severe hearing impairments, follow these steps:

- Look for a medical alert bracelet (or necklace or tag) indicating hearing loss.
- Determine whether the client wears a hearing aid and whether it is functioning.
- Observe whether the client is attempting to see your face to read lips.
- Observe whether the client is attempting to use hands to communicate with sign language.

Cognitive Impairments

Any disorder that impairs cognitive functioning (e.g., cerebrovascular disease, Alzheimer’s disease, and brain tumors or injuries) may affect a client’s ability to use and understand language. These clients may develop total loss of speech, impaired articulation, or the inability to find or name words. Certain medications such as sedatives, antidepressants, and neuroleptics may also impair speech, causing the client to use incomplete sentences or to slur words.

The nurse assesses whether these clients respond when asked a question and, if so, assesses the following: Is the client’s speech fluent or hesitant? Does the client use words correctly? Can the client

LIFESPAN CONSIDERATIONS Communication with Older Adults

Older adults may have physical or cognitive problems that necessitate nursing interventions for improvement of communication skills. Some of the common ones are as follows:

- Sensory deficits, such as vision and hearing
- Cognitive impairment, as in dementia
- Neurologic deficits from strokes or other neurologic conditions, such as aphasia (expressive and/or receptive) and lack of movement
- Psychosocial problems, such as depression.

Recognition of specific needs and obtaining appropriate resources for clients can greatly increase their socialization and quality of life. Interventions directed toward improving communication in clients with these special needs are as follows:

- Make sure that assistive devices, glasses, and hearing aids are being used and are in good working order.
- Make referrals to appropriate resources, such as speech therapy.
- Make use of communications aids, such as communication boards, computers, or pictures, when possible.

- Keep environmental distractions to a minimum.
- Speak in short, simple sentences, one subject at a time—reinforce or repeat what is said when necessary.
- Always face the person when speaking—coming up behind someone may be frightening.
- Include family and friends in conversation.
- Use reminiscing, either in individual conversations or in groups, to maintain memory connections and to enhance self-identity and self-esteem in the older adult.
- When verbal expression and nonverbal expression are incongruent, believe the nonverbal. Clarification of this and attentiveness to their feelings will help promote a feeling of caring and acceptance.
- Find out what has been important and has meaning to the person and try to maintain these things as much as possible. Even simple things such as bedtime rituals become important if they are lost in a hospital or extended care setting.

comprehend instructions as evidenced by following directions? Can the client repeat words or phrases? In addition, the nurse assesses the client's ability to understand written words: Can the client follow written directions? Can the client respond correctly by pointing to a written word? Can the client read aloud? Can the client recognize words or letters if unable to read whole sentences? The nurse uses large, clearly written words when trying to establish abilities in this area.

When the client is unconscious, the nurse looks for any indication that suggests comprehension of what is communicated (e.g., tries to arouse the client verbally and through touch). Ask a closed question like "Can you hear me?" and watch for a nonverbal response such as a nod of the head for yes or a shake for no; or ask for a hand squeeze or blink of the eye once for yes or twice for no.

Structural Deficits

Structural deficits of the oral and nasal cavities and respiratory system can alter a person's ability to speak clearly and spontaneously. Examples include cleft palate, artificial airways such as an endotracheal tube or tracheostomy, and laryngectomy (removal of the larynx). Extreme dyspnea (shortness of breath) can also impair speech patterns.

Paralysis

If verbal impairment is combined with paralysis of the upper extremities that impairs the client's ability to write, the nurse should determine whether the client can point, nod, shrug, blink, or squeeze a hand. Any of these gestures could be used to devise a beginning communication system.

Style of Communication

In assessing communication style, the nurse considers both verbal and nonverbal communication. In addition to physical barriers, some psychological illnesses (e.g., depression or psychosis) influence the ability to communicate. The client may demonstrate constant verbalization of the same words or phrases, a loose association of ideas, or flight of ideas.

Verbal Communication

When assessing verbal communication, the nurse focuses on three areas: the content of the message, the themes, and verbalized emotions. In addition, the nurse considers the following:

- Whether the communication pattern is slow, rapid, quiet, spontaneous, hesitant, evasive, and so on
- The vocabulary of the individual, particularly any changes from the vocabulary normally used (For example, a person who normally never swears may indicate increased stress or illness by an uncharacteristic use of profanity.)
- The presence of hostility, aggression, assertiveness, reticence, hesitance, anxiety, or loquaciousness (incessant verbalization) in communication
- Difficulties with verbal communication, such as slurring, stuttering, inability to pronounce a particular sound, lack of clarity in enunciation, inability to speak in sentences, loose association of ideas, flight of ideas, or the inability to find or name words or identify objects
- Refusal or inability to speak.

Nonverbal Communication

Consider nonverbal communication in relation to the client's culture. Pay particular attention to facial expression, gestures, body movements, affect, tone of voice, posture, and eye contact.

Diagnosing

Impaired Verbal Communication may be used as a nursing diagnosis when an individual experiences a "decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols" (Herdman & Kamitsuru, 2014, p. 261). Communication problems may be *receptive* (e.g., difficulty hearing) or *expressive* (e.g., difficulty speaking).

The nursing diagnosis *Impaired Verbal Communication* may *not* be useful when an individual's communication problems are caused by a psychiatric illness. For example, a client with depression may have difficulty expressing feelings or have slowed thinking or responses; clients who have anxiety have decreased ability to focus; and

clients with schizophrenia may have auditory hallucinations (hearing voices) and have difficulty hearing the nurse's voice at the same time (Boyd, 2012; Kneisl & Trigoboff, 2013). If the communication issue is due to the client having a problem coping, the diagnoses of *Fear* or *Anxiety* may be more appropriate. Other NANDA nursing diagnoses (Herdman & Kamitsuru, 2014) used for clients experiencing communication problems that involve impaired verbal communication as the *etiology* could include the following:

- *Anxiety* related to impaired verbal communication
- *Powerlessness* related to impaired verbal communication
- *Situational Low Self-Esteem* related to impaired verbal communication
- *Social Isolation* related to impaired verbal communication
- *Impaired Social Interaction* related to impaired verbal communication.

Planning

When a nursing diagnosis related to impaired verbal communication has been made, the nurse and client determine outcomes and begin planning ways to promote effective communication. The overall client outcome for individuals with *Impaired Verbal Communication* is to reduce or resolve the factors impairing the communication. Specific nursing interventions will be planned from the stated etiology. Examples of outcome criteria to evaluate the effectiveness of nursing interventions and achievement of client goals follow.

The client:

- Communicates that needs are being met.
- Begins to establish a method of communication:
 - Signals yes/no to direct questions using vocalization or agreed-on physical cue (i.e., eye blink, hand squeeze).
 - Uses verbal or nonverbal techniques to indicate needs.
- Perceives the message accurately, as evidenced by appropriate verbal and/or nonverbal responses.
- Communicates effectively:
 - Using dominant language
 - Using translator/interpreter
 - Using sign language
 - Using word board or picture board
 - Using a computer.
- Regains maximum communication abilities.
- Expresses minimum fear, anxiety, frustration, and depression.
- Uses resources appropriately.

Implementing

Nursing interventions to facilitate communication with clients who have problems with speech or language include manipulating the environment, providing support, employing measures to enhance communication, and educating the client and support person.

Manipulate the Environment

A quiet environment with limited distractions will make the most of the communication efforts of both the client and the nurse and increase the possibility of effective communication. Sufficient light will help in conveying nonverbal messages, which is especially important if visual or auditory acuity is impaired. Initially, the nurse needs to provide a calm, relaxed environment, which will help reduce any

anxiety the client may have. Remember that any factor that affects communication can create feelings of frustration, anxiety, depression, or hostility in the client. Communication normally contributes to a client's sense of security and feelings that he or she is not alone, so communication problems may cause some clients to feel isolated and confused. To further reduce these emotions, the nurse should acknowledge and praise the client's attempts at communication.

Provide Support

The nurse should convey encouragement to the client and provide non-verbal reassurance, perhaps by touch if appropriate. If the nurse does not understand, it is critical to let the client know so that he or she can provide clarification with other words or through some other means of communication. When speaking with a client who will have difficulty understanding, the nurse should check frequently to determine what the client has heard and understood. Using open-ended questions will assist the nurse in obtaining accurate information about the effectiveness of communication. For example, a female client, who has limited English skills, is being taught about diet related to her Crohn's disease. If the nurse asks, "Do you understand what to eat?" the client may nod her head yes. However, this does not give the nurse confirmation that the client received the message given. Rather the nurse needs to say, "What do you think will be good for you to eat when you go home?" The nurse's body language (e.g., gestures, posture, facial expression, and eye contact) should convey acceptance and approval.

Employ Measures to Enhance Communication

First determine how the client can best receive messages: by listening, by looking, through touch, or through an interpreter. Ways to help communication include keeping words simple and concrete and discussing topics of interest to the client. It is often helpful to use alternative communication strategies such as word boards, pictures, or paper and pencil.

Often interpreters can assist a client and nurse to communicate when the client lacks fluency in the dominant language. Some hospitals have a list of interpreters for various languages who can assist at the bedside. If the client's support person offers to interpret, it is important to ask the client's permission, for the sake of confidentiality. Then instruct the person interpreting to translate as precisely as possible, without interruption.

Educate the Client and Support People

Sometimes clients and support people can be prepared in advance for communication problems, for example, before an intubation or throat surgery. By explaining anticipated problems, the client is often less anxious when problems arise.

Evaluating

Evaluation is useful for both client and nurse communication.

Client Communication

To establish whether client outcomes have been met in relation to communication, the nurse must listen actively, observe nonverbal cues, and use therapeutic communication skills to determine that communication was effective. Examples of statements indicating outcome achievement include "Using picture board effectively to indicate needs" or "The client stated, 'I listened more closely to my daughter yesterday and found out how she feels about our divorce.'"

Nurse Communication

For nurses to evaluate the effectiveness of their own communication with clients, process recordings are frequently used. A **process recording** is a verbatim (word-for-word) account of a conversation. It can be taped or written and includes all verbal and nonverbal interactions of both the client and nurse.

One method of writing a process recording is to make two columns on a page. The first column lists what the nurse and the client said along with the associated nonverbal behavior. The second

column contains an analysis about the nurse's responses. An example of a process recording is given in Table 26–5.

Once a process recording has been completed, it should be analyzed in terms of the content and meaning of the interaction based on communication theory. Each of the nurse's statements is interpreted in terms of the communication skill used, with the rationale for and effectiveness of its use. Any barriers to effective communication can be identified with a possible alternative response noted. The outcome for nurses should be increased awareness and insight regarding their

TABLE 26–5 Sample Process Recording

Mary Jane Adams, a nursing aide, reports to Irene Olsen, the staff nurse, that Sandra Barrett, the client in room 815, had finished only her orange juice when Ms. Adams collected the breakfast trays. Mrs. Barrett had been admitted 2 days earlier for diagnostic studies. Concerned about her client, Ms. Olsen walks down the corridor to room 815, knocks, and enters. Mrs. Barrett turns away from the window, tears in her eyes, as Ms. Olsen enters.

Nurse/Client Dialogue	Analysis
<i>Nurse:</i> Good morning, Mrs. Barrett.	Acknowledging.
<i>Client:</i> Hello.	
<i>Nurse:</i> I understand you didn't eat your breakfast.	Making a specific statement but ignoring the nonverbal.
<i>Client:</i> I wasn't hungry.	
<i>Nurse:</i> Is something wrong?	Asking a closed question that fails to facilitate exploration.
<i>Client:</i> No. (Eyes fill with tears.)	
<i>Nurse:</i> You look sad, as if you're about to cry.	Giving feedback.
<i>Client:</i> (Cries)	
<i>Nurse:</i> I'll sit here awhile with you. (Sits down)	Offering self.
<i>Client:</i> (Continues to cry)	
<i>Nurse:</i> (After a 30-second pause) Sometimes it's hard to share the things you're concerned about with someone you don't know well. I'd like to be able to help.	Empathizing. Supporting. Offering self.
<i>Client:</i> (Angrily) You can help me by telling me the truth.	
<i>Nurse:</i> (Leans forward and maintains eye contact)	Actively listening and demonstrating interest.
<i>Client:</i> Everyone beats around the bush when I ask them what's wrong with me. The nurse manager said, "What do you think is wrong?" That kind of put-off drives me up the wall!	
<i>Nurse:</i> You're angry because you're not getting any answers. It seems as if the staff knows something about your condition and they're keeping it from you.	Paraphrasing.
<i>Client:</i> They all seem to be in cahoots. Nobody tells me anything. (Pause) (Softly) If the news was good, they wouldn't beat around the bush.	
<i>Nurse:</i> I'm wondering if you're worried that because people haven't answered your question it means that you have a serious illness?	Paraphrasing.
<i>Client:</i> Good news is always easy to give.	
<i>Nurse:</i> Yes, people do seem to be able to deliver good news easier and faster. I also know that we don't have any news—good or bad—to give you because none of the laboratory or x-ray results are back yet. I know that doesn't help answer your questions, but I hope it relieves you a bit from worrying that there is some bad news that's being withheld.	Giving information. Supporting.
<i>Client:</i> Well, when my father-in-law had surgery for a bleeding ulcer, the x-ray and laboratory results were available immediately.	
<i>Nurse:</i> When there's a question of emergency surgery being needed, then test results are asked for immediately. Usually, though, it's preferable to wait for an accurate reading and a thorough written report.	Giving information.
<i>Client:</i> Are you absolutely sure?	

TABLE 26-5 Sample Process Recording—*continued*

Nurse/Client Dialogue	Analysis
<i>Nurse:</i> You don't sound convinced.	Acknowledging the implied.
<i>Client:</i> Listen, I don't mean to give you a hard time. It's just that . . . it may not seem like an emergency to my doctor or the lab people, but it sure is to me. I can't stand not knowing. I don't know the results of the tests I had yesterday. I don't know how many more tests I have to have. Will I have to have surgery? When can I go home?	
<i>Nurse:</i> The problem you need help with now is finding out the answers to four questions: What are the results of yesterday's tests? Is your doctor considering any other tests for you and, if so, what are they? Is surgery being planned? And when can you go home? Let's try to figure out how you can get the answers to these questions.	Summarizing. Encouraging problem solving.
<i>Client:</i> Well, I can't call my doctor on the phone. All his receptionist will do is take the message. And, anyway, I'm afraid that he'll be offended if he thinks I'm complaining about him. You won't tell him, will you?	
<i>Nurse:</i> No, not unless you and I decide together that it would be the best solution.	Encouraging collaboration.
<i>Client:</i> I suppose I could try to forget about it and be patient, just like everyone tells me to.	
<i>Nurse:</i> You've tried that, but you're still worried, fearful, and angry. Let's think of some other possibilities.	Encouraging further exploration.
<i>Client:</i> Maybe you could call his office for me! Since you're a nurse, they'll probably put your call right through.	
<i>Nurse:</i> So far there are three possible solutions—calling his office yourself, waiting until he comes to visit you later this afternoon, or having me call his office. Are there any other possible solutions that we haven't considered?	Focusing on solutions.
<i>Client:</i> I can't think of any other.	
<i>Nurse:</i> Okay, then, which do you think would be best?	
<i>Client:</i> I guess I'd feel better if you called his office. I just don't want him to think that I'm criticizing him.	
<i>Nurse:</i> You're concerned about what he might think of you because of this phone call. Let's discuss how I should handle the call and what I should say.	Demonstrating respect for the client. Paraphrasing. Encouraging collaboration and problem solving.

communication strengths, as well as identification of areas for future skills development.

COMMUNICATION AMONG HEALTH PROFESSIONALS

Effective communication among the health professions is as important as the promotion of therapeutic communication between the nurse and the client. For example, communication problems among health care personnel threaten client well-being and have contributed to poor postoperative care, incorrect or delayed medication orders, and prolonged client suffering (Gessler, Rosenstein, & Ferron, 2012). According to a survey of more than 2,100 nurses and physicians conducted by the American College of Physician Executives, outrageous behavior is still common in health care facilities (Clinical Rounds, 2010, p. 21). Besides undermining client care, disruptive behaviors also negatively affect staff morale.

Many nurses report verbal abuse, incivility, and bullying from physicians and other nurses (Dombrowsky, 2012; Gessler et al., 2012). These disruptive behaviors have a negative impact on the work

environment and are one of the reasons nurses leave the profession, which subsequently contributes to the nursing shortage.

The Joint Commission recognized workplace intimidation as a threat to client safety and subsequently required health care facilities to design and implement a system-wide approach for ensuring employee awareness of disruptive and/or bullying behaviors (Longo, 2010). Nevertheless, the literature reflects that the disruptive behaviors of incivility and bullying continue to steadily increase.

Disruptive Behaviors

Three common disruptive behaviors reported among nurses are incivility, lateral violence, and bullying.

INCIVILITY

Clark (2010), a national leader in the research area of incivility in nursing, defines **incivility** as “rude or disruptive behavior that may result in psychological or physiological distress for the people involved and, if left unaddressed, may progress into threatening situations.” Uncivil behavior exists along a continuum ranging from distracting, annoying, irritating behaviors (e.g., things that nurses often excuse

by saying “so and so is having a bad day,” eye rolling, sarcastic comments) to bullying, menacing, and potentially violent behavior (e.g., withholding vital client information, intimidating others, or making threats of physical harm) (Clark, 2010; Stokowski, 2011).

Research literature supports a relationship between workplace incivility and negative health consequences, such as emotional exhaustion. The literature also describes a relationship between incivility and productivity. Examples include absenteeism, decreased commitment to the organization, decreased effort at work, incivility toward others, decreased communication, decreased reporting of problems, and leaving the organization (Smith, Andrusyszyn, & Laschinger, 2010).

Incivility and its consequences destroy the ideal organizational climate of mutual respect. Clark (2010) emphasizes that while acting civilly and respectfully is not always easy, especially in a stressful environment, it is imperative that nurses make civility a priority for their clients, colleagues, and classmates. She states: “Civility is the right thing to do. It requires courage, concern for others, presence, and patience.”

LATERAL VIOLENCE

Lateral violence, also known as horizontal violence and horizontal hostility, are terms that describe physical, verbal, or emotional abuse or aggression directed at RN coworkers at the same organizational level. It usually includes verbal or nonverbal (rather than physical) aggressive behaviors. Examples of these behaviors include gossiping, verbal abuse (speech that is intended to humiliate or embarrass another person), withholding information, snide remarks, abrupt responses, sabotage, scapegoating, not available to help, complaining to others about one individual, ostracism, and failure to respect the privacy of others (ANA, 2011; Dombrowsky, 2012; Walrafen, Brewer, & Mulvenon, 2012).

The literature reports that horizontal violence is fairly widespread at 65% to 80% of nurses surveyed (Becher & Visovsky, 2012). A particularly vulnerable group is nursing students during their clinical rotations and the newly graduated nurse (Becher & Visovsky, 2012; Walrafen et al., 2012). Failing to address horizontal violence may cause students and new graduates to leave the profession. Moreover, the financial costs of horizontal violence have been estimated at \$30,000 to \$100,000 per year for each individual. These costs are a result of work absenteeism, treatment for depression and anxiety, decreased work performance, and increased turnover (Becher & Visovsky, 2012, p. 211).

BULLYING

Workplace **bullying** is defined as “repeated, unreasonable actions of individuals (or a group) directed towards an employee (or a group of employees), which are intended to intimidate, degrade, humiliate, or undermine; or which create a risk to the health or safety of the employee(s)” (Longo, 2012, p. 2). The perpetrator is usually at a higher level of power (actual or perceived) compared with the victim. Bullying involves an abuse or misuse of this power (Stokowski, 2011). Bullying usually consists of repeated negative acts that target one or more individuals. Bullying causes health problems for the target, a hostile work environment that hinders effective communication, and nurse retention problems for the organization.

Responding to Disruptive Behaviors

A number of nursing organizations have issued statements regarding the harmful effect of disruptive behaviors on both nurses and client safety. For example, the American Association of Critical-Care Nurses developed a set of national standards for establishing and sustaining healthy work environments. One of their six standards, skilled communication, states that nurses must be as proficient in communication skills as they are in clinical skills.

Evidence-Based Practice Is There a Difference in Perceptions of Nurse–Physician Relationships Between Nurses Working in Medical–Surgical and ICU Settings?

EVIDENCE-BASED PRACTICE

Effective collaboration between nurses and physicians is essential for improved client care outcomes and client care satisfaction. Historically the nurse–physician relationship has not been of equal status and a great deal of progress is needed. Johnson and Kring (2012) state that power, distance, and ineffective communication remain barriers to achieving collaboration. One factor that had not been explored is clinical specialty. Different specialties often require different levels of interaction between nurses and physicians. As a result the authors conducted a quasi-experimental design study to explore perceived nurse–physician collaboration between ICU and medical–surgical nurses. The participants in the study consisted of 170 nurses with 54% being medical–surgical nurses and 46% being ICU nurses. Most participants were direct-care nurses and 93% worked full time. The only significant difference in demographics was that a greater percentage of ICU nurses held a bachelor’s degree compared to the medical–surgical nurses. All participants completed a 25-item survey that evaluated collaborative efforts between nurses and physicians, professionalism and disruptive behavior, and managerial and administrative support. In general, both groups of nurses were satisfied with the RN–MD relationship. Both groups believed physicians respected nurses’ decisions. Both ICU and medical–surgical nurses indicated that they had witnessed disruptive behavior by physicians; however, only a minority reported the

disruptive behavior. The ICU nurses were more likely to report the unprofessional behavior displayed by physicians than the medical–surgical nurses. A majority of the nurses perceived they were subordinate to physicians and about half of the nurses perceived that physicians do not really understand what nurses do. The majority of nurses reported that physicians addressed them by their first name while nurses almost never addressed physicians by their first name.

IMPLICATIONS

It is encouraging that both groups were satisfied with RN–MD relationships overall. One concern that affects collaboration was the small number of nurses who reported physician disruptive behaviors. Is it because nurses are not aware of the reporting process, or because they do not believe it is an effective process? Other concerns were that most nurses perceived they were subordinate to physicians, and they did not perceive the physicians as understanding their roles and responsibilities. The researchers raised the question of how to facilitate better collegial relationships between nurses and physicians (e.g., a mentoring relationship or joint educational activities). This could be another area for study. Nurses and physicians need positive, respectful relationships to ensure quality client care. Thus, positive relationships between RNs and MDs must be assessed and improved.

BOX 26-4

Needed Actions to Stop Disruptive Behaviors and Promote an Emotionally Safe Work Environment

INDIVIDUAL

- Be respectful of others.
- Raise awareness of disruptive behaviors in self and others.
- Increase communication skills to intervene when others display disruptive behaviors.

ADMINISTRATIVE

- Develop a position statement that supports zero tolerance for disruptive behavior.
- Clearly define the disruptive behavior that is not allowed.
- Develop an emotionally safe work environment.
- Develop and implement a strong code of conduct.
- Intervene when disruptive behaviors occur.
- Assess the culture of the work unit(s) for the presence of disruptive behavior.
- Model professional ethical behavior.

NURSING ACADEMIC PROGRAMS AND NURSING CONTINUING EDUCATION

- Develop and implement curricula that educate nursing students on the incidence of disruptive behaviors along with steps to stop the behavior.
- Provide training in conflict management.
- Develop educational programs regarding strategies on how to recognize and address disruptive behaviors.

Interventions for disruptive behaviors are needed at individual, administrative, and educational levels (Box 26-4). The goal is to create a respectful work environment that empowers nurses and enhances the well-being of their clients.

Nurse and Physician Communication

There are guidelines for written documentation and for nurses communicating with clients. However, few guidelines exist for the frequent verbal communication that occurs between nurses and physicians. This lack of guidelines or format may contribute to medical errors as a result of communication problems.

COMMUNICATION STYLES

The differences between nurse and physician communication can make collaboration difficult. In general, nurses have been taught

to be descriptive in verbal and written communication. On the other hand, physicians are trained to be concise, to the point, and focused on a problem. Therefore, they may become impatient waiting for a nurse to come to the point (Mannahan, 2010; Rosenthal, 2013). Communication errors in the health care setting often have severe consequences that can lead to negative client outcomes such as increased length of stay, client dissatisfaction, and even death (Vardaman et al., 2012). Thus, The Joint Commission and the Institute for Healthcare Improvement have mandated that health care organizations improve professional communication. One model, called SBAR (situation, background, assessment, recommendations) provides a standardized framework for communicating important information. The SBAR format can be used by nurses in almost all forms of communication, including when calling a primary care provider about a change in a client's condition, providing shift reports, giving reports on clients being transferred within or outside the health facility, and sending clients for procedures. Box 26-5 contains more details on this communication framework.

CLINICAL ALERT!

Prepare before calling the primary care provider to report a client problem. You will be using the SBAR method. However, you also need to think about what information may be asked of you and be prepared to answer those questions. This means knowing the most recent client assessment data, including vital signs, laboratory data, and other tests, if appropriate. Have the client's medical record, MAR, and other flow sheets as needed available to you.

Historically, nursing, medicine, and other health care professions often had their own schools on the same campus, and they rarely interacted. As a result, these students did not understand the importance of communication and team collaboration until they entered practice as novice clinicians (Montgomery, Griswold-Theodorson, Morse, Montgomery, & Farabaugh, 2012). During the past decade, however, multiple academic health centers have implemented interdisciplinary health care curricula. For example, interdisciplinary simulations enhance communication between nurses, physicians, and other health professionals. This type of early experience in collaboration while in school can do much to create better communication and teamwork in clinical practice.

BOX 26-5 SBAR: Situation, Background, Assessment, Recommendation Model

A FRAMEWORK FOR NURSE-HEALTH CARE PROVIDER COMMUNICATION

- S** = Situation: What is the situation you are calling about? Provide your name, health agency, client name, and brief information about the problem.
- B** = Background: Provide information pertinent to the current situation, such as admitting diagnosis, date of admission, and important clinical information that relates to the call.
- A** = Assessment: This refers to the current condition of the client (e.g., VS, oxygen saturation, pain scale, level of consciousness) and any change in the assessment since the previous communication. Indicate the severity of the problem.
- R** = Recommendation: What is your recommendation for resolving the problem or what do you need from the health care provider (e.g., come see the client, transfer to another unit, or an order for a medication)?

EXAMPLE OF USING SBAR WHEN CALLING A HEALTH CARE PROVIDER ABOUT A CLIENT PROBLEM

- S:** Health care provider called. Nurse has given name and unit of health care agency. "I'm calling about Sally Somers, a 19-year-old admitted this morning with a ruptured appendix. She is now 6 hours postop and has not voided."
- B:** Her bladder is distended. She is complaining of urgency to void but unable to do so even with sitting on commode, running water, etc. Everything else is stable.
- A:** She is very uncomfortable and crying because of her urinary retention.
- R:** "Could you give an order for a straight urinary catheterization?"

From "SBAR 'Flattens the Hierarchy' Among Caregivers," by W. L. Heinrichs, E. Bauman, and P. Dev, 2012, *Studies in Health Technology & Informatics*, 173, pp. 175-182; "Looking to Improve Your Bedside Report? Try SBAR," by M. J. Schroeder, 2011, *Nursing Made Incredibly Easy*, 9(5), pp. 53-54; "Beyond Communication: The Role of Standardized Protocols in a Changing Health Care Environment," by J. M. Vardaman, P. Cornell, M. B. Gondo, J. M. Amis, M. Townsend-Genic, and C. Thetford, 2012, *Health Care Management Review*, 37(1), pp. 88-97.

EMOTIONAL INTELLIGENCE

Emotional intelligence is the ability to form work relationships with colleagues, display maturity in a variety of situations, and resolve conflicts while taking into consideration the emotions of others. A nurse or primary care provider with emotional intelligence may be viewed as mature, approachable, or easygoing. In work environments, professionals can demonstrate emotional intelligence by accurately identifying their own emotions and the emotions of others, managing those emotions, and then deciding how to interact with colleagues constructively to achieve a positive outcome. Littlejohn (2012) describes research evidence that individuals with high emotional intelligence are “able to deal with environmental demands and workplace stress” (p. 364) and that higher levels of emotional intelligence would “lead to more positive attitudes, greater adaptability, improved relationships, and increased orientation towards positive values” (p. 365).

ASSERTIVE COMMUNICATION

Assertive communication promotes client safety by minimizing miscommunication with colleagues. People who use assertive communication are honest, direct, and appropriate while being open to ideas and respecting the rights of others.

An important characteristic of assertive communication includes the use of “I” statements versus “you” statements. The “you” statement places blame and puts the listener in a defensive position. On the other hand, the “I” statement encourages discussion. For

example, a nurse who states “I am concerned about . . .” will be gaining the attention of the primary care provider while also giving a message about the importance of working together for the benefit of the client. It is then important for the nurse to be clear, concise, organized, and fully informed when verbally presenting the client concern.

NONASSERTIVE COMMUNICATION

Two types of interpersonal behaviors are considered nonassertive: submissive and aggressive.

SUBMISSIVE When people use a submissive or passive communication style they allow their rights to be violated by others (Kneisl & Trigoboff, 2013). They meet the demands and requests of others without regard to their own feelings and needs because they believe their own feelings are not important. Some experts believe that people who use the submissive behaviors or communication style are insecure and try to maintain their self-esteem by avoiding conflict (e.g., negative criticism and disagreement from others).

AGGRESSIVE There is a fine line between assertive and aggressive communication. Assertive communication is an open expression of ideas and opinions while respecting the rights, opinions, and ideas of others. Aggressive communication is “directed toward what one wants without considering the feelings of others” (Kneisl & Trigoboff, 2013, p. 376). This type of communication is ineffective and leads to frustration for the nurse and the primary care provider.

Critical Thinking Checkpoint

You are the nursing student assigned to care for Mr. Manasovitz, a 45-year-old man who will be returning from the recovery room after undergoing the removal of a mass from his abdomen. While you are preparing his room for his return, the nurse and primary care provider arrive to talk with Mrs. Manasovitz about her husband’s surgery. The primary care provider explains that the mass was malignant and invasive. Mr. Manasovitz is a candidate for chemotherapy, but his prognosis is guarded because of the extent of the tumor growth. Mrs. Manasovitz looks away, closes her eyes, and only nods her head “yes.” As the primary care provider leaves, the nurse approaches Mrs. Manasovitz, sits next to her, and puts her arm around Mrs. Manasovitz, who begins to cry. The nurse uses a soothing voice to tell Mrs. Manasovitz that it is okay to cry and assures her she will

remain with her. The two of them sit in silence until Mrs. Manasovitz is able to express her feelings. The nurse listens attentively. Later the nurse offers to get a cup of coffee for Mrs. Manasovitz and asks if there is anything she can do to assist Mrs. Manasovitz at this difficult time.

1. Interpret Mrs. Manasovitz’s nonverbal behavior in response to the news about her husband’s surgery.
2. Evaluate the nurse’s response toward Mrs. Manasovitz based on the concepts of caring and comforting.
3. Why is it important for the nurse to effectively communicate with Mrs. Manasovitz at this time?
4. The nurse was described as listening attentively to Mrs. Manasovitz. Cite actions that portray attentive listening.

See Critical Thinking Possibilities on student resource website.

Chapter 26 Review

CHAPTER HIGHLIGHTS

- Communication is a critical nursing skill used to gather assessment data for nursing diagnoses, to teach and persuade, and to express caring and comfort.
- Communication is a two-way interpersonal process involving the sender of the message and the receiver of the message. It also involves intrapersonal messages, or self-talk, which can affect the message, the interpretation of the message, and the response.
- The communication process includes four elements: sender, message, receiver, and response/feedback. The sender must encode the message and determine the appropriate form for transmitting it. The receiver must perceive the message, decode it, and then respond.
- Verbal communication is effective when the criteria of pace and intonation, simplicity, clarity and brevity, timing and relevance, adaptability, credibility, and humor are met.

- Nonverbal communication often reveals more about a person's thoughts and feelings than verbal communication; it includes personal appearance, posture, gait, facial expressions, and gestures.
- When assessing verbal and nonverbal communication, the nurse needs to consider cultural influences and be aware that a single nonverbal expression can indicate any of a variety of feelings and that words can have various meanings.
- The use of electronic communication, particularly e-mail, in nursing practice is evolving. Although e-mail provides positive advantages for improving communication and continuity of client care, the nurse needs to be aware of the risk to client confidentiality.
- Many factors influence the communication process: development, gender, values and perceptions, personal space (intimate, personal, social, and public distances), territoriality, roles and relationships, environment, congruence, interpersonal attitudes, and boundaries.
- Many techniques facilitate therapeutic communication: using silence, providing general leads, being specific and tentative, using open-ended questions, using touch, restating or paraphrasing, seeking clarification, perception checking or seeking consensual validation, offering self, giving information, acknowledging, clarifying time or sequence, presenting reality, focusing, reflecting, summarizing, and planning.
- Techniques that inhibit communication include stereotyping, being defensive, challenging, testing, rejecting, changing topics and subjects, unwarranted reassurance, passing judgment, and giving common advice.
- The effective nurse–client relationship is a helping relationship that facilitates growth of the client.
- Four phases of the helping relationship include the preinteraction phase, the introductory phase, the working phase, and the termination phase; each has specific tasks and skills.
- To help clients with communication problems, the nurse manipulates the environment, provides support, employs measures to enhance communication, and educates the client and support people.
- Process recordings are frequently made by nurses to evaluate the effectiveness of their own communication. With them, nurses can analyze both the process and the content of the communication.
- Effective communication between health professionals is vital for client safety.
 - Many nurses report disruptive behaviors from physicians and other nurses. Disruptive behavior is defined as behavior that interferes with effective communication among health care providers and negatively impacts performance and outcomes. Three common disruptive behaviors include incivility, lateral violence, and bullying.
 - A number of nursing organizations have issued statements regarding the harmful effects of disruptive behaviors on both nurses and client safety. Nurses must be as proficient in communication skills as they are in clinical skills.
- Communication styles can differ between nurses and physicians. Nurses tend to be more narrative and descriptive and strive for consensus. Physicians focus on a need or problem and are trained to give and want information in bullet points. The SBAR model is one approach aimed at addressing these differences in communication style and approach. Studies have shown that interdisciplinary simulations can also enhance communication between nurses and physicians.
- Assertive communication promotes client safety by minimizing miscommunication with colleagues. An important characteristic of assertive communication is to use “I” statements.
- Nonassertive communication includes two types of interpersonal behaviors: submissive and aggressive.

TEST YOUR KNOWLEDGE

1. A student nurse is caring for a 72-year-old client with Alzheimer's disease who is very confused. Which is the most appropriate communication strategy to be used by the student nurse?
 1. Written directions for bathing
 2. Speaking very loudly
 3. Gentle touch while providing ADLs
 4. Flat facial expression
2. Place the following descriptions of the helping relationship phases in the correct sequence.
 1. After introductions, the nurse asks, “What plans do you have for the upcoming holiday weekend?”
 2. The nurse states, “It sounds like you are concerned about the possible complications of having diabetes. What would be the most helpful for you at this time?”
 3. The nurse reads in the medical history that the client was diagnosed with diabetes 1 week ago.
 4. The nurse states, “When we met, you knew very little about diabetes and now you are able to use your new information and apply it to your own personal situations.”
3. The nurse who uses appropriate therapeutic listening skills will display which behaviors? Select all that apply.
 1. Absorb both the content and the feeling the client is conveying.
 2. Presume an understanding of the client needs.
 3. Adopt an open professional posture.
 4. React quickly to the message.
 5. Reassure the client that everything will be fine.
4. A nurse tells a client who is struggling with cancer pain, “It is normal to feel frustrated about the discomfort.” Which is most representative of the skills associated with the working phase of the helping relationship?
 1. Respect
 2. Genuineness
 3. Concreteness
 4. Confrontation
5. A depressed client who has not bathed or dressed in clean clothes today is reading the lunch menu but is unable to make a decision. Which would be the most appropriate nursing diagnosis for this client?
 1. *Anxiety*
 2. *Powerlessness*
 3. *Chronic Low Self-Esteem*
 4. *Social Isolation*
6. After being admitted for emergency surgery, an 80-year-old client has just returned to the room from the PAR (postanesthesia room). Which nursing interventions are most likely to facilitate effective communication with this client? Select all that apply.
 1. Ask the client, “Do you know where you are?”
 2. Ask the client or support person about visual or learning problems.
 3. Inform the client and support person(s) about events likely to occur during the next 2 hours.
 4. Provide the client with instructions about discharge.
 5. Tell the client, “You will feel better soon.”

7. The nurse is communicating with a well-oriented older adult client in a long-term care setting. Which statement best reflects respectful and caring communication?
1. "Are we ready for our shower?"
 2. "It's time to go to the dining room, honey."
 3. "Are you comfortable, Mrs. Smith?"
 4. "You would rather wear the slacks, wouldn't you?"
8. The client made the following statement to the nurse, "My doctor just told me that he cannot save my leg and that I need to have an above-the-knee amputation." Which response by the nurse is most appropriate?
1. "Dr. Jones is an excellent surgeon."
 2. "Are you in pain?"
 3. "If I were you, I'd get a second opinion."
 4. "Tell me more. . . ."
9. The nurse is communicating with a primary care provider about medical interventions prescribed for a client. Which statement is most representative of a collaborative relationship?
1. "That new medication you prescribed for Mr. Black is ineffective."
 2. "I am worried about Mr. Black's blood pressure. It is not decreasing even with the new antihypertensive medication."
 3. "Can we talk about Mr. Black?"
 4. "Excuse me doctor. I think we need to talk about Mr. Black's blood pressure."
10. The nurse asks the client, "What do you fear most about your surgery tomorrow?" This is an example of which communication technique?
1. Providing general leads
 2. Seeking clarification
 3. Presenting reality
 4. Summarizing

See Answers to Test Your Knowledge in Appendix A.

Suggested Readings

Dombrowsky, T. A. (2012). Responding to verbal abuse.

Nursing 2012, 42(11), 58–61. doi:10.1097/01.NURSE.0000421376.75122.4F

The author discusses a form of horizontal violence, verbal abuse, and provides a guide to identifying and responding to verbal abuse.

Forni, P. M. (2008). *The civility solution: What to do when people are rude*. New York, NY: St. Martin's Press.

A simple and practical handbook in which the author shows the reader how to break the rudeness cycle by responding to a variety of confrontations, from bullying to rude Internet behavior or the hurtful words of an insensitive family member.

Schuster, P. M., & Nykolyk, L. (2010). *Communication for nurses: How to prevent harmful events and promote patient safety*. Philadelphia, PA: F.A. Davis.

The authors state that the purpose of this book is to guide the development of comprehensive professional communication strategies in nursing students to prevent communication errors that result in client injuries and death.

Stickley, T. (2011). SOLER to SURETY for effective non-verbal communication. *Nurse Education in Practice*, 11, 395–398. doi:10.1016/j.nepr.2011.03.021

This author, based on 15 years of teaching counseling skills to both counselors and nurses, proposes an adaptation of the SOLER acronym to SURETY for effective non-verbal communication.

27 Teaching

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Discuss the importance of the teaching role of the nurse.
2. Compare and contrast andragogy, pedagogy, and geragogy.
3. Describe the three learning domains.
4. Discuss the learning theories of behaviorism, cognitivism, and humanism and how nurses can use each of these theories.
5. Identify factors that affect learning.
6. Discuss the implications of using the Internet as a source of health information.
7. Assess learning needs of learners and the learning environment.
8. Discuss the implications of low health literacy skills.
9. Identify nursing diagnoses, outcomes, and interventions that reflect the learning needs of clients.
10. Describe the essential aspects of a teaching plan.
11. Discuss guidelines for effective teaching.
12. Discuss strategies to use when teaching clients of different cultures.
13. Identify methods to evaluate learning.
14. Describe effective documentation of teaching–learning activities.

INTRODUCTION

Teaching client education is a major aspect of nursing practice and an important independent nursing function. In 1992, the American Hospital Association passed *A Patient's Bill of Rights* mandating client education as a right of all clients. State nurse practice acts include client teaching as a function of nursing, thereby making teaching a legal and professional responsibility. In addition, The Joint Commission includes standards for Patient and Family Education (PFE) to “help patients better participate in their care and make informed care decisions” (Joint Commission International, 2011). This requirement means that providers must “perform a learning needs assessment that includes the patient’s cultural and religious beliefs, emotional barriers, desire and motivation to learn, physical or cognitive limitations, and barriers to communication” (The Joint Commission, 2012).

Client education is multifaceted, involving promoting, protecting, and maintaining health. It involves teaching about reducing health risk factors, increasing a person’s level of wellness, and taking specific protective health measures. Box 27–1 lists specific areas of health teaching.

TEACHING

Teaching is a system of activities intended to produce learning. The teaching process is intentionally designed to produce specific learning.

The teaching–learning process involves dynamic interaction between teacher and learner. Each participant in the process communicates information, emotions, perceptions, and attitudes to the

other. The teaching process and the nursing process are much alike (Table 27–1).

Nurses teach a variety of learners in various settings. They teach clients and their families or significant others in the hospital, primary care clinics, urgent care, managed care, the home, and assisted living and long-term care facilities. Nurses teach large and small groups of learners in community health education programs.

Nurses also teach professional colleagues and other health care personnel in academic institutions such as vocational schools, colleges, and universities, and in health care facilities such as hospitals or nursing homes.

Teaching Clients and Their Families

Nurses may teach individual clients in one-to-one teaching episodes. For example, the nurse may teach about wound care while changing a client’s dressing or may teach about diet, exercise, and other lifestyle behaviors that minimize the risk of a heart attack for a client who has a cardiac problem. The nurse may also be involved in teaching family members or other support people who are caring for the client. Nurses working in obstetric and pediatric areas teach parents and sometimes grandparents how to care for children.

Because of decreased length of hospital stays, time constraints on client education may occur. Nurses need to provide client education that will ensure the client’s safe transition from one level of care to another and make appropriate plans for follow-up education in the client’s home. Discharge plans must include information about what the client has been taught before transfer or discharge and what

BOX 27-1 Areas for Client Education**PROMOTION OF HEALTH**

- Increasing a person's level of wellness
- Growth and development topics
- Fertility control
- Hygiene
- Nutrition
- Exercise
- Stress management
- Lifestyle modification
- Resources within the community

PREVENTION OF ILLNESS/INJURY

- Health screening (e.g., blood glucose levels, blood pressure, blood cholesterol, Pap test, mammograms, vision, hearing, routine physical examinations)
- Reducing health risk factors (e.g., lowering cholesterol level)
- Specific protective health measures (e.g., immunizations, use of condoms, use of sunscreen, use of medication, umbilical cord care)

- First aid
- Safety (e.g., using seat belts, helmets, walkers)

RESTORATION OF HEALTH

- Information about tests, diagnosis, treatment, medications
- Self-care skills or skills needed to care for family member
- Resources within health care setting and community

ADAPTING TO ALTERED HEALTH AND FUNCTION

- Adaptations in lifestyle
- Problem-solving skills
- Adaptation to changing health status
- Strategies to deal with current problems (e.g., home IV skills, medications, diet, activity limits, prostheses)
- Strategies to deal with future problems (e.g., fear of pain with terminal cancer, future surgeries, or treatments)
- Information about treatments and likely outcomes
- Referrals to other health care facilities or services
- Facilitation of strong self-image
- Grief and bereavement counseling

TABLE 27-1 Comparison of the Teaching Process and the Nursing Process

Step	Teaching Process	Nursing Process
1	Collect data; analyze client's learning strengths and deficits.	Collect data; analyze client's strengths and deficits.
2	Make educational diagnoses.	Make nursing diagnoses.
3	Develop teaching plan: <ul style="list-style-type: none"> • Write learning outcomes. • Select content and time frame. • Select teaching strategies. 	Plan nursing goals/desired outcomes and select interventions.
4	Implement teaching plan.	Implement nursing strategies.
5	Evaluate client learning based on achievement of learning outcomes.	Evaluate client outcomes based on achievement of goal criteria.

remains for the client to learn to perform self-care in the home or other residence (see Chapter 7 .

Teaching in the Community

Nurses are often involved in community health education programs. Such teaching activities may be voluntary as part of the nurse's involvement in an organization such as the Red Cross or Planned Parenthood, or they may be compensated as part of the nurse's work role, such as school nurses. Community teaching activities may be aimed at large groups of people who have an interest in some aspect of health, such as nutrition classes, CPR or cardiac risk factor reduction classes, and bicycle or swimming safety programs. Community education programs can also be designed for small groups or individual learners, such as childbirth classes or family planning classes.

Teaching Health Personnel

Nurses are also involved in the instruction of professional colleagues through continuing education, in-service programs, and staff development. For example, experienced nurses may function as preceptors for new graduate nurses or for newly employed nurses. Nurses with specialized knowledge and experience share that knowledge and

experience with nurses who are new to that practice area. Examples of such specialized courses include critical-care nursing, perioperative nursing, and quality improvement/quality assurance. In addition, nurses in nursing practice settings are often involved in the clinical instruction of nursing students.

Nurses are also involved in teaching other health professionals. Nurses may participate in the education of medical students or allied health students. In this capacity, the nurse educator clarifies the role of the nurse for other health professionals and/or how nurses can assist them in their care of clients.

LEARNING

Like all people, clients have a variety of learning needs. A **learning need** is a desire or a requirement to know something that is presently unknown to the learner. Learning needs include new knowledge or information but can also include a new or different skill or physical ability, or a new behavior or a need to change an old behavior. **Learning** is a change in human disposition or capability that persists and that cannot be solely accounted for by growth. Learning is represented by a change in behavior. See Client Teaching for attributes of learning.

CLIENT TEACHING

Attributes of Learning

Learning is:

- An experience that occurs inside the learner.
- The discovery of the personal meaning and relevance of ideas.
- A consequence of experience.
- A collaborative and cooperative process.
- An evolutionary process that builds on past learning and experiences.
- A process that is both intellectual and emotional.

An important aspect of learning is the individual's desire to learn and to act on the learning, referred to as **compliance**. In the health care context, compliance is the extent to which a person's behavior coincides with medical or health advice. Compliance is best illustrated when the person recognizes and accepts the need to learn, and then follows through with the appropriate behaviors that reflect the learning. For example, a person diagnosed as having diabetes willingly learns about the needed special diet and then plans and follows the learned diet. Many people, however, view the term *compliance* in a negative perspective because the term implies the learner is submissive and this is in conflict with the learner's right to determine his or her own health care decisions rather than be told what to do by a health care professional. In addition, it is important not to label a client as noncompliant without obtaining further information. For example, the client intended to comply but was unable to do so because he could not afford the cost of the medications.

Another term seen in health care literature is **adherence**, which is the degree to which clients follow the agreed-on recommendations of health care providers (Miller & Stoeckel, 2011, p. 370). Adherence implies a collaborative and cooperative relationship between nurses and clients that is based on shared responsibility. Nurses view clients as active participants in promoting, maintaining, and restoring their health.

Andragogy is the art and science of teaching adults, in contrast to **pedagogy**, the discipline concerned with helping children learn. **Geragogy** is the term used to describe the process involved in helping older adults to learn (Kimball et al., 2010). An individual's developmental stage influences the learning abilities of children, adults, and older adults.

Nurses can use the following andragogic concepts about adult learners as a guide for client teaching (Knowles, 1984; Miller & Stoeckel, 2011):

- As people mature, they move from dependence to independence.
- An adult's previous experiences can be used as a resource for learning.
- Learning is related to an immediate need, problem, or deficit.
- An adult is more oriented to learning when the material is useful immediately, not sometime in the future.
- Learning is reinforced by application and prompt feedback.

Learning Domains

Bloom (1956) identified three domains or areas of learning: cognitive, affective, and psychomotor. The **cognitive domain**, the "thinking" domain, includes six intellectual abilities and thinking processes

beginning with knowing, comprehending, and applying to analysis, synthesis, and evaluation. The **affective domain**, known as the "feeling" domain, deals with personal issues such as "attitudes, beliefs, behaviors, and emotions" (Miller & Stoeckel, 2011, p. 36). The **psychomotor domain**, the "skill" domain, includes fine and gross motor abilities such as giving an injection.

Nurses should include each of Bloom's three domains in client teaching plans. For example, teaching a client how to self-administer insulin is in the psychomotor domain. But an important part of a teaching plan for a client with diabetes is to teach why insulin is needed and what to do when not feeling well; this is in the cognitive domain. Helping the client accept the chronic implications of diabetes and maintain self-esteem is in the affective domain.

Learning Theories

Three main theoretical constructs are behaviorism, cognitivism, and humanism.

BEHAVIORISM

Thorndike originally advanced behaviorism. His major contribution that applied to teaching is that learning should be based on the learner's behavior and what is directly observable. In addition to Thorndike, major behaviorism theorists include Pavlov, Skinner, and Bandura.

In the behaviorist school of thought, an act is called a *response* when it can be traced to the effects of a stimulus. Behaviorists closely observe responses and then manipulate the environment to bring about the intended change. Thus, to modify a person's attitude and response, a behaviorist would either alter the stimulus condition in the environment or change what happens after a response occurs.

Skinner's and Pavlov's work focused on conditioning behavioral responses to a stimulus that causes the response or behavior. To increase the probability of a response, Skinner introduced the importance of **positive reinforcement** (e.g., a pleasant experience such as praise and encouragement) in fostering repetition of an action. Bandura, however, claims that most learning comes from observational learning and instruction rather than trial-and-error behavior. Bandura's research focuses on **imitation**, the process by which individuals copy or reproduce what they have observed, and **modeling**, the process by which a person learns by observing the behavior of others.

Nurses using the **behaviorist theory** identify what is to be taught, and they immediately identify and reward correct responses. However, the theory is not easily applied to complex learning situations and limits the learner's role in the teaching process. In summary, nurses applying behavioristic theory will:

- Provide sufficient practice time including both immediate and repeat testing and return demonstration.
- Provide opportunities for learners to solve problems by trial and error.
- Select teaching strategies that avoid distracting information and that evoke the desired response.
- Praise the learner for correct behavior and provide positive feedback at intervals throughout the learning experience.
- Provide role models of desired behavior.

COGNITIVISM

Cognitivism depicts learning as a complex cognitive activity. In other words, learning is largely a mental or intellectual or thinking process. The learner structures and processes information. Perceptions are selectively chosen by the individual, and personal characteristics have an impact on how a cue is perceived. Cognitivists also emphasize the importance of social, emotional, and physical contexts in which learning occurs, such as the teacher–learner relationship and the environment. Developmental readiness and individual readiness (expressed as motivation) are other key factors associated with cognitive approaches.

Major cognitive theorists include Piaget, Lewin, and Bloom. Piaget's five major phases of cognitive development include the sensorimotor phase, the preconceptual phase, the intuitive thought phase, the concrete operations phase, and the formal operations phase. Each phase is discussed in Chapter 20 ∞. According to Lewin, learning involves four different types of changes: change in cognitive structure, change in motivation, change in one's sense of belonging to the group, and gain in voluntary muscle control. His widely known theory of change has three basic stages: unfreezing, moving, and refreezing. These stages are discussed in detail in Chapter 28 ∞. As previously mentioned, Bloom identified the three domains of learning. Users of **cognitive theory** recognize the developmental level of the learner and acknowledge the learner's motivation and environment. However, some or many of the motivational and environmental factors may be beyond the teacher's control.

Nurses applying cognitive theory will:

- Provide a social, emotional, and physical environment conducive to learning.
- Encourage a positive teacher–learner relationship.
- Select multisensory teaching strategies because perception is influenced by the senses.
- Recognize that personal characteristics have an impact on how cues are perceived and develop appropriate teaching approaches to target different learning styles.
- Assess a person's developmental and individual readiness to learn and adapt teaching strategies to the learner's developmental level.
- Select behavioral objectives and teaching strategies that encompass the cognitive, affective, and psychomotor domains of learning.

HUMANISM

Humanistic learning theory focuses on both the cognitive and affective qualities of the learner. Prominent members of this school of thought include Abraham Maslow and Carl Rogers. According to humanistic theory, learning is believed to be self-motivated, self-initiated, and self-evaluated. Each individual is viewed as a unique composite of biologic, psychological, social, cultural, and spiritual factors. Learning focuses on self-development and achieving full potential; it is best when it is relevant to the learner. Autonomy and self-determination are important; the learner identifies the learning needs and takes the initiative to meet these needs. The learner is an active participant and takes responsibility for meeting individual learning needs. Using **humanistic learning theory**, the nurse focuses on the feelings and attitudes of learners, on the importance of the individual in identifying learning needs and in taking responsibility for them, and on the self-motivation of the learners to work toward self-reliance and independence.

Nurses applying humanistic theory will:

- Convey empathy in the nurse–client relationship.
- Encourage the learner to establish goals and promote self-directed learning.
- Encourage active learning by serving as a facilitator, mentor, or resource for the learner.
- Use active learning strategies to assist the client's adoption of new behavior.
- Expose the learner to new relevant information and ask appropriate questions to encourage the learner to seek answers.

Being aware of the focus and limitations of the various learning theories allows the nurse to use one or more of them when developing a teaching plan for a client. Knowing what is important (e.g., knowledge, motivation, feelings, attitudes) assists the nurse in choosing the appropriate learning theory or theories. The nurse also needs to be aware of the different factors that can affect the client's learning.

Factors Affecting Learning

Many factors can facilitate or hinder learning by a client. The nurse should be aware of these factors, particularly when available teaching time is limited.

AGE AND DEVELOPMENTAL STAGE

The nurse needs to consider the age and developmental stage of the learner because they influence the client's ability to learn. Three major developmental stage factors associated with learner readiness include physical, cognitive, and psychosocial maturation. These factors must be considered at each developmental period throughout the life cycle (Miller & Stoeckel, 2011). Furthermore, The Joint Commission mandates that health care agencies provide teaching plans that address developmental stage-specific competencies of the learner.

MOTIVATION

Motivation to learn is the desire to learn. It greatly influences how quickly and how much a person learns. Motivation is generally greatest when a person recognizes a need and believes the need will be met through learning. It is not enough for the need to be identified and verbalized by the nurse; it must be experienced by the client. Often the nurse's task is to help the client personally work through the problem and identify the need. Sometimes clients or support people need help identifying information relevant to their situation before they can see a need. For instance, clients with heart disease may need to know the effects of smoking before they recognize the need to stop smoking. Adolescents may need to know the consequences of an untreated sexually transmitted infection before they see the need for treatment.

READINESS

Readiness to learn is the demonstration of behaviors or cues that reflect the learner's motivation to learn at a specific time. Readiness reflects not only the desire or willingness to learn but also the ability to learn at a specific time. For example, a client may want to learn self-care during a dressing change, but if the client experiences pain or discomfort he or she may not be able to learn. The nurse can provide pain medication to make the client more comfortable and more able to learn. The nurse's role is often to encourage the development of readiness.

Figure 27–1 ■ Learning is facilitated when the client is interested and actively involved.
Nancy Louie/Getty Images.

ACTIVE INVOLVEMENT

When the learner is actively involved in the process of learning, learning becomes more meaningful. If the learner actively participates in planning and discussion, learning is faster and retention is better (Figure 27–1 ■). Active learning promotes critical thinking, enabling learners to problem solve more effectively. Clients who are actively involved in learning about their health care may be more able to apply the learning to their own situation. For example, clients who are actively involved in learning about their therapeutic diets may be more able to apply the principles being taught to their cultural food preferences and their usual eating habits. Passive learning, such as listening to a lecture or watching a film, does not foster optimal learning.

RELEVANCE

The knowledge or skill to be learned must be personally relevant to the learner. Clients learn more easily if they can connect the new knowledge to that which they already know or have experienced. For example, if a client is diagnosed with hypertension, is overweight, and has symptoms of headaches and fatigue, he is more likely to understand the need to lose weight if he remembers having more energy when he weighed less. The nurse needs to validate the relevance of learning with the client throughout the learning process.

FEEDBACK

Feedback is information regarding a person's performance in reaching a desired goal. It has to be meaningful to the learner. Feedback that accompanies the practice of psychomotor skills helps the person to learn those skills. Support of desired behavior through praise, positively worded corrections, and suggestions of alternative methods are ways of providing positive feedback. Negative feedback such as ridicule, anger, or sarcasm can lead people to withdraw from learning. Such feedback, viewed as a type of punishment, may cause the client to avoid the teacher in order to avoid punishment.

NONJUDGMENTAL SUPPORT

People learn best when they believe they are accepted and will not be judged. The person who expects to be judged as a “poor” or “good” client will not learn as well as the person who feels no such threat. Once learners have succeeded in accomplishing a task or understanding a concept, they gain self-confidence in their ability to learn. This reduces

their anxiety about failure and can motivate greater learning. Successful learners have increased confidence with which to accept failure.

SIMPLE TO COMPLEX LEARNING

Learning is facilitated by material that is logically organized and proceeds from the simple to the complex. Such organization enables the learner to comprehend new information, assimilate it with previous learning, and form new understandings. Of course, *simple* and *complex* are relative terms, depending on the level at which the person is learning. What is simple for one person may be complex for another.

REPETITION

Repetition of key concepts and facts facilitates retention of newly learned material. Practice of psychomotor skills, particularly with feedback from the nurse, improves performance of those skills and facilitates their transfer to another setting.

TIMING

People retain information and psychomotor skills best when the time between learning and active use of the learning is short; the longer the time interval, the easier it is to forget the learning. For example, a client who is only shown literature and videotapes about administering insulin but is not permitted to administer his or her own insulin until discharge from the hospital is unlikely to remember what was learned. However, giving his or her own injections while in the hospital enhances the client's learning.

ENVIRONMENT

An optimal learning environment facilitates learning by reducing distraction and providing physical and psychological comfort. It has adequate lighting that is free from glare, a comfortable room temperature, and good ventilation. Most students know what it is like to try to learn in a hot, stuffy room; the consequent drowsiness interferes with concentration. Noise can also distract the student and interfere with listening and thinking. To facilitate learning in a hospital setting, nurses should choose a time when no visitors are present and interruptions are unlikely.

Privacy is essential for some learning. For example, when a client is learning to change a colostomy bag, the presence of others can be embarrassing and thus interfere with learning. However, when a client is particularly anxious, having a support person present may give the client confidence.

Many factors inhibit learning. Some of the most common barriers to learning are described next and in Table 27–2.

EMOTIONS

Emotions such as fear, anger, and depression can impede learning. A high level of anxiety resulting in agitation and the inability to focus or concentrate can also inhibit learning. Clients or families who are experiencing extreme emotional states may not hear spoken words or may retain only part of the communication. Emotional responses such as fear and anxiety decrease with information that relieves uncertainty. Medications may be prescribed for extremely distraught clients or families to reduce their anxiety and put them in an emotional state in which understanding or learning can occur.

PHYSIOLOGICAL EVENTS

Physiological events such as a critical illness, pain, or sensory deficits inhibit learning. Because the client cannot concentrate and apply energy to learning, the learning itself is impaired. The nurse should try

TABLE 27–2 Barriers to Learning

Barrier	Explanation	Nursing Implications
Acute illness	Client requires all resources and energy to cope with illness.	Defer teaching until client is less ill.
Pain	Pain decreases ability to concentrate.	Conduct pain assessment before teaching.
Prognosis	Client can be preoccupied with illness and unable to concentrate on new information.	Defer teaching to a better time.
Biorhythms	Mental and physical performances have a circadian rhythm.	Adapt time of teaching to suit client.
Emotion (e.g., anxiety, denial, depression, grief)	Emotions require energy and distract from learning.	Deal with emotions and possible misinformation first.
Language	Client may not be fluent in the nurse's language.	Obtain services of an interpreter or nurse with appropriate language skills.
Age		
• Older adults	Vision, hearing, and motor control can be impaired in older adults.	Consider sensory and motor deficits and adapt teaching plan as needed.
• Children	Children have a shorter attention span and vocabulary differences.	Plan shorter and more active learning episodes.
Culture/religion	A client's culture or religion may place restrictions on certain types of knowledge, for example, birth control information.	Assess the client's cultural/religious needs when planning learning activities.
Physical disability	Visual, hearing, sensory, or motor impairments may interfere with a client's ability to learn.	Plan teaching activities appropriate to learner's physical abilities. For example, provide audio learning tools for the client who is blind, or large-print materials for the client whose vision is impaired.
Mental disability	Impaired cognitive ability may affect the client's capacity for learning.	Assess client's capacity for learning and plan teaching activities to complement the client's ability while planning more complex learning for the client's caregivers.

to reduce the physiological barriers to learning as much as possible before teaching. For example, providing analgesics and rest before teaching is often helpful.

CULTURAL ASPECTS

Cultural barriers to learning include language and values. The client who does not understand the nurse's language may learn little. Western medicine may conflict with a client's cultural healing beliefs and practices. To be effective, nurses must be culturally sensitive and competent; otherwise the client may be partially or totally non-compliant with recommended treatments. Another impediment to learning is differing values held by the client and the health team. For example, if a client comes from a culture that views being overweight or "plump" as positive, the nurse should present information in the client's cultural context. Then the nurse and the client should together determine an acceptable weight and develop a plan for achieving that weight (Dayer-Berenson, 2014; Miller & Stoeckel, 2011).

PSYCHOMOTOR ABILITY

It is important for the nurse to be aware of a client's psychomotor skills when planning teaching. Psychomotor skills can be affected by health. For example, an older client who has severe osteoarthritis of the hands may not be able to self-administer insulin. The following physical abilities are important for learning psychomotor skills:

1. **Muscle strength.** For example, an older client who cannot rise from a chair because of insufficient leg and muscle strength cannot be expected to learn to lift herself out of a bathtub.

2. **Motor coordination.** Gross motor coordination is required for movements such as walking, and fine motor coordination is needed when using utensils such as a fork for eating. For example, a client who has advanced amyotrophic lateral sclerosis (ALS) involving the lower limbs will probably be unable to use a walker.
3. **Energy.** Energy is required for most psychomotor skills, and learning these skills uses more energy. Older adults and people who are ill often have limited energy resources; learning and carrying out these skills must be timed for when the client's energy sources are at their peak.
4. **Sensory acuity.** Sight is used for most learning (i.e., walking with crutches, changing a dressing, drawing a medication into a syringe). Clients who have a visual impairment often need the assistance of a support person to carry out such tasks.

THE INTERNET AND HEALTH INFORMATION

The Internet has become a part of the lives of many Americans, allowing them to communicate and obtain information quickly. Internet technology has dramatically changed the activities of business, including health care. The term *e-health* is a broad term often used interchangeably with the term *telehealth* to refer to the provision of electronic health information, products, and services using information technologies (Hebda & Czar, 2013, p. 506). E-health includes many aspects such as online appointment access, electronic prescriptions,

billing review, e-mail access between the client and health care provider, and online health information. Hebda and Czar (2013) describe e-patients as “individuals who assume access to health care information 24/7 and expect to be a partner in health care decision making” (p. 483). The term, consumer health informatics (CHI) has evolved with the increasing use of the Internet by consumers for health care information. This new medical informatics subspecialty studies how clients/consumers use electronic information to improve their health outcomes.

Online Health Information

Findings from a national survey by the Pew Research Center’s Internet & American Life Project (Fox & Duggan, 2013a) reported that 81% of U.S. adults use the Internet, and 59% say they have looked online for health information in the past year. The report called this group “online health seekers.” Thirty-five percent said that they went online specifically to try to figure out what medical condition they or someone else might have. The report called these individuals “online diagnosers.” Of this group, 46% sought the attention of a medical professional with 41% stating that the medical professional confirmed their diagnosis. These findings point out that many consumers are using the Internet as another resource to search for health information for either themselves or on behalf of someone else.

The Social Life of Health Information, 2011 (Fox, 2011) reported that “doctors, nurses, and other health professionals continue to be the first choice for most people with health concerns, but online resources, including advice from peers, is a significant source of health information in the U.S.” Also, of interest, is the growing number of adults who track online their weight, diet, exercise routine, or symptom (i.e., a health indicator). For example, Fox (2011) reported that 20% of U.S. adults tracked health indicators online in 2011 and this increased to 69% who tracked any health indicator for themselves or a loved one in 2013 (Fox & Duggan, 2013b).

Although health professional experts remain vital to providing health information, technology increases the amount of information consumers can access and use to improve their health.

Older Adults and Use of the Internet

Older adults are increasingly using the Internet, and they agree that the Internet is a valuable tool for finding health information. The frequency of Internet use by older adults, however, is much lower than that of younger users (Miller & Bell, 2012). Although the number of health information resources available online for older adults has exploded, the quality of online information and readability level of this information are concerns. Additionally, age-related physical changes can interfere with computer use. For example, motor skill decreases with age and arthritis can affect typing, manipulation of the mouse, and scrolling down a page. Visual changes that accompany aging may also impact the older adult especially if the website uses a small type size or fancy fonts (Cresci & Jarosz, 2010). Adjustments to the computer can overcome these challenges.

Older adults with low incomes, lower education levels, or from rural areas often do not own a computer or have Internet access. As a result, these groups do not benefit from Internet health resources, resulting in a gap between older Americans who have the privilege of Internet access and those who do not. Older adults often learn about computer use at public libraries and learning centers that provide

access to computer use and education. Community partnerships can facilitate activities to bridge the gap of older adult computer usage.

Implications

The Internet is an important source of health information for many adult clients in the United States. Therefore, nurses need to know and be able to integrate this technology into the teaching plans for those clients who use the Internet. Nurses involved in e-health can advocate for website designs that provide accessibility accommodations for older adults. On the other hand, nurses also need to apply effective teaching strategies for those clients who do not use the Internet.

NURSE AS EDUCATOR

Being an educator or teacher is an important and primary role for the nurse. Clients and families have the right to health education in order to make informed decisions about their health. The nurse is in a position to promote healthy lifestyles through the application of health knowledge, the change process, learning theories, and the nursing and teaching process when teaching clients and their families.

●○○ NURSING MANAGEMENT

Assessing

A comprehensive assessment of learning needs combines data from the nursing history and physical assessment and addresses the client’s support system. It also considers client characteristics that may influence the learning process: readiness to learn, motivation to learn, and reading and comprehension level, for example. Assessing a person’s stage of change and any barriers to change is also important and often overlooked (see Chapter 16 ∞).

The nurse’s knowledge of common learning needs required by clients experiencing similar health problems is another source of information. Learning needs change as the client’s health status changes, so nurses must constantly reassess them.

Nursing History

Several elements in the nursing history provide clues to learning needs. These elements include (a) age, (b) the client’s understanding and perceptions of the health problem, (c) health beliefs and practices, (d) cultural factors, (e) economic factors, (f) learning style, and (g) the client’s support systems. Examples of interview questions to elicit this information are in the accompanying Assessment Interview. Note the number of open-ended questions.

Age

Age provides information on the person’s developmental status that may indicate distinctive health teaching content and teaching approaches. Simple questions to school-age children and adolescents will elicit information on what they know. Observing children at play provides information about their motor and intellectual development as well as relationships with other children. For older people, conversation and questioning may reveal slow recall or limited psychomotor skills, sensory deficits, and learning difficulties (see Lifespan Considerations).

Client’s Understanding of Health Problem

A client’s perception of a current health problem and concerns may indicate deficient knowledge or misinformation. In addition, the

ASSESSMENT INTERVIEW Learning Needs and Characteristics

PRIMARY HEALTH PROBLEM

- Tell me what you know about your current health problem. What do you think caused it?
- What concerns do you have about it?
- How has the problem affected what you can or cannot do during your usual activities (e.g., work, recreation, shopping, housework)?
- What do you or did you do at home to relieve the problem? How helpful was it?
- How have the treatments you have started helped your problem?
- What, if any, difficulties have the treatments caused you (e.g., inconvenience, cost, discomfort)?
- Tell me about the tests (surgery, treatments) you are going to have.

HEALTH BELIEFS

- How would you describe your health generally?
- What things do you usually do to keep healthy?
- What health problems do you think you may be at risk for because of family history, age, diet, occupation, inadequate exercise, or other habits, such as smoking?
- What changes would you be willing to make to decrease your risk for these problems or to improve your health?

CULTURAL FACTORS

- What language do you use most often when speaking and writing?
- Do you seek the advice of another health practitioner?

- Do you use herbs or other medications or treatments commonly used in your cultural group? Does your current primary care provider know about these?
- What advice or treatments given previously by your primary care provider conflicted with values or beliefs you consider important?
- When a conflict arose, what did you do?

LEARNING STYLE

- Note the client's age and developmental level.
- What level of education have you received?
- Do you like to read?
- Where do you obtain health information (primary care provider, nurse, magazines, books, pharmacist, and so on)?
- How do you best learn new things?
 - a. By reading about them
 - b. By talking about them
 - c. By watching a movie or demonstration
 - d. By computer
 - e. By listening to the teacher
 - f. By first being shown how something works and then doing it
 - g. On your own or in a group.

CLIENT SUPPORT SYSTEM

- Would you like a family member or friend to help you learn about things you need to do to take care of yourself?
- Who do you think would be interested in learning with you?

effects of the problem on the client's usual activities can alert the nurse to other areas requiring instruction. For example, people who cannot manage self-care at home often need information about community resources and services.

Health Beliefs and Practices

A client's health beliefs and practices are important to consider in any teaching plan. The health belief model described in Chapter 17 ∞ provides a predictor of preventive health behavior. However, even if a nurse is convinced that a particular client's health beliefs should be changed, doing so may not be possible because so many factors are involved in an individual's health beliefs.

Cultural Factors

Many cultural groups have their own folk beliefs and practices with a number of them related to diet, health, illness, and lifestyle. It is therefore important to discuss the client's cultural perspective on illness and therapy. The cultural practices and values held by clients will affect their learning needs. For example, the client may understand the health care information being taught, but this learning may not be used if the client primarily believes in folk medical practices (see Chapter 18 ∞).

Economic Factors

Economic factors can also affect a client's learning. For example, a client who cannot afford to obtain a new sterile syringe for each injection of insulin may find it difficult to learn to administer the insulin when the nurse teaches that a new syringe should be used each time.

Learning Style

Considerable research has been done on people's learning styles. The best way to learn varies with the individual. Some people are visual learners and learn best by watching. Other people do not visualize an activity well; they learn best by actually manipulating equipment and discovering how it works. Other people can learn well from reading things presented in an orderly fashion. Still other people learn best in groups where they can relate to other people. For some, stressing the thinking part of a skill and its logic will promote learning. For other people, stressing the feeling part or interpersonal aspect motivates and promotes learning.

A client's learning style may be based in his or her cultural background. For example, clients from cultures that have a strong oral tradition may prefer educational videos presented in their language.

The nurse seldom has the time or skills to assess each learner, identify the person's particular learning style, and then adapt teaching accordingly. What the nurse can do, however, is ask clients how they have learned things best in the past or how they like to learn. Many people know what helps them learn, and the nurse can use this information in planning the teaching. Using a variety of teaching techniques and varying activities during teaching are good ways to match learners with learning styles. One technique will be most effective for some clients, whereas other techniques will be suited to clients with different learning styles.

Client's Support System

The nurse explores the client's support system to determine the extent to which others may enhance learning and offer support. Family members or a close friend may help the client perform required skills at home and maintain required lifestyle changes.

LIFESPAN CONSIDERATIONS Special Teaching Considerations

OLDER ADULTS

Older adults often have chronic illnesses that require multiple treatments and/or medications. Health teaching will focus on the same areas as with other ages—health and wellness promotion and prevention of illness and accidents—but often the needs are greatest in learning to manage their lives in order to live with their chronic health conditions and to maintain optimal health and functioning. For older adults to be motivated to learn, the material must be practical and have meaning for them individually, especially if the information is new to them. Special considerations in teaching older adults include the following:

- Health promotion is a priority need and should include these areas:
 - Exercise
 - Nutrition
 - Safety habits
 - Having regular health checkups
 - Understanding medications.
- Set achievable goals—involve the client and family in doing this.
- If developing written materials:
 - Use large print (e.g., at least 14-point type size) in bulleted format.
 - Use buff-colored paper or white paper that has a matte (dull) finish (to avoid glare).
 - Present the information at a sixth- to eighth-grade reading level.
- Increase time for teaching and allow for rest periods because processing of information is slower in older adults.
 - Verbal presentation of material should be well organized.
 - Ensure that there is minimal distraction.
- Repeat information if necessary.
- Use return demonstrations with psychomotor skills, such as teaching someone how to do insulin injections.
- Determine where clients obtain most of their health information (e.g., newspapers, magazines, television).
- Use examples that clients can relate to in their daily lives.
- Be aware of sensory deficits, such as hearing and vision.
- Use the setting with which the individual is most comfortable—either a group or one-on-one setting.

- If noncompliance is a problem, investigate the cause. It could be due to lack of finances, transportation problems, poor access to medical care, and so on.

Older adults come with a lifetime of experiences and learned knowledge of their own. Respect this and always have them use their strengths to work with any problems. Positive reinforcement and ongoing evaluation of what has been taught are important factors in effective health teaching with older adults.

CHILDREN

It has often been said that the parent is a child's first and most important teacher. Every interaction between a child and parent (or other adults and children) is a moment in which teaching and learning occur, often unconsciously. Sometimes the results are ones parents desire and strive for; sometimes they are not what the parent would have wished.

Nurses need to take every opportunity to teach parents about health promotion and disease prevention and to provide guidelines regarding normal growth and development. Considerations in teaching children include the following:

PRESCHOOL CHILDREN (3–5 YEARS OF AGE)

- Concerned about fear of pain and bodily harm. Reassure them and allow them to tell you about these fears. Use words carefully. For example, use “fix” instead of “cut”; “bandage” instead of “dressing.”
- Allow the child to play with replicas or dolls to learn about body parts.
- Give praise and approval to motivate learning.

MIDDLE AND LATE CHILDHOOD (6–11 YEARS OF AGE)

- Are able to think logically but abstract thought is limited.
- Like to be actively involved in the learning process.
- Teaching for health promotion often occurs through the school nurse.

ADOLESCENT (12–19 YEARS OF AGE)

- Have a strong need to belong to a group and a need for friendships and peer support.
- Need to develop a mutually respectful and trusting relationship with them.

Physical Examination

The general survey part of the physical examination provides useful clues to the client's learning needs, such as mental status, energy level, and nutritional status. Other parts of the physical examination reveal data about the client's physical capacity to learn and to perform self-care activities. For example, visual ability, hearing ability, and muscle coordination affect the selection of content and approaches to teaching.

Readiness to Learn

Clients who are ready to learn often behave differently from those who are not. A client who is ready may search out information, for instance, by asking questions, reading books or articles, talking to others, and generally showing interest. The person who is not ready to learn is more likely to avoid the subject or situation. In addition, the unready client may change the subject when it is brought up by the nurse. For example, the nurse might say, “I was wondering about a good time to show you how to change your dressing,” and the client responds, “Oh, my wife will take care of everything.”

The nurse assesses for these readiness characteristics:

- **Physical readiness.** Is the client able to focus on things other than physical status, or are pain, fatigue, and immobility using up all of the client's time and energy?
- **Emotional readiness.** Is the client emotionally ready to learn self-care activities? Clients who are extremely anxious, depressed, or grieving over their health status are not ready.
- **Cognitive readiness.** Can the client think clearly at this point? Are the effects of anesthesia and analgesia altering the client's level of consciousness?

Nurses can promote readiness to learn by providing physical and emotional support during the critical stage of recovery. As the client stabilizes physically and emotionally, the nurse can provide opportunities to learn.

Motivation

Motivation relates to whether the client wants to learn and is usually greatest when the client is ready, the learning need is recognized,

Evidence-Based Practice Can a Student Nurse's Knowledge of Health Literacy Improve After Completing an Online Educational Module?

EVIDENCE-BASED PRACTICE

Many clients have limited health literacy; thus, it is important for nurses to help them understand and use health information effectively. McCleary-Jones (2012) states that although most nursing curricula include information on client education, they do not specifically address low health literacy (p. 214). As a result, her comparative study had the goal of increasing the health literacy knowledge of BSN students. She developed an online PowerPoint presentation with the following learning objectives: (a) Define health literacy, (b) discuss the impact of low health literacy on client outcomes, (c) identify tools that can be used to assess health literacy, (d) discuss common signs that indicate low health literacy, and (e) identify effective strategies for teaching clients with low literacy.

The students in the study first learned about health literacy in their pharmacology course. The researcher approached the 89 students in this course and asked if they wished to voluntarily participate in the study to examine entering baccalaureate nursing students' knowledge of health literacy. The results of a five-item pre- and post-test were collected anonymously. All 89 students enrolled in the course completed the pretest; however, only 53 students completed the

health literacy education online module and post-test. The majority of these 53 students were women, and White, with an average age of 21.6 years. There was a significant increase between the pre-test and post-test scores with the greatest increase relating to which strategies are effective for teaching clients with low health literacy. Note that among the students who participated in the study, only 3% reported that they were "very familiar," 48% "somewhat familiar," and 8% "unfamiliar" with the term *health literacy* upon entering the BSN program.

IMPLICATIONS

The study supported other research findings conducted with a health literacy education session in a traditional classroom setting. It is important to know that an online module can also positively impact student knowledge of health literacy. Because research has shown that limited health literacy negatively impacts a client's health outcomes, it is crucial for nursing programs to include this topic in their curriculum. Further research is needed to determine whether nursing students retain and apply the knowledge they obtained through the online module.

and the information being offered is meaningful to the client. Assessment of motivation, however, may be difficult. Communication skills used by the nurse can obtain helpful information indicating a readiness for change such as "I'm really ready to lose weight this time." On the other hand, nonverbal behaviors such as disinterest, lack of attention, and missed appointments can indicate a decreased motivation to learn.

Nurses can increase a client's motivation in several ways:

- By relating the learning to something the client values and helping the client see the relevance of the learning
- By helping the client make the learning situation pleasant and nonthreatening
- By encouraging self-direction and independence
- By demonstrating a positive attitude about the client's ability to learn
- By offering continuing support and encouragement as the client attempts to learn (i.e., positive reinforcement)
- By creating a learning situation in which the client is likely to succeed (Succeeding in small tasks motivates the client to continue learning.)
- By assisting the client to identify the benefits of changing behavior.

Health Literacy

Health information can be confusing to understand; yet, it is so important that health literacy was identified as a target area in the goals and objectives for *Healthy People 2020* (2012). This is supported by the fact that more than one third of U.S. adults have limited health literacy (DeWalt et al., 2011, p. 86). The Centers for Disease Control and Prevention (n.d.) defines **health literacy** as the ability "to obtain, process and understand basic health information and services to make appropriate health decisions." This includes such tasks as comprehending prescription labels, interpreting appointment slips, completing health insurance forms, and following instructions for diagnostic tests. Individuals with the lowest health literacy skills often have the following characteristics: 65 years or older; limited English-speaking skills; have

less than a high school diploma; underserved minority groups; and immigrants (Miller & Stoeckel, 2011; Pfizer, 2012c).

Low health literacy skills are associated with poor health outcomes and higher health care costs. For example, a client may not be able to read a prescription to know how many pills to take or may take the wrong number of pills (e.g., *once* means "eleven" in Spanish). This places the client at a greater risk of preventable adverse events. Clients with low literacy skills have less information about health promotion and/or management of a disease process for themselves and their families because they are unable to read the educational materials and they often fail to seek preventive care (e.g., vaccinations, mammograms). As a result, they are more likely to seek care in emergency departments and be admitted to the hospital than people with adequate health literacy (Pfizer, 2012b).

Low health literacy is a silent epidemic and there is no physical exam, blood test, or diagnostic imaging procedure that can tell you who is at risk. There are, however, a variety of health literacy assessment tools. Many are only available in English and are time consuming (e.g., 36 to 66 questions), which creates a challenge for the busy nurse to incorporate into the client's plan of care. The latest health literacy assessment tool is the six-question Newest Vital Sign (NVS) health literacy test (Pfizer, 2011). It is available in English and Spanish, takes about 3 minutes to administer, and tests reading and math skills. The NVS uses an ice cream nutritional food label to determine health literacy (Figure 27–2 ■). The nurse reads six questions for the client to answer while the client refers to the food label. One point is given for each correct answer. Figure 27–3 ■ shows the score sheet. If the results indicate a client has limited health literacy skills, the nurse knows to use clear communication techniques and a variety of teaching strategies to increase understanding by the client and family. It is a challenge for the nurse to teach clients with low or no reading and writing skills. However, such teaching is vitally important because clients with low literacy skills need learning opportunities to improve their health practices.

Even with the availability of health literacy assessment tools, research indicates that clinicians do not accurately identify people with

limited health literacy (DeWalt et al., 2011, p. 86). As a result, health care professionals should practice "universal precautions" when communicating to ensure that all people have all the information they need to make appropriate health decisions (DeWalt et al., 2011; Pfizer, 2012d). That means using clear communication and plain language that creates a foundation for clients to be able to understand and act on health information. It is imperative to use this technique when working with *all* clients. The Agency for Healthcare Research and Quality commissioned the development and validity testing of a Health Literacy Universal Precautions (HLUP) Toolkit to help adult and pediatric primary care practices implement health literacy universal precautions with all clients (DeWalt et al., 2010).

CLINICAL ALERT!

The majority of people at the lowest reading levels will report that they "read well."

The National Patient Safety Foundation developed an educational tool titled "Ask Me 3™." This tool promotes three simple questions that clients should ask all health care providers in all health care interactions (DeWalt et al., 2010):

- What is my main problem?
- What do I need to do?
- Why is it important for me to do this?

When verbally teaching clients it is important to use communications techniques that will enhance their understanding. The HLUP Toolkit (DeWalt et al., 2010) suggests the following techniques:

- Use plain, nonmedical language.
- Speak clearly and at a moderate pace.
- Limit information to two or three important points at a time.
- Repeat key points.
- Use graphics such as drawings or models.
- Encourage questions (i.e., "What questions do you still have?" and "That was a lot of information; what do I need to go over again?").
- Use "teach back" and "show back" techniques. "Teach back" is when the nurse has clients say in their own words what is important that they know and/or do. The "show back" technique is when the nurse asks clients to perform a return demonstration.

CLINICAL ALERT!

When using the "teach back" technique, you do not want clients to feel that you are testing them. Place the responsibility on yourself. For example, tell the client that you want to be sure that you did a good job of explaining (topic) because it can be confusing. Ask: "Please tell me what information was most helpful to you or that you will now do differently?"

Nurses involved in developing written health teaching materials should write for lower reading levels (see Client Teaching: Developing Written Teaching Aids). The goal is for the education materials to be at a sixth-grade readability level (Pfizer, 2012a). People with good reading skills do not take offense with simple reading material and prefer easy-to-read information. Even the simplest written directions, however, will not be helpful for the client with low or no reading skills. See the Client Teaching: Teaching Clients with Low Literacy Levels box for suggestions on how to teach clients with low literacy levels.

Diagnosing

Nursing diagnoses for clients with learning needs can be designated in two ways: as the client's primary concern or problem, or as the etiology of a nursing diagnosis associated with the client's response to health alterations or dysfunction.

Learning Need as the Diagnostic Label

NANDA International (Herdman & Kamitsuru, 2014) includes the following diagnostic labels appropriate to a client's learning needs when the learning need is the primary concern:

- *Deficient Knowledge*: absence or deficiency of cognitive information related to a specific topic (Herdman & Kamitsuru, 2014, p. 257).

Whenever the diagnostic label *Deficient Knowledge* is used, either the client is seeking health information or the nurse has identified a learning need. The area of deficiency should always be included in the diagnosis. The following examples use the NANDA label *Deficient Knowledge* as the primary concern:

- *Deficient Knowledge (Low-Calorie Diet)* related to inexperience with newly ordered therapy
- *Deficient Knowledge (Home Safety Hazards)* related to denial of declining health and living alone.

Score Sheet for the Newest Vital Sign

READ TO SUBJECT: This information is on the back of a container of a pint of ice cream.

1. If you eat the entire container, how many calories will you eat?
Answer: 1,000 is the only correct answer
2. If you are allowed to eat 60 grams of carbohydrates as a snack, how much ice cream could you have?
Answer: Any of the following is correct: 1 cup (or any amount up to 1 cup), Half the container Note: If patient answers "two servings," ask "How much ice cream would that be if you were to measure it into a bowl."
3. Your doctor advises you to reduce the amount of saturated fat in your diet. You usually have 42 g of saturated fat each day, which includes one serving of ice cream. If you stop eating ice cream, how many grams of saturated fat would you be consuming each day?
Answer: 33 is the only correct answer
4. If you usually eat 2500 calories in a day, what percentage of your daily value of calories will you be eating if you eat one serving?
Answer: 10% is the only correct answer

READ TO SUBJECT: Pretend that you are allergic to the following substances: Penicillin, peanuts, latex gloves, and bee stings.

5. Is it safe for you to eat this ice cream?
Answer: No
6. (Ask only if the patient responds "no" to question 5): Why not?
Answer: Because it has peanut oil.

ANSWER CORRECT?	
yes	no

Interpretation Number of correct answers:

Score of 0-1 suggests high likelihood (50% or more) of limited literacy
Score of 2-3 indicates the possibility of limited literacy.
Score of 4-6 almost always indicates adequate literacy.

Figure 27–3 ■ Score sheet for the Newest Vital Sign (NVS) questions and answers. Reprinted with permission from Pfizer.

CLIENT TEACHING

Developing Written Teaching Aids

- Keep language level at or below the sixth-grade level.
- Use active, not passive, voice (e.g., take your medicine before breakfast [active] versus medicine should be taken before breakfast [passive]).
- Use plain language; that is, easy, common words of one or two syllables (e.g., use instead of utilize, or give instead of administer).
- Use the second person (you) rather than the third person (the client).
- Use a large type size (14 to 16 point).
- Write short sentences.
- Avoid using all capital letters.
- Place priority information first and repeat more than once.
- Use bold for emphasis.
- Use simple pictures, drawings, or cartoons, if appropriate.
- Leave plenty of white space.
- Focus material on desired behavior rather than on medical fact.
- Make it look easy to read.

CLIENT TEACHING

Teaching Clients with Low Literacy Levels

- Use multiple teaching methods: Show pictures. Read important information. Lead a small group discussion. Role-play. Demonstrate a skill. Provide hands-on practice.
- Emphasize key points in simple terms and provide examples.
- Avoid acronyms (e.g., CAT scan, HDL).
- Limit the amount of information in a single teaching session. Instead of one long session with a great deal of information, it is better to have more frequent sessions with a major point at each session.
- Associate new information with something the client already knows and/or associates with his or her job or lifestyle.
- Reinforce information through repetition.
- Involve the client in the teaching.
- Use the “teach back” method by asking clients to repeat *in their own words* what they need to know. This will help you assess clients’ understanding of your instructions.
- Avoid handouts with many pages and classroom lecture format with a large group.

Wilkinson (2014) stresses that if *Deficient Knowledge* is used as the primary concern, one client goal must be “client will acquire knowledge about” (p. 431). The nurse needs to provide information that has the potential to change the client’s behavior rather than focus on the behaviors caused by the client’s lack of knowledge.

A second nursing diagnostic label where a learning need may be the primary concern is:

- *Readiness for Enhanced Knowledge*: A pattern of cognitive information related to a specific topic, or its acquisition, that is sufficient for meeting health-related goals and can be strengthened. This is a health promotion diagnosis in which the client’s behaviors are congruent with their knowledge. The client is able to explain the topic, can describe previous experiences pertaining to the topic, and expresses an interest in learning more about the topic (Herdman, 2012, p. 272).

When this diagnostic label is used, the client may or may not have an altered response or dysfunction at the time but may be seeking information to improve health or prevent illness. In the following examples the NANDA label *Readiness for Enhanced Knowledge* is used as the primary concern:

- *Readiness for Enhanced Knowledge (Exercise and Activity)* related to a desire to improve health behaviors and decrease risk of heart disease. This diagnosis may be appropriate for the client who has knowledge of cardiac risk factors, has identified a personal health risk for a cardiac condition, and wants more information to minimize that risk through exercise.
- *Readiness for Enhanced Knowledge (Home Safety Hazards)* related to a desire to minimize risk of injury. This diagnosis may be appropriate for parents of a toddler who are seeking additional information to ensure that their home is safe for their child. The diagnosis might also be used when an adult child seeks information to ensure that the home of an aging parent is free of risk factors for falls or other injuries common to the older adult.

A third nursing diagnostic label where a learning need may be the primary concern is:

- *Noncompliance*. This diagnosis indicates that the behavior of the person and/or caregiver fails to coincide with a health promotion or therapeutic plan agreed on by the person (and/or family and/or community) and health care professional. In the presence of an agreed-on, health promotion or therapeutic plan, the person’s or caregiver’s behavior is fully or partially nonadherent and

may lead to clinically ineffective or partially ineffective outcomes (Herdman, 2012, p. 400).

The diagnostic label *Noncompliance* should be used with caution. In general, the diagnosis *Noncompliance* is associated with the *intent* to comply, but situational factors make it difficult (Wilkinson, 2014, p. 486). Factors that influence a client’s compliance with health teaching include understanding or comprehension of the teaching, the experienced negative side effects of the treatment, financial inability to carry out the treatment plan, language barriers, or poor teaching on the part of the health care team. *Noncompliance* should *not* be used for a client who is unable to follow instructions (e.g., cognitive disability) or for a client who makes an informed decision to refuse or not follow the medical treatment (Wilkinson, 2014, p. 486).

CLINICAL ALERT!

The term *noncompliance* is often perceived as a negative label. Be sure to state the etiology in neutral, nonjudgmental words.

Deficient Knowledge as the Etiology

Another way to deal with identified learning needs of clients is to write deficient knowledge as the etiology, or second part, of the diagnosis statement. Such nursing diagnoses are written in the following format:

- *Risk for (Specify)* related to deficient knowledge (specify).

Examples include the following:

- *Risk for Impaired Parenting* related to deficient knowledge (skills in infant care and feeding)
- *Risk for Infection* related to deficient knowledge (sexually transmitted infections and their prevention)
- *Anxiety* related to deficient knowledge (bone marrow aspiration).

Other nursing diagnoses in which a knowledge deficit can be the etiology follow:

- *Risk for Injury*
- *Ineffective Breastfeeding*
- *Ineffective Coping*
- *Ineffective Health Maintenance*.

Note also that most NANDA-approved nursing diagnoses imply a teaching–learning need. For example, the nursing diagnosis *Constipation* suggests the need for a review of bowel hygiene practices including diet, hydration, and exercise/activity.

CLIENT TEACHING

Sample Teaching Plan for Wound Care

Assessment of Learner: A 24-year-old male college student suffered a 7-cm (2.5-in.) laceration on the left lower anterior leg during a hockey game. The laceration was cleaned, sutured, and bandaged. The client was given an appointment to return to the health clinic in 10 days for suture removal. Client states that he lives in the college dormitory and is able to do wound care if given instructions. Client is able to understand and read English. Assessed to be in the “preparation” and “action” stages of change.

Nursing Diagnosis: *Deficient Knowledge* (Care of Sutured Wound) related to no prior experience.

Long-Term Goal: Client’s wound will heal completely without infection or other complications.

Intermediate Goal: At clinic appointment, client’s wound will be healing without signs of infection, loss of function, or other complication.

Short-Term Goals: Client will (a) correctly list three signs and symptoms of wound infection and (b) correctly perform a return demonstration of wound cleansing and bandaging.

Learning Outcomes	Content Outline	Teaching Methods
Upon completion of the instructional session, the client will:		
1. Describe normal wound healing.	i. Normal wound healing	Describe normal wound healing with the use of audiovisuals.
2. Describe signs and symptoms of wound infection.	ii. Infection Signs and symptoms include wound warm to touch, misalignment of wound edges, and purulent wound drainage. Signs of systemic infection include fever and malaise.	Discuss the mechanism of wound infection. Use audiovisuals to demonstrate infected wound appearance. Provide handout describing signs and symptoms of wound infection.
3. Identify equipment needed for wound care.	iii. Wound care equipment a. Cleansing solution as prescribed by primary care provider (e.g., clear water, mild soap and water, or antimicrobial solution) b. Bandaging material: Telfa, gauze wrap, adhesive tape.	Demonstrate equipment needed for cleansing and bandaging wound. Provide handout listing equipment needed.
4. Demonstrate wound cleansing and bandaging.	v. Demonstration of wound cleansing and bandaging on the client’s wound or a mannequin	Demonstrate wound cleansing and bandaging on the client’s wound or a mannequin. Provide handout describing procedure for cleansing and bandaging wound.
5. Describe appropriate action if questions or complications arise.	vi. Resources available for client questions include health clinic, emergency department.	Discuss available resources. Provide handout listing available resources and follow-up treatment plan.
6. Identify date, time, and location of follow-up appointment for suture removal.	vi. Follow-up treatment plan; where and when	Provide written instructions.

Evaluation: The client will:

1. Respond to questions regarding self-care of wound.
2. Return demonstration of wound cleansing and bandaging.
3. State contact person and telephone number to obtain assistance.
4. State date, time, and location of follow-up appointment.

Planning

Developing a teaching plan is accomplished in a series of steps. Involving the client at this time promotes the formation of a meaningful plan and stimulates client motivation. The client who helps develop the teaching plan is more likely to achieve the desired outcomes (see Client Teaching).

CLINICAL ALERT!

Knowing the client’s stage of change helps determine which interventions will be useful to help the client change.

Determining Teaching Priorities

The client’s learning needs must be ranked according to priority. The client and the nurse should do this together, with the client’s

priorities always being considered. Once a client’s priorities have been addressed, the client is generally more motivated to concentrate on other identified learning needs. For example, a man who wants to know all about coronary artery disease may not be ready to learn how to change his lifestyle until he meets his own need to learn more about the disease. Nurses can also use theoretical frameworks, such as Maslow’s hierarchy of needs, to establish priorities.

Setting Learning Outcomes

Learning outcomes can be considered the same as desired outcomes for other nursing diagnoses. They are written in the same way. Like client outcomes, learning outcomes:

- State the client (learner) behavior or performance, not nurse behavior. For example, “Identify personal risk factors for heart

BOX 27-2 Examples of Verbs for Writing Learning Outcomes

Writes		

disease” (client behavior), *not* “Teach the client about cardiac risk factors” (nurse behavior).

- Reflect an observable, measurable activity. The performance may be visible (e.g., walking) or invisible (e.g., adding numbers). It is necessary, however, to be able to evaluate whether an unobservable activity has been mastered from some performance that represents the activity. For example, the performance of an outcome might be written: “Selects low-fat foods from a menu” (observable), *not* “Understands low-fat diet” (unobservable). Examples of measurable verbs used for learning outcomes are shown in Box 27-2. Avoid using words such as *knows*, *understands*, *believes*, and *appreciates* because they are neither observable nor measurable.
- May add conditions or modifiers as required to clarify what, where, when, or how the behavior will be performed. Examples are “Demonstrates four-point crutch gait *correctly*” (condition), “Administers own insulin *independently* (condition) as taught,” or “States *three* (condition) factors that affect blood sugar level.”
- Include criteria specifying the time by which learning should have occurred. For example, “The client will state three things that affect blood sugar level *by end of second diabetic class.*”

Learning outcomes can reflect the learner’s command of simple to complex concepts. For example, the learning outcome “The client will list cardiac risk factors” is a low-level knowledge outcome that simply requires the learner to identify all cardiac risk factors; it does not suggest application of the knowledge to the learner’s own behaviors. The learning outcome “The client will list personal cardiac risk factors” requires that the learner not only know cardiac risk factors in general but also know his own behaviors that place him at risk for cardiac disease.

In writing learning outcomes, the nurse must be specific about what behaviors and knowledge (cognitive, psychomotor, and affective) learners must have to be able to positively influence their health state. In most cases, the learning needs are more complex than simple acquisition of knowledge and include the application of that knowledge to oneself.

Choosing Content

The content, or what is to be taught, is determined by learning outcomes. For instance, “Identify appropriate sites for insulin injection” means the nurse must include content about the body sites suitable

Figure 27-4 ■ Teaching materials and strategies should be suited to the client’s age and learning abilities.
Gary Alvis/Getty images.

for insulin injections. Nurses can select among many sources of information including books, nursing journals, the Internet, and other nurses and primary care providers. Whatever sources the nurse chooses, content should be:

- Accurate.
- Current.
- Based on learning outcomes.
- Adjusted for the learner’s age, culture, and ability.
- Consistent with information the nurse is teaching.
- Selected with consideration of how much time and what resources are available for teaching.

Selecting Teaching Strategies

The method of teaching that the nurse chooses should be suited to the individual and to the material to be learned (Figure 27-4 ■). For example, the person who cannot read needs material presented in other ways; a discussion is usually not the best strategy for teaching how to give an injection; and a nurse using group discussion for teaching should be a competent group leader. As stated earlier, some people are visually oriented and learn best through seeing; others learn best through hearing and having the skill explained. Table 27-3 lists selected teaching strategies.

Organizing Learning Experiences

To save nurses time in constructing their own teaching guides, some health agencies have developed guides for teaching sessions that nurses commonly give. These guides standardize content and teaching methods and make it easier for the nurse to plan and implement client teaching. Standardized teaching plans also ensure consistency of content for the learner, thereby decreasing the risk of confusion if different practices are taught. For example, when teaching infant bathing, the nurse on the unit should be consistent about which soaps

TABLE 27-3 Selected Teaching Strategies

Strategy	Major Type of Learning	Characteristics
Explanation or description (e.g., lecture)	Cognitive	Teacher controls content and pace. Learner is passive; therefore retains less information than when actively participating. Feedback is determined by teacher. May be given to individual or group.
One-on-one discussion	Affective, cognitive	Encourages participation by learner. Permits reinforcement and repetition at learner's level. Permits introduction of sensitive subjects.
Answering questions	Cognitive	Teacher controls most of content and pace. Teacher must understand question and what it means to learner. Learner may need to overcome cultural perception that asking questions is impolite and may embarrass the teacher. Can be used with individuals and groups. Teacher sometimes needs to confirm whether question has been answered by asking learner, for example, "Does that answer your question?"
Demonstration	Psychomotor	Often used with explanation. Can be used with individuals, small or large groups. Does not permit use of equipment by learner; learner is passive.
Discovery	Cognitive, affective	Teacher guides problem-solving situation. Learner is active participant; therefore, retention of information is high.
Group discussions	Affective, cognitive	Learner can obtain assistance from supportive group. Group members learn from one another. Teacher needs to keep the discussion focused and prevent monopolization by one or two learners.
Practice	Psychomotor	Allows repetition and immediate feedback. Permits hands-on experience.
Printed and audiovisual materials	Cognitive	Types include books, pamphlets, films, programmed instruction, and computer learning. Learners can proceed at their own speed. Nurse can act as resource person, need not be present during learning. Potentially ineffective if reading level of the materials is too high. Teacher needs to select language of materials that meets learner needs if English is a second language.
Role-playing	Affective, cognitive	Permits expression of attitudes, values, and emotions. Can assist in development of communication skills. Involves active participation by learner. Teacher must create supportive, safe environment for learners to minimize anxiety.
Modeling	Affective, psychomotor	Nurse sets example by attitude, psychomotor skill.
Computer learning resources	All types of learning	Learner is active. Learner controls pace. Provides immediate reinforcement and review. Use with individuals or groups.

are appropriate for the infant's bath and distinguish those that are not. Whether the nurse is implementing a plan devised by another or developing an individualized teaching plan, some guidelines can help the nurse sequence the learning experience:

- Start with something the learner is concerned about; for example, before learning how to administer insulin to himself, an adolescent wants to know how to adjust his lifestyle and yet still play football.

CLINICAL ALERT!

Leave a note pad and pen at the client's bedside and encourage the client to write down questions for the nurse or the primary care provider.

- Discover what the learner knows, and then proceed to the unknown. This gives the learner confidence. Sometimes you will not know the client's knowledge or skill base and will need to elicit this information either by asking questions or by having the client fill out a form, such as a pretest.
- Address early on any area that is causing the client anxiety. A high level of anxiety can impair concentration in other areas. For example, a woman highly anxious about her fear of the needle breaking off into the skin may not be able to learn how to self-administer an insulin injection until her fear is resolved.
- Teach the basics before proceeding to the variations or adjustments (e.g., simple to complex). It is confusing to learners to have to consider possible adjustments and variations before they master the basic concepts. For example, when teaching a client how

to perform intermittent self-catheterization, it is best to teach the basic procedure before teaching any adjustments that might be needed if the catheter stops draining after insertion.

- Schedule time for review of content and questions the client(s) may have to clarify information.

CLINICAL ALERT!

If the client has no questions, you can help introduce questions by saying, “A few frequently asked questions are:”

Implementing

The nurse needs to be flexible in implementing any teaching plan because the plan may need revising. The client may become tired sooner than anticipated or be faced with too much information too quickly, the client's needs may change, or external factors may intervene. For instance, the nurse and the client plan to change his dressing at 10 AM, but when the time comes, the client wants to observe the nurse once more before actually doing it himself.

In this case, the nurse alters the teaching plan and discusses any desired information, provides another demonstration, and defers teaching the psychomotor skill until the next day. It is also important for nurses to use teaching techniques that enhance learning and reduce or eliminate any barrier to learning such as pain or fatigue (see Table 27–2 earlier in this chapter).

CLINICAL ALERT!

Many nurses find that they teach while performing nursing care (e.g., giving medication). Remember to document this informal teaching.

Guidelines for Teaching

Knowledge alone is not enough to motivate a person to change a behavior. Do not assume that providing information will automatically result in clients changing their behavior. Learning what needs to be done to change behavior and acting on that knowledge are two different processes. The stages of change, the person's willingness and perceived need to change, and barriers to change are important elements to reflect on when implementing a teaching plan (see Chapter 16 ∞). When a client is ready to change a health behavior and when implementing a teaching plan, the nurse may find the following guidelines helpful:

- A respectful relationship between teacher and learner is essential. A relationship that is accepting, friendly, and positive will best assist learning. The following attitudes are important for the nurse to exhibit: Value seeing the health care situation “through the clients’ eyes”; respect and encourage individual expression of the client's values, preferences, and expressed needs; value the client's expertise with his or her own health and symptoms (QSEN Institute, n.d.). Knowing the learner and the previously described factors that affect learning should be established before planning the teaching.
- The teacher who uses the client's previous learning in the present situation encourages the client and facilitates learning new skills. For instance, a person who already knows how to cook can use this knowledge when learning to prepare food for a special diet.

- The optimal time for each session depends largely on the learner. Whenever possible, ask the client for help to choose the best time, for example, when she feels most rested or when no other activities are scheduled. Look for “teachable moments” that may occur during normal routine care. For example, if a client asks why a certain medication (e.g., Coumadin) is needed, it is an opportunity (“teachable moment”) to explain the reason for the medication, signs to watch for, and if follow-up laboratory work is needed.
- The nurse-teacher must be able to communicate clearly and concisely. The words used need to have the same meaning to the client as to the teacher. A client who is taught not to put water on an area of skin may think a wet washcloth is permissible for washing the area. In effect, the nurse needs to explain that no water or moisture should touch the area.
- Using a layperson's vocabulary enhances communication. Often nurses use terms and abbreviations that have meaning to other health professionals but make little sense to clients. Even words such as *urine* or *feces* may be unfamiliar to clients, and abbreviations such as ICU (intensive care unit) or PACU (postanesthesia care unit) are often misunderstood.
- The pace of each teaching session also affects learning. Nurses should be sensitive to any signs that the pace is too fast or too slow. A client who appears confused or does not comprehend material when questioned may be finding the pace too fast. When the client appears bored and loses interest, the pace may be too slow, the learning period may be too long, or the client may be tired.
- An environment can detract from or assist learning; for example, noise or interruptions usually interfere with concentration, whereas a comfortable environment promotes learning. If possible, the client should be out of bed for learning activities. Most people associate their bed with rest and sleep, not with learning. Placing the client in a position and location associated with activity or learning may influence the amount of learning that takes place. For instance, a client who is shown a videotape while in bed may be more likely to become drowsy during instruction than a client who is sitting in a bedside chair.
- Teaching aids can foster learning and help focus a learner's attention. To ensure the transfer of learning, the nurse should use the type of supplies or equipment the client will eventually use. Before the teaching session, the nurse needs to assemble all equipment and visual aids and ensure that all audiovisual equipment is functioning effectively. See Client Teaching for teaching tools for children.
- Teaching that involves a number of the learner's senses often enhances learning. For instance, when teaching about changing a surgical dressing, the nurse can tell the client about the procedure (hearing), show how to change the dressing (sight), and show how to manipulate the equipment (touch).
- Learning is more effective when the learners discover the content for themselves. Ways to increase learning include stimulating motivation and self-direction, for example, (a) by providing specific, realistic, achievable outcomes; (b) by giving feedback; and (c) by helping the learner derive satisfaction from learning. The nurse may also encourage self-directed independent learning by encouraging the client to explore sources of information required. If certain activities do not assist the learner to attain outcomes, these need to be reassessed; perhaps other activities can replace them. Explanation alone may not be able to teach a

CLIENT TEACHING

Teaching Tools for Children

- *Visits.* Visiting the hospital and treatment rooms; seeing people dressed in uniforms, scrub suits, protective gear.
- *Dress-up.* Touching and dressing up in the clothing they will see and wear.
- *Coloring books.* Using coloring books to prepare for treatments, surgery, or hospitalization; shows what rooms, people, and equipment will look like.
- *Storybooks.* Storybooks describe how the child will feel, what will be done, and what the place will look like. Parents can read these stories to children several times before the experience. Younger children like this repetition.
- *Dolls.* Practicing procedures on dolls or teddy bears that they will later experience; gives a sense of mastery of the situation. Custom dolls are often available for inserting tubes and giving injections, for example.
- *Puppet play.* Puppets can be used in role-play situations to provide information and show the child what the experience will be like; they help the child express emotions.
- *Health fairs.* Health fairs can educate children about their bodies and ways to stay healthy. Fairs can focus on high-risk problems children face, such as accident prevention, poison control, and other topics identified in the community as a concern.

Figure 27-5 ■ Teaching activities may need to include hands-on client participation.

Terry Vine/Getty images.

client to handle a syringe. Actually handling the syringe may be more effective (Figure 27-5 ■).

- Repetition reinforces learning. Summarizing content, rephrasing (using other words), and approaching the material from another point of view are ways of repeating and clarifying content. For instance, after discussing the kinds of foods that can be included in a diet, the nurse describes the foods again, but in the context of the three meals eaten during one day.
- It is helpful to employ “organizers” to introduce material to be learned. Advanced organizers provide a means of connecting unknown material to known material and generating logical

relationships. The following statement can be an advanced organizer: “You understand how urine flows down a catheter from the bladder. Now I will show you how to inject fluid so that it flows up the catheter into the bladder.” The details that follow are then seen within a framework that adds meaning.

- The anticipated behavioral changes that indicate learning has taken place must always be within the context of the client’s life-style and resources. It would be unreasonable to expect a woman to soak in a tub of hot water two times a day if she did not have a bathtub or had to heat water on a stove.

Special Teaching Strategies

One-on-one discussion is the most common method of teaching used by nurses. However, nurses can choose from a number of special teaching strategies: client contracting, group teaching, computer learning resources, discovery/problem solving, and behavior modification. Any strategy the nurse selects must be appropriate for the learner and the learning objectives.

Client Contracting

Client contracting involves establishing a learning contract with a client that specifies certain outcomes and when they are to be met. Here is an example of a self-contract:

I, Amy Martin, will exercise strenuously for 20 minutes three times per week for a period of 2 weeks and will then buy myself six yellow roses.

Amy Martin

A. Ward, RN
July 30, 2015

The contract, drawn up and signed by the client and the nurse, may specify the learning outcomes, the responsibilities of the client and the nurse, and the methods of follow-up and evaluation. The contract can be changed in two ways: if the client meets the contract outcomes and wants to negotiate new learning outcomes, and if the client decides that he or she is unable to meet the existing learning outcomes and wants to revise them. The learning contract allows for freedom, mutual respect, and mutual responsibility.

Group Teaching

Group instruction is economical, and it provides members with an opportunity to share with and learn from others. A small group allows for discussion in which everyone can participate. A large group often necessitates a lecture technique or use of films, videos, slides, or role-playing by teachers.

All members involved in group instruction should have a common need (e.g., prenatal health or preoperative instruction), and sociocultural factors should be considered in the formation of a group.

Computer Learning Resources

Using computers for instruction is becoming common. Computers were initially used primarily for the learning of facts. Now, however, computers can also be used to teach the following:

- Application and retention of information (e.g., answering questions after reading the information about a health subject)
- Psychomotor skills (e.g., filling a syringe on the computer screen to the correct dosage line on the syringe)
- Complex problem-solving skills (e.g., responding to questions based on a client situation).

Computers can be used in a variety of ways:

- Individual health care professionals or clients using one computer
- Families or small groups of three to five clients gathered around one computer taking turns running the program and answering questions together
- Large groups with the computer display screen projected onto an overhead screen and a teacher or one learner using the keyboard
- Individuals or small groups at computers using programs through shared network platforms or through Internet websites.

Individuals using a computer are able to set the pace that meets their particular learning needs. Small groups are less able to do this, and large groups progress through the program at a pace that may be too slow for some learners and too fast for others. It is therefore helpful to group learners of similar needs and abilities together. Whether using the computer alone or in large groups, learners read and view informational material, answer questions, and receive immediate feedback. The correct answer is usually indicated by the use of colors, flashing signs, or written praise. When the learner selects an incorrect answer, the computer may respond with an explanation of why that was not the best answer and encouragement to try again. Many programs ask learners whether they want to review material on which the question and answer were based. Some computer programs feature simulated situations that allow learners to manipulate objects on the screen to learn psychomotor skills. When used to teach such skills, computer instruction must be followed up with practice on actual equipment supervised by the teacher.

Some clients may have a negative attitude about computers that could act as a barrier to learning. The nurse helps these clients by explaining how the computer can help meet their needs. Matching a computer program or website to the client's individual health circumstances may encourage computer use. Providing a resource list of free community sites for training and access may also help.

Most media catalogs, professional journals, and health care libraries contain information about computer software programs available to the nurse for client education. The media specialist or librarian in a health care facility or educational institution is an excellent resource to help the nurse locate appropriate computer programs. Computer educational material is also available for clients with different language needs, for clients with special visual needs, and for clients at different growth and development levels.

The Internet is an important source of health information, particularly for clients with chronic illnesses. It is important for the nurse to teach the client who uses the Internet how to evaluate if the site is a relevant and credible source for health information. Unfortunately, studies have found that a significant number of nurses do not routinely assess the client's use of online health information as part of their teaching practice (Gilmour, Huntington, Broadbent, Strong, & Hawkins, 2012). Gilmour et al. (2012) conducted a research study and found that there was a significant relationship between assessing clients' use of online information and assisting clients with evaluation of online information. That is, 51% of the nurses assessing also assisted with evaluation compared to 16% of nonassessing nurses (p. 1354).

Discovery/Problem Solving

In using the discovery/problem-solving technique, the nurse presents some initial information and then asks the learners a question or presents a situation related to the information. The learner applies

the new information to the situation and decides what to do. Learners can work alone or in groups. This technique is well suited to family learning. The teacher guides the learners through the thinking process necessary to reach the best solution to the question or the best action to take in the situation. This may also be referred to as *anticipatory problem solving*. For example, the nurse educator might present information on diabetes and glucose management. Then the nurse might ask the learners how they think their insulin and/or diet should be adjusted if their morning glucose was too low. In this way, clients learn what critical components they need to consider to reach the best solution to the problem.

Behavior Modification

The behavior modification system for changing behavior has as its basic assumptions (a) that human behaviors are learned and can be selectively strengthened, weakened, eliminated, or replaced; and (b) that a person's behavior is under conscious control. Under this system, desirable behavior is rewarded and undesirable behavior is ignored. The client's response is the key to behavior change. For example, clients trying to quit smoking are not criticized when they smoke, but they are praised or rewarded when they go without a cigarette for a certain period of time. For some people, a learning contract is combined with behavior modification and includes the following pertinent features:

- Positive reinforcement (e.g., praise) is used.
- The client participates in the development of the learning plan.
- Undesirable behavior is ignored, not criticized.
- The expectation of the client and the nurse is that the task will be mastered (i.e., the behavior will change).

Transcultural Teaching

The nurse and clients of different cultural and ethnic backgrounds have additional barriers to overcome in the teaching-learning process. These barriers include language and communication challenges, differing concepts of time, conflicting cultural healing practices, beliefs that may positively or negatively influence compliance with health teaching, and unique high-risk or high-frequency health problems that can be addressed with health promotion instruction (see Chapter 16 ∞). Nurses should consider the following guidelines when teaching clients from various ethnic backgrounds:

- **Obtain teaching materials, pamphlets, and instructions in languages used by clients.** Nurses who are unable to read the foreign language material for themselves can have the translator read the material to them. The nurse can then evaluate the quality of the information and update it with the translator's help as needed.
- **Use visual aids, such as pictures, charts, or diagrams, to communicate meaning.** Audiovisual material may be helpful if the English is spoken clearly and slowly. Even if understanding the verbal message is a problem for the client, seeing a skill or procedure may be helpful. In some instances, a translator can be asked to clarify the video. Alternatively, the video may be available in several languages, and the nurse can request the necessary version from the company.
- **Use concrete rather than abstract words.** Use simple language (short sentences, short words), and present only one idea at a time.
- **Allow time for questions.** This helps the client mentally separate one idea or skill from another.

- **Avoid the use of medical terminology or health care language**, such as “taking your vital signs” or “apical pulse.” Rather, nurses should say they are going to take a blood pressure or listen to the client’s heart.
- **If understanding another’s pronunciation is a problem, validate brief information in writing.** For example, during assessments, write down numbers, words, or phrases and have the client read them to verify accuracy.
- **Use humor very cautiously.** Meaning can change in the translation process.
- **Do not use slang words or colloquialisms.** These may be interpreted literally.
- **Do not assume that a client who nods, uses eye contact, or smiles is indicating an understanding of what is being taught.** These responses may simply be the client’s way of indicating respect. The client may feel that asking the nurse questions or stating a lack of understanding is inappropriate because it might embarrass the nurse or cause the nurse to “lose face.”
- **Invite and encourage questions during teaching.** Let clients know they are urged to ask questions and be involved in making information clearer. When asking questions to evaluate client understanding, avoid asking negative questions, which can be interpreted differently by people for whom English is a second language. “Do you understand how far you can bend your hip after surgery?” is better than the negative question “You don’t understand how far you can bend your hip after surgery, do you?” Even better, is the question, “What do you remember about how far you can bend your hip after surgery?” With particularly difficult information or skills teaching, the nurse might say, “This is a lot of information. Can I please review the key points one more time?” In some cultures, expressing a need is not appropriate, and expressing confusion or asking to be shown something again is considered rude.
- **When explaining procedures or functioning related to personal areas of the body, it may be appropriate to have a nurse of the same gender do the teaching.** Because of modesty concerns in many cultures and beliefs about what is considered appropriate and inappropriate male–female interaction, it is wise to have a female nurse teach a female client about personal care, birth control, sexually transmitted infections, and other potentially sensitive areas. If a translator is needed during explanation of procedures or teaching, the translator should also be female.
- **Include the family in planning and teaching. This promotes trust and mutual respect.** Identify the authoritative family member and incorporate that person into the planning and teaching to promote compliance and support of health teaching. In some cultures, the male head of household is the critical family member to include in health teaching; in other cultures, it is the eldest female member (see Culturally Responsive Care).
- **Consider the client’s time orientation.** The client may be more oriented to the present than the nurse. Cultures with a predominant orientation to the present include the Mexican American, Navajo Native American, Appalachian, Eskimo, and Filipino American cultures. Preventing future problems may be less significant for these clients than for others, so teaching prevention may be more difficult. For example, teaching a client why and when to take medications may be more difficult if the client is oriented to the present. In such instances, the nurse can emphasize

Culturally Responsive Care

PATIENT-CENTERED CARE

Examples of Cultures That Value Family Inclusion in Client Teaching

HISPANIC/LATINO AMERICANS

- Because of the value of family, it is important for the nurse to direct teaching to include all interested family members. Hispanic families provide support to each other and decisions are usually made by the male and older members of the family.
- Ensure adequate physical space when teaching to allow room for all of the family members who may accompany the client seeking health information and care.

BLACK/AFRICAN AMERICANS

- The family structure has traditionally been matriarchal.
- It is important to recognize the central role that women have in decision making and to share health information with them.
- Grandmothers often have an essential role in the family and may be involved in support and care of their grandchildren.

ASIAN/PACIFIC ISLANDERS

- Decision making is often a family matter. Therefore, it is important to include the family, especially the male authority figure, in the process of decision making for a situation.
- Respect is automatically given to health care professionals because they are viewed as knowledgeable.
- Asians often want to “save face” for themselves and others. As a result, they may agree to what is being said or nod their heads in agreement to avoid being considered offensive or disruptive by disagreeing with the nurse or physician. They may need to be given permission to ask questions. Care must also be taken to not interpret nods as gestures of informed consent.

Adapted from *Client Education: Theory and Practice*, by M. A. Miller and P. R. Stoeckel, 2011, Boston, MA: Jones & Bartlett; and *Cultural Competencies for Nurses: Impact on Health and Illness* (2nd ed.), by L. Dayer-Berenson, 2014, Burlington, MA: Jones & Bartlett.

preventing short-term problems rather than long-term problems. Failure to keep clinic appointments or to arrive on time is common in clients who have a present-time orientation. The nurse can help by accommodating these clients when they arrive for their appointment.

Schedules may be very flexible in present-oriented societies, with sleeping and eating patterns varying greatly. Teaching clients to take medications at bedtime or with a meal does not necessarily mean that these activities will occur at the same time each day. For this reason, the nurse should assess the client’s daily routine before teaching the client to pair a treatment or medication with an event the nurse assumes occurs at the same time every day. When teaching a client when to take medication, the nurse should determine whether a clock or watch is available to the client and whether the client can tell time.

- **Identify cultural health practices and beliefs.** Nonadherence with health teaching may be related to conflict with folk medicine beliefs. It may also be related to lack of understanding or fatalism, a belief system in which life events are held to be predestined or fixed in advance and the individual is powerless to change them. To encourage adherence, the nurse needs to learn the client’s explanation of why the illness developed and how it might be treated.

The nurse should treat the client’s cultural healing beliefs with respect and identify whether any are in agreement or in conflict with

what is being taught. The nurse can then focus on the ones in agreement to promote the integration of new learning with the familiar health practices. The goal is to arrive at a mutually agreeable plan: Decide which instructions must be followed for client safety and negotiate less crucial folk healing practices.

Evaluating

Evaluating is both an ongoing and a final process in which the client, the nurse, and often the support people determine what has been learned.

Evaluating Learning

The process of evaluating learning is the same as evaluating client achievement of desired outcomes for other nursing diagnoses. Learning is measured against the predetermined learning outcomes selected in the planning phase of the teaching process. Thus the outcomes serve not only to direct the teaching plan but also to provide outcome criteria for evaluation. For example, the outcome “Selects foods that are low in carbohydrates” can be evaluated by asking the client to name such foods or to select low-carbohydrate foods from a list.

The best method for evaluating depends on the type of learning. In *cognitive learning*, the client demonstrates acquisition of knowledge. Examples of the evaluation tools for cognitive learning include the following:

- Direct observation of behavior (e.g., observing the client selecting the solution to a problem using the new knowledge)
- Written measurements (e.g., tests)
- Oral questioning (e.g., asking the client to restate information or correct verbal responses to questions)
- Self-reports and self-monitoring. These can be useful during follow-up phone calls and home visits. Evaluating individual self-paced learning, as might occur with computer instruction, often incorporates self-monitoring.

The acquisition of *psychomotor skills* is best evaluated by observing how well the client carries out a procedure such as self-administration of insulin.

Affective learning is more difficult to evaluate. Whether attitudes or values have been learned may be inferred by listening to the client's responses to questions, noting how the client speaks about relevant subjects, and observing the client's behavior that expresses feelings and values. For example, have parents learned to value health sufficiently to have their children immunized? Do clients who state that they value health actually use condoms every time they have sex with a new partner?

Following evaluation, the nurse may find it necessary to modify or repeat the teaching plan if the objectives have not been met or have been met only partially. Follow-up teaching in the home or by phone may be needed for the client discharged from a health facility.

Behavior change does not always take place immediately after learning. Often individuals accept change intellectually first and then change their behavior only periodically (for example, a client knows that she must lose weight, but diets and exercises off and on). If the new behavior is to replace the old behavior, it must emerge gradually; otherwise, the old behavior may prevail. The nurse can assist clients with behavior change by allowing for client vacillation and by providing encouragement.

Evaluating Teaching

It is important for nurses to evaluate their own teaching and the content of the teaching program just as they evaluate the effectiveness of nursing interventions for other nursing diagnoses. Evaluation should include a consideration of all factors—the timing, the teaching strategies, the amount of information, whether the teaching was helpful, and so on. The nurse may find, for example, that the client was overwhelmed with too much information, was bored, or was motivated to learn more.

Both the client and the nurse should evaluate the learning experience. The client may tell the nurse what was helpful, interesting, and so on. Feedback questionnaires and videotapes of the learning sessions can also be helpful.

The nurse should not feel ineffective as a teacher if the client forgets some of what is taught. Forgetting is normal and should be anticipated. Having the client write down information, repeating it during teaching, giving handouts on the information, and having the client be active in the learning process all promote retention.

Documenting

Documentation of the teaching process is essential because it provides a legal record that the teaching took place and communicates the teaching to other health professionals. If teaching is not documented, legally it did not occur.

It is also important to document the responses of the client and support people to teaching activities. What did the client or support person say or do to indicate that learning occurred? Has the client demonstrated mastery of a skill or the acquisition of knowledge? The nurse records this in the client's chart as evidence of learning. A sample documentation of charting follows:

6/8/2015 1130 Learning to use glucometer to check her own capillary blood glucose levels. Noted a slight hesitation with each step. Demonstrated correct technique. Stated that she is “feeling more comfortable” each time she does it but still “needs to stop and think about the process.” Will continue to monitor client's progress. _____ S. Brown, RN

Many agencies have multiple-copy client teaching forms that include the medical and nursing diagnoses, the treatment plan, and the client education. After the teaching session is completed, the client and the nurse sign the form and a copy of the form is given to the client as a record of teaching and as reinforcement of the content taught. A second copy of the completed and signed form is placed in the client's chart. The parts of the teaching process that should be documented in the client's chart include the following:

- Diagnosed learning needs
- Learning outcomes
- Topics taught
- Client outcomes
- Need for additional teaching
- Resources provided.

The written teaching plan that the nurse uses as a resource to guide future teaching sessions might also include these elements:

- Actual information and skills taught
- Teaching strategies used
- Time framework and content for each class
- Teaching outcomes and methods of evaluation.

Critical Thinking Checkpoint

Mrs. Yorty is a 59-year-old African American bank vice president who is heavily relied on by her boss and coworkers. Three days ago she was admitted to the hospital with complaints of shortness of breath and mild chest pain. A diagnostic evaluation indicates that she has significant coronary artery disease but has not yet suffered a heart attack. Her primary care provider has indicated that Mrs. Yorty will need to make significant lifestyle changes to reduce her heart attack risk. As her nurse, you have been requested to teach Mrs. Yorty about her disease process, diet, exercise, and stress reduction. As you begin teaching Mrs. Yorty, you note that she is very pleasant and frequently nods her head, but she also seems preoccupied and is readily distracted.

1. How would you evaluate Mrs. Yorty's readiness to learn?
2. Of what benefit would a learning needs assessment be since Mrs. Yorty is obviously a well-educated client?
3. You recognize that you have a great deal of information to deliver to Mrs. Yorty and you are concerned that you will not be able to teach it all. What can you do to help Mrs. Yorty and still accomplish the learning outcomes?
4. How will you know if your teaching is effective?
5. How might your teaching differ if you were teaching Mrs. Yorty at home rather than in a hospital or acute care setting?

See Critical Thinking Possibilities on student resource website.

Chapter 27 Review

CHAPTER HIGHLIGHTS

- Teaching clients and families about their health needs is a major role of the nurse. Nurses also teach colleagues, subordinates, nursing and other health care students, and groups in community education programs.
- Learning is represented by a change in behavior.
- Bloom identified three learning domains: cognitive, affective, and psychomotor.
- Three main theories of learning are behaviorism, cognitivism, and humanism.
- A number of factors affect learning, including age and developmental stage, motivation, readiness, active involvement, relevance, feedback, nonjudgmental support, simple to complex learning, repetition, timing, environment, emotions, physiological events, cultural aspects, and psychomotor ability.
- Many adults in the United States use the Internet to access health information. Nurses need to know and integrate this technology into their teaching plans.
- Low health literacy is a silent epidemic. It is associated with poor health outcomes and higher health care costs. Using the “teach

back” technique helps the nurse assess the client's understanding of what was taught.

- Teaching, like the nursing process, consists of six activities: assessing the learner, diagnosing learning needs, developing a teaching plan, implementing the plan, evaluating learning outcomes and teaching effectiveness, and documenting instructional activities.
- Teaching strategies chosen by the nurse should be suited to the client and to the material to be learned.
- A teaching plan is a written plan consisting of learning outcomes, content to teach, and strategies to use in teaching the content. The plan must be revised when the client's needs change or the teaching strategies prove ineffective.
- Evaluating the teaching–learning process is both an ongoing and a final process in which the client, nurse, and support people determine what has been learned.
- Documentation of client teaching is essential to communicate the teaching to other health professionals and to provide a record for legal purposes.

TEST YOUR KNOWLEDGE

1. Which learning activity reflects Bloom's affective domain?
 1. Administering an injection
 2. Accepting the loss of a limb
 3. Inserting a catheter
 4. Learning how to read
2. Which is the best method of helping a client newly diagnosed with diabetes to learn the dietary requirements associated with the disease?
 1. Provide a videotape that addresses the dietary requirements associated with the disease.
 2. Ask a nutritionist to visit the client to present information and handouts about the diabetic diet.
 3. Ask the client to make a list of her favorite foods and how to work them into her diet.
 4. Have the client attend a group meeting for clients with diabetes to discuss their adaptation to this chronic health condition.

3. A nurse is scheduling a teaching situation. Which client is most ready to learn?
 1. A 45-year-old man whose health care provider has just informed him that he has cancer
 2. A 3-year-old child whose parents are reading a storybook about going to the hospital
 3. A 60-year-old female who received medication 5 minutes ago for relief of abdominal pain
 4. A 70-year-old man, recovering from a stroke who has returned from physical therapy
4. How can the nurse best assess a client's style of learning?
 1. Ask the client how he or she learns best.
 2. Use a variety of teaching strategies.
 3. Observe the client's interactions with others.
 4. Ask family members.
5. A 74-year-old client who takes multiple medications tells the nurse, "I have no idea what that little yellow pill is for." What is the best nursing diagnosis for this client?
 1. *Deficient Knowledge*
 2. *Health-Seeking Behavior*
 3. *Deficient Knowledge (Medication Information)*
 4. *Noncompliance*
6. A client is scheduled to have a diagnostic procedure. Which questions by the nurse will most likely produce a "teachable moment"? Select all that apply.
 1. "Have you ever had this procedure before?"
 2. "What are your concerns about this procedure?"
 3. "What would you like to know about the procedure?"
 4. "Are you prepared for this procedure?"
 5. "What have you heard or read about the procedure?"
7. A client needs to learn to self-administer insulin injections. Which statements reflect possible low literacy skills? Select all that apply.
 1. "I will read the information later—I'm too tired right now."
 2. "I've watched my brother give his own shots. I know how to do it."
 3. "Just show my wife."
 4. "Do you have a video showing how I should give myself the shot?"
 5. "I don't understand this one section in the handout."
8. A primary care provider admitted a client experiencing hypertensive crisis because of the failure to take his prescribed medications. To determine learning needs, which client assessment by the nurse would have the highest priority?
 1. Age
 2. Perception of the effects of hypertension
 3. Ability to purchase needed medications
 4. Support system
9. A client has a learning outcome of "Select foods that are low in fat content." Which statement reflects that the client has met this learning outcome?
 1. "I understand the importance of maintaining a low-fat diet."
 2. "I feel better about myself now."
 3. "See how I revised my favorite recipe to be lower in fat."
 4. "Since changing my diet, my husband is also losing weight."
10. A client's learning outcome is "Client will verbalize medication name, purpose, and appropriate precautions." Which documented statement reflects evidence of learning?
 1. Taught name, purpose, and precautions for the new cardiac medication; seemed to understand.
 2. Written information about the medication provided and reviewed; correct responses were given to follow-up questions.
 3. Written information read to client; stated he would read it when he got home.
 4. Asked questions about the new cardiac medication; satisfied with the information.

28 Leading, Managing, and Delegating

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Compare and contrast leadership and management.
2. Compare and contrast different leadership styles.
3. Identify characteristics of an effective leader.
4. Compare and contrast the levels of management.
5. Describe the four functions of management.
6. Discuss the roles and functions of nurse managers.
7. Identify the skills and competencies needed by a nurse manager.
8. Describe the characteristics of tasks appropriate to delegate to unlicensed and licensed assistive personnel.
9. List the five rights of delegation.
10. Describe the role of the leader/manager in planning for and implementing change.

KEY TERMS

INTRODUCTION

Although aspects of the individual nurse's role vary according to practice location and type, leadership, management, delegation, and change are consistent aspects of the role. Nurses function within health care systems, working with multiple clients and other health care providers. As a part of multidisciplinary teams, the nurse is often in a leadership position and frequently delegates aspects of care to others. There are opportunities in nursing to become leaders at various levels and also many situations in which the nurse functions as a manager and as a change agent.

THE NURSE AS LEADER AND MANAGER

The professional nurse frequently assumes the roles of leader and manager. These two roles are linked; that is, managers must have leadership abilities, and leaders often manage, but the two roles differ.

A **leader** influences others to work together to accomplish a specific goal. Leaders are often visionary; they are informed, articulate, confident, and self-aware. Leaders also usually have outstanding interpersonal skills and are excellent listeners and communicators. They have initiative and the ability and confidence to innovate change, motivate, facilitate, and mentor others. Within their organizations, nurse leaders participate in and guide teams that assess the effectiveness of care, implement evidence-based practice, and construct process improvement strategies. They may be employed in a variety of positions—from shift team leader to institutional president.

462

Leaders may also hold volunteer positions such as chairperson of a professional organization or a community board of directors.

A **manager** is an employee of an organization who is given authority, power, and responsibility for planning, organizing, coordinating, and directing the work of others, and for establishing and evaluating standards. Managers understand organizational structure and culture. They control human, financial, and material resources. Managers set goals, make decisions, and solve problems. They initiate and implement change.

Nurses are responsible for managing client care. Some nurses assume a position within the organization as unit manager, supervisor, or executive. As a manager, the nurse is responsible for (a) efficiently accomplishing the goals of the organization, (b) efficiently using the organization's resources, (c) ensuring effective client care, and (d) ensuring compliance with institutional, professional, regulatory, and governmental standards. Managers are also responsible for development of licensed and unlicensed personnel within their work group. Table 28-1 further compares the leader and manager roles. Figure 28-1 ■ illustrates some of the leading and managing roles.

LEADERSHIP

Leadership may be formal or informal. The **formal leader**, or appointed leader, is selected by an organization and given official authority to make decisions and act. An **informal leader** is not officially appointed to direct the activities of others, but because of

TABLE 28-1 Comparison of Leader and Manager Roles

Leaders	Managers
May or may not be officially appointed to the position	Are appointed officially to the position
Have power and authority to enforce decisions only as long as followers are willing to be led	Have power and authority to enforce decisions
Influence others toward goal setting, either formally or informally	Carry out predetermined policies, rules, and regulations
Are interested in risk taking and exploring new ideas	Maintain an orderly, controlled, rational, and equitable structure
Relate to people personally in an intuitive and empathetic manner	Relate to people according to their roles
Feel rewarded by personal achievements	Feel rewarded when fulfilling organizational mission or goals
May or may not be successful as managers	Are managers as long as the appointment holds
Manage relationships	Manage resources
Focus on people	Focus on systems

Figure 28-1 ■ Nurses as leaders and managers: A, The nurse manager discusses work assignments during change-of-shift report. seniority, age, or special abilities is recognized by the group as its leader, and plays an important role in influencing colleagues, co-workers, or other group members to achieve the group’s goals.

Leadership Theory

Early leadership theories focused on what leaders are (trait theories), what leaders do (behavioral theories), and how leaders adapt their leadership style according to the situation (contingency theories). Theories about **leadership style** describe traits, behaviors, motivations, and choices used by individuals to effectively influence others.

CLASSIC LEADERSHIP THEORIES

The trait theorists found that leaders often possess specific qualities and abilities including good judgment, decisiveness, knowledge, adaptability, integrity, tact, self-confidence, and cooperativeness. The behaviorists believed that through education, training, and life experiences, leaders develop a particular leadership style. These styles have been characterized as autocratic, democratic, laissez-faire, and bureaucratic.

An **autocratic (authoritarian) leader** makes decisions for the group. The leader believes individuals are externally motivated (their driving force is extrinsic, they desire rewards from others) and are incapable of independent decision making. Likened to a dictator, the autocratic leader determines policies, giving orders and directions to the group. Under this leadership style, the group may feel secure because procedures are well defined and activities are predictable. Productivity may also be high. However, the group’s needs for creativity, autonomy, and self-motivation are not met, and the degree of openness and trust between the leader and the group members is minimal or absent. Members are often dissatisfied with this leadership style; however, at times an autocratic style is the most effective.

When urgent decisions are necessary (e.g., a cardiac arrest, a unit fire, or a terrorist attack), one person must assume the responsibility for making decisions without being challenged by other team members. When group members are unable to or do not wish to participate in making a decision, the authoritarian style solves the problem and enables the individual or group to move on. This style can also be effective when a project must be completed quickly and efficiently.

A **democratic leader** encourages group discussion and decision making. This type of leader acts as a catalyst or facilitator, actively

guiding a group toward achieving the group’s goals. Group productivity and satisfaction are high as group members contribute to the work effort. The democratic leader assumes individuals are internally motivated (their driving force is intrinsic, they desire self-satisfaction), are capable of making decisions, and value independence. Providing constructive feedback, offering information, making suggestions, and asking questions become the focus of the democratic leader. This leadership style demands that the leader have faith in the group members to accomplish the goals. Although democratic leadership has been shown to be less efficient and more cumbersome than authoritarian leadership, it allows for more self-motivation and more creativity among group members. It also calls for a great deal of cooperation and coordination among group members. This leadership style can be extremely effective in the health care setting.

The **laissez-faire (permissive) leader** recognizes the group’s need for autonomy and self-regulation. The leader assumes a “hands-off” approach. The leader presupposes the group is internally motivated. However, group members may act independently and at opposing purposes because of a lack of cooperation and coordination. A laissez-faire style is most effective for groups whose members have both personal and professional maturity. When the group has made a decision, the members become committed to it. Individual group members then perform tasks in their area of expertise while the leader acts as resource person.

The **bureaucratic leader** does not trust self or others to make decisions. Instead, this type of leader relies on the organization’s rules, policies, and procedures to direct the group’s work efforts. Group members are usually dissatisfied with the leader’s inflexibility and impersonal relations with them. Table 28–2 compares the autocratic, democratic, laissez-faire, and bureaucratic leadership styles.

According to contingency theorists, effective leaders adapt their leadership style to the situation. A popular contingency theory describes the situational leader. The **situational leader** (a) flexes task and relationship behaviors, (b) considers the staff members’ abilities, (c) knows the nature of the task to be done, and (d) is sensitive to the context or environment in which the task takes place. The task-orientation focuses the leader on activities that encourage group productivity to get the work done. The relationship-orientation style is concerned with interpersonal relationships and focuses on activities that meet group members’ needs.

Situational leaders adapt their leadership style to the readiness and willingness of the individual or group to perform the assigned task. When employees are insecure, or unable or unwilling to perform

the task, the leader uses a highly directive style, providing specific instructions and close supervision. If the group is motivated and willing but unable to perform the task, the leader again uses a highly directive style, but in this case, explains decisions and provides the opportunity for clarification. When the group is able but unwilling or lacking in confidence, the leader shares ideas and facilitates decision making. For a group that is willing, able, and confident to perform the task, the leader delegates, turning responsibility for decision making and implementation over to the group.

CONTEMPORARY LEADERSHIP THEORIES

Contemporary theorists have described charismatic leaders, transactional leaders, transformational leaders, and shared leadership.

A **charismatic leader** is rare and is characterized by having an emotional relationship with the group members. The charming personality of the leader evokes strong feelings of commitment to both the leader and the leader’s cause and beliefs. When this type of nurse leader speaks to a group, nurses feel inspired and motivated to do whatever they can to meet the leader’s expectations. The followers of a charismatic leader often overcome extreme hardship to achieve the group’s goals because of faith in the leader.

The **transactional leader** has a relationship with followers based on an exchange for some resource valued by the follower. These incentives are used to promote loyalty and performance. For example, to ensure adequate staffing on the night shift, the nurse manager entices a staff nurse to work the night shift in exchange for a weekend shift off. The transactional leader represents the traditional manager, focused on the day-to-day tasks of achieving organizational goals, and understanding and meeting the needs of the group.

In contrast, a **transformational leader** fosters creativity, risk taking, commitment, and collaboration by empowering the group to share in the organization’s vision. The leader inspires others with a clear, attractive, and attainable goal and enlists the group to participate in attaining the goal. The group is empowered because members and leader share values, honesty, trust, and continual learning. Independence, individual growth, and change are facilitated. For example, the nurses working with this type of leader to implement a major change in the model of nursing care delivered to a group of clients will each accept responsibility for a segment of the project, keep all members informed of their progress, and consider the impact of their actions on the larger group. One subtype of transformational leadership is servant leadership, based on the concept that leaders serve their constituencies. Members of an organization act as both servants and leaders

TABLE 28–2 Comparison of Autocratic, Democratic, Laissez-Faire, and Bureaucratic Leadership Styles

	Autocratic	Democratic	Laissez-Faire	Bureaucratic
Degree of control	Makes decisions alone	Collaborative	No control	Strict reliance on policy
Leader activity level	High	High	Minimal	High
Assumption of responsibility	Primarily the leader	Shared	Relinquished	Leader
Output of the group	High quantity, good quality	Creative, high quality	Variable, may be of poor quality	Good quality through following standard procedures
Efficiency	Very efficient	Less efficient than autocratic	Inefficient	Efficient

Evidence-Based Practice What Does It Take To Be an Authentic Nurse Leader?

EVIDENCE-BASED PRACTICE

The purpose of this qualitative study by Murphy (2012) was to explore the experiences of hospital chief nurse executives in becoming and remaining authentic nurse leaders. The research question was “What can the life stories of hospital nurse executives tell us about the development of authentic nurse leaders and the challenges to sustained authenticity?” Two themes emerged about how the study participants maintained their authenticity and authentic leadership: (1) the importance of values and (2) having the moral courage to do the right thing. Both themes included emphasis on keeping the client at the center of the nurse leaders’ concerns. This helped them to stay the course as authentic leaders despite pressures to take an easier path. This is sometimes referred to as having a clear moral compass guiding them to their “true north.”

IMPLICATIONS

The small sample size in this study (three) does not negate the value of the findings. A major implication of this research for nurse leaders is the critical importance of not allowing decisions about cost containment and efficiency to cause a loss of focus on core values of quality client care. Nurses who can keep their balance in making these decisions and stay focused on key priorities and core values are the ones most likely to become and remain authentic nurse leaders. They are the ones who can be trusted to act with courage and integrity when the tough decisions must be made.

within a work environment of mutual respect, trust, and collaboration. As is true in many situations, servant leadership can be effectively demonstrated by both formal and informal leaders (Mahon, 2011). In nursing, this concept is internally consistent with a focus on caring.

Shared leadership recognizes that a professional workforce is made up of many leaders. No one person is considered to have knowledge or ability beyond that of other members of the work group. Appropriate leadership is thought to emerge in relation to the challenges that confront the work group. Examples of shared leadership in nursing are self-directed work teams, coleadership, and shared governance. **Shared governance** is a method that aims to distribute decision making among a group of people. It provides structure by articulating a mechanism for advocacy and influence of the staff nurse through all levels of nursing. It empowers ownership of quality nursing practice and influences the work environment and administrative functions (Rheingans, 2012).

Effective Leadership

Much has been written about effective leadership and style; some descriptive statements about effective leaders are listed in Box 28–1. Leadership is a learned process. To be an effective leader requires an

understanding of factors such as the needs, goals, and rewards that motivate people; knowledge of leadership skills and of the group’s activities; and possession of the interpersonal skills to influence others. Principles of effective leadership include vision, influence, and acting as a role model.

Vision is a mental image of a possible and desirable future state. Leaders transform visions into realistic goals and communicate their visions to others who accept them as their own.

Influence is an informal strategy used to gain the cooperation of others without exercising formal authority. Influence is exercised through persuasion and excellent communication skills; it is based on a trusting relationship with the followers.

An effective leader needs to show sensitivity to being a positive **role model**, someone who sets the example for others to follow. As is appropriate for any health and caring profession, leadership should also be humanistic; that is, leaders should act in ways that stress individuals’ dignity and worth. Being a good leader takes thought, care, insight, commitment, and energy. The leader demonstrates caring toward coworkers and clients.

MANAGEMENT

The manager’s job is to accomplish the work of the organization. To this end, managers perform roles and functions that vary with the type of organization and the level of management.

Levels of Management

Traditional management is divided into three levels of responsibility. The reporting relationship among staff and managers is often referred to as the chain of command. **First-level managers** are responsible for managing the work of nonmanagerial personnel and the day-to-day activities of a specific work group or groups. Their primary responsibility is to motivate staff to achieve the organization’s goals. This level of manager communicates staff issues to upper administration and reports administrative messages back to staff. Titles may include primary care nurse, team leader, or charge nurse.

Middle-level managers supervise a number of first-level managers and are responsible for the activities in the departments they supervise. Middle-level managers serve as liaisons between first-level managers and upper-level managers. They may be called supervisors, nurse managers, or head nurses.

Upper-level (top-level) managers are organizational executives who are primarily responsible for establishing goals and

BOX 28–1 Characteristics of Effective Leaders

Effective leaders:

- Use a leadership style that is natural to them.
- Use a leadership style appropriate to the task and the members.
- Assess the effects of their behavior on others and the effects of others’ behavior on themselves.
- Are sensitive to forces acting for and against change.
- Express an optimistic view about human nature.
- Are energetic.
- Are open and encourage openness, so that real issues are confronted.
- Facilitate personal relationships.
- Plan and organize activities of the group.
- Are consistent in behavior toward group members.
- Delegate tasks and responsibilities to develop members’ abilities, not merely to get tasks performed.
- Involve members in all decisions.
- Value and use group members’ contributions.
- Encourage creativity.
- Encourage feedback about their leadership style.
- Assess for and promote use of current technology.

developing strategic plans. Nurse executives are registered nurses who are responsible for the management of nursing within the organization and the practice of nursing. Some nurse executives are also responsible for auxiliary units such as the pharmacy, laboratory, and dietary departments. Nurses in these positions may be called vice president for client care services, vice president for nursing, director of nursing, or chief nurse.

CLINICAL ALERT!

Nurses generally move from first- to middle- to upper-level management positions through promotion. In addition, nursing administration graduate academic programs are available at some nursing schools.

Management Functions

Four management functions are planning, organizing, directing, and coordinating. These four functions help to achieve the broad goal of quality client care.

PLANNING

Planning is an ongoing process that involves (a) assessing a situation, (b) establishing goals and objectives based on assessment of a situation or future trends, and (c) developing a plan of action that identifies priorities, delineates who is responsible, determines deadlines, and describes how the intended outcome is to be achieved and evaluated. In short, it involves deciding what, when, where, and how to do it, by whom, and with what resources. Distribution of money, personnel, equipment, and physical space are included in the planning for resource allocation. An upper-level manager spends considerable time planning goals and services, determining numbers and types of nurses and other personnel needed to provide these services. On the other hand, a first-level manager such as a staff nurse spends less time planning but manages individual clients by use of the nursing process.

An example of the planning function is **risk management**, having in place a system to reduce danger to clients and staff. The steps of risk management include anticipating and seeking sources of risk; analyzing, classifying, and prioritizing risks; developing a plan to avoid and manage risk; gathering data that indicate success at avoiding or minimizing risk; and evaluating and modifying risk reduction programs. Central to the process of risk management is communication among all involved individuals.

ORGANIZING

Organizing is also an ongoing process of coordinating work. After identifying the work and evaluating human and material resources, the manager arranges the work into smaller units. Organizing involves determining responsibilities, communicating expectations, and establishing the chain of command for authority and communication. Although upper-level managers delegate much of the work and responsibility and accountability for the work to others, they need to ensure that department objectives, priorities, job descriptions, lines of communication, nursing standards, procedures, and policies clearly describe the expectations.

DIRECTING

Directing is the process of getting the organization's work accomplished. Directing involves assigning and communicating expectations about the task to be completed, providing instruction and guidance,

and ongoing decision making. Upper-level managers devote less time to directing than to planning, organizing, and controlling. Directing at this level of management generally involves supervision of the next level of managers such as those in middle management. Unit managers (charge nurses) and staff nurses devote more time to directing. For example, charge nurses direct shift work by assigning clients and scheduling meal and break times. Staff nurses direct the care of clients by ordering nursing care, communicating care in written care plans and shift reports, and supervising care that is given by others.

COORDINATING

Coordinating is the process of ensuring that plans are carried out and evaluating outcomes. The manager measures results or actions against standards or desired outcomes and then reinforces effective actions or changes ineffective ones. For example, an upper-level manager evaluates the effectiveness of recruitment, staff turnover, and budget performance. The charge nurse appraises staff performance. The staff nurse determines whether nursing interventions have helped the client achieve desired outcomes.

Principles of Management

A manager has authority, accountability, and responsibility. **Authority** is defined as the legitimate right to direct the work of others. It is an integral component of managing. Authority is conveyed through leadership actions; it is determined largely by the situation, and it is always associated with responsibility and accountability. The manager must accept the authority granted.

Accountability is the ability and willingness to assume ownership for one's actions and to accept the consequences of one's behavior. Accountability can be viewed as hierarchic, starting at the individual level, then the institutional or professional level, and finally the societal level. At the individual or client level, accountability is reflected in the nurse's ethical integrity. At the institutional level, it is reflected in the statement of philosophy and objectives of the nursing department and nursing audits. At the professional level, it is reflected in standards of practice developed by national nursing associations. At the societal level, it is reflected in legislated nurse practice acts.

Responsibility is an obligation to perform a task. Managers are responsible for effective utilization of resources, communication to subordinates, and implementation of organizational goals and objectives. Responsibility for nursing actions can be transferred to another practitioner but accountability is always shared (Sullivan, 2013).

Skills and Competencies of Nurse Managers

To be effective managers, nurses need to think critically, communicate well, manage resources effectively and efficiently, enhance employee performance, build and manage teams, manage conflict, manage time, and initiate and manage change. Change is discussed on pages 471–472.

CRITICAL THINKING

Critical thinking is a creative cognitive process that includes problem solving and decision making. The nurse manager reasons with logic and explores assumptions, alternatives, and the consequences of actions. See Chapter 10  for further discussion of critical thinking.

COMMUNICATING

Managers report spending much of their day communicating. Good communication is essential and often determines the manager's success. Managers use both verbal and written communication. Effective managers communicate assertively, expressing their ideas clearly, accurately, and honestly.

Managers use **networking**, a process whereby professional links are established through which people can share ideas, knowledge, and information; offer support and direction to each other; and facilitate accomplishment of professional goals.

MANAGING RESOURCES

One of the greatest responsibilities of managers is their accountability for human, fiscal, and material resources. Budgeting and determining variances between the actual and budgeted expenses are crucial skills for any manager.

ENHANCING EMPLOYEE PERFORMANCE

Several ways of enhancing employee performance are available to managers. Managers are responsible for ensuring that employees develop by providing appropriate learning opportunities, such as in-service education; by facilitating attendance at professional workshops and conventions; and by encouraging achievement of advanced education such as higher degrees or certifications. The nurse manager who empowers the staff by providing information, support, resources, and opportunities to participate will find that employees have greater commitment to the institution, are more effective in their role, have increased self-esteem, and are better able to meet their goals.

In addition, the manager may provide day-to-day coaching or serve as a mentor or preceptor. A **mentor** “is a wiser and more experienced person who guides, supports, and nurtures a less experienced person” (Sullivan, 2013, p. 233). Having a mentor is recognized as important for career development.

In the clinical area, the term **preceptor** is used to describe an experienced nurse who assists the “new” nurse in improving clinical nursing skill and judgment. The preceptor also instills understanding of the routines, policies, and procedures of the institution and the unit.

BUILDING AND MANAGING TEAMS

In addition to personnel development, managers are responsible for building and managing work teams. Familiarity with group processes facilitates a manager's ability to lead a group and enhances development of that group into a work team. Groups develop in stages, during which roles and relationships are established. The purposes of the team as a whole and the role of each member must be clear. Each member must feel that the manager and the other members recognize his or her contributions. In health care, the team may consist of any health care providers: nurses, therapists, unlicensed personnel, clergy, and so on. All members of the team need to use effective communication skills.

Evaluating the group's work is another responsibility of the manager. Effectiveness, efficiency, and productivity are three outcome measures that are frequently used. In health care, **effectiveness** is a measure of the quality or quantity of services provided. **Efficiency** is a measure of the resources used in the provision of nursing services. In nursing, **productivity** is a performance measure of both the effectiveness and efficiency of nursing care. Productivity is frequently measured by the amount of nursing resources used per client or in terms of required versus actual hours of care provided.

MANAGING CONFLICT

Nurse managers are frequently in a position to manage conflict among people, groups, or teams. The conflict may arise from differing values, philosophies, or personalities. For example, employees may have strong disagreements about whether each member of the nursing team is doing a fair share of the work. In health care, conflict can also arise due to competition for resources, especially funding for staff positions or equipment.

There are many methods the nurse can use to manage conflict and each has its advantages and disadvantages. Among the most common are compromise, negotiation, and collaboration. The new nurse manager may require training to become proficient in the use of these methods. Basic principles for all types of conflict management include demonstrating respect for all parties, avoiding blame, allowing full discussion, using ground rules during meetings to promote fairness, encouraging active listening, identifying the themes in the discussion, and exploring alternative solutions. An effective manager recognizes that, if the problem is significant to any of the individuals involved, avoiding or failing to handle the conflict is likely to result in the problem becoming larger and more difficult (Pfundt & Anderson, 2012).

MANAGING TIME

The effective nurse manager uses time effectively and assists others to do the same. Many factors inhibit good use of time such as preference for doing things the nurse likes to do before things the nurse prefers not to have to do, emergencies or crises that divert one's attention, and unrealistic demands from others. Strategies that the manager—and all nurses—can use in order to use time well involve setting goals and priorities, delegating appropriately, examining how time is used, minimizing paperwork (automating whenever possible), and using regular schedules that avoid interruptions and set time limits on activities.

THE NURSE AS DELEGATOR

Delegation is the act of transferring to a competent individual the authority to perform a selected nursing task in a selected situation (National Council of State Boards of Nursing [NCSBN], 2012). The delegate assumes responsibility for the actual performance of the task or procedure. The delegator retains accountability for the outcome. Delegation is a tool that allows the delegator to devote more time to tasks that cannot be delegated. It also enhances the skills and abilities of the delegate, which builds self-esteem, promotes morale, and enhances teamwork and attainment of the organization's goals. In nursing, delegation refers to indirect care—the intended outcome is achieved through the work of someone supervised by the nurse—and involves defining the task, determining who can perform the task, describing the expectation, seeking agreement, monitoring performance, and providing feedback to the delegate regarding performance.

Registered nurses increasingly delegate components of nursing care to other health care workers, especially unlicensed assistive personnel (UAP). An RN who delegates a task to another health care worker is accountable for selecting an appropriately skilled caregiver and for continued evaluation of the client's care. These “nurse extenders” may be identified by a variety of titles including certified nursing aides/assistants, home health aides, medication assistants, patient care technicians, orderlies, or surgical technicians. They have had diverse degrees of training and experience. They are employees and do not include family members or friends who provide some client care.

Each state nurse practice act specifies which actions constitute the legal practice of nursing, which actions are the purview only of nurses, and which may be delegated to others. The model state nursing practice act authored by the NCSBN (2012) states that both the registered nurse (including advanced practice nurses) and the licensed vocational/practical nurse (LVN/LPN) may delegating nursing interventions to implement the plan of care.

The NCSBN (1997) published five “rights” of delegation: The nurse delegates the *right task*, under the *right circumstances*, to the *right person*, with the *right direction and communication*, and the *right supervision and evaluation*. “The steps of the delegation process include assessment of the client, the staff and the context of the situation; communication to provide direction and opportunity for interaction during the completion of the delegated task; surveillance and monitoring to assure compliance with standards of practice, policies and procedures; and evaluation to consider the effectiveness of the delegation and whether the desired client outcome was attained” (NCSBN, 2005, p. 1).

It is not possible to generate an exhaustive list of exactly which actions can be delegated to UAP. Examples of tasks that may and may not be delegated are given in Box 28–2. A statement regarding delegation to UAP is included with the steps for each skill in this text.

The unlicensed person may not delegate tasks to another person. Principles guiding the nurse’s decision to delegate ensure the safety and quality of outcomes. These principles are listed in Box 28–3. Even if the task is one that may legally be delegated, the

individual nurse must still determine if the task can be delegated to a particular UAP for a specific client. The NCSBN has created decision trees to assist the nurse in determining if delegation is safe (Figure 28–2 ■). Once the decision has been made to delegate, the nurse must communicate clearly to the UAP and verify that the UAP understands:

- The specific tasks to be done for each client
- When each task is to be done
- The expected outcomes for each task, including parameters outside of which the unlicensed person must immediately report to the nurse (and any action that must urgently be taken)
- Who is available to serve as a resource if needed
- When and in what format (written or verbal) a report on the tasks is expected.

A specific task that can be delegated to one UAP may not be appropriate for another UAP, depending on each UAP’s experience and individual skill sets. Also, a task that is appropriate for the UAP to perform with one client may not be appropriate with a different client or the same client under altered circumstances. For example, the taking of routine vital signs may be delegated to the UAP for a client in stable condition but would not be delegated for the same client who has become unstable. It is important to note that the nurse is not held legally responsible for the acts of the unlicensed person, but is accountable for the quality of the act of delegation and has the ultimate responsibility for ensuring that proper care is provided.

BOX 28–2 Examples of Tasks That May and May Not Be Delegated to Unlicensed Assistive Personnel

TASKS THAT MAY BE DELEGATED TO UNLICENSED ASSISTIVE PERSONNEL

- Taking of vital signs
- Measuring and recording intake and output
- Client transfers and ambulation
- Postmortem care
- Bathing
- Feeding
- Gastrostomy feedings in established systems
- Attending to safety
- Weighing
- Performing simple dressing changes
- Suctioning of chronic tracheostomies
- Performing basic life support (CPR)

TASKS THAT MAY NOT BE DELEGATED TO UNLICENSED ASSISTIVE PERSONNEL

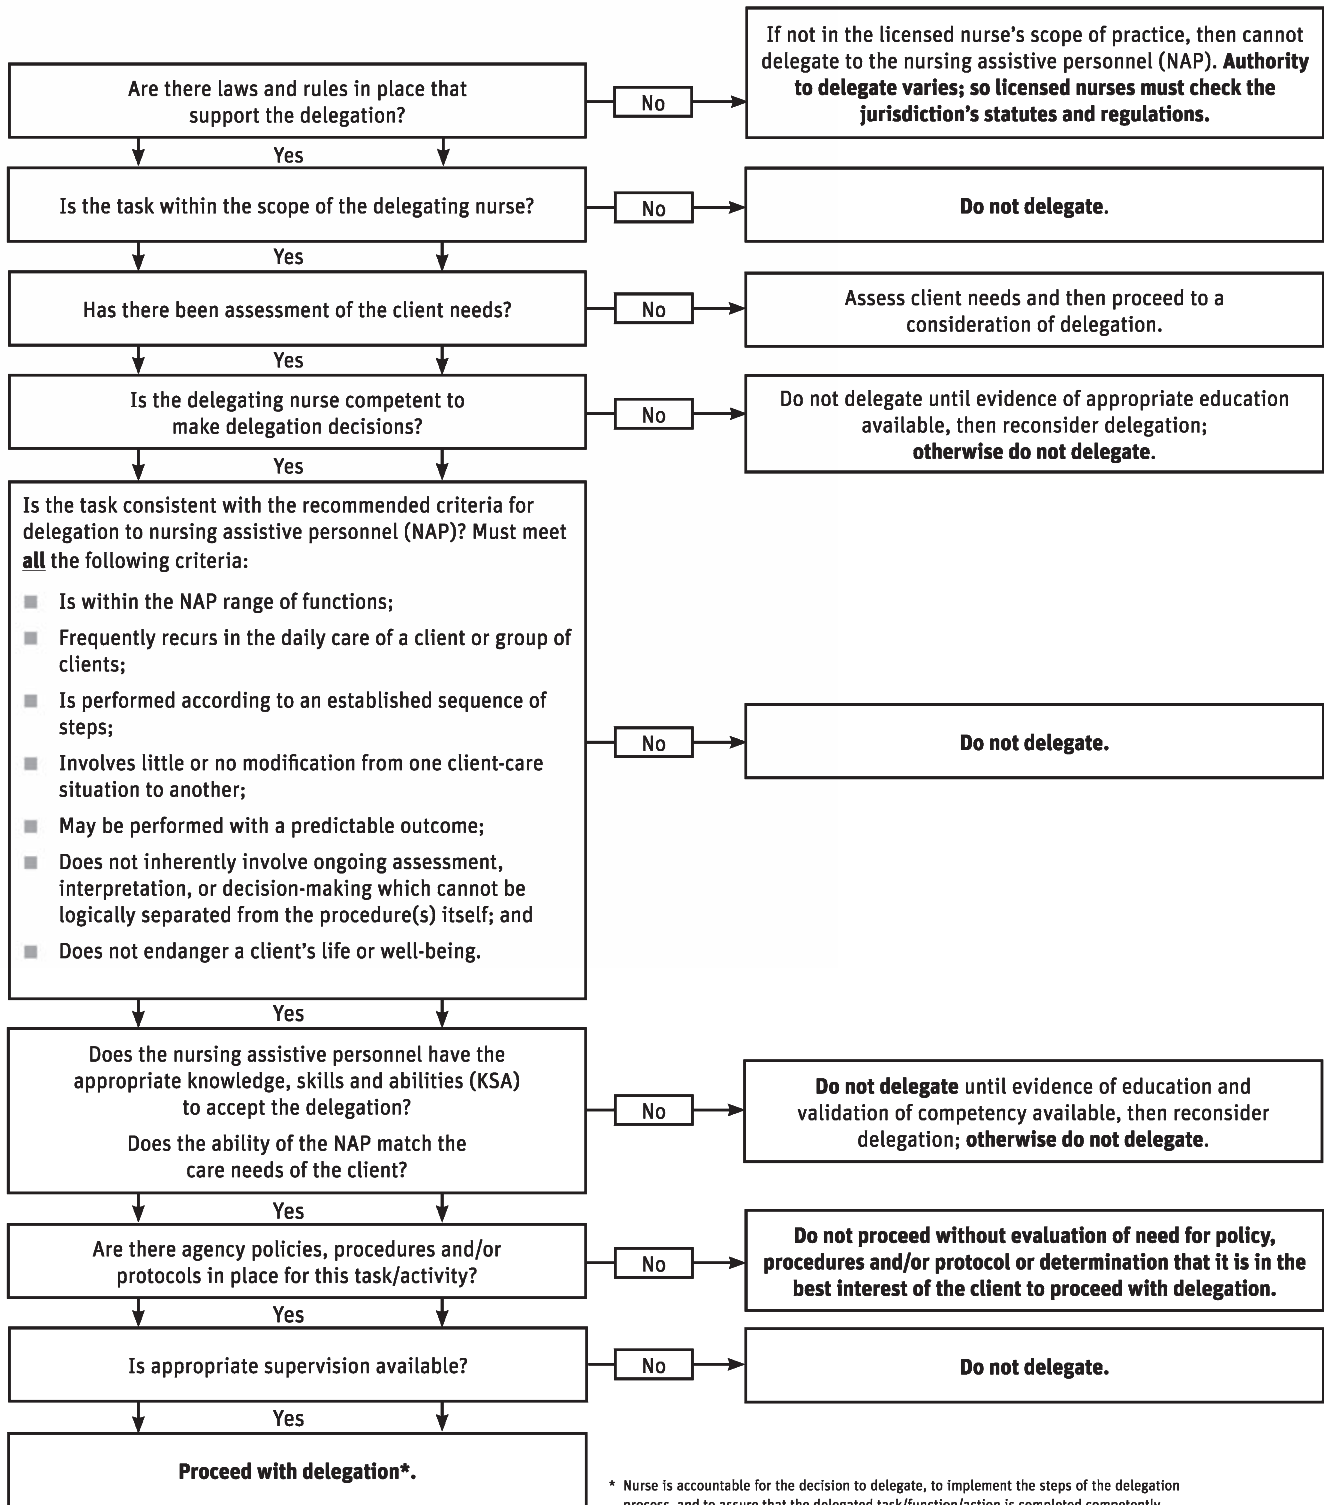

- Assessment
- Interpretation of data
- Making a nursing diagnosis
- Creation of a nursing care plan
- Evaluation of care effectiveness
- Care of invasive lines
- Administering parenteral medications
- Insertion of nasogastric tubes
- Client education
- Performing triage
- Giving telephone advice

BOX 28–3 Principles Used by the Nurse to Determine Delegation to Unlicensed Assistive Personnel

1. The nurse must assess the individual client prior to delegating tasks.
2. The client must be medically stable or in a chronic condition and not fragile.
3. The task must be considered routine for this client.
4. The task must not require a substantial amount of scientific knowledge or technical skill.
5. The task must be considered safe for this client.
6. The task must have a predictable outcome.
7. Learn the agency’s procedures and policies about delegation.
8. Know the scope of practice and the customary knowledge, skills, and job description for each health care discipline represented on your team.
9. Be aware of individual variations in work abilities. Each individual caregiver has different experiences and may not be capable of performing every task cited in the job description.
10. When unsure about an assistant’s abilities to perform a task, observe while the person performs it, or demonstrate it to the person and get a return demonstration before allowing the person to perform it independently.
11. Clarify reporting expectations to ensure the task is accomplished.
12. Create an atmosphere that fosters communication, teaching, and learning. For example, encourage staff to ask questions, listen carefully to their concerns, and make use of every opportunity to teach.

Decision Tree – Delegation to Nursing Assistive Personnel

Step One – Assessment and Planning

Decision Tree – Accepting Assignment to Supervise Unlicensed Assistive Personnel

* Nurse is accountable for decision to accept the assignment to supervise, for monitoring so the task or procedure is performed correctly, and that there is appropriate follow-up on problems.

B

Figure 28-2 ■ Continued

SAFETY ALERT!

Each nurse or other licensed or unlicensed health care provider is responsible for his or her own actions. Anyone who feels unqualified to perform a delegated task must decline to perform it.

In addition to delegating to UAP, the RN also delegates to LVN/LPNs and other RNs. Because LVN/LPNs are licensed, the nurse must know their state-specific scope of practice in order to delegate effectively. LVN/LPNs require less direct supervision than UAPs. In some regions and some agencies, LVN/LPNs may perform tasks generally considered the role of the registered nurse if they have received special training. For example, in most U.S. states they may assess intravenous (IV) infusion sites, but in only some states can LVN/LPNs administer IV fluids or medications, initiate IVs, administer parenteral nutrition, or delegate to others. The process of delegating to these nurses is the same as it is in delegating to UAP. For example, LVN/LPNs may be authorized to provide client teaching from a standard teaching plan but the RN must still confirm that the particular LVN/LPN's job description, education, and competency meet the needs of the specific situation (Kelly & Marthaler, 2011). When delegating to this nurse, the RN retains primary responsibility and accountability for implementation of the nursing process.

The RN also delegates to other RNs. This is part of the daily routine of determining which of the available nurses should care for which clients or when specific additional assistance is required for one client. When delegating to RNs who are new to a particular setting—such as when the nurse from one unit in a hospital is temporarily assigned to a different unit (called “floating”)—the delegating nurse must confirm that the five rights are still met.

Delegation can be an extremely useful strategy in providing thorough and effective nursing care. Skill in delegation, however, must be learned and developed over time. The nurse should not hesitate to consult with others regarding the appropriateness of delegation.

Culturally Responsive Care**PATIENT-CENTERED CARE****Cultural Considerations in Leadership, Management, and Delegation**

In the same way that nurses consider how care is influenced by the client's culture, the nurse must consider how leading, managing, delegating, and promoting change are influenced by the culture of the caregivers. Specific examples include:

- *Communication:* Volume, tone, and choice of words plus nonverbal behavior used in communicating ideas and instructions may be interpreted differently in different cultures.
- *Space:* The distance between two individuals or the seating arrangement in a group may either promote or impede effective teamwork.
- *Time:* There are culturally defined perspectives on what situations are considered emergencies as well as how much time is meant by words such as *now*, *soon*, or *immediately*. Also, a specific culture may be more focused on the present, past, or future than on the other time frames.
- *Power/control:* Cultures vary in their views of whether events are internally or externally controlled and this may influence personnel's initiative. Some individuals may always wait to be told when to perform activities, whereas others may do so independently. Beliefs also vary related to luck, fate, destiny, and personal choice.

CHANGE

Change is the process of making something different from what it was. Change can involve gaining new knowledge or adapting what is currently known in the light of new information. It can also involve obtaining new skills. Change is an integral aspect of nursing, and nurses are often **change agents**, that is, individuals who initiate, motivate, and implement change. Change agents:

- Have excellent communication and interpersonal skills with individuals, groups, administration, and all levels of the organization involved in change.
- Have knowledge of available resources and how to use them: people, time, money, facilities, and information.
- Are skilled in problem solving.
- Are skilled in teaching.
- Are respected by those involved in the change.
- Have the ability to encourage and nurture those going through change.
- Are self-confident, are able to take risks, and inspire trust in themselves and others.
- Are able to make decisions.
- Have a broad base of knowledge.
- Have a good sense of timing.

Types of Change

Planned change is an intended, purposeful attempt by an individual, group, organization, or larger social system to influence its own current status. Problem-solving skills, decision-making skills, and interpersonal skills are important factors in planned change.

Change may be considered covert or overt. A *covert change* is hidden or occurs without the individual's awareness. An example is the gradual, subtle increase in the severity of the clients on a nursing unit. *Overt change* is change of which a person is aware. An example might be that a piece of equipment will no longer be available since the agency has changed suppliers. People who experience overt change may experience anxiety. Overt change often necessitates behavioral changes that are in conflict with the person's needs or goals.

Unplanned change is an alteration imposed by external events or individuals. It occurs when unexpected events force a reaction. It is usually haphazard, and the results can be unpredictable. Drift is a type of unplanned change in which change occurs without effort on anyone's part. Situational, or natural, change also may be considered unplanned and occurs without any control by the person or group impacted. An example is the change that occurs because of a war or a natural disaster. Not all situational changes are negative. For example, as agencies open or close units, the nurse may have the opportunity to change to a new workplace.

SELF-CARE ALERT

Change that is viewed as a threat by one nurse may be viewed as an opportunity by another nurse.

The Nurse's Role in Change

In his classic work, Lewin (1951) described change as involving three stages: unfreezing, moving, and refreezing. During the unfreezing stage, the need for change is recognized, driving and restraining forces are identified, alternative solutions are generated, and participants are

BOX 28-4 Common Driving and Restraining Forces for Change

DRIVING FORCES

- Perception that the change is challenging
- Economic gain
- Perception that the change will improve the situation
- Visualization of the future impact of change
- Potential for self-growth, recognition, achievement, and improved relationships

RESTRAINING FORCES

- Fear that something of personal value will be lost (e.g., threat to job security or self-esteem)
- Misunderstanding of the change and its implications
- Low tolerance for change related to intellectual or emotional insecurity
- Perception that the change will not achieve goals; failure to see the big picture
- Lack of time or energy
- Perceived loss of freedom to engage in particular behaviors

motivated to change. In the second stage, moving, participants agree the status quo is undesirable and the actual change is planned in detail and implemented. In the final stage, refreezing, the change is integrated and stabilized.

An important aspect of planning change is establishing the likelihood of the acceptance of the change and then determining the criteria by which that acceptance can be identified. Accepting change often takes time, particularly when it does not fit into a person's attitudinal framework. The course of acceptance is easier for people if they are involved in the process. If possible, change should be instituted on a small or pilot scale before full implementation. To facilitate acceptance of the change, the change agent needs to identify common driving and restraining forces (Box 28-4). Guidelines for dealing with resistance to change are found in Box 28-5.

Change requires energy, much of which comes from those who have power. To access optimal power, use the following strategies:

1. Analyze the organizational chart; know the formal lines of authority. Identify informal lines as well.
2. Identify key persons who will be affected by the change. Pay attention to those immediately above and below the point of change.
3. Find out as much as possible about these key people. What are their "tickle points"? What interests them, gets them excited, turns

Critical Thinking Checkpoint

You have just interviewed for two nursing positions and are trying to decide which job to pursue. During your first interview for a team member position, the nurse manager, Mr. Caruso, was cheerful, spoke highly of his current staff and complimented them for their ability to set goals and participate in decision making, listened to your ideas, and explored ways in which you could contribute to this team's effectiveness. The second nurse manager, Mrs. Turner, was also cheerful and talkative. She provided you with a job description as a primary nurse caregiver, explained her expectations of you as a new employee, and spoke of new programs she was attempting to implement. Both nurse managers talked about changes taking place in their facilities and the need for employees to remain flexible.

BOX 28-5 Guidelines for Dealing with Resistance to Change

1. Talk with those who oppose the change. Get to the root of their reasons for opposition.
2. Clarify information, and provide accurate information.
3. Be open to revisions but clear about what must remain.
4. Present the negative consequences of resistance (e.g., threats to organizational survival, compromised client care).
5. Emphasize the positive consequences of the change and how the individual or group will benefit. However, do not spend too much energy on rational analysis of why the change is good and why the arguments against it do not hold up. People's resistance frequently flows from feelings that are not rational.
6. Keep resisters involved in face-to-face contact with supporters. Encourage proponents to empathize with opponents, recognize valid objections, and relieve unnecessary fears.
7. Maintain a climate of trust, support, and confidence.
8. Divert attention by creating a different disturbance. Energy can shift to a more important problem inside the system, thereby redirecting resistance. Alternately, attention can be brought to an external threat to create a bully phenomenon. When members perceive a greater environmental threat (such as competition or restrictive governmental policies), they tend to unify internally.

From *Effective Leadership and Management in Nursing* (8th ed., pp. 63-64), by E. J. Sullivan, 2013, Upper Saddle River, NJ: Prentice Hall. Reprinted with permission.

them off? What is on their personal and organizational agendas? Who typically aligns with whom on important decisions?

4. Begin to build a coalition of support before you start the change process. Identify the key people who will most likely support your idea and those who are most likely to be persuaded easily. Talk informally with them to flush out possible objections to your idea and potential opponents. What will the costs and benefits be to them—especially in political terms? Can your idea be modified in ways that retain your objectives but appeal to more key people?
5. Follow the organizational chain of command in communicating with administrators. Do not bypass anyone to avoid having an excellent proposal undermined. (Sullivan, 2013, pp. 64-65)

All nurses are affected by change; nobody can avoid it. Nurses knowledgeable about the historical and current trends in nursing and current political, social, technologic, and economic issues make rational plans to deal with opportunities to initiate and guide needed change and to respond to change that affects them in the workplace, government, organizations, and the community.

1. Based on the brief data provided, speculate about the leadership style of each of these nurse managers.
2. Think about managers (or leaders) you have known and admired. What characteristics did they have that you would like to integrate into your own management style should you become a nurse manager?
3. Both nurse managers spoke of changes that were taking place in their facility. As a nurse, how can you assist your peers who are unhappy and seem to resist change even when it is positive?
4. How might the delegation of tasks to other nurses or UAPs be different in the two settings?

See Critical Thinking Possibilities on student resource website.

Chapter 28 Review

CHAPTER HIGHLIGHTS

- The professional nurse frequently assumes the roles of leader and manager. Leaders, as employees or volunteers, influence others to accomplish a specific goal, whereas managers have responsibility and accountability for accomplishing the tasks of an organization.
- Several leadership styles have been described, including autocratic, democratic, laissez-faire, and bureaucratic. These styles are often blended to fit the situation. Nurses need to know which style is most consistent with their behavior and learn to incorporate aspects of other styles into their practice.
- Four major management functions are planning, organizing, directing, and coordinating.
- Nurse managers work within the organizational framework of the employing agency. Principles of management include authority, accountability, and responsibility.
- Effective managers need to be skilled at critical thinking, communication, resource management, enhancing employee performance, building and managing teams, and managing conflict, time, and change.
- Delegation is a tool that allows the nurse delegator to devote more time to tasks that cannot be delegated. The nurse transfers responsibility and authority to another but retains accountability for the task.
- Nurses function as change agents to initiate, motivate, and implement change.

TEST YOUR KNOWLEDGE

1. The nurse leader informs the staff of a local emergency and instructs them to stay at the hospital to prepare for major casualties. The staff displays high levels of anxiety and disorganization. Which is the most appropriate leadership style at this time?
 1. Autocratic
 2. Democratic
 3. Laissez-faire
 4. Bureaucratic
2. During client rounds, a client tells the nurse manager that he has not received his medications all shift. In using the skills and competencies of a manager, what will be the nurse's first action?
 1. Communicate: Discuss the client's statement with the assigned nurse.
 2. Manage resources: Assign another nurse to administer the client's medications.
 3. Enhance employee performance: Provide the client's nurse with a mentor to review proper medication procedures.
 4. Manage conflict: Call the nurse into the client's room and mediate a discussion between them.
3. Which example reflects a nurse manager with accountability but not authority?
 1. To reduce costs, administrators instruct the manager to inform the staff to reduce overtime.
 2. The manager evaluates the unit staff but cannot promote or terminate staff.
 3. The manager is to recommend a new staffing procedure to the institution's nurse manager group.
 4. The manager prepares a monthly budget variance report that includes plans to correct overspending.
4. An unlicensed assistant (UAP) has previously performed client transfers safely (bed to chair) on many occasions. It would be inappropriate to delegate this unsupervised task to the UAP under which condition?
 1. The unit had a new wheelchair.
 2. This was an older client.
 3. It was the client's first time out of bed after surgery.
 4. The UAP has just returned from an extended leave of absence.
5. The nurse manager plans to implement a new method for scheduling staff vacations. Senior staff members oppose the change, whereas newer staff members are more accepting. Which is the most effective strategy for resolving this difference?
 1. Provide an extensive and detailed rationale for the proposed change, then implement.
 2. Explain that the change will occur as designed, regardless of the staff's preference.
 3. Withdraw the proposal to prevent a decrease in staff morale.
 4. Encourage interaction between the opposing sides to attempt resolution.
6. Which is more commonly a characteristic of a manager rather than a leader?
 1. Is visionary.
 2. Has been given legitimate power by the organization.
 3. Primary effectiveness is through influencing others.
 4. Often takes risks and explores new solutions to problems.
7. A leader is most likely to be effective when acting which way? Select all that apply.
 1. Adopts the leadership style of the leader who had the position before him or her.
 2. Gives equal consideration to group members who are in favor of and opposed to a desired change.
 3. Plans and organizes group activities.
 4. Modifies his or her own behaviors based on the needs of individual members of the group.
 5. Asks members for opinion of the leader's effectiveness.
8. When economic conditions are tight, a hospital may reduce the number of middle-level nurse managers. This can potentially disrupt nursing care because middle-level managers are responsible for which of the following?
 1. Supervision of nonmanagerial staff
 2. Reporting institutional changes to direct-care staff
 3. Productivity and effectiveness of a group of managers
 4. Creating institutional goals and strategic plans

9. A management function of bedside direct-care nurses includes determining whether the client has reached the intended outcomes designated in the care plan. This is an example of which of the four management functions?
1. Planning
 2. Organizing
 3. Directing
 4. Coordinating
10. The nurse asks an unlicensed assistant (UAP) to weigh a client. The UAP carefully assists the client out of bed to stand on the scale, weighs the client, and safely returns the client to bed. Later, when the UAP reports the weight to the nurse, it is discovered that the client had been placed on bed rest and should not have been allowed out of bed. This situation violates which of the following five rights of delegation?
1. Right task
 2. Right person
 3. Right direction and communication
 4. Right supervision and evaluation

UNIT

6

Meeting the Standards

This unit looks at aspects integral to the profession of nursing including caring, communicating, teaching, and leading, managing, and delegating. In order for nurses to provide high-quality care, they must demonstrate caring, communicate effectively with both the client and the health care team, teach clients and their family members, act as leaders of the nursing team, and delegate tasks to others. Only when the nurse incorporates all of these aspects into the care of the client can optimal care be delivered.

CLIENT: Michael AGE: 62 CURRENT MEDICAL DIAGNOSIS: Lung Cancer

Medical History: Michael was diagnosed with an advanced stage of lung cancer 2 months ago following a lung biopsy that revealed oat cell carcinoma, one of the fastest growing forms of lung cancer. His oncologist recommended treatment with chemotherapy and radiation therapy, but informed him that the prognosis was poor and his condition was most likely terminal. Since that time, Michael has undergone four chemotherapy treatments and 6 weeks of radiation therapy, but additional chemotherapy treatments needed to be held until his platelet count improved. Diagnostic tests revealed metastasis to the brain and the bone. He has decided to discontinue all treatments and was admitted to hospice home care.

Personal and Social History: Michael lives with his wife of 40 years. They have two sons who are grown and live out of state

with their wives and families. Michael's wife accompanies him to all of his doctor's appointments and therapies and they are frequently seen in the waiting room or examination room holding hands and laughing together. Michael works as an architect and his wife owns her own business selling children's clothing. They have a comfortable life together and were looking forward to spending their retirement years together traveling. Michael says he can't stop apologizing to his wife because "I would never have developed lung cancer if I had quit smoking, and now she has to live alone because of my stupid habit." His wife tells him it is not his fault whenever he apologizes, and that she loves him, but tells the nurse privately that she feels angry that he is dying so young.

Questions

American Nurses Association Standard of Practice #5 is Implementation: *The registered nurse demonstrates caring behaviors toward healthcare consumers, significant others, and groups of people receiving care.*

1. Using Roach's six C's of caring discussed in Chapter 25 ∞, how would you demonstrate caring to Michael and his wife?
2. Using the nonverbal communication methods discussed in Chapter 26 ∞, how can the nurse communicate caring to this family?

American Nurses Association Standard of Practice #5B is Health Teaching and Health Promotion: *The registered nurse uses health promotion and health teaching methods appropriate to the situation and the healthcare consumer's values, beliefs, health practices, developmental level, learning needs, readiness and ability to learn, language preferences, spirituality, culture, and socioeconomic status.*

3. The hospice nurse sees that Michael's death is imminent within the next few hours or days and wants to teach his wife about what to expect. Based on what you learned in Chapter 27 ∞, what factors would the nurse interpret as indicating his wife's readiness to learn?

American Nurses Association Standard of Professional Performance #12 is Leadership: *The registered nurse demonstrates leadership in the professional practice setting and the profession by overseeing the nursing care given by others while retaining accountability for the quality of care given to the healthcare consumer.*

4. The hospice nurse arranges for 24-hour care during Michael's final days. Using the decision tree on pages 469–470, what types of care will the nurse delegate to the unlicensed assistive personnel (UAP)? What care will only the registered nurse perform?
5. What instructions will the nurse provide the UAP related to things to report immediately if they occur?

American Nurses Association Standard of Professional Performance #12 is Leadership: *Another competency for this standard is that the nurse mentors colleagues for the advancement of nursing practice, the profession, and quality health care.*

6. On the next visit to the family, the nurse reviews the UAP's care of the client and notes that the client is not being repositioned and is developing signs of a pressure ulcer. What should the nurse do?

Assessing Health

29 Vital Signs 477

30 Health Assessment 513

29 Vital Signs

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Describe factors that affect the vital signs and accurate measurement of them.
2. Identify the variations in normal body temperature, pulse, respirations, and blood pressure that occur from infancy to old age.
3. Verbalize the steps used in:
 - a. Assessing body temperature.
 - b. Assessing a peripheral pulse.
 - c. Assessing the apical pulse and the apical-radial pulse.
 - d. Assessing respirations.
 - e. Assessing blood pressure.
 - f. Assessing blood oxygenation using pulse oximetry.
4. Describe appropriate nursing care for alterations in vital signs.
5. Identify nine sites used to assess the pulse and state the reasons for their use.
6. List the characteristics that should be included when assessing pulses.
7. Describe the mechanics of breathing and the mechanisms that control respirations.
8. Recognize when it is appropriate to delegate measurement of vital signs to unlicensed assistive personnel.
9. Demonstrate appropriate documentation and reporting of vital signs.

INTRODUCTION

The traditional **vital signs** are body temperature, pulse, respirations, and blood pressure. Many agencies such as the Veterans Administration, American Pain Society, and The Joint Commission have designated pain as a fifth vital sign, to be assessed at the same time as each of the other four. Pain assessment is covered in Chapter 46 . Oxygen saturation is also commonly measured at the same time as the traditional vital signs. Vital signs, which should be looked at in total, are checked to monitor the functions of the body. The signs reflect changes in function that otherwise might not be observed. Monitoring a client's vital signs should not be an automatic or routine procedure; it should be a thoughtful, scientific assessment. Vital signs should be evaluated with reference to clients' present and prior health status, their usual vital sign results (if known), and accepted normal standards.

When and how often to assess a specific client's vital signs are chiefly nursing judgments, depending on the client's health status. Some agencies have policies about when to take clients' vital signs. The primary care provider may specifically order a vital sign (e.g., "Blood pressure q2h"). Ordered vital sign measurements, however, should be considered the minimum; a nurse should assess vital signs more often if the client's health status requires it. Examples of times to assess vital signs are listed in Box 29–1.

Often, someone other than the nurse measures the client's vital signs. The nurse must recall, however, that prior to delegating this task to unlicensed assistive personnel (UAP), the nurse must have assessed the individual client and determined that the client is medically stable or in a chronic condition and not fragile and that the vital sign measurement is considered routine for this client. Under those circumstances, the UAP may measure, record, and report vital signs

BOX 29-1 Times to Assess Vital Signs

- On admission to a health care agency to obtain baseline data
- When a client has a change in health status or reports symptoms such as chest pain or feeling hot or faint
- Before and after surgery or an invasive procedure
- Before and/or after the administration of a medication that could affect the respiratory or cardiovascular systems; for example, before giving a digitalis preparation
- Before and after any nursing intervention that could affect the vital signs (e.g., ambulating a client who has been on bed rest)

but real assessment, interpretation of the measurements, rests with the registered nurse.

BODY TEMPERATURE

Body temperature reflects the balance between the heat produced and the heat lost from the body, and is measured in heat units called degrees. There are two kinds of body temperature: core temperature and surface temperature. **Core temperature** is the temperature of the deep tissues of the body, such as the abdominal cavity and pelvic cavity. It remains relatively constant. The normal core body temperature is a range of temperatures (Figure 29-1 ■). The **surface temperature** is the temperature of the skin, the subcutaneous tissue, and fat. It, by contrast, rises and falls in response to the environment.

The body continually produces heat as a by-product of metabolism. When the amount of heat produced by the body equals the amount of heat lost, the person is in **heat balance** (Figure 29-2 ■).

A number of factors affect the body's heat production. The most important are these five:

1. **Basal metabolic rate.** The **basal metabolic rate (BMR)** is the rate of energy utilization in the body required to maintain essential activities such as breathing. Metabolic rates decrease with age. In general, the younger the person, the higher the BMR.

Figure 29-1 ■ Estimated ranges of body temperatures in healthy adults.

Figure 29-2 ■ As long as heat production and heat loss are properly balanced, body temperature remains constant. Factors contributing to heat production (and temperature rise) are shown on the left; those contributing to heat loss (and temperature fall) are shown on the right.

2. **Muscle activity.** Muscle activity, including shivering, increases the metabolic rate.
3. **Thyroxine output.** Increased thyroxine output increases the rate of cellular metabolism throughout the body.
4. **Epinephrine, norepinephrine, and sympathetic stimulation/stress response.** These hormones immediately increase the rate of cellular metabolism in many body tissues.
5. **Fever.** Fever increases the cellular metabolic rate and thus increases the body's temperature further.

Heat is lost from the body through radiation, conduction, convection, and evaporation. **Radiation** is the transfer of heat from the surface of one object to the surface of another without contact between the two objects, mostly in the form of infrared rays. **Conduction** is the transfer of heat from one molecule to a molecule of lower temperature. Conductive transfer cannot take place without contact between the molecules and normally accounts for minimal heat loss except, for example, when a body is immersed in cold water. The amount of heat transferred depends on the temperature difference and the amount and duration of the contact.

Convection is the dispersion of heat by air currents. The body usually has a small amount of warm air adjacent to it. This warm air rises and is replaced by cooler air, so people always lose a small amount of heat through convection.

Evaporation is continuous vaporization of moisture from the respiratory tract and from the mucosa of the mouth and from the skin. This continuous and unnoticed water loss is called **insensible water loss**, and the accompanying heat loss is called **insensible heat loss**. Insensible heat loss accounts for about 10% of basal heat loss. When the body temperature increases, vaporization accounts for greater heat loss.

Regulation of Body Temperature

The system that regulates body temperature has three main parts: sensors in the periphery and in the core, an integrator in the hypothalamus, and an effector system that adjusts the production and loss of heat. Most sensors or sensory receptors are in the skin. The skin has more receptors for cold than warmth. Therefore, skin sensors detect cold more efficiently than warmth.

When the skin becomes chilled over the entire body, three physiological processes to increase the body temperature take place:

1. Shivering increases heat production.
2. Sweating is inhibited to decrease heat loss.
3. Vasoconstriction decreases heat loss.

The hypothalamic integrator is the center that controls the core temperature. When the integrator detects heat, it sends out signals intended to reduce the temperature, that is, to decrease heat production and increase heat loss. In contrast, when the cold sensors are stimulated, the integrator sends out signals to increase heat production and decrease heat loss.

The signals from the cold-sensitive receptors of the hypothalamus initiate effectors, such as vasoconstriction, shivering, and the release of epinephrine, which increases cellular metabolism and hence heat production. When the warmth-sensitive receptors in the hypothalamus are stimulated, the effector system sends out signals that initiate sweating and peripheral vasodilation. Also, when this system is stimulated, the person consciously makes appropriate adjustments, such as putting on additional clothing in response to cold or turning on a fan in response to heat.

Factors Affecting Body Temperature

Nurses should be aware of the factors that can affect a client's body temperature so that they can recognize normal temperature variations and understand the significance of body temperature measurements that deviate from normal. Among the factors that affect body temperature are the following:

1. **Age.** Infants are greatly influenced by the temperature of the environment and must be protected from extreme changes. Children's temperatures vary more than those of adults do until puberty. Many older people, particularly those over 75 years, are at risk of hypothermia (temperatures below 36°C, or 96.8°F) for a variety of reasons, such as inadequate diet, loss of subcutaneous fat, lack of activity, and reduced thermoregulatory efficiency. Older adults are also particularly sensitive to extremes in the environmental temperature due to decreased thermoregulatory controls.
2. **Diurnal variations (circadian rhythms).** Body temperatures normally change throughout the day, varying as much as 1.0°C (1.8°F) between the early morning and the late afternoon. The point of highest body temperature is usually reached between 1600 and 1800 hours (4:00 PM and 6:00 PM), and the lowest point is reached during sleep between 0400 and 0600 hours (4:00 AM and 6:00 AM) (Figure 29-3 ■). Older adults' temperatures may vary less than those of younger persons due to the changes in autonomic functioning common in aging (Marigold, Arias, Vassallo, Allen, & Kwan, 2011).
3. **Exercise.** Hard work or strenuous exercise can increase body temperature to as high as 38.3°C to 40°C (101°F to 104°F) measured rectally.
4. **Hormones.** Women usually experience more hormone fluctuations than men. In women, progesterone secretion at the time

Figure 29-3 ■ Range of oral temperatures during 24 hours for a healthy young adult.

of ovulation raises body temperature by about 0.3°C to 0.6°C (0.5°F to 1.0°F) above basal temperature.

5. **Stress.** Stimulation of the sympathetic nervous system can increase the production of epinephrine and norepinephrine, thereby increasing metabolic activity and heat production. Nurses should anticipate that a highly stressed or anxious client could have an elevated body temperature for that reason.
6. **Environment.** Extremes in environmental temperatures can affect a person's temperature regulatory systems. If the temperature is assessed in a very warm room and the body temperature cannot be modified by convection, conduction, or radiation, the temperature will be elevated. Similarly, if the client has been outside in cold weather without suitable clothing, or if a medical condition prevents the client from controlling the temperature in the environment (e.g., the client has altered mental status or cannot dress self), the body temperature may be low.

Alterations in Body Temperature

The normal range for adults is considered to be between 36°C and 37.5°C (96.8°F to 99.5°F). There are two primary alterations in body temperature: pyrexia and hypothermia.

PYREXIA

A body temperature above the usual range is called **pyrexia**, **hyperthermia**, or (in lay terms) **fever**. A very high fever, such as 41°C (105.8°F), is called **hyperpyrexia** (Figure 29-4 ■). The client who has a fever is referred to as **febrile**; the one who does not is **afebrile**.

Four common types of fevers are intermittent, remittent, relapsing, and constant. During an **intermittent fever**, the body temperature alternates at regular intervals between periods of fever and periods of normal or subnormal temperatures. An example is with the disease malaria. During a **remittent fever**, such as with a cold or influenza, a wide range of temperature fluctuations (more than 2°C [3.6°F]) occurs over a 24-hour period, all of which are above normal. In a **relapsing fever**, short febrile periods of a few days are interspersed with periods of 1 or 2 days of normal temperature. During a **constant fever**, the body temperature fluctuates minimally but always remains above normal. This can occur with typhoid fever. A temperature that rises to fever level rapidly following a normal temperature and then returns to normal within a few hours is called a **fever spike**. Bacterial blood infections often cause fever spikes.

In some conditions, an elevated temperature is not a true fever. Two examples are heat exhaustion and heat stroke. **Heat exhaustion** is a result of excessive heat and dehydration. Signs of heat exhaustion include paleness, dizziness, nausea, vomiting, fainting, and a moderately increased temperature (38.3°C to 38.9°C [101°F to 102°F]).

Figure 29-4 ■ Terms used to describe alterations in body temperature (oral measurements) and ranges in Fahrenheit and Celsius (centigrade) scales.

Persons experiencing **heat stroke** generally have been exercising in hot weather, have warm, flushed skin, and often do not sweat. They usually have a temperature of 41.1°C (106°F) or higher, and may be delirious, unconscious, or having seizures.

The clinical signs of fever vary with the onset, course, and abatement stages of the fever (see Clinical Manifestations). These signs occur as a result of changes in the set point of the temperature control mechanism regulated by the hypothalamus. Under normal conditions, whenever the core temperature rises, the rate of heat loss is increased, resulting in a fall in temperature toward the set-point level. Conversely, when the core temperature falls, the rate of heat production is increased, resulting in a rise in temperature toward the set point.

In a fever, however, the set point of the hypothalamic thermostat changes suddenly from the normal level to a higher than normal value (e.g., 39.5°C [103.1°F]) as a result of the effects of tissue destruction, pyrogenic substances, or dehydration on the hypothalamus. Although the set point changes rapidly, the core body temperature (i.e., the blood temperature) reaches this new set point only after several hours. During this interval, the usual heat production responses that cause elevation of the body temperature occur: chills, feeling of coldness, cold skin due to vasoconstriction, and shivering. This is referred to as the chill phase.

When the core temperature reaches the new set point, the person feels neither cold nor hot and no longer experiences chills (the plateau phase). Depending on the degree of temperature elevation, other signs may occur during the course of the fever. Very high temperatures, such as 41°C to 42°C (106°F to 108°F), damage the parenchyma of cells throughout the body, particularly in the brain where destruction of neuronal cells is irreversible. Damage to the liver, kidneys, and other body organs can also be great enough to disrupt functioning and eventually cause death.

When the cause of the high temperature is suddenly removed, the set point of the hypothalamic thermostat is suddenly reduced to

CLINICAL MANIFESTATIONS

Fever

ONSET (COLD OR CHILL PHASE)

- Increased heart rate
- Increased respiratory rate and depth
- Shivering
- Pallid, cold skin
- Complaints of feeling cold
- Cyanotic nail beds
- “Gooseflesh” appearance of the skin
- Cessation of sweating

COURSE (PLATEAU PHASE)

- Absence of chills
- Skin that feels warm
- Photosensitivity
- Glassy-eyed appearance
- Increased pulse and respiratory rates
- Increased thirst
- Mild to severe dehydration
- Drowsiness, restlessness, delirium, or convulsions
- Herpetic lesions of the mouth
- Loss of appetite (if the fever is prolonged)
- Malaise, weakness, and aching muscles

DEFERESCENCE (FEVER ABATEMENT/FLUSH PHASE)

- Skin that appears flushed and feels warm
- Sweating
- Decreased shivering
- Possible dehydration

a lower value, perhaps even back to the original normal level. In this instance, the hypothalamus now attempts to lower the temperature, and the usual heat loss responses that cause a reduction of the body temperature occur: excessive sweating and hot, flushed skin due to sudden vasodilation. This is referred to as the flush phase. Nursing interventions for a client who has a fever are designed to support the body's normal physiological processes, provide comfort, and prevent complications. During the course of a fever, the nurse needs to monitor the client's vital signs closely.

Nursing interventions during the chill phase are designed to help the client decrease heat loss. At this time, the body's physiological processes are attempting to raise the core temperature to the new set-point temperature. During the flush or crisis phase, the body processes are attempting to lower the core temperature to the reduced or normal set-point temperature. At this time, the nurse takes measures to increase heat loss and decrease heat production. Nursing interventions for a client with fever are shown in Box 29-2.

HYPOTHERMIA

Hypothermia is a core body temperature below the lower limit of normal. The three physiological mechanisms of hypothermia are (a) excessive heat loss, (b) inadequate heat production to counteract heat loss, and (c) impaired hypothalamic thermoregulation. The clinical signs of hypothermia are listed in the Clinical Manifestations box.

Hypothermia may be induced or accidental. Induced hypothermia is the deliberate lowering of the body temperature to decrease the need for oxygen by the body tissues such as during certain surgeries. Accidental hypothermia can occur as a result of (a) exposure to a cold environment, (b) immersion in cold water, and (c) lack of adequate clothing, shelter, or heat. In older adults, the problem can be compounded by a decreased metabolic rate and the use of sedative medications. If skin and underlying tissues are damaged by freezing cold,

BOX 29–2 Nursing Interventions for Clients with Fever

- Monitor vital signs.
- Assess skin color and temperature.
- Monitor white blood cell count, hematocrit value, and other pertinent laboratory reports for indications of infection or dehydration.
- Remove excess blankets when the client feels warm, but provide extra warmth when the client feels chilled.
- Provide adequate nutrition and fluids (e.g., 2,500–3,000 mL/day) to meet the increased metabolic demands and prevent dehydration.
- Measure intake and output.
- Reduce physical activity to limit heat production, especially during the flush stage.
- Administer antipyretics (drugs that reduce the level of fever) as ordered.
- Provide oral hygiene to keep the mucous membranes moist.
- Provide a tepid sponge bath to increase heat loss through conduction.
- Provide dry clothing and bed linens.

BOX 29–3 Nursing Interventions for Clients with Hypothermia

- Provide a warm environment.
- Provide dry clothing.
- Apply warm blankets.
- Keep limbs close to body.
- Cover the client's scalp with a cap or turban.
- Supply warm oral or intravenous fluids.
- Apply warming pads.

with severe hypothermia, a hyperthermia blanket (an electronically controlled blanket that provides a specified temperature) is applied, and warm intravenous fluids are given. Wet clothing, which increases heat loss because of the high conductivity of water, should be replaced with dry clothing. See Box 29–3 for nursing interventions for clients who have hypothermia.

Assessing Body Temperature

The most common sites for measuring body temperature are oral, rectal, axillary, tympanic membrane, and skin/temporal artery. Each of the sites has advantages and disadvantages (Table 29–1).

The body temperature may be measured *orally*. If a client has been taking cold or hot food or fluids or smoking, the nurse should wait 30 minutes before taking the temperature orally to ensure that the temperature of the mouth is not affected by the temperature of the food, fluid, or warm smoke.

Rectal temperature readings are considered to be very accurate. Rectal temperatures are contraindicated for clients who are undergoing rectal surgery, have diarrhea or diseases of the rectum, are immunosuppressed, have a clotting disorder, or have significant hemorrhoids.

The *axilla* is often the preferred site for measuring temperature in newborns because it is accessible and safe. Axillary temperatures are lower than rectal temperatures. Some clinicians recommend rechecking an elevated axillary temperature with one taken from another site to confirm the degree of elevation. Nurses should check agency protocol when taking the temperature of newborns, infants, toddlers, and children. Adult clients for whom the axillary method of temperature assessment is appropriate include those for whom other temperature sites are contraindicated.

CLINICAL MANIFESTATIONS**Hypothermia**

- Decreased body temperature, pulse, and respirations
- Severe shivering (initially)
- Feelings of cold and chills
- Pale, cool, waxy skin
- Frostbite (discolored, blistered nose, fingers, toes)
- Hypotension
- Decreased urinary output
- Lack of muscle coordination
- Disorientation
- Drowsiness progressing to coma

this results in frostbite. Frostbite most commonly occurs in hands, feet, nose, and ears.

Managing hypothermia involves removing the client from the cold and rewarming the client's body. For the client with mild hypothermia, the body is rewarmed by applying blankets; for the client

TABLE 29–1 Advantages and Disadvantages of Sites Used for Body Temperature Measurements

Site	Advantages	Disadvantages
Oral	Accessible and convenient	Thermometers can break if bitten. Inaccurate if client has just ingested hot or cold food or fluid or smoked. Could injure the mouth following oral surgery.
Rectal	Reliable measurement	Inconvenient and more unpleasant for clients; difficult for client who cannot turn to the side. Could injure the rectum. Presence of stool may interfere with thermometer placement.
Axillary	Safe and noninvasive	The thermometer may need to be left in place a long time to obtain an accurate measurement.
Tympanic membrane	Readily accessible; reflects the core temperature; very fast	Can be uncomfortable and involves risk of injuring the membrane if the probe is inserted too far. Repeated measurements may vary. Right and left measurements can differ. Presence of cerumen can affect the reading.
Temporal artery	Safe and noninvasive; very fast	Requires electronic equipment that may be expensive or unavailable. Variation in technique needed if the client has perspiration on the forehead.

The *tympanic membrane*, or nearby tissue in the ear canal, is a frequent site for estimating core body temperature. However, tympanic temperature measurements have been shown to be imprecise (Rubia-Rubia, Arias, Sierra, & Aguirre-Jaime, 2011). If the probe fits too loosely in the ear canal, the reading can be lower than the true value. Electronic tympanic thermometers are found extensively in both inpatient and ambulatory care settings.

The temperature may also be measured on the forehead using a chemical thermometer or a *temporal artery* thermometer. Forehead temperature measurements are most useful for infants and children when a more invasive measurement is not necessary. However, temporal artery temperature measurements have shown inconsistent reliability (Penning, van der Linden, Tibboel, & Evenhuis, 2011; Rubia-Rubia et al., 2011).

TYPES OF THERMOMETERS

Traditionally, body temperatures were measured using mercury-in-glass thermometers. Such thermometers, however, can be hazardous due to exposure to mercury, which is toxic to humans, and broken glass should the thermometer crack or break. In 1998, the U.S. Environmental Protection Agency and the American Hospital Association agreed to the goal of eliminating mercury from health care environments. Hospitals no longer use mercury-in-glass thermometers, and several cities have banned the sale and manufacture of them. However, the nurse may still encounter this type of thermometer, especially in the home. In some cases, plastics have replaced glass and safer chemicals (e.g., gallium) have replaced mercury in modern versions of the thermometer.

Although the amount of mercury in a thermometer (or in a fluorescent light bulb) is minimal, should it break, cleanup involves several “dos and don’ts.” Unsealed mercury slowly vaporizes into the air and these mercury vapors are toxic. Keep children and pets away from the area. Wearing rubber gloves, wipe mercury beads off clothing, skin, or disposable items with a paper towel and immediately place the towel into a plastic bag. Discard the bag. If the spill is on a porous material that cannot be discarded (e.g., carpet), a contractor trained in mercury disposal may be needed. If the mercury is on a hard surface, use folded stiff cardboard to slowly gather the beads and pour them into a wide-mouthed container. Use a flashlight to search for the beads since the light will reflect off the mercury. Dispose of all items used in the cleanup in a plastic bag that is sealed with tape. Shower or wash well. Keep the area well ventilated for several days. Do not use any type of vacuum cleaner or broom since these will disperse the mercury and be contaminated. Do not pour the mercury down a toilet or drain and do not wash or reuse contaminated materials.

SAFETY ALERT!

SAFETY

Whenever mercury-in-glass thermometers are encountered, the nurse should recommend their immediate replacement with less hazardous thermometers and their safe disposal.

Electronic thermometers can provide a reading in only 2 to 60 seconds, depending on the model. The equipment consists of an electronic base, a probe, and a probe cover, which is usually disposable (Figure 29–5 ■). Some institutional models have a different circuit and probe for oral and rectal measurement.

Two special types of oral thermometers are basal and hypothermia. A basal thermometer is calibrated with 0.1°F intervals and is for fertility purposes, indicating the temperature rise that is associated

A

B

Figure 29–5 ■ Electronic thermometers: A, institutional model, note the probe and probe cover; B, one-piece home electronic thermometer.

with ovulation. Hypothermia thermometers have a greater low range than everyday thermometers, usually measuring temperatures from 27.2°C to 42.2°C (81°F to 108°F).

Chemical disposable thermometers are also used to measure body temperatures. Chemical thermometers have liquid crystal dots or bars that change color to indicate temperature. Some of these are single use and others may be reused several times. One type that has small chemical dots at one end is shown in Figure 29–6 ■. To read the temperature, the nurse notes the highest reading among the dots that have changed color. These thermometers can be used orally, rectally, or in the axilla.

Temperature-sensitive tape may also be used to obtain a general indication of body surface temperature. It does not indicate the core temperature. The tape contains liquid crystals that change color according to temperature. When applied to the skin, usually of the forehead or abdomen, the temperature digits on the tape respond by changing color (Figure 29–7 ■). The skin area should be dry. After the length of time specified by the manufacturer (e.g., 15 seconds), a color appears on the tape. This method is particularly useful at home and for infants whose temperatures are to be monitored.

Figure 29-6 ■ Chemical dot thermometers: A, axillary (note the “Ax” on the stem); B, rectal (note the plastic cover); C, oral; D, an enlargement showing a reading of 99.2°F.

Figure 29-7 ■ A temperature-sensitive skin tape.

Infrared thermometers sense body heat in the form of infrared energy given off by a heat source, which, in the ear canal, is primarily the tympanic membrane (Figure 29-8 ■). The infrared thermometer makes no contact with the tympanic membrane.

Temporal artery thermometers determine temperature using a scanning infrared thermometer that compares the arterial temperature in the temporal artery of the forehead to the temperature in the room and calculates the heat balance to approximate the core temperature of the blood in the pulmonary artery. The probe is placed in the middle of the forehead and then drawn laterally to the hairline. If the client has perspiration on the forehead, the probe is also touched behind the earlobe so the thermometer can compensate for evaporative cooling (Figure 29-9 ■).

TEMPERATURE SCALES

Sometimes a nurse needs to convert a body temperature reading in Celsius (centigrade) to Fahrenheit, or vice versa. Although the conversion can be accomplished using several different formulas, the most common is described here. To convert from Fahrenheit to Celsius, deduct 32 from the Fahrenheit reading and then multiply by the fraction 5/9; that is:

$$C = (\text{Fahrenheit temperature} - 32) \times 5/9$$

For example, when the Fahrenheit reading is 100:

$$C = (100 - 32) \times 5/9 = (68) \times 5/9 = 37.8$$

To convert from Celsius to Fahrenheit, multiply the Celsius reading by the fraction 9/5 and then add 32; that is:

$$F = (\text{Celsius temperature} \times 9/5) + 32$$

Figure 29-8 ■ An infrared (tympanic) thermometer used to measure the tympanic membrane temperature.

Figure 29-9 ■ A temporal artery thermometer.
© A. Wilson / Custom Medical Stock Photo.

For example, when the Celsius reading is 40:

$$F = (40 \times 9/5) + 32 = (72 + 32) = 104$$

Skill 29-1 explains how to measure body temperature.

Assessing Body Temperature

PURPOSES

- To establish baseline data for subsequent evaluation
- To identify whether the core temperature is within normal range
- To determine changes in the core temperature in response to specific therapies (e.g., antipyretic medication, immunosuppressive therapy, invasive procedure)
- To monitor clients at risk for imbalanced body temperature (e.g., clients at risk for infection or diagnosis of infection; those who have been exposed to temperature extremes)

ASSESSMENT

Assess

- Clinical signs of fever
- Clinical signs of hypothermia
- Site and method most appropriate for measurement
- Factors that may alter core body temperature

PLANNING

DELEGATION

Routine measurement of the client's temperature can be delegated to unlicensed assistive personnel (UAP), or be performed by family members/caregivers in nonhospital settings. The nurse must explain the appropriate type of thermometer and site to be used and ensure that the person knows when to report an abnormal temperature and how to record the finding. The interpretation of an abnormal temperature and determination of appropriate responses are done by the nurse.

Equipment

- Thermometer
- Thermometer sheath or cover
- Water-soluble lubricant for a rectal temperature

IMPLEMENTATION

Preparation

Check that all equipment is functioning normally.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe appropriate infection prevention procedures. Apply gloves if performing a rectal temperature.
3. Provide for client privacy.
4. Position the client appropriately (e.g., lateral or Sims' position for inserting a rectal thermometer).
5. Place the thermometer (Box 29-4).
 - Apply a protective sheath or probe cover if appropriate.
 - Lubricate a rectal thermometer.
6. Wait the appropriate amount of time. Electronic and tympanic thermometers will indicate that the reading is complete through a light or tone. Check package instructions for length of time to wait prior to reading chemical dot or tape thermometers.

EVALUATION

- Compare the temperature measurement to baseline data, normal range for age of client, and client's previous temperatures. Analyze considering time of day and any additional influencing factors and other vital signs.
- Conduct appropriate follow-up such as notifying the primary care provider if a temperature is outside of a specific range or is not responding to interventions, giving a medication, or

INTERPROFESSIONAL PRACTICE

Measuring the temperature may be within the scope of practice for many health care providers. Although these other providers may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

- Clean gloves for a rectal temperature
- Towel for axillary temperature
- Tissues/wipes

CLINICAL ALERT!

Be sure to record the temperature from an electronic thermometer before replacing the probe into the charging unit. With many models, replacing the probe erases the temperature from the display.

7. Remove the thermometer and discard the cover or wipe with a tissue if necessary. If gloves were applied, remove and discard them.
 - Perform hand hygiene.
8. Read the temperature and record it on your worksheet. If the temperature is obviously too high, too low, or inconsistent with the client's condition, recheck it with a thermometer known to be functioning properly.
9. Wash the thermometer if necessary and return it to the storage location.
10. Document the temperature in the client record. ① A rectal temperature may be recorded with an "R" next to the value or with the mark on a graphic sheet circled. An axillary temperature may be recorded with "AX" or marked on a graphic sheet with an X.

altering the client's environment. This includes teaching the client how to lower an elevated temperature through actions such as increasing fluid intake, coughing and deep breathing, cool compresses, or removing heavy coverings. Interventions for hypothermia include intake of warm fluids and use of warm or electric blankets.

BOX 29-4 Thermometer Placement

Oral

Place the tip on either side of the frenulum. 1

1 Oral thermometer placement.

Rectal

Apply clean gloves.
Instruct the client to take a slow deep breath during insertion. 2
Never force the thermometer if resistance is felt.
Insert 3.5 cm (1.5 in.) in adults.

2 Inserting a rectal thermometer.

Axillary

Pat the axilla dry if very moist.
The tip is placed in the center of the axilla. 3

3 Placing the tip of the thermometer in the center of the axilla.

Tympanic

Pull the pinna slightly upward and backward for an adult. 4
Point the probe slightly anteriorly, toward the eardrum.
Insert the probe slowly using a circular motion until snug.

4 Pull the pinna of the ear up and back for an adult while inserting the tympanic thermometer.

Temporal Artery

Brush hair aside if covering the temporal artery area.
With the probe flush on the center of the forehead, depress the red button; keep depressed. Slowly slide the probe midline across the forehead to the hairline, not down the side of the face. Lift the probe from the forehead and touch on the neck just behind the earlobe. Release the button. 5

5 Positioning a temporal artery thermometer.

LIFESPAN CONSIDERATIONS Temperature**INFANTS**

- The body temperature of newborns is extremely labile, and newborns must be kept warm and dry to prevent hypothermia.
- Using the axillary site, you need to hold the infant's arm against the chest (Figure 29–10 ■).
- The axillary route may not be as accurate as other routes for detecting fevers in children.
- The tympanic route is fast and convenient. Place the infant supine and stabilize the head. Pull the pinna straight back and slightly downward. Remember that the pinna is pulled upward for children over 3 years of age and adults, but downward for children younger than age 3. Direct the probe tip anteriorly and insert far enough to seal the canal. The tip will not touch the tympanic membrane.
- Avoid the tympanic route in a child with active ear infections or tympanic membrane drainage tubes.
- The tympanic membrane route may be more accurate in determining temperature in febrile infants.
- When using a temporal artery thermometer, touching only the forehead or behind the ear is needed.
- The rectal route is least desirable in infants.

CHILDREN

- Tympanic or temporal artery sites are preferred.
- For the tympanic route, have the child held on an adult's lap with the child's head held gently against the adult for support. Pull the pinna straight back and upward for children over age 3 (Figure 29–11 ■).

Figure 29–10 ■ Axillary thermometer placement for a child.

- Avoid the tympanic route in a child with active ear infections or tympanic membrane drainage tubes.
- The oral route may be used for children over age 3, but nonbreakable, electronic thermometers are recommended.
- For a rectal temperature, place the child prone across your lap or in a side-lying position with the knees flexed. Insert the thermometer 2.5 cm (1 in.) into the rectum.

OLDER ADULTS

- Older adults' temperatures tend to be lower than those of middle-aged adults.
- Older adults' temperatures are strongly influenced by both environmental and internal temperature changes. Their thermoregulation control processes are not as efficient as when they were younger, and they are at higher risk for both hypothermia and hyperthermia.
- Older adults can develop significant buildup of ear cerumen (earwax) that may interfere with tympanic thermometer readings.
- Older adults are more likely to have hemorrhoids. Inspect the anus before taking a rectal temperature.
- Older adults' temperatures may not be a valid indication of the seriousness of the pathology of a disease. They may have pneumonia or a urinary tract infection and have only a slight temperature elevation. Other symptoms, such as confusion and restlessness, may be displayed and need follow-up to determine if there is an underlying process.

Figure 29–11 ■ Pull the pinna of the ear back and up for placement of a tympanic thermometer in a child over 3 years of age; back and down for children under age 3.

Home Care Considerations Temperature**PATIENT-CENTERED CARE**

- Teach the client accurate use and reading of the type of thermometer to be used. Examine the thermometer used by the client in the home for safety and proper functioning. Facilitate the replacement of mercury thermometers with nonmercury ones. See page 482 for instructions regarding management of a broken mercury thermometer.
- Observe the client/caregiver taking and reading a temperature. Reinforce the importance of reporting the site and type of thermometer used and the value of using the same site and thermometer consistently.
- Discuss means of keeping the thermometer clean, such as warm water and soap, and avoiding cross contamination.
- Ensure that the client has water-soluble lubricant if using a rectal thermometer.
- Instruct the client or family member to notify the health care provider if the temperature is 38.5°C (101.3°F) or higher.
- When making a home visit, take a thermometer with you in case the clients do not have a functional thermometer of their own.
- Check that the client knows how to record the temperature. Provide a recording chart/table if indicated.
- Discuss environmental control modifications that should be made during illness or extreme climate conditions (e.g., heating, air conditioning, appropriate clothing and bedding).

- Pacifier thermometers (Figure 29–12 ■) may be used in the home setting for children under 2 years old. The manufacturer's instructions must be followed carefully since many require adding 0.5°F in order to estimate rectal temperature.

Figure 29–12 ■ A pacifier thermometer.

PULSE

The **pulse** is a wave of blood created by contraction of the left ventricle of the heart. Generally, the pulse wave represents the stroke volume output or the amount of blood that enters the arteries with each ventricular contraction. **Compliance** of the arteries is their ability to contract and expand. When a person's arteries lose their distensibility, as can happen with age, greater pressure is required to pump the blood into the arteries.

Cardiac output is the volume of blood pumped into the arteries by the heart and equals the result of the stroke volume (SV) times the heart rate (HR) per minute. For example, $65 \text{ mL} \times 70 \text{ beats per minute} = 4.55 \text{ L per minute}$. When an adult is resting, the heart pumps about 5 liters of blood each minute.

In a healthy person, the pulse reflects the heartbeat; that is, the pulse rate is the same as the rate of the ventricular contractions of the heart. However, in some types of cardiovascular disease, the heartbeat and pulse rates can differ. For example, a client's heart may produce very weak or small pulse waves that are not detectable in a peripheral pulse far from the heart. In these instances, the nurse should assess the heartbeat and the peripheral pulse. A **peripheral pulse** is a pulse located away from the heart, for example, in the foot or wrist. The **apical pulse**, in contrast, is a central pulse; that is, it is located at the apex of the heart. It is also referred to as the **point of maximal impulse (PMI)**.

Factors Affecting the Pulse

The rate of the pulse is expressed in beats per minute (beats/min). A pulse rate varies according to a number of factors. The nurse should consider each of the following factors when assessing a client's pulse:

- **Age.** As age increases, the pulse rate gradually decreases overall. See Table 29–2 for specific variations in pulse rates from birth to adulthood.
- **Sex.** After puberty, the average male's pulse rate is slightly lower than the female's.
- **Exercise.** The pulse rate normally increases with activity. The rate of increase in the professional athlete is often less than in the average person because of greater cardiac size, strength, and efficiency.
- **Fever.** The pulse rate increases (a) in response to the lowered blood pressure that results from peripheral vasodilation associated with elevated body temperature and (b) because of the increased metabolic rate.
- **Medications.** Some medications decrease the pulse rate, and others increase it. For example, cardiotonics (e.g., digitalis preparations) decrease the heart rate, whereas epinephrine increases it.

- **Hypovolemia/dehydration.** Loss of blood from the vascular system increases the pulse rate. In adults, the loss of circulating volume results in an adjustment of the heart rate to increase blood pressure as the body compensates for the lost blood volume.
- **Stress.** In response to stress, sympathetic nervous stimulation increases the overall activity of the heart. Stress increases the rate as well as the force of the heartbeat. Fear and anxiety as well as the perception of severe pain stimulate the sympathetic system.
- **Position.** When a person is sitting or standing, blood usually pools in dependent vessels of the venous system. Pooling results in a transient decrease in the venous blood return to the heart and a subsequent reduction in blood pressure and increase in heart rate.
- **Pathology.** Certain diseases such as some heart conditions or those that impair oxygenation can alter the resting pulse rate.

Pulse Sites

A pulse may be measured in nine sites (Figure 29–13 ■):

1. **Temporal**, where the temporal artery passes over the temporal bone of the head. The site is superior (above) and lateral to (away from the midline of) the eye.

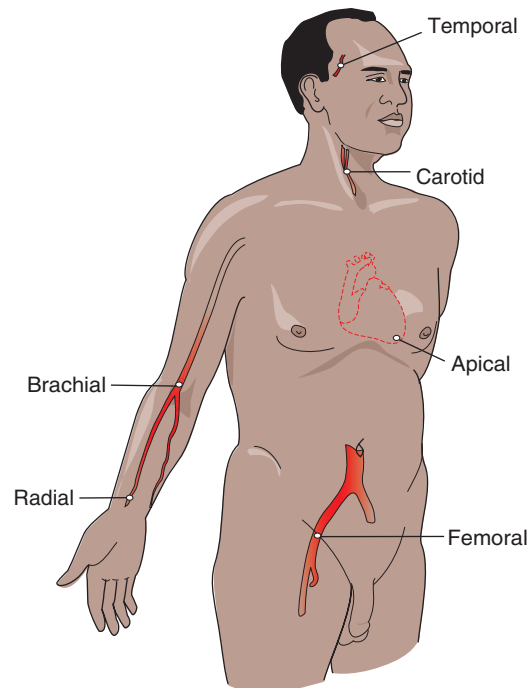

Figure 29–13 ■ Nine sites for assessing pulse.

TABLE 29–2 Variations in Pulse and Respirations by Age

Age	Pulse Average (and Ranges)	Respirations Average (and Ranges)
Newborn	130 (80–180)	35 (30–60)
1 year	120 (80–140)	30 (20–40)
5–8 years	100 (75–120)	20 (15–25)
10 years	70 (50–90)	19 (15–25)
Teen	75 (50–90)	18 (15–20)
Adult	80 (60–100)	16 (12–20)
Older adult	70 (60–100)	16 (15–20)

2. Carotid, at the side of the neck where the carotid artery runs between the trachea and the sternocleidomastoid muscle.

CLINICAL ALERT!

Never press both carotids at the same time because this can cause a reflex drop in blood pressure or pulse rate.

3. Apical, at the apex of the heart. In an adult, this is located on the left side of the chest, about 8 cm (3 in.) to the left of the sternum (breastbone) at the fifth intercostal space (area between the ribs). In older adults, the apex may be further left if conditions are present that have led to an enlarged heart. Before 4 years of age, the apex is left of the midclavicular line (MCL); between 4 and 6 years, it is at the MCL (Figure 29–14 ■). For a child 7 to 9 years of age, the apical pulse is located at the fourth or fifth intercostal space.
4. Brachial, at the inner aspect of the biceps muscle of the arm or medially in the antecubital space.
5. Radial, where the radial artery runs along the radial bone, on the thumb side of the inner aspect of the wrist.
6. Femoral, where the femoral artery passes alongside the inguinal ligament.
7. Popliteal, where the popliteal artery passes behind the knee.
8. Posterior tibial, on the medial surface of the ankle where the posterior tibial artery passes behind the medial malleolus.
9. Dorsalis pedis, where the dorsalis pedis artery passes over the bones of the foot, on an imaginary line drawn from the middle of the ankle to the space between the big and second toes.

The radial site is most commonly used in adults. It is easily found in most people and readily accessible. Some reasons for use of each site are given in Table 29–3.

Assessing the Pulse

A pulse is commonly assessed by palpation (feeling) or auscultation (hearing). The middle three fingertips are used for palpating all pulse sites except the apex of the heart. A stethoscope is used for

Figure 29–14 ■ Location of the apical pulse for a child under 4 years, a child 4 to 6 years, and an adult.

TABLE 29–3 Reasons for Using Specific Pulse Site

Pulse Site	Reasons for Use
Radial	Readily accessible
Temporal	Used when radial pulse is not accessible
Carotid	Used during cardiac arrest/shock in adults Used to determine circulation to the brain
Apical	Routinely used for infants and children up to 3 years of age Used to determine discrepancies with radial pulse Used in conjunction with some medications
Brachial	Used to measure blood pressure Used during cardiac arrest for infants
Femoral	Used in cases of cardiac arrest/shock Used to determine circulation to a leg
Popliteal	Used to determine circulation to the lower leg
Posterior tibial	Used to determine circulation to the foot
Dorsalis pedis	Used to determine circulation to the foot

assessing apical pulses. A Doppler ultrasound stethoscope (DUS; Figure 29–15 ■) is used for pulses that are difficult to assess. The DUS headset has earpieces similar to standard stethoscope earpieces, but it has a long cord attached to a volume-controlled audio unit and an ultrasound transducer. The DUS detects movement of red blood cells through a blood vessel. In contrast to the conventional stethoscope, it eliminates environmental sounds.

A pulse is normally palpated by applying moderate pressure with the three middle fingers of the hand. The pads on the most distal aspects of the finger are the most sensitive areas for detecting a pulse. With excessive pressure, one can obliterate a pulse, whereas with too little pressure one may not be able to detect it. Before the nurse assesses the resting pulse, the client should assume a comfortable position. The nurse should also be aware of the following:

- Any medication that could affect the heart rate.
- Whether the client has been physically active. If so, wait 10 to 15 minutes until the client has rested and the pulse has slowed to its usual rate.

Figure 29–15 ■ A Doppler ultrasound stethoscope (DUS).

- Any baseline data about the normal heart rate for the client. For example, a physically fit athlete may have a resting heart rate below 60 beats/min.
- Whether the client should assume a particular position (e.g., sitting). In some clients, the rate changes with the position because of changes in blood flow volume and autonomic nervous system activity.

When assessing the pulse, the nurse collects the following data: the rate, rhythm, volume, arterial wall elasticity, and presence or absence of bilateral equality. An excessively fast heart rate (e.g., over 100 beats/min in an adult) is referred to as **tachycardia**. A heart rate in an adult of less than 60 beats/min is called **bradycardia**. If a client has either tachycardia or bradycardia, the apical pulse should be assessed.

The **pulse rhythm** is the pattern of the beats and the intervals between the beats. Equal time elapses between beats of a normal pulse. A pulse with an irregular rhythm is referred to as a **dysrhythmia** or **arrhythmia**. It may consist of random, irregular beats or a predictable pattern of irregular beats (documented as “regularly irregular”). When a dysrhythmia is detected, the apical pulse should be assessed. An electrocardiogram (ECG) is necessary to define the dysrhythmia further.

Pulse volume, also called the pulse strength or amplitude, refers to the force of blood with each beat. Usually, the pulse volume is the same with each beat. It can range from absent to bounding. A normal pulse can be felt with moderate pressure of the fingers and can be

obliterated with greater pressure. A forceful or full blood volume that is obliterated only with difficulty is called a full or bounding pulse. A pulse that is readily obliterated with pressure from the fingers is referred to as weak, feeble, or thready.

The elasticity of the arterial wall reflects its expansibility or its deformities. A healthy, normal artery feels straight, smooth, soft, and pliable. Older adults often have inelastic arteries that feel twisted (tortuous) and irregular on palpation.

When assessing a peripheral pulse to determine the adequacy of blood flow to a particular area of the body (perfusion), the nurse should also assess the corresponding pulse on the other side of the body. The second assessment gives the nurse data with which to compare the pulses. For example, when assessing the blood flow to the right foot, the nurse assesses the right dorsalis pedis pulse and then the left dorsalis pedis pulse. If the client’s right and left pulses are the same volume and elasticity, the client’s dorsalis pedis pulses are bilaterally equal. The pulse rate does not need to be counted when assessing for perfusion and equality.

When a peripheral pulse is located, it indicates that pulses more proximal to that location will also be present. For example, if the dorsalis pedis, the most distal pulse of the lower extremity, cannot be felt, the nurse next palpates for the posterior tibial pulse. If it is not felt, the popliteal pulse must be assessed. If the popliteal pulse is found, it is not necessary to assess the femoral pulse since it must also be present in order for the more distal pulse to exist.

Skill 29–2 provides guidelines for assessing a peripheral pulse.

Assessing a Peripheral Pulse

PURPOSES

- To establish baseline data for subsequent evaluation
- To identify whether the pulse rate is within normal range
- To determine the pulse volume and whether the pulse rhythm is regular
- To determine the equality of corresponding peripheral pulses on each side of the body

- To monitor and assess changes in the client’s health status
- To monitor clients at risk for pulse alterations (e.g., those with a history of heart disease or experiencing cardiac arrhythmias, hemorrhage, acute pain, infusion of large volumes of fluids, or fever)
- To evaluate blood perfusion to the extremities

ASSESSMENT

Assess

- Clinical signs of cardiovascular alterations such as dyspnea (difficult respirations), fatigue, pallor, cyanosis (bluish discoloration of skin and mucous membranes), palpitations, syncope (fainting), or impaired peripheral tissue perfusion (as evidenced by skin discoloration and cool temperature)

- Factors that may alter pulse rate (e.g., emotional status and activity level)
- Which site is most appropriate for assessment based on the purpose

PLANNING

DELEGATION

Measurement of the client’s radial or brachial pulse can be delegated to UAP, or be performed by family members/caregivers in nonhospital settings. Reports of abnormal pulse rates or rhythms require reassessment by the nurse, who also determines appropriate action if the abnormality is confirmed. UAP are generally not delegated these techniques due to the skill required in locating and interpreting peripheral pulses other than the radial or brachial artery and in using Doppler ultrasound devices.

Equipment

- Clock or watch with a sweep second hand or digital seconds indicator

INTERPROFESSIONAL PRACTICE

Assessing a peripheral pulse may be within the scope of practice for many health care providers. For example, in addition to nurses, both physical therapists and respiratory therapists may check the client’s pulse before, during, and after treatment. Although these therapists may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client’s medical record.

- If using a DUS: transducer probe, stethoscope headset (some models), transmission gel, and tissues/wipes

Assessing a Peripheral Pulse—continued

SKILL 29-2

IMPLEMENTATION

Preparation

If using a DUS, check that the equipment is functioning normally.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.

1 Assessing pulses: **A** Radial

1 **C** Carotid

1 **E** Popliteal

2. Perform hand hygiene and observe appropriate infection prevention procedures.
3. Provide for client privacy.
4. Select the pulse point. Normally, the radial pulse is taken, unless it cannot be exposed or circulation to another body area is to be assessed.
5. Assist the client to a comfortable resting position. When the radial pulse is assessed, with the palm facing downward, the client's arm can rest alongside the body or the forearm can rest at a 90-degree angle across the chest. For the client who can sit, the forearm can rest across the thigh, with the palm of the hand facing downward or inward.
6. Palpate and count the pulse. Place two or three middle fingertips lightly and squarely over the pulse point. 1

1 **B** Brachial

1 **D** Femoral

1 **F** Posterior tibial

Assessing a Peripheral Pulse—continued

1 G Dorsalis pedis

2 Using a DUS to assess the posterior tibial pulse.

1 Rationale: Using the thumb is contraindicated because the nurse's thumb has a pulse that could be mistaken for the client's pulse.

- Count for 15 seconds and multiply by 4. Record the pulse in beats per minute on your worksheet. If taking a client's pulse for the first time, when obtaining baseline data, or if the pulse is irregular, count for a full minute. If an irregular pulse is found, also take the apical pulse.

7. Assess the pulse rhythm and volume.

- Assess the pulse rhythm by noting the pattern of the intervals between the beats. A normal pulse has equal time periods between beats. If this is an initial assessment, assess for 1 minute.
- Assess the pulse volume. A normal pulse can be felt with moderate pressure, and the pressure is equal with each beat. A forceful pulse volume is full; an easily obliterated pulse is weak. Record the rhythm and volume on your worksheet.

8. Document the pulse rate, rhythm, and volume and your actions in the client record (see Figure 1 in Skill 29-1). Also record in the nurse's notes pertinent related data such as variation in pulse rate compared to normal for the client and abnormal skin color and skin temperature.

Variation: Using a DUS

- If used, plug the stethoscope headset into one of the two output jacks located next to the volume control. DUS units may have two jacks so that a second person can listen to the signals.

EVALUATION

- Compare the pulse rate to baseline data or normal range for age of client.
- Relate pulse rate and volume to other vital signs; relate pulse rhythm and volume to baseline data and health status.

- Apply transmission gel either to the probe at the narrow end of the plastic case housing the transducer, or to the client's skin.
- Press the "on" button.
- Hold the probe against the skin over the pulse site. Use a light pressure, and keep the probe in contact with the skin.

2 Rationale: *Too much pressure can stop the blood flow and obliterate the signal.*

- Adjust the volume if necessary. Distinguish artery sounds from vein sounds. The artery sound (signal) is distinctively pulsating and has a pumping quality. The venous sound is intermittent and varies with respirations. Both artery and vein sounds are heard simultaneously through the DUS because major arteries and veins are situated close together throughout the body. If arterial sounds cannot be easily heard, reposition the probe. If you cannot hear any pulse, move the probe to several different locations in the same area before determining that no pulse is present.
- After assessing the pulse, remove all gel from the probe to prevent damage to the surface. Clean the transducer with water-based solution.

Rationale: Alcohol or other disinfectants may damage the face of the transducer.

- Remove all gel from the client.

- If assessing peripheral pulses, evaluate equality, rate, and volume in corresponding extremities.
- Conduct appropriate follow-up such as notifying the primary care provider or giving medication.

Apical Pulse Assessment

Assessment of the apical pulse is indicated for clients whose peripheral pulse is irregular or unavailable and for clients with known cardiovascular, pulmonary, and renal diseases. It is commonly assessed

prior to administering medications that affect heart rate. The apical site is also used to assess the pulse for newborns, infants, and children up to 2 to 3 years old. Skill 29-3 presents guidelines for assessing the apical pulse.

Assessing an Apical Pulse

PURPOSES

- To obtain the heart rate of an adult with an irregular peripheral pulse
- To establish baseline data for subsequent evaluation
- To determine whether the cardiac rate is within normal range and the rhythm is regular
- To monitor clients with cardiac, pulmonary, or renal disease and those receiving medications to improve heart action

ASSESSMENT

Assess

- Clinical signs of cardiovascular alterations such as dyspnea (difficult respirations), fatigue/weakness, pallor, cyanosis (bluish discoloration of skin and mucous membranes), palpitations, syncope (fainting), or impaired peripheral tissue perfusion as evidenced by skin discoloration and cool temperature
- Factors that may alter pulse rate (e.g., emotional status, activity level, and medications that affect heart rate such as digoxin, beta-blockers, or calcium channel blockers)

PLANNING

DELEGATION

Due to the degree of skill and knowledge required, UAP are generally not responsible for assessing apical pulses.

Equipment

- Clock or watch with a sweep second hand or digital seconds indicator
- Stethoscope
- Antiseptic wipes
- If using a DUS: the transducer probe, the stethoscope headset, transmission gel, and tissues/wipes

IMPLEMENTATION

Preparation

If using a DUS, check that the equipment is functioning normally.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe appropriate infection prevention procedures.
3. Provide for client privacy.
4. Position the client appropriately in a comfortable supine position or in a sitting position. Expose the area of the chest over the apex of the heart.
5. Locate the apical impulse. This is the point over the apex of the heart where the apical pulse can be most clearly heard.
 - Palpate the angle of Louis (the angle between the manubrium, the top of the sternum, and the body of the sternum). It is palpated just below the suprasternal notch and is felt as a prominence (see Figure 29-14).
 - Slide your index finger just to the left of the sternum, and palpate the second intercostal space. ❶

CLINICAL ALERT!

When "left" and "right" are used to describe the nurse's hand placement on the client, the terms refer to the client's right or left side, not the nurse's.

INTERPROFESSIONAL PRACTICE

Assessing an apical pulse may be within the scope of practice for many health care providers. For example, in addition to nurses, respiratory therapists may check the client's apical pulse before, during, and after treatment, and physicians often check the apical pulse when assessing the chest during examinations. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

❶ Second intercostal space.

Shirlee Snyder.

2. Place your middle or next finger in the third intercostal space, and continue palpating downward until you locate the fifth intercostal space. ❷
3. Move your index finger laterally along the fifth intercostal space toward the MCL. ❸ Normally, the apical impulse is palpable at or just medial to the MCL (see Figure 29-14).
6. Auscultate and count heartbeats.
 - Use antiseptic wipes to clean the earpieces and diaphragm of the stethoscope.

Rationale: The diaphragm needs to be cleaned and disinfected if soiled with body substances. Both earpieces and diaphragms have been shown to harbor pathogenic bacteria (Muniz, Sethi, Zaghi, Ziniel, & Sandora, 2012).

Assessing an Apical Pulse—continued

2 Third intercostal space.
Shirlee Snyder.

3 Fifth intercostal space, MCL.
Shirlee Snyder.

- Warm the diaphragm of the stethoscope by holding it in the palm of the hand for a moment.
Rationale: The metal of the diaphragm is usually cold and can startle the client when placed immediately on the chest.
- Insert the earpieces of the stethoscope into your ears in the direction of the ear canals, or slightly forward.
Rationale: This position facilitates hearing.
- Tap your finger lightly on the diaphragm.
Rationale: This is to be sure it is the active side of the head. If necessary, rotate the head to select the diaphragm side. 4
- Place the diaphragm of the stethoscope over the apical impulse and listen for the normal S₁ and S₂ heart sounds, which are heard as “lub-dub.” 5
Rationale: The heartbeat is normally loudest over the apex of the heart.
Each lub-dub is counted as one heartbeat.
Rationale: The two heart sounds are produced by closure of the heart valves. The S₁ heart sound (lub) occurs when the atrioventricular valves close after the ventricles have been sufficiently filled. The S₂ heart sound (dub) occurs when the semilunar valves close after the ventricles empty.
- If you have difficulty hearing the apical pulse, ask the supine client to roll onto his or her left side or the sitting client to lean slightly forward.
Rationale: This positioning moves the apex of the heart closer to the chest wall.
- If the rhythm is regular, count the heartbeats for 30 seconds and multiply by 2. If the rhythm is irregular or for giving certain medications such as digoxin, count the beats for 60 seconds.

A

B

- 4 A, Stethoscope with both a bell and a diaphragm.
B, Close-up of a bell (left) and a diaphragm (right).

- 5 Taking an apical pulse using the flat-disc stethoscope. Note how the amplifier is held against the chest.

- Rationale:** A 60-second count provides a more accurate assessment of an irregular pulse than a 30-second count.
7. Assess the rhythm and the strength of the heartbeat.
- Assess the rhythm of the heartbeat by noting the pattern of intervals between the beats. A normal pulse has equal time periods between beats.
 - Assess the strength (volume) of the heartbeat. Normally, the heartbeats are equal in strength and can be described as strong or weak.

Assessing an Apical Pulse—continued

8. Document the pulse rate and rhythm, and nursing actions in the client record. Also record pertinent related data such as variation in pulse rate compared to normal for the client and abnormal skin color and skin temperature.

SAMPLE DOCUMENTATION

2/24/16 1000 Radial pulse 116 & irregular. Had been 82 & regular at 0600. T, R, & BP within client's usual range. C/o being a "little dizzy." Skin warm & dry. Apical pulse 120, irregular, with brief pause after q 3rd beat. MD notified & ECG ordered. _____ G. Chapman, RN

EVALUATION

- Relate the pulse rate to other vital signs. Relate the pulse rhythm to baseline data and health status.
- Report to the primary care provider any abnormal findings such as irregular rhythm, reduced ability to hear the heartbeat, pallor, cyanosis, dyspnea, tachycardia, or bradycardia.
- Conduct appropriate follow-up such as administering medication ordered based on apical heart rate.

LIFESPAN CONSIDERATIONS Pulse

INFANTS

- Use the apical pulse for the heart rate of newborns, infants, and children 2 to 3 years old to establish baseline data for subsequent evaluation, to determine whether the cardiac rate is within normal range, and to determine if the rhythm is regular.
- Place a baby in a supine position, and offer a pacifier if the baby is crying or restless. Crying and physical activity will increase the pulse rate. For this reason, take the resting apical pulse rate of infants and small children before assessing body temperatures.
- Locate the apical pulse in the left fourth intercostal space, lateral to the midclavicular line during infancy.
- Brachial, popliteal, and femoral pulses may be palpated. Due to a normally low blood pressure and rapid heart rate, infants' other distal pulses may be hard to feel.
- Newborn infants may have heart murmurs that are not pathologic, but reflect functional incomplete closure of fetal heart structures (ductus arteriosus or foramen ovale).

CHILDREN

- To take a peripheral pulse, position the child comfortably in the adult's arms or have the adult remain close by. This may decrease anxiety and yield more accurate results.
- To assess the apical pulse, assist a young child to a comfortable supine or sitting position.

- Demonstrate the procedure to the child using a stuffed animal or doll, and allow the child to handle the stethoscope before beginning the procedure. This will decrease anxiety and promote cooperation.
- The apex of the heart is normally located in the left fourth intercostal space in young children; fifth intercostal space in children 7 years of age and over, between the MCL and the anterior axillary line (see Figure 29-14).
- Count the pulse prior to other uncomfortable procedures so that the rate is not artificially elevated by the discomfort.

OLDER ADULTS

- If the client has severe hand or arm tremors, the radial pulse may be difficult to count.
- Cardiac changes in older adults, such as decrease in cardiac output, sclerotic changes to heart valves, and dysrhythmias, may suggest that obtaining an apical pulse will be more accurate than a peripheral pulse.
- Older adults often have decreased peripheral circulation. To detect these, pedal pulses should also be checked for regularity, volume, and symmetry.
- The pulse returns to baseline after exercise more slowly than with other age groups.

APICAL-RADIAL PULSE ASSESSMENT

An **apical-radial pulse** may need to be assessed for clients with certain cardiovascular disorders. Normally, the apical and radial rates are identical. An apical pulse rate greater than a radial pulse rate can indicate that the thrust of the blood from the heart is too weak for the wave to be felt at the peripheral pulse site, or it can indicate that vascular disease is preventing impulses from being transmitted. Any

discrepancy between the two pulse rates is called a **pulse deficit** and needs to be reported promptly. In no instance is the radial pulse greater than the apical pulse.

An apical-radial pulse can be taken by two nurses or one nurse, although the two-nurse technique may be more accurate. Skill 29-4 outlines the steps for assessing an apical-radial pulse.

Assessing an Apical-Radial Pulse

PURPOSE

- To determine adequacy of peripheral circulation or presence of pulse deficit

ASSESSMENT

Assess

- Clinical signs of hypovolemic shock (hypotension, pallor, cyanosis, and cold, clammy skin)

PLANNING

DELEGATION

UAP are generally not responsible for assessing apical-radial pulses using the one-nurse technique. UAP may perform the radial pulse count for the two-nurse technique.

Equipment

- Clock or watch with a sweep second hand or digital seconds indicator
- Stethoscope
- Antiseptic wipes

IMPLEMENTATION

Preparation

If using the two-nurse technique, ensure that the other nurse is available at this time.

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
- Perform hand hygiene and observe appropriate infection prevention procedures.
- Provide for client privacy.
- Position the client appropriately. Assist the client to a comfortable supine or sitting position. Expose the area of the chest over the apex of the heart. If previous measurements were taken, determine what position the client assumed, and use the same position.

Rationale: This ensures an accurate comparative measurement.

- Locate the apical and radial pulse sites. In the two-nurse technique, one nurse locates the apical impulse by palpation or with the stethoscope while the other nurse palpates the radial pulse site (see Skills 29-2 and 29-3).
- Count the apical and radial pulse rates.

Two-Nurse Technique

- Place the clock or watch where both nurses can see it. The nurse who is taking the radial pulse may hold the watch.

EVALUATION

- Relate pulse rate and rhythm to other vital signs, to baseline data, and to general health status.
- Report to the primary care provider any changes from previous measurements or any discrepancy between the two pulse rates.

INTERPROFESSIONAL PRACTICE

Assessing an apical-radial pulse may be within the scope of practice for many health care providers. Any provider who assesses a pulse can serve as the second person in the two-person technique.

Home Care Considerations Pulse

PATIENT-CENTERED CARE

- Assist in obtaining and using an electronic pulse-measuring device if indicated.
- Teach the client to monitor the pulse prior to taking medications that affect the heart rate. Tell the client to report any notable changes in heart rate or rhythm (regularity) to the health care provider.
- Inform the client/family of activities known to significantly affect pulse rate such as emotional stress, exercise, ingesting caffeine, and sleep. Clients sensitive to pulse rate changes should consider whether any of these activities should be modified in order to stabilize the pulse.
- Some clients require lengthy monitoring of the pulse and cardiac pattern (electrocardiogram). A special device, often referred to as a Holter monitor, is used for this type of monitoring. It is usually applied in an office or clinic setting, and the client wears the portable recorder for 24 hours. Other portable devices used for recording episodic arrhythmias include cardiac event monitors. The client activates the device during times when symptoms appear and then the recorded data can be transmitted to a central location through a telephone.

DRUG CAPSULE

Cardiac Glycoside or Digitalis Glycoside Digoxin (Lanoxin)**CLIENT WITH CARDIAC MEDICATIONS THAT AFFECT HEART RATE**

Cardiac glycosides increase cardiac contractility, which increases cardiac output. As a result, perfusion to the kidneys is increased, which increases the production of urine. Cardiac glycosides also decrease heart rate by prolonging cardiac conduction, especially at the AV node.

Digoxin is commonly used for the clinical management of heart failure, atrial fibrillation, atrial flutter, and paroxysmal atrial tachycardia.

NURSING RESPONSIBILITIES

- Take the apical pulse for 1 minute before administering the dose. If the apical pulse is < 60 beats/min or another specific parameter set by the health care provider, do not administer the dose and retake the pulse in 1 hour. If pulse remains < 60 , call the prescriber. *Note:* If the initial resting pulse is significantly < 60 or the client has symptoms of bradycardia such as dizziness, notify the primary care provider without waiting to retake.
- Monitor electrolyte levels: Low potassium and low magnesium and high levels of calcium place the client at risk for digitalis toxicity. Check the client's most recent electrolyte laboratory work for safe levels before administering the dose.
- Avoid giving with meals because this will delay absorption.
- Monitor for therapeutic drug levels: 0.5–2 ng/mL. Digoxin has a narrow therapeutic index, which means that there is not much difference between a therapeutic effect and a toxic effect.

- Assess for signs of digoxin toxicity: anorexia, nausea, vomiting, diarrhea, blurred or “yellow” vision, unusual tiredness and weakness.

CLIENT AND FAMILY TEACHING

- Explain the reason for taking digoxin and the importance of medical checkups that may include laboratory work to evaluate the effects and dosage of the drug.
- Teach the client and/or family how to check the radial or carotid pulse for a full minute. Inform them to take the pulse at the same time each day and to write it on the calendar. Provide pulse parameters and tell them when it is appropriate to call the health care provider.
- Caution the client not to stop taking the digoxin without approval of the health care provider.
- Caution the client to avoid over-the-counter drugs, except on the advice of the health care provider, because many can interact with digoxin.
- Explain the signs and symptoms of digoxin toxicity and the importance of calling the health care provider.

Note: Prior to administering any medication, review all aspects with a current drug handbook or other reliable source.

RESPIRATIONS

Respiration is the act of breathing. **Inhalation** or **inspiration** refers to the intake of air into the lungs. **Exhalation** or **expiration** refers to breathing out or the movement of gases from the lungs to the atmosphere. **Ventilation** is also used to refer to the movement of air in and out of the lungs.

There are basically two types of breathing: **costal (thoracic) breathing** and **diaphragmatic (abdominal) breathing**. Costal breathing involves the external intercostal muscles and other accessory muscles, such as the sternocleidomastoid muscles. It can be observed by the movement of the chest upward and outward. By contrast, diaphragmatic breathing involves the contraction and relaxation of the diaphragm, and it is observed by the movement of the abdomen, which occurs as a result of the diaphragm's contraction and downward movement.

Mechanics and Regulation of Breathing

During inhalation, the following processes normally occur (Figure 29–16 ■): The diaphragm contracts (flattens), the ribs move upward and outward, and the sternum moves outward, thus enlarging the thorax and permitting the lungs to expand. During exhalation (Figure 29–17 ■), the diaphragm relaxes, the ribs move downward and inward, and the sternum moves inward, thus decreasing the size of the thorax as the lungs are compressed. Normal breathing is automatic and effortless. A normal adult inspiration lasts 1 to 1.5 seconds, and an expiration lasts 2 to 3 seconds.

Respiration is controlled by (a) respiratory centers in the medulla oblongata and the pons of the brain and (b) chemoreceptors located centrally in the medulla and peripherally in the carotid and aortic bodies. These centers and receptors respond to changes in the concentrations of oxygen (O_2), carbon dioxide (CO_2), and hydrogen (H^+) in the arterial blood. See Chapter 50 ∞ for details.

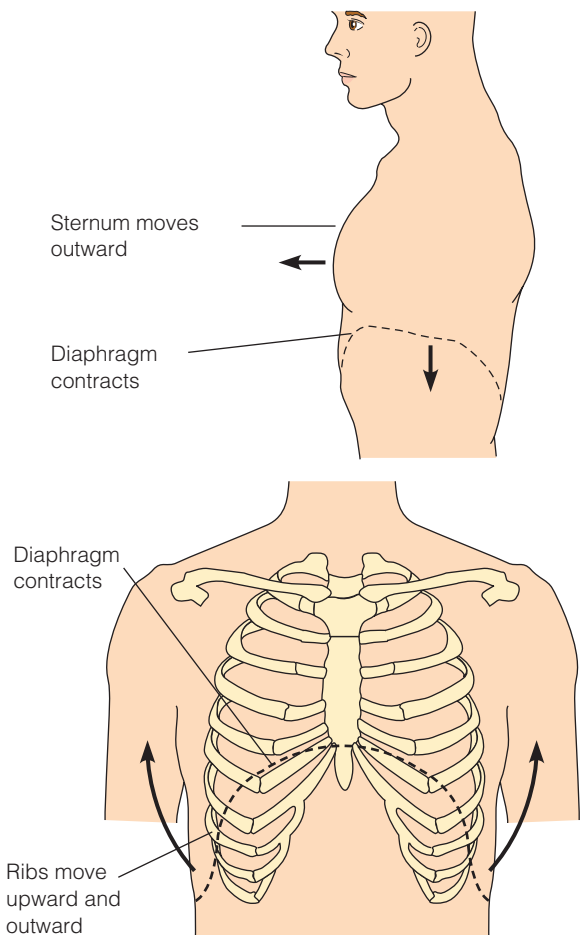

Figure 29–16 ■ Respiratory inhalation: *top*: lateral view; *bottom*: anterior view.

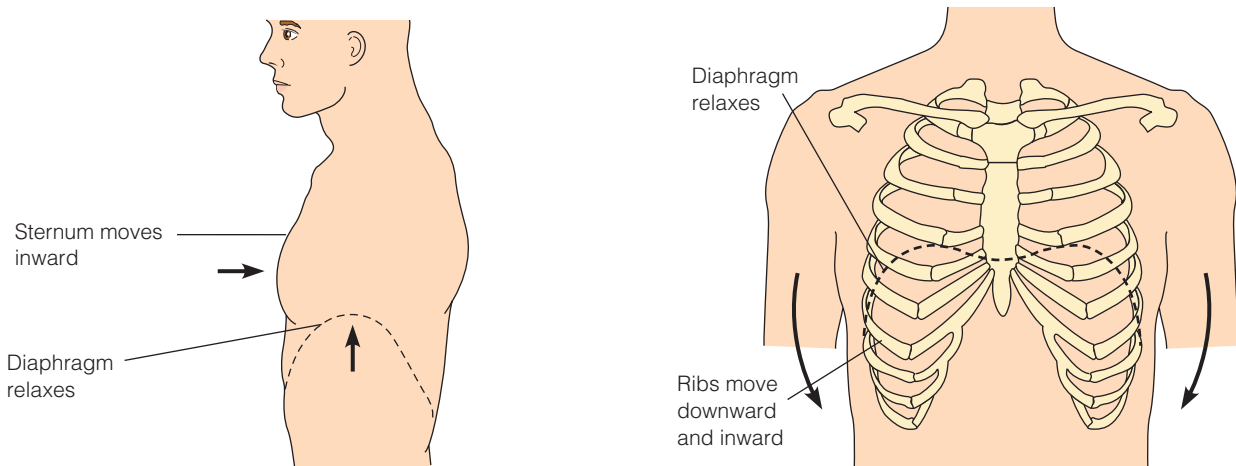

Figure 29-17 ■ Respiratory exhalation: *left*: lateral view; *right*: anterior view.

Assessing Respirations

Resting respirations should be assessed when the client is relaxed because exercise affects respirations, increasing their rate and depth. Anxiety is likely to affect respiratory rate and depth as well. Respirations may also need to be assessed after exercise to identify the client's tolerance to activity. Before assessing a client's respirations, a nurse should be aware of the following:

- The client's normal breathing pattern
- The influence of the client's health problems on respirations
- Any medications or therapies that might affect respirations
- The relationship of the client's respirations to cardiovascular function.

The rate, depth, rhythm, quality, and effectiveness of respirations should be assessed. The respiratory rate is normally described in breaths per minute. Breathing that is normal in rate and depth is called *eupnea*. Abnormally slow respirations are referred to as **bradypnea**, and abnormally fast respirations are called **tachypnea** or **polypnea**. **Apnea** is the absence of breathing. For the respiratory rates for different age groups, see Table 29-2 on page 487.

CLINICAL ALERT!

An adult sleeping client's respirations can fall to fewer than 10 shallow breaths per minute. Use other vital signs to validate the client's condition.

Factors Affecting Respirations

Several factors influence respiratory rate. Those that increase the rate include exercise (increases metabolism), stress (readies the body for "fight or flight"), increased environmental temperature, and lowered oxygen concentration at increased altitudes. Factors that may decrease the respiratory rate include decreased environmental temperature, certain medications (e.g., narcotics), and increased intracranial pressure.

The depth of a person's respirations can be established by watching the movement of the chest. Respiratory depth is generally described as normal, deep, or shallow. Deep respirations are those in which a large volume of air is inhaled and exhaled, inflating most of the lungs. Shallow respirations involve the exchange of a small volume of air and often the minimal use of lung tissue. During a normal

inspiration and expiration, an adult takes in about 500 mL of air. This volume is called the **tidal volume**. For further information about pulmonary volumes and pulmonary capacities, see Chapter 50 ∞.

Body position also affects the amount of air that can be inhaled. People in a supine position experience two physiological processes that suppress respiration: an increase in the volume of blood inside the thoracic cavity and compression of the chest. Consequently, clients lying on their back have poorer lung aeration, which predisposes them to the stasis of fluids and subsequent infection. Certain medications also affect the respiratory depth. For example, narcotics such as morphine and large doses of barbiturates such as pentobarbital depress the respiratory centers in the brain, thereby depressing the respiratory rate and depth. **Hyperventilation** refers to very deep, rapid respirations; **hypoventilation** refers to very shallow respirations.

Respiratory rhythm refers to the regularity of the expirations and the inspirations. Normally, respirations are evenly spaced. Respiratory rhythm can be described as regular or irregular. An infant's respiratory rhythm may be less regular than an adult's. See Chapter 50 ∞ for details about abnormal respiratory rhythms.

Respiratory quality or **character** refers to those aspects of breathing that are different from normal, effortless breathing. Two of these aspects are the amount of effort a client must exert to breathe and the sound of breathing. Usually, breathing does not require noticeable effort. Sometimes, however, clients can breathe only with substantial effort—this is referred to as labored breathing.

The sound of breathing is also significant. Normal breathing is silent, but a number of abnormal sounds such as a wheeze are obvious to the nurse's ear. Many sounds occur as a result of the presence of fluid in the lungs and are most clearly heard with a stethoscope. See Chapter 30 ∞ for methods used to assess lung sounds. For details about altered breathing patterns and terms used to describe various patterns and sounds, see Box 29-5.

The effectiveness of respirations is measured in part by the uptake of oxygen from the air into the blood and the release of carbon dioxide from the blood into expired air. The amount of hemoglobin in arterial blood that is saturated with oxygen can be measured indirectly through pulse oximetry. A pulse oximeter provides a digital readout of both the client's pulse rate and the oxygen saturation (see Skill 29-7 later in this chapter).

Skill 29-5 outlines the steps for assessing respirations.

BOX 29-5 Altered Breathing Patterns and Sounds**BREATHING PATTERNS****Rate**

- *Tachypnea*—quick, shallow breaths
- *Bradypnea*—abnormally slow breathing
- *Apnea*—cessation of breathing

Volume

- *Hyperventilation*—overexpansion of the lungs characterized by rapid and deep breaths
- *Hypoventilation*—underexpansion of the lungs, characterized by shallow respirations

Rhythm

- *Cheyne-Stokes breathing*—rhythmic waxing and waning of respirations, from very deep to very shallow breathing and temporary apnea

Ease or Effort

- *Dyspnea*—difficult and labored breathing during which the individual has a persistent, unsatisfied need for air and feels distressed
- *Orthopnea*—ability to breathe only in upright sitting or standing positions

BREATH SOUNDS**Audible Without Amplification**

- *Stridor*—a shrill, harsh sound heard during inspiration with laryngeal obstruction
- *Stertor*—snoring or sonorous respiration, usually due to a partial obstruction of the upper airway
- *Wheeze*—continuous, high-pitched musical squeak or whistling sound occurring on expiration and sometimes on inspiration when air moves through a narrowed or partially obstructed airway
- *Bubbling*—gurgling sounds heard as air passes through moist secretions in the respiratory tract

CHEST MOVEMENTS

- *Intercostal retraction*—indrawing between the ribs
- *Substernal retraction*—indrawing beneath the breastbone
- *Suprasternal retraction*—indrawing above the clavicles

SECRETIONS AND COUGHING

- *Hemoptysis*—the presence of blood in the sputum
- *Productive cough*—a cough accompanied by expectorated secretions
- *Nonproductive cough*—a dry, harsh cough without secretions

Assessing Respirations**PURPOSES**

- To acquire baseline data against which future measurements can be compared
- To monitor abnormal respirations and respiratory patterns and identify changes
- To monitor respirations before or after the administration of a general anesthetic or any medication that influences respirations
- To monitor clients at risk for respiratory alterations (e.g., those with fever, pain, acute anxiety, chronic obstructive pulmonary disease, asthma, respiratory infection, pulmonary edema or emboli, chest trauma or constriction, brainstem injury)

ASSESSMENT**Assess**

- Skin and mucous membrane color (e.g., cyanosis or pallor)
- Position assumed for breathing (e.g., use of orthopneic position)
- Signs of lack of oxygen to the brain (e.g., irritability, restlessness, drowsiness, or loss of consciousness)
- Chest movements (e.g., retractions between the ribs or above or below the sternum)
- Activity tolerance
- Chest pain
- Dyspnea
- Medications affecting respiratory rate

PLANNING**DELEGATION**

Counting and observing respirations may be delegated to UAP. The follow-up assessment, interpretation of abnormal respirations, and determination of appropriate responses are done by the nurse.

Equipment

- Clock or watch with a sweep second hand or digital seconds indicator

IMPLEMENTATION**Preparation**

For a routine assessment of respirations, determine the client's activity schedule and choose a suitable time to monitor the respirations. A client who has been exercising will need to rest for a few minutes to permit the accelerated respiratory rate to return to normal.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client

INTERPROFESSIONAL PRACTICE

Assessing respirations may be within the scope of practice for many health care providers. For example, in addition to nurses, respiratory therapists will check the client's breathing before, during, and after treatment. Although these therapists may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.

2. Perform hand hygiene and observe appropriate infection prevention procedures.
3. Provide for client privacy.

Assessing Respirations—continued

4. Observe or palpate and count the respiratory rate.
 - The client's awareness that the nurse is counting the respiratory rate could cause the client to purposefully alter the respiratory pattern. If you anticipate this, place a hand against the client's chest to feel the chest movements with breathing, or place the client's arm across the chest and observe the chest movements while supposedly taking the radial pulse.
 - Count the respiratory rate for 30 seconds if the respirations are regular. Count for 60 seconds if they are irregular. An inhalation and an exhalation count as one respiration.
5. Observe the depth, rhythm, and character of respirations.
 - Observe the respirations for depth by watching the movement of the chest.

Rationale: During deep respirations, a large volume of air is exchanged; during shallow respirations, a small volume is exchanged.
 - Observe the respirations for regular or irregular rhythm.

Rationale: Normally, respirations are evenly spaced.
 - Observe the character of respirations—the sound they produce and the effort they require.

Rationale: Normally, respirations are silent and effortless.
6. Document the respiratory rate, depth, rhythm, and character on the appropriate record (see 1 in Skill 29-1).

SAMPLE DOCUMENTATION

5/17/16 1320 Respirations irregular, from 18–34/min in past hour. Shallower respirations during tachypnea. Inspiratory wheeze noted. Respiratory therapist called to provide treatment.

_____ D. Katano, RN

EVALUATION

- Relate respiratory rate to other vital signs, in particular pulse rate; relate respiratory rhythm and depth to baseline data and health status.
- Report to the primary care provider a respiratory rate significantly above or below the normal range and any notable change in

respirations from previous assessments; irregular respiratory rhythm; inadequate respiratory depth; abnormal character of breathing—orthopnea, wheezing, stridor, or bubbling; and any complaints of dyspnea.

LIFESPAN CONSIDERATIONS Respirations

INFANTS AND CHILDREN

- An infant or child who is crying will have an abnormal respiratory rate and rhythm and needs to be quieted before respirations can be accurately assessed.
- Infants and young children use their diaphragms for inhalation and exhalation. If necessary, place your hand gently on the infant's abdomen to feel the rapid rise and fall during respirations.
- Most newborns are complete nose breathers, so nasal obstruction can be life threatening.
- Some newborns display "periodic breathing" in which they pause for a few seconds between respirations. This condition can be normal, but parents should be alert to prolonged or frequent pauses (apnea) that require medical attention.
- Compared to adults, infants have fewer alveoli and their airways have a smaller diameter. As a result, infants' respiratory rate and effort of breathing will increase with respiratory infections.
- Count respirations prior to other uncomfortable procedures so that the respiratory rate is not artificially elevated by the discomfort.

OLDER ADULTS

- Ask the client to remain quiet, or count respirations after taking the pulse.
- Older adults experience anatomic and physiological changes that cause the respiratory system to be less efficient. Any changes in rate or type of breathing should be reported immediately.

Home Care Considerations Respirations SAFETY

- Monitor respiratory rate following the administration of respiratory depressants such as morphine.
- Assess the home setting for factors that could interfere with breathing such as exhaust, gas, or paint fumes or individuals who smoke.
- If the client has just come in from another room, allow the client to rest a minute or two before counting respirations.
- Have an adult hold a child gently to reduce movement while counting respirations.

the ventricles, that is, the pressure of the height of the blood wave. The **diastolic pressure** is the pressure when the ventricles are at rest. Diastolic pressure, then, is the lower pressure, present at all times within the arteries. The difference between the diastolic and the systolic pressures is called the **pulse pressure**. A normal pulse pressure is about 40 mmHg but can be as high as 100 mmHg during exercise.

Blood pressure is measured in millimeters of mercury (mmHg) and recorded as a fraction: systolic pressure over the diastolic pressure. A typical blood pressure for a healthy adult is 120/80 mmHg (pulse pressure of 40). Because blood pressure can vary considerably among individuals, it is important for the nurse to know a specific client's baseline blood pressure. For example, if a client's usual blood pressure is 180/100 mmHg, and it is assessed following surgery to be 120/80 mmHg, this significant drop in pressure may indicate complications and must be reported to the primary care provider.

A consistently elevated pulse pressure occurs in arteriosclerosis. A low pulse pressure (e.g., less than 25 mmHg) occurs in conditions such as severe heart failure. Sometimes, it is useful to also determine the **mean arterial pressure (MAP)** because this represents the

BLOOD PRESSURE

Arterial blood pressure is a measure of the pressure exerted by the blood as it flows through the arteries. Because the blood moves in waves, there are two blood pressure measurements. The **systolic pressure** is the pressure of the blood as a result of contraction of

pressure actually delivered to the body's organs. The MAP can be calculated in several different ways, one of which is to add two-thirds of the diastolic pressure to one-third of the systolic pressure. A normal MAP is 70 to 110 mmHg.

Determinants of Blood Pressure

Arterial blood pressure is the result of several factors: the pumping action of the heart, the peripheral vascular resistance (the resistance supplied by the blood vessels through which the blood flows), and the blood volume and viscosity.

PUMPING ACTION OF THE HEART

When the pumping action of the heart is weak, less blood is pumped into arteries (lower cardiac output), and the blood pressure decreases. When the heart's pumping action is strong and the volume of blood pumped into the circulation increases (higher cardiac output), the blood pressure increases.

PERIPHERAL VASCULAR RESISTANCE

Peripheral resistance can increase blood pressure. The diastolic pressure especially is affected. Some factors that create resistance in the arterial system are the capacity of the arterioles and capillaries, the compliance of the arteries, and the viscosity of the blood.

The internal diameter or capacity of the arterioles and the capillaries determines in great part the peripheral resistance to the blood in the body. The smaller the space within a vessel, the greater the resistance. Normally, the arterioles are in a state of partial constriction. Increased vasoconstriction, such as occurs with smoking, raises the blood pressure, whereas decreased vasoconstriction lowers the blood pressure.

If the elastic and muscular tissues of the arteries are replaced with fibrous tissue, the arteries lose much of their ability to constrict and dilate. This condition, most common in middle-aged and older adults, is known as **arteriosclerosis**.

BLOOD VOLUME

When the blood volume decreases (for example, as a result of a hemorrhage or dehydration), the blood pressure decreases because of decreased fluid in the arteries. Conversely, when the volume increases (for example, as a result of a rapid intravenous infusion), the blood pressure increases because of the greater fluid volume within the circulatory system.

BLOOD VISCOSITY

Blood pressure is higher when the blood is highly viscous (thick), that is, when the proportion of red blood cells to the blood plasma is high. This proportion is referred to as the **hematocrit**. The viscosity increases markedly when the hematocrit is more than 60% to 65%.

Factors Affecting Blood Pressure

Among the factors influencing blood pressure are age, exercise, stress, race, gender, medications, obesity, diurnal variations, medical conditions, and temperature.

- **Age.** Newborns have a systolic pressure of about 75 mmHg. The pressure rises with age, reaching a peak at the onset of puberty, and then tends to decline somewhat. In older adults, elasticity of the arteries is decreased—the arteries are more rigid and less yielding to the pressure of the blood. This produces an elevated systolic

pressure. Because the walls no longer retract as flexibly with decreased pressure, the diastolic pressure may also be high.

- **Exercise.** Physical activity increases the cardiac output and hence the blood pressure. For reliable assessment of resting blood pressure, wait 20 to 30 minutes following exercise.
- **Stress.** Stimulation of the sympathetic nervous system increases cardiac output and vasoconstriction of the arterioles, thus increasing the blood pressure reading; however, severe pain can decrease blood pressure greatly by inhibiting the vasomotor center and producing vasodilation.
- **Race.** African Americans older than 35 years tend to have higher blood pressures than European Americans of the same age although the exact reasons for these differences are unclear (Covelli, Wood, & Yarandi, 2012).
- **Sex.** After puberty, females usually have lower blood pressures than males of the same age; this difference is thought to be due to hormonal variations. After menopause, women generally have higher blood pressures than before.
- **Medications.** Many medications, including caffeine, may increase or decrease the blood pressure.
- **Obesity.** Both childhood and adult obesity predispose to hypertension.
- **Diurnal variations.** Pressure is usually lowest early in the morning, when the metabolic rate is lowest, then rises throughout the day and peaks in the late afternoon or early evening.
- **Medical conditions.** Any condition affecting the cardiac output, blood volume, blood viscosity, and/or compliance of the arteries has a direct effect on the blood pressure.
- **Temperature.** Because of increased metabolic rate, fever can increase blood pressure. However, external heat causes vasodilation and decreased blood pressure. Cold causes vasoconstriction and elevates blood pressure.

Hypertension

A blood pressure that is persistently above normal is called **hypertension**. A single elevated blood pressure reading indicates the need for reassessment. Hypertension cannot be diagnosed unless an elevated blood pressure is found when measured twice at different times. It is usually asymptomatic and is often a contributing factor to myocardial infarctions (heart attacks). An elevated blood pressure of unknown cause is called *primary hypertension*. An elevated blood pressure of known cause is called *secondary hypertension*. Hypertension is a widespread health problem. Individuals with diastolic blood pressures of 80 to 89 mmHg or systolic blood pressures of 120 to 139 mmHg should be considered prehypertensive and, without intervention, may develop cardiac disease. Hypertension is when either the systolic BP is higher than 140 mmHg or when the diastolic blood pressure (BP) is 90 mmHg or higher (see Table 29–4). The stage of hypertension is determined by the higher of the two values. For example, if either of the systolic or diastolic values falls in the stage 2 range, stage 2 hypertension is assigned. Factors associated with hypertension include thickening of the arterial walls, which reduces the size of the arterial lumen, and inelasticity of the arteries as well as such lifestyle factors as cigarette smoking, obesity, heavy alcohol consumption, lack of physical exercise, high blood cholesterol levels, and continued exposure to stress.

The national guidelines for high blood pressure management recommend that hypertensive individuals age 60 years or older

TABLE 29-4 Classification of Blood Pressure

Category	Systolic BP (mmHg)	and	Diastolic BP (mmHg)
Normal	<120	and	<80
Prehypertension	120–139	or	80–89
Hypertension, stage 1	140–159	or	90–99
Hypertension, stage 2	>160	or	>100

From the "The Seventh Report of the Joint National Committee for the Detection, Evaluation, and Treatment of High Blood Pressure—Completed Report," by National Institutes of Health, National Heart, Lung, and Blood Institute, 2004. Retrieved from <http://www.nhlbi.nih.gov/guidelines/hypertension/jnc7full.htm>.

receive treatment toward a goal of less than 150/90 mmHg and hypertensive individuals age 30 through 59 years have a diastolic goal of less than 90 mmHg. For all other individuals, the goal is less than 140/90 mmHg (James et al., 2014).

Hypotension

Hypotension is a blood pressure that is below normal, that is, a systolic reading consistently between 85 and 110 mmHg in an adult whose normal pressure is higher than this. **Orthostatic hypotension** is a blood pressure that decreases when the client sits or stands. It is usually the result of peripheral vasodilation in which blood leaves the central body organs, especially the brain, and moves to the periphery, often causing the person to feel faint. Hypotension can also be caused by analgesics such as meperidine hydrochloride (Demerol), bleeding, severe burns, and dehydration. It is important to monitor hypotensive clients carefully to prevent falls. When assessing for orthostatic hypotension:

- Place the client in a supine position for 10 minutes.
- Record the client's blood pressure.
- Assist the client to slowly sit or stand. Support the client in case of faintness.
- Immediately recheck the blood pressure in the same sites as previously.
- Repeat the pulse and blood pressure after 3 minutes.
- Record the results. A drop in blood pressure of 20 mmHg systolic or 10 mmHg diastolic indicates orthostatic hypotension (Mager, 2012).

Assessing Blood Pressure

Blood pressure is measured with a blood pressure cuff, a sphygmomanometer, and a stethoscope. The blood pressure cuff consists of a bag, called a bladder, that can be inflated with air (Figure 29-18 ■). It is covered with cloth and has two tubes attached to it. One tube connects to a bulb that inflates the bladder. A small valve on the side of this bulb traps and releases the air in the bladder.

The other tube is attached to a sphygmomanometer. The **sphygmomanometer** indicates the pressure of the air within the bladder. There are two types of sphygmomanometers: aneroid and digital. The aneroid sphygmomanometer has a calibrated dial with a needle that points to the calibrations (Figure 29-19 ■).

Many agencies use digital (electronic) sphygmomanometers (Figure 29-20 ■), which eliminate the need to listen for the sounds of the client's systolic and diastolic blood pressures through

Figure 29-18 ■ A, Blood pressure cuff and bulb; B, bladder inside the cuff.

Figure 29-19 ■ Blood pressure equipment: an aneroid manometer and cuff.

a stethoscope. Electronic blood pressure devices should be calibrated periodically to check accuracy. All health care facilities should have manual blood pressure equipment available as backup.

Doppler ultrasound stethoscopes are also used to assess blood pressure (see Figure 29-15). These are of particular value when blood pressure sounds are difficult to hear, such as in infants, obese clients, and clients in shock. Systolic pressure may be the only blood pressure obtainable with some ultrasound models.

Blood pressure cuffs come in various sizes because the bladder must be the correct width and length for the client's arm (Figure 29-21 ■). If the bladder is too narrow, the blood pressure reading will be erroneously elevated; if it is too wide, the reading will be erroneously low. The width should be 40% of the circumference, or 20% wider than the diameter of the midpoint, of the limb

Figure 29-20 ■ Electronic blood pressure monitors register blood pressures.

Figure 29-21 ■ Standard cuff sizes: smaller cuffs are used for infants, small children, or frail adults; midsize cuffs are used for most adults; and larger cuffs are used for measuring the blood pressure on the leg or arm of an adult who is obese.

on which it is used. The arm circumference, not the age of the client, should always be used to determine bladder size. The nurse can determine whether the width of a blood pressure cuff is appropriate: Lay the cuff lengthwise at the midpoint of the upper arm, and hold the outermost side of the bladder edge laterally on the arm. With the other hand, wrap the width of the cuff around the arm, and ensure that the width is 40% of the arm circumference (Figure 29-22 ■).

The length of the bladder also affects the accuracy of measurement. The bladder should be sufficiently long to cover at least two-thirds of the limb's circumference. For obese clients, a standard sized bladder in an extra-long cuff may be the most appropriate (McFarlane, 2012).

Blood pressure cuffs are made of nondistensible material so that an even pressure is exerted around the limb. Most cuffs are held in place by hooks, snaps, or hook-and-loop fabric. Others have a cloth bandage that is long enough to encircle the limb several times; this type is closed by tucking the end of the bandage into one of the bandage folds.

Figure 29-22 ■ Determining that the bladder of a blood pressure cuff is 40% of the arm circumference or 20% wider than the diameter of the midpoint of the limb.

BLOOD PRESSURE ASSESSMENT SITES

The blood pressure is usually assessed in the client's upper arm using the brachial artery and a standard stethoscope. Assessing the blood pressure on a client's thigh is indicated in these situations:

- The blood pressure cannot be measured on either arm (e.g., because of burns or other trauma).
- The blood pressure in one thigh is to be compared with the blood pressure in the other thigh.

Blood pressure is not measured on a particular client's limb in the following situations:

- The shoulder, arm, or hand (or the hip, knee, or ankle) is injured or diseased.
- A cast or bulky bandage is on any part of the limb.
- The client has had surgical removal of breast or axillary (or inguinal) lymph nodes on that side.
- The client has an intravenous infusion or blood transfusion in that limb.
- The client has an arteriovenous fistula (e.g., for renal dialysis) in that limb.

METHODS

Blood pressure can be assessed directly or indirectly. Direct (invasive monitoring) measurement involves the insertion of a catheter into

Figure 29-23 ■ Korotkoff's sounds can be differentiated into five phases. In the illustration the blood pressure is 138/90 or 138/102/90.

the brachial, radial, or femoral artery. Arterial pressure is represented as wavelike forms displayed on a monitor. With correct placement, this pressure reading is highly accurate.

Two noninvasive indirect methods of measuring blood pressure are the auscultatory and palpatory methods. The auscultatory method is most commonly used in hospitals, clinics, and homes. External pressure is applied to a superficial artery and the nurse reads the pressure from the sphygmomanometer while listening with a stethoscope. When carried out correctly, the auscultatory method is relatively accurate.

When taking a blood pressure using a stethoscope, the nurse identifies phases in the series of sounds called **Korotkoff's sounds** (Figure 29-23 ■). Five phases occur but may not always be audible (Box 29-6). The systolic pressure is the point where the first tapping sound is heard (phase 1). In adults, the diastolic pressure is the point where the sounds become inaudible (phase 5). The phase 5 reading may be zero; that is, the muffled sounds are heard even when there is no air pressure in the blood pressure cuff. For complete accuracy, the phase 4 and 5 readings should be recorded.

The palpatory method is sometimes used when Korotkoff's sounds cannot be heard and electronic equipment to amplify the sounds is not available, or to prevent misdirection from the presence of an **auscultatory gap**, which occurs

BOX 29-6 Korotkoff's Sounds

- **Phase 1:** The pressure level at which the first faint, clear tapping or thumping sounds are heard. These sounds gradually become more intense. To ensure that they are not extraneous sounds, the nurse should identify at least two consecutive tapping sounds. The first tapping sound heard during deflation of the cuff is the systolic blood pressure.
- **Phase 2:** The period during deflation when the sounds have a muffled, whooshing, or swishing quality.
- **Phase 3:** The period during which the blood flows freely through an increasingly open artery and the sounds become crisper and more intense and again assume a thumping quality but softer than in phase 1.
- **Phase 4:** The time when the sounds become muffled and have a soft, blowing quality.
- **Phase 5:** The pressure level when the last sound is heard. This is followed by a period of silence. The pressure at which the last sound is heard is the diastolic blood pressure in adults.*

*In agencies where the fourth phase is considered the diastolic pressure, three measures are recommended (systolic pressure, diastolic pressure, and phase 5). These may be referred to as systolic, first diastolic, and second diastolic pressures. The phase 5 (second diastolic pressure) reading may be zero; that is, the muffled sounds are heard even when there is no air pressure in the blood pressure cuff. In some instances, muffled sounds are never heard, in which case a dash is inserted where the reading would normally be recorded (e.g., /-/110).

particularly in hypertensive clients, is the temporary disappearance of sounds normally heard over the brachial artery when the cuff pressure is high followed by the reappearance of the sounds at a lower level. This temporary disappearance of sounds occurs in the latter part of phase 1 and phase 2 and may cover a range of 40 mmHg. If a palpated estimation of the systolic pressure is not made prior to auscultation, the nurse may begin listening in the middle of this range and underestimate the systolic pressure. In the palpatory method of blood pressure determination, instead of listening for the blood flow sounds, the nurse uses light to moderate pressure to palpate the pulsations of the artery as the pressure in the cuff is released. The pressure is read from the sphygmomanometer when the first pulsation is felt. A single whiplike vibration, felt in addition to the pulsations, identifies the point at which the pressure in the cuff nears the diastolic pressure. This vibration is no longer felt when the cuff pressure is below the diastolic pressure.

Common Errors in Assessing Blood Pressure

The importance of the accuracy of blood pressure assessments cannot be overemphasized. Many judgments about a client's health are made based on blood pressure. It is an important indicator of the client's condition and is used extensively as a basis for nursing interventions. Two possible reasons for blood pressure errors are hurrying on the part of the nurse and subconscious bias in which a nurse may be influenced by the client's previous blood pressure measurements or diagnosis and "hear" a value consistent with the nurse's expectations. Some reasons for erroneous blood pressure readings are given in Table 29-5.

Skill 29-6 provides guidelines for assessing blood pressure.

TABLE 29–5 Selected Sources of Error in Blood Pressure Assessment

Error	Effect
Bladder cuff too narrow	Erroneously high
Bladder cuff too wide	Erroneously low
Arm unsupported	Erroneously high
Insufficient rest before the assessment	Erroneously high
Repeating assessment too quickly	Erroneously high systolic or low diastolic readings
Cuff wrapped too loosely or unevenly	Erroneously high
Deflating cuff too quickly	Erroneously low systolic and high diastolic readings
Deflating cuff too slowly	Erroneously high diastolic reading
Failure to use the same arm consistently	Inconsistent measurements
Arm above level of the heart	Erroneously low
Assessing immediately after a meal or while client smokes or has pain	Erroneously high
Failure to identify auscultatory gap	Erroneously low systolic pressure and erroneously low diastolic pressure

Assessing Blood Pressure

PURPOSE

- To obtain a baseline measurement of arterial blood pressure for subsequent evaluation
- To determine the client's hemodynamic status (e.g., cardiac output: stroke volume of the heart and blood vessel resistance)
- To identify and monitor changes in blood pressure resulting from a disease process or medical therapy (e.g., presence or history of cardiovascular disease, renal disease, circulatory shock, or acute pain; rapid infusion of fluids or blood products)

ASSESSMENT

Assess

- Signs and symptoms of hypertension (e.g., headache, ringing in the ears, flushing of face, nosebleeds, fatigue)
- Signs and symptoms of hypotension (e.g., tachycardia, dizziness, mental confusion, restlessness, cool and clammy skin, pale or cyanotic skin)
- Factors affecting blood pressure (e.g., activity, emotional stress, pain, and time the client last smoked or ingested caffeine)
- Some blood pressure cuffs contain latex. Assess the client for latex allergy and obtain a latex-free cuff if indicated.

PLANNING

DELEGATION

Blood pressure measurement may be delegated to UAP. The interpretation of abnormal blood pressure readings and determination of appropriate responses are done by the nurse.

Equipment

- Stethoscope or DUS
- Blood pressure cuff of the appropriate size
- Sphygmomanometer

IMPLEMENTATION

Preparation

- Ensure that the equipment is intact and functioning properly. Check for leaks in the tubing between the cuff and the sphygmomanometer.
- Make sure that the client has not smoked or ingested caffeine within 30 minutes prior to measurement.

Rationale: Smoking constricts blood vessels, and caffeine increases the pulse rate. Both of these cause a temporary increase in blood pressure.

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client

INTERPROFESSIONAL PRACTICE

Measurement of blood pressure is within the scope of practice for many health care providers. For example, in addition to nurses, therapists may check the client's blood pressure before, during, and after treatment. Although these therapists may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.

- Perform hand hygiene and observe appropriate infection prevention procedures.
- Provide for client privacy.
- Position the client appropriately.
 - The adult client should be sitting unless otherwise specified. Both feet should be flat on the floor.

Rationale: Legs crossed at the knee results in elevated systolic and diastolic blood pressures (Pinar, Ataalkin, & Watson, 2010).

Assessing Blood Pressure—continued

- The elbow should be slightly flexed with the palm of the hand facing up and the arm supported at heart level. Readings in any other position should be specified. The blood pressure is normally similar in sitting, standing, and lying positions, but it can vary significantly by position in certain persons.
Rationale: The blood pressure increases when the arm is below heart level and decreases when the arm is above heart level.
 - Expose the upper arm.
5. Wrap the deflated cuff evenly around the upper arm. Locate the brachial artery (see Figure 29–13, page 487). Apply the center of the bladder directly over the artery.
Rationale: The bladder inside the cuff must be directly over the artery to be compressed if the reading is to be accurate.
- For an adult, place the lower border of the cuff approximately 2.5 cm (1 in.) above the antecubital space.
6. If this is the client's initial examination, perform a preliminary palpatory determination of systolic pressure.
Rationale: The initial estimate tells the nurse the maximal pressure to which the sphygmomanometer needs to be elevated in subsequent determinations. It also prevents underestimation of the systolic pressure or overestimation of the diastolic pressure should an auscultatory gap occur.
- Palpate the brachial artery with the fingertips.
 - Close the valve on the bulb.
 - Pump up the cuff until you no longer feel the brachial pulse. At that pressure the blood cannot flow through the artery. Note the pressure on the sphygmomanometer at which pulse is no longer felt.
Rationale: This gives an estimate of the systolic pressure.
 - Release the pressure completely in the cuff, and wait 1 to 2 minutes before making further measurements.
Rationale: A waiting period gives the blood trapped in the veins time to be released. Otherwise, false high systolic readings will occur.
7. Position the stethoscope appropriately.
- Cleanse the earpieces with antiseptic wipe.
 - Insert the ear attachments of the stethoscope in your ears so that they tilt slightly forward.
Rationale: Sounds are heard more clearly when the ear attachments follow the direction of the ear canal.
 - Ensure that the stethoscope hangs freely from the ears to the diaphragm.
Rationale: If the stethoscope tubing rubs against an object, the noise can block the sounds of the blood within the artery.
 - Place the bell side of the amplifier of the stethoscope over the brachial pulse site.
Rationale: Because the blood pressure is a low-frequency sound, it is best heard with the bell-shaped diaphragm.
 - Place the stethoscope directly on the skin, not on clothing over the site.
Rationale: This is to avoid noise made from rubbing the amplifier against cloth.
 - Hold the diaphragm with the thumb and index finger.
8. Auscultate the client's blood pressure.
- Pump up the cuff until the sphygmomanometer reads 30 mmHg above the point where the brachial pulse disappeared.
 - Release the valve on the cuff carefully so that the pressure decreases at the rate of 2 to 3 mmHg per second.
Rationale: If the rate is faster or slower, an error in measurement may occur.
 - As the pressure falls, identify the manometer reading at Korotkoff phases 1, 4, and 5.
Rationale: There is no clinical significance to phases 2 and 3.

- Deflate the cuff rapidly and completely.
 - Wait 1 to 2 minutes before making further determinations.
Rationale: This permits blood trapped in the veins to be released.
 - Repeat the above steps to confirm the accuracy of the reading—especially if it falls outside the normal range (although this may not be routine procedure for hospitalized or well clients). If there is greater than 5 mmHg difference between the two readings, additional measurements may be taken and the results averaged.
9. If this is the client's initial examination, repeat the procedure on the client's other arm. There should be a difference of no more than 10 mmHg between the arms. The arm found to have the higher pressure should be used for subsequent examinations (Fonseca-Reyes, Forsyth-Macquarrie, & Garcia de Alba-Garcia, 2012).

Variation: Obtaining a Blood Pressure by the Palpation Method

If it is not possible to use a stethoscope to obtain the blood pressure or if the Korotkoff sounds cannot be heard, palpate the radial or brachial pulse site as the cuff pressure is released. The manometer reading at the point where the pulse reappears is an estimate of systolic value.

Variation: Taking a Thigh Blood Pressure

- Help the client to assume a prone position. If the client cannot assume this position, measure the blood pressure while the client is in a supine position with the knee slightly flexed. Slight flexing of the knee will facilitate placing the stethoscope on the popliteal space.
- Expose the thigh, taking care not to expose the client unduly.
- Locate the popliteal artery (see Figure 29–13).
- Wrap the cuff evenly around the midthigh with the compression bladder over the posterior aspect of the thigh and the bottom edge above the knee. ①
Rationale: The bladder must be directly over the posterior popliteal artery if the reading is to be accurate.
- If this is the client's initial examination, perform a preliminary palpatory determination of systolic pressure by palpating the popliteal artery.
- In adults, the systolic pressure in the popliteal artery is usually 20 to 30 mmHg higher than that in the brachial artery; the diastolic pressure is usually the same.

Variation: Using an Electronic Indirect Blood Pressure Monitoring Device (see Figure 29–20, page 502)

- Place the blood pressure cuff on the extremity according to the manufacturer's guidelines.
- Turn on the blood pressure switch.

① Measuring blood pressure in a client's thigh.

Assessing Blood Pressure—continued

- If appropriate, set the device for the desired number of minutes between blood pressure determinations.
 - When the device has determined the blood pressure reading, note the digital results.
10. Remove the cuff from the client's arm.

SAFETY ALERT!

SAFETY

Electronic/automatic blood pressure cuffs can be left in place for many hours. Remove the cuff and check skin condition periodically.

11. Wipe the cuff with an approved disinfectant.

Rationale: Cuffs can become significantly contaminated. Many institutions use disposable blood pressure cuffs.

EVALUATION

- Relate blood pressure to other vital signs, to baseline data, and to health status. If the findings are significantly different from previous values without obvious reasons, consider possible causes (see Table 29-5).
- Report any significant change in the client's blood pressure. Also report these findings:
 - Systolic blood pressure (of an adult) above 140 mmHg
 - Diastolic blood pressure (of an adult) above 90 mmHg
 - Systolic blood pressure (of an adult) below 100 mmHg.

The client uses it for the length of stay and then it is discarded.

Rationale: This decreases the risk of spreading infection by sharing cuffs.

12. Document and report pertinent assessment data according to agency policy. Record two pressures in the form "130/80" where "130" is the systolic (phase 1) and "80" is the diastolic (phase 5) pressure. Record three pressures in the form "130/90/0," where "130" is the systolic, "90" is the first diastolic (phase 4), and sounds are audible even after the cuff is completely deflated. Use the abbreviations RA or RL for right arm or right leg and LA or LL for left arm or left leg.

LIFESPAN CONSIDERATIONS Blood Pressure

INFANTS

- Use a pediatric stethoscope with a small diaphragm.
- The lower edge of the blood pressure cuff can be closer to the antecubital space of an infant.
- Use the palpation method if auscultation with a stethoscope or DUS is unsuccessful.
- Arm and thigh pressures are equivalent in children under 1 year of age.
- The systolic blood pressure of a newborn averages about 75 mmHg (D'Amico & Barbarito, 2012).

CHILDREN

- Blood pressure should be measured in all children over 3 years of age and in children less than 3 years of age with certain medical conditions (e.g., congenital heart disease, renal malformation, medications that affect blood pressure).
- Explain each step of the process and what it will feel like. Demonstrate on a doll.
- Use the palpation technique for children under 3 years old.
- Cuff bladder width should be 40% and length should be 80% to 100% of the arm circumference (Figure 29-24 ■).
- Take the blood pressure prior to other uncomfortable procedures so that the blood pressure is not artificially elevated by the discomfort.
- In children, the diastolic pressure is considered to be the onset of phase 4, where the sounds become muffled.
- In children, the thigh pressure is about 10 mmHg higher than the arm pressure.
- One quick way to determine the normal systolic blood pressure of a child is to use the following formula:

$$\text{Normal systolic BP} = 80 + (2 \times \text{child's age in years})$$

OLDER ADULTS

- Skin may be very fragile. Do not allow cuff pressure to remain high any longer than necessary.
- Determine if the client is taking antihypertensives and, if so, when the last dose was taken.

Figure 29-24 ■ Pediatric blood pressure cuffs.

- Medications that cause vasodilation (antihypertensive medications) and also the loss of baroreceptor efficiency in older clients place them at increased risk for having orthostatic hypotension. Measuring blood pressure while the client is in the lying, sitting, and standing positions—and noting any changes—can determine this.
- If the client has arm contractures, assess the blood pressure by palpation, with the arm in a relaxed position. If this is not possible, take a thigh blood pressure.

Home Care Considerations Blood Pressure

PATIENT-CENTERED CARE

- If the client takes blood pressure readings at home, the nurse should use the same equipment or calibrate it against a system known to be accurate.
- Observe the client or family member taking the blood pressure and provide feedback if further instruction is needed.
- Home blood pressure measurement done by the client or family can confirm pressures identified when the client is seen in a clinic or office setting. This may be significant because so-called “white coat” hypertension can occur, which is an elevation in

blood pressure due to mild anxiety associated with the health care provider’s presence—who historically wore a white laboratory coat. An elevated blood pressure may be dismissed as the white coat phenomenon when, in fact, the blood pressure is truly elevated.

- If the client is in a chair or low bed, position yourself so that you maintain the client’s arm at heart level and you can read the sphygmomanometer at eye level.

OXYGEN SATURATION

A **pulse oximeter** is a noninvasive device that estimates a client’s arterial blood **oxygen saturation (SaO₂)** by means of a sensor attached to the client’s finger (Figure 29–25 ■), toe, nose, earlobe, or forehead (or around the hand or foot of a neonate). The oxygen saturation value is the percent of all hemoglobin binding sites that are occupied by oxygen. The pulse oximeter can detect hypoxemia (low oxygen saturation) before clinical signs and symptoms, such as a dusky color to skin and nail beds, develop.

The pulse oximeter’s sensor has two parts: (a) two light-emitting diodes (LEDs)—one red, the other infrared—that transmit light through nails, tissue, venous blood, and arterial blood; and (b) a photodetector placed directly opposite the LEDs (e.g., the other side of the finger, toe, or nose). Because the photodetector measures the amount of red and infrared light absorbed by oxygenated and deoxygenated hemoglobin in *peripheral* arterial blood, it is reported as SpO₂. Normal oxygen saturation is 95% to 100%, and below 70% is life threatening.

Pulse oximeters with various types of sensors are available from several manufacturers. The oximeter unit consists of an inlet connection for the sensor cable, and a faceplate that indicates (a) the oxygen saturation measurement and (b) the pulse rate. Cordless units are also available (Figure 29–26 ■). A preset alarm system signals high and

low SpO₂ measurements and a high and low pulse rate. The high and low SpO₂ levels are generally preset at 100% and 85%, respectively, for adults. The high and low pulse rate alarms are usually preset at 140 and 50 beats/min for adults. These alarm limits can, however, be changed using the manufacturer’s directions.

Factors Affecting Oxygen Saturation Readings

Among the factors influencing oxygen saturation readings are hemoglobin levels, circulation, activity, and exposure to carbon monoxide.

- **Hemoglobin.** If the hemoglobin is fully saturated with oxygen, the SpO₂ will appear normal even if the total hemoglobin level is low. Thus, the client could be severely anemic and have inadequate oxygen to supply the tissues but the pulse oximeter would return a normal value.
- **Circulation.** The oximeter will not return an accurate reading if the area under the sensor has impaired circulation.
- **Activity.** Shivering or excessive movement of the sensor site may interfere with accurate readings.
- **Carbon monoxide poisoning.** Pulse oximeters cannot discriminate between hemoglobin saturated with carbon monoxide versus oxygen. In this case, other measures of oxygenation are needed.

Skill 29–7 outlines the steps in measuring oxygen saturation.

Figure 29–25 ■ Fingertip oximeter sensor (adult).

Figure 29–26 ■ Fingertip oximeter sensor (cordless). Amelie-Benoist/BSIP/Alamy.

Evidence-Based Practice Are Pulse Oximeter Readings Accurate If Measured on a Restrained Arm?

EVIDENCE-BASED PRACTICE

The aim of this study by Korhan, Yönt, and Khorshid (2011) was to compare the pulse oximetry values obtained from a finger on restrained or unrestrained sides of the body. In clinical settings such as intensive care, physical restraints may be indicated to lessen the chances that clients will displace tubes and monitors. However, the most important complication in using physical restraints is impaired circulation. Thus, oxygen saturation from body parts in which circulation is impaired can be inaccurate. The research sample consisted of 30 hospitalized clients. A significant difference was found between the oxygen saturation values obtained from a finger of an arm that had been physically restrained and a finger of an arm that had not been physically restrained. The mean oxygen saturation

value measured from a finger of an arm that had been physically restrained was found to be 93.40 and the mean oxygen saturation value measured from a finger of an arm that had not been physically restrained was found to be 95.53.

IMPLICATIONS

The results of this study indicate that nurses should use a finger of an arm that is not physically restrained when evaluating oxygen saturation values. The use of physical restraints is carefully evaluated because there are many possible adverse effects of their use. This study provides one additional physiological consideration: that assessment data gathered from a restrained limb may not be accurate.

Measuring Oxygen Saturation

PURPOSES

- To estimate the arterial blood oxygen saturation
- To detect the presence of hypoxemia before visible signs develop

ASSESSMENT

Assess

- The best location for a pulse oximeter sensor based on the client's age and physical condition. Unless contraindicated, the finger is usually selected for adults.
- The client's overall condition including risk factors for development of hypoxemia (e.g., respiratory or cardiac disease) and hemoglobin level
- Vital signs, skin color and temperature, nail bed color, and tissue perfusion of extremities as baseline data
- Adhesive allergy

PLANNING

Many hospitals and clinics have pulse oximeters readily available for use with other vital signs equipment (or even as an integrated part of the electronic blood pressure device). Other facilities may have a limited supply of oximeters, and the nurse may need to request it from the central supply department.

DELEGATION

Application of the pulse oximeter sensor and recording of the SpO₂ value may be delegated to UAP. The interpretation of the oxygen saturation value and determination of appropriate responses are done by the nurse.

Equipment

- Nail polish remover as needed
- Alcohol wipe
- Sheet or towel
- Pulse oximeter

INTERPROFESSIONAL PRACTICE

Measuring oxygen saturation may be within the scope of practice for many health care providers. For example, in addition to nurses, respiratory therapists may check the client's oxygen saturation before, during, and after treatment. Although these therapists may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Preparation

Check that the oximeter equipment is functioning normally.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe appropriate infection prevention procedures.
3. Provide for client privacy.
4. Choose a sensor appropriate for the client's weight, size, and desired location. Because weight limits of sensors overlap, a pediatric sensor could be used for a small adult.
 - If the client is allergic to adhesive, use a clip or sensor without adhesive.
5. Prepare the site.
 - If using an extremity, apply the sensor only if the proximal pulse and capillary refill at the point closest to the site are present. If the client has low tissue perfusion due to peripheral vascular disease or therapy using vasoconstrictive medications, use a nasal sensor or a reflectance sensor on the forehead. Avoid using lower extremities that have a compromised circulation and extremities that are used for infusions or other invasive monitoring.
 - Clean the site with an alcohol wipe before applying the sensor.
 - It may be necessary to remove a female client's dark nail polish.

Rationale: Nail polish may interfere with accurate measurements although the data about this are inconsistent.

 - Alternatively, position the sensor on the side of the finger rather than perpendicular to the nail bed.

Measuring Oxygen Saturation—continued

6. Apply the sensor, and connect it to the pulse oximeter.
 - Make sure the LED and photodetector are accurately aligned, that is, opposite each other on either side of the finger, toe, nose, or earlobe. Many sensors have markings to facilitate correct alignment of the LEDs and photodetector.
 - Attach the sensor cable to the connection outlet on the oximeter. Turn on the machine according to the manufacturer's directions. Appropriate connection will be confirmed by an audible beep indicating each arterial pulsation. Some devices have a wheel that can be turned clockwise to increase the pulse volume and counterclockwise to decrease it.
 - Ensure that the bar of light or waveform on the face of the oximeter fluctuates with each pulsation.
7. Set and turn on the alarm when using continuous monitoring.
 - Check the preset alarm limits for high and low oxygen saturation and high and low pulse rates. Change these alarm limits according to the manufacturer's directions as indicated. Ensure that the audio and visual alarms are on before you leave the client. A tone will be heard and a number will blink on the faceplate.
8. Ensure client safety.
 - Inspect and/or move or change the location of an adhesive toe or finger sensor every 4 hours and a spring-tension sensor every 2 hours.
 - Inspect the sensor site tissues for irritation from adhesive sensors.
9. Ensure the accuracy of measurement.
 - Minimize motion artifacts by using an adhesive sensor, or immobilize the client's monitoring site.

Rationale: Movement of the client's finger or toe may be misinterpreted by the oximeter as arterial pulsations.
 - If indicated, cover the sensor with a sheet or towel to block large amounts of light from external sources (e.g., sunlight, procedure lamps, or bilirubin lights in the nursery).

Rationale: Bright room light may be sensed by the photodetector and alter the SpO₂ value.
 - Compare the pulse rate indicated by the oximeter to the radial pulse periodically.

Rationale: A large discrepancy between the two values may indicate oximeter malfunction.
10. Document the oxygen saturation on the appropriate record at designated intervals.

EVALUATION

- Compare the oxygen saturation to the client's previous oxygen saturation level. Relate to pulse rate and other vital signs.
- Conduct appropriate follow-up such as notifying the primary care provider, adjusting oxygen therapy, or providing breathing treatments.

LIFESPAN CONSIDERATIONS Pulse Oximetry

INFANTS

- If an appropriate-sized finger or toe sensor is not available, consider using an earlobe or forehead sensor.
- The high and low SpO₂ levels are generally preset at 95% and 80%, respectively, for neonates.
- The high and low pulse rate alarms are usually preset at 200 and 100, respectively, for neonates.
- The oximeter may need to be taped, wrapped with an elastic bandage, or covered by a stocking to keep it in place.

CHILDREN

- Instruct the child that the sensor does not hurt. Disconnect the probe whenever possible to allow for movement.

OLDER ADULTS

- Use of vasoconstrictive medications, poor circulation, or thickened nails may make finger or toe sensors inaccurate.
- Use a forehead or earlobe sensor if indicated (Figure 29-27 ■).

Figure 29-27 ■ Oximeter sensor.
Bruno Boissonnet/Photo Researchers/Science Source.

Home Care Considerations Pulse Oximetry

PATIENT-CENTERED CARE

- Pulse oximetry is a quick, inexpensive, noninvasive method of assessing oxygenation. Like an automatic blood pressure cuff, it also provides a pulse rate reading. Use in the ambulatory or home setting whenever indicated.
- If the client requires frequent or continuous home monitoring, teach the client and family how to apply and maintain the equipment. Remind them to rotate the site periodically and assess for skin trauma.

Critical Thinking Checkpoint

1. When you approach your older client to take her blood pressure, she tells you she doesn't want you to take it. What questions will you ask the client at this time?
2. After much exploration, the client agrees to let you take the blood pressure. After pumping up the cuff, you are unable to hear any sounds during release of the valve. What would you say to her?
3. Once you are able to measure the blood pressure, your reading is 180/110 mmHg. Before taking any action on this blood pressure, what do you need to know?
4. The pulse oximeter on the client's finger reads 85%. Her skin is warm and its color is normal, she is awake and oriented, temperature is 37.1°C (98.8°F), and apical pulse is 78. What would be your next actions and why?

See Critical Thinking Possibilities on student resource website.

Chapter 29 Review

CHAPTER HIGHLIGHTS

- Vital signs reflect changes in body function that otherwise might not be observed.
- Body temperature is the balance between heat produced by and heat lost from the body.
- Factors affecting body temperature include age, diurnal variations, exercise, hormones, stress, and environmental temperatures.
- Four common types of fever are intermittent, remittent, relapsing, and constant.
- During a fever, the set point of the hypothalamic thermostat changes suddenly from the normal level to a higher than normal level, but several hours elapse before the core temperature reaches the new set point.
- Hypothermia involves three mechanisms: excessive heat loss, inadequate heat production by body cells, and increasing impairment of hypothalamic thermoregulation.
- The nurse selects the most appropriate site to measure temperature according to the client's age and condition.
- Pulse rate and volume reflect the stroke volume output, the compliance of the client's arteries, and the adequacy of blood flow.
- Normally a peripheral pulse reflects the client's heartbeat, but it may differ from the heartbeat in clients with certain cardiovascular diseases; in these instances, the nurse takes an apical pulse and compares it to the peripheral pulse.
- Many factors may affect a person's pulse rate: age, sex, exercise, presence of fever, certain medications, hypovolemia/dehydration, stress (in some situations), position changes, and pathology.
- Although the radial pulse is the site most commonly used, eight other sites may be used in certain situations.
- The difference between the apical and radial pulses is called the pulse deficit.
- Respirations are assessed by observing respiratory rate, depth, rhythm, quality, and effectiveness.
- Blood pressure reflects the pumping action of the heart, peripheral vascular resistance, blood volume, and blood viscosity.
- Among the factors influencing blood pressure are age, exercise, stress, race, sex, medications, obesity, diurnal variations, medical conditions, and temperature.
- Orthostatic hypotension occurs when the blood pressure falls as the client assumes an upright position.
- A blood pressure cuff that is too narrow or too wide will give false readings.
- During blood pressure measurement, the artery must be held at heart level.
- A pulse oximeter measures the percent of hemoglobin saturated with oxygen. A normal result is 95% to 100%.
- Pulse oximeter sensors may be placed on the finger, toes, nose, earlobe, forehead, or around the hand or foot of the neonate.

TEST YOUR KNOWLEDGE

- The client's temperature at 8:00 AM using an oral electronic thermometer is 36.1°C (97.2°F). If the respiration, pulse, and blood pressure were within normal range, what would the nurse do *next*?
 - Wait 15 minutes and retake it.
 - Check what the client's temperature was the last time it was taken.
 - Retake it using a different thermometer.
 - Chart the temperature; it is normal.
- Which client meets the criteria for selection of the apical site for assessment of the pulse rather than a radial pulse?
 - A client who is in shock
 - A client whose pulse changes with body position changes
 - A client with an arrhythmia
 - A client who had surgery less than 24 hours ago
- When the nurse enters a client's room to measure routine vital signs, the client is on the phone. What technique should the nurse use to determine the respiratory rate?
 - Count the respirations during conversational pauses.
 - Ask the client to end the phone call now and resume it at a later time.
 - Wait at the client's bedside until the phone call is completed and then count respirations.
 - Since there is no evidence of distress or urgency, postpone the measurement until later.
- For a client with a previous blood pressure of 138/74 mmHg and pulse of 64 beats/min, approximately how long should the nurse take to release the blood pressure cuff in order to obtain an accurate reading?
 - 10–20 seconds
 - 30–45 seconds
 - 1–1.5 minutes
 - 3–3.5 minutes
- It would be appropriate to delegate the taking of vital signs of which client to unlicensed assistive personnel?
 - A client being prepared for elective facial surgery with a history of stable hypertension
 - A client receiving a blood transfusion with a history of transfusion reactions
 - A client recently started on a new antiarrhythmic agent
 - A client who is admitted frequently with asthma attacks
- An 85-year-old client has had a stroke resulting in right-sided facial drooping, difficulty swallowing, and the inability to move self or maintain position unaided. The nurse determines that which sites are most appropriate for taking the temperature? Select all that apply.
 - Oral
 - Rectal
 - Axillary
 - Tympanic
 - Temporal artery
- A nursing diagnosis of *Ineffective Peripheral Tissue Perfusion* would be validated by which one of the following?
 - Bounding radial pulse
 - Irregular apical pulse
 - Carotid pulse stronger on the left side than the right
 - Absent posterior tibial and pedal pulses
- The nurse reports that the client has dyspnea when ambulating. The nurse is most likely to have assessed which of the following?
 - Shallow respirations
 - Wheezing
 - Shortness of breath
 - Coughing up blood
- When auscultating the blood pressure, the nurse hears: From 200 to 180 mmHg: silence; then: a thumping sound continuing down to 150 mmHg; muffled sounds continuing down to 130 mmHg; soft thumping sounds continuing down to 105 mmHg; muffled sounds continuing down to 95 mmHg; then silence. The nurse records the blood pressure as _____.
- In Figure 29–28 ■, which number indicates the client's oxygen saturation as measured by pulse oximetry? _____

Figure 29–28 ■ Vital signs monitor.

- Technologic advances have led to improvements in measuring blood pressure in medical offices and other settings. This review outlines various methods for evaluating blood pressure and the clinical utility of each type of measurement. For example, measuring blood pressures at home may lead to more active client participation in health care and has the potential to improve blood pressure control. Ambulatory blood pressure monitoring enables measuring nighttime blood pressures and diurnal changes, which may be the most accurate predictors of risk associated with elevated blood pressure.*

30 Health Assessment

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Identify the purposes of the physical examination.
2. Explain the four techniques used in physical examination: inspection, palpation, percussion, and auscultation.
3. Identify expected findings during health assessment.
4. Verbalize the steps used in performing selected examination procedures:
 - a. Assessing appearance and mental status.
 - b. Assessing the skin.
 - c. Assessing the hair.
 - d. Assessing the nails.
 - e. Assessing the skull and face.
 - f. Assessing the eye structures and visual acuity.
 - g. Assessing the ears and hearing.
 - h. Assessing the nose and sinuses.
 - i. Assessing the mouth and oropharynx.
 - j. Assessing the neck.
 - k. Assessing the thorax and lungs.
 - l. Assessing the heart and central vessels.
 - m. Assessing the peripheral vascular system.
 - n. Assessing the breasts and axillae.
 - o. Assessing the abdomen.
 - p. Assessing the musculoskeletal system.
 - q. Assessing the neurologic system.
 - r. Assessing the female genitals and inguinal area.
 - s. Assessing the male genitals and inguinal area.
 - t. Assessing the anus.
5. Describe suggested sequencing to conduct a physical health examination in an orderly fashion.
6. Discuss variations in examination techniques appropriate for clients of different ages.
7. Recognize when it is appropriate to delegate assessment skills to unlicensed assistive personnel.
8. Demonstrate appropriate documentation and reporting of health assessment.

INTRODUCTION

Assessing a client's health status is a major component of nursing care and has two aspects: (1) the nursing health history discussed in Chapter 11 ∞ and (2) the physical examination discussed in this chapter. A physical examination can be any of three types: (1) a complete assessment (e.g., when a client is admitted to a health care agency), (2) examination of a body system (e.g., the cardiovascular system), or (3) examination of a body area (e.g., the lungs, when difficulty with breathing is observed). *Note:* Some nurses consider *assessment* to be the broad term used in applying the nursing process to health data and *examination* to be the physical process used to gather the data. In this text, the terms *assessment* and *examination* are sometimes used interchangeably—both referring to a critical investigation and evaluation of client status.

PHYSICAL HEALTH ASSESSMENT

A complete health assessment may be conducted starting at the head and proceeding in a systematic manner downward (head-to-toe assessment). However, the procedure can vary according to the age of the individual, the severity of the illness, the preferences of the nurse,

the location of the examination, and the agency's priorities and procedures. The order of head-to-toe assessment is given in Box 30–1. Regardless of the procedure used, the client's energy and time need to be considered. The health assessment is therefore conducted in a systematic and efficient manner that results in the fewest position changes for the client.

Frequently, nurses assess a specific body area instead of the entire body. These specific assessments are made in relation to client complaints, the nurse's own observation of problems, the client's presenting problem, nursing interventions provided, and medical therapies. Examples of these situations and assessments are provided in Table 30–1.

These are some of the purposes of the physical examination:

- To obtain baseline data about the client's functional abilities.
- To supplement, confirm, or refute data obtained in the nursing history.
- To obtain data that will help establish nursing diagnoses and plans of care.
- To evaluate the physiological outcomes of health care and thus the progress of a client's health problem.
- To make clinical judgments about a client's health status.
- To identify areas for health promotion and disease prevention.

BOX 30–1 Head-to-Toe Framework

TABLE 30–1 Nursing Assessments Addressing Selected Client Situations

Situation	Physical Assessment
Client complains of abdominal pain.	Inspect, auscultate, percuss, and palpate the abdomen; assess vital signs.
Client is admitted with a head injury.	Assess level of consciousness using Glasgow Coma Scale (see Table 30–10 later in this chapter); assess pupils for reaction to light and accommodation; assess vital signs.
The nurse prepares to administer a cardiotonic drug to a client.	Assess apical pulse and compare with baseline data.
The client has just had a cast applied to the lower leg.	Assess peripheral perfusion of toes, capillary blanch test, pedal pulse if able, and vital signs.
The client's fluid intake is minimal.	Assess tissue turgor, fluid intake and output, and vital signs.

BOX 30–2 Cancer Screening Guidelines for Asymptomatic People**COLORECTAL CANCER (MALES AND FEMALES)**

- Fecal occult blood test or fecal immunochemical test annually beginning at age 50 **or**
- Stool DNA test may be done beginning at age 50.
- Flexible sigmoidoscopy every 5 years beginning at age 50 **or**
- Colonoscopy every 10 years beginning at age 50 **or**
- Double contrast barium enema every 5 years beginning at age 50.
- Computerized tomography colonography every 5 years beginning at age 50.

BREAST CANCER (FEMALES)

- Beginning in their early 20s, women should be told about the benefits and limitations of breast self-examination (BSE) and the importance of reporting breast symptoms to a health professional. Those who choose to perform BSE should receive instruction and have their technique reviewed regularly. Women may choose to perform BSE regularly, occasionally, or not at all.
- Clinical breast examination every 3 years from ages 20 to 40, and then annually beginning at age 40.
- Mammogram annually at age 40 and over.

CERVICAL AND UTERINE CANCER (FEMALES)

- For women ages 21 to 29, screening every 3 years with Pap tests.
- For women ages 30 to 65, screening every 5 years with both HPV test and the Pap test, or every 3 years with the Pap test alone.
- Women ages 65 and older who have had ≥ 3 consecutive negative Pap tests or ≥ 2 consecutive negative HPV and Pap tests in the last 10 years, the most recent test in the last 5 years, and women who have had a total hysterectomy should stop cervical cancer screening.

PROSTATE CANCER (MALES)

- For men who have at least a 10-year life expectancy, discussion with the primary care provider about the benefits, risks, and uncertainties associated with prostate cancer screening.

HEALTH COUNSELING AND CANCER CHECKUP (MALES AND FEMALES) OVER AGE 20

- Examination for cancers of the thyroid, testicles, ovaries, lymph nodes, oral region, and skin during the regular health examination

From "Cancer Screening in the United States, 2014: A Review of Current American Cancer Society Guidelines and Current Issues in Cancer Screening" by R. A. Smith, D. Manassaram-Baptiste, D. Brooks, V. Cokkinides, M. Doroshenko, D. Saslow, . . . O. W. Brawley, 2014, *CA: A Cancer Journal for Clinicians*, 64, pp. 31–51.

Nurses use national guidelines and evidence-based practice to focus health assessment on specific conditions. The nurse's judgment is key when the evidence is inconclusive or conflicting. For example, when screening for cancer, nurses should keep in mind the American Cancer Society's guidelines for early detection (Box 30–2). However, whereas those guidelines call for mammography every year beginning at age 40, the U.S. Preventive Services Task Force (2009) recommends breast mammography only every 2 years for women ages 50 to 74 and none thereafter.

Preparing the Client

Most people need an explanation of the physical examination. Often clients are anxious about what the nurse will find. They can be reassured during the examination by explanations at each step. The nurse should explain when and where the examination will take place, why it is important, and what will happen. Instruct the client that all information gathered and documented during the assessment is kept confidential in accordance with the Health Insurance Portability and Accountability Act (HIPAA). This means that only those health care providers who have a legitimate need to know the client's information will have access to it.

Health examinations are usually painless; however, it is important to determine in advance any positions that are contraindicated for a particular client. The nurse assists the client as needed to undress and put on a gown. Clients should empty their bladders before the examination. Doing so helps them feel more relaxed and facilitates palpation of the abdomen and pubic area. If a urinalysis is required, the urine should be collected in a container for that purpose.

When assessing adults it is important to recognize that people of the same age differ markedly. Box 30–3 provides special considerations for assessing adults, especially older adults.

The sequence of the assessment differs with children and adults. With children, always proceed from the least invasive or uncomfortable aspect of the exam to the more invasive. Examination of the head

BOX 30–3 Health Assessment of the Adult

- Be aware of normal physiological changes that occur with aging (see the Lifespan Considerations later in this chapter).
- Be aware of stiffness of muscles and joints from aging or history of orthopedic surgery. The client may need modification of the usual positioning necessary for examination and assessment.
- Expose only areas of the body to be examined in order to avoid chilling.
- Permit ample time for the client to answer your questions and assume the required positions.
- Be aware of cultural differences. The client may want a family member present during disrobing.
- Arrange for an interpreter if the client's language differs from that of the nurse.
- Ask clients how they wish to be addressed, such as "Mrs." or "Miss."
- Adapt assessment techniques to any sensory impairment; for example, make sure eyeglasses or hearing aids are nearby.
- If clients are older or frail, it is wise to conduct the assessment in several segments in order to not overtire them.

and neck, heart and lungs, and range of motion can be done early in the process, with the ears, mouth, abdomen, and genitals being left for the end of the exam.

Preparing the Environment

It is important to prepare the environment before starting the assessment. The time for the physical assessment should be convenient to both the client and the nurse. The environment needs to be well lighted and the equipment should be organized for efficient use. A client who is physically relaxed will usually experience little discomfort. The room should be warm enough to be comfortable for the client.

Providing privacy is important. Most people are embarrassed if their bodies are exposed or if others can overhear or view them during the assessment. Culture, age, and gender of both the client and the

nurse influence how comfortable the client will be and what special arrangements might be needed. For example, if the client and nurse are of different genders, the nurse should ask if it is acceptable to perform the physical examination. Family and friends should not be present unless the client asks for someone.

Positioning

Several positions are frequently required during the physical assessment. It is important to consider the client's ability to assume a position. The client's physical condition, energy level, and age should also be taken into consideration. Some positions are embarrassing and uncomfortable and therefore should not be maintained for long. The assessment is organized so that several body areas can be assessed in one position, thus minimizing the number of position changes needed (Table 30–2).

Draping

Drapes should be arranged so that the area to be assessed is exposed and other body areas are covered. Exposure of the body is frequently embarrassing to clients. Drapes provide not only a degree of privacy but also warmth. Drapes are made of paper, cloth, or bed linen.

Instrumentation

All equipment required for the health assessment should be clean, in good working order, and readily accessible. Equipment is frequently set up on trays, ready for use. Various instruments are shown in Table 30–3.

Methods of Examining

Four primary techniques are used in the physical examination: inspection, palpation, percussion, and auscultation. These techniques

TABLE 30–2 Client Positions and Body Areas Assessed

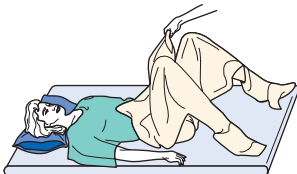

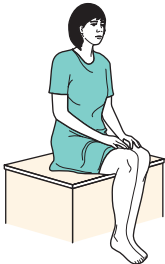

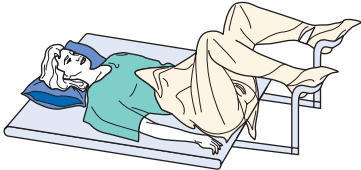

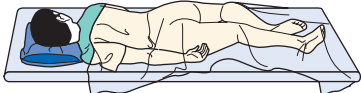

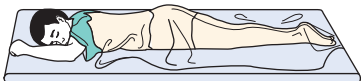

Position	Description	Areas Assessed	Cautions
Dorsal recumbent 	Back-lying position with knees flexed and hips externally rotated; small pillow under the head; soles of feet on the surface	Female genitals, rectum, and female reproductive tract	May be contraindicated for clients who have cardiopulmonary problems.
Supine (horizontal recumbent) 	Back-lying position with legs extended; with or without pillow under the head	Head, neck, axillae, anterior thorax, lungs, breasts, heart, vital signs, abdomen, extremities, peripheral pulses	Tolerated poorly by clients with cardiovascular and respiratory problems.
Sitting 	A seated position, back unsupported and legs hanging freely	Head, neck, posterior and anterior thorax, lungs, breasts, axillae, heart, vital signs, upper and lower extremities, reflexes	Older adults and weak clients may require support.
Lithotomy 	Back-lying position with feet supported in stirrups; the hips should be in line with the edge of the table	Female genitals, rectum, and female reproductive tract	May be uncomfortable and tiring for older adults and often embarrassing.
Sims' 	Side-lying position with lowermost arm behind the body, uppermost leg flexed at hip and knee, upper arm flexed at shoulder and elbow	Rectum, vagina	Difficult for older adults and people with limited joint movement.
Prone 	Lies on abdomen with head turned to the side, with or without a small pillow	Posterior thorax, hip joint movement	Often not tolerated by older adults and people with cardiovascular and respiratory problems.

TABLE 30–3 Equipment and Supplies Used for a Health Examination

Supplies		Purpose
Flashlight or penlight		To assist viewing of the pharynx or to determine the reactions of the pupils of the eye
Ophthalmoscope		A lighted instrument to visualize the interior of the eye
Otoscope		A lighted instrument to visualize the eardrum and external auditory canal (a nasal speculum may be attached to the otoscope to inspect the nasal cavities)
Percussion (reflex) hammer		An instrument with a rubber head to test reflexes
Tuning fork		A two-pronged metal instrument used to test hearing acuity and vibratory sense
Cotton applicators		To obtain specimens
Gloves		To protect the nurse
Tongue blades (depressors)		To depress the tongue during assessment of the mouth and pharynx

are discussed throughout this chapter as they apply to each body system.

INSPECTION

Inspection is the visual examination, which is assessing by using the sense of sight. It should be deliberate, purposeful, and systematic. The nurse inspects with the naked eye and with a lighted instrument such as an otoscope (used to view the ear). In addition to visual observations, olfactory (smell) and auditory (hearing) cues are noted. Nurses frequently use visual inspection to assess moisture, color, and texture of body surfaces, as well as shape, position, size, color, and symmetry of the body. Lighting must be sufficient for the nurse to see clearly; either natural or artificial light can be used. When using the auditory senses, it is important to have a quiet environment for accurate hearing. Inspection can be combined with the other assessment techniques.

PALPATION

Palpation is the examination of the body using the sense of touch. The pads of the fingers are used because their concentration of nerve endings makes them highly sensitive to tactile discrimination. Palpation is used to determine (a) texture (e.g., of the hair); (b) temperature (e.g., of a skin area); (c) vibration (e.g., of a joint); (d) position, size, consistency, and mobility of organs or masses; (e) distention (e.g., of the urinary bladder); (f) pulsation; and (g) tenderness or pain.

There are two types of palpation: light and deep. *Light* (superficial) *palpation* should always precede *deep palpation* because heavy pressure on the fingertips can dull the sense of touch. For light palpation, the nurse extends the dominant hand's fingers parallel to the skin surface and presses gently while moving the hand in a circle (Figure 30–1 ■). With light palpation, the skin is slightly depressed. If it is necessary to determine the details of a mass, the nurse presses lightly several times rather than holding the pressure. See Box 30–4 for the characteristics of masses.

Figure 30–1 ■ The position of the hand for light palpation.

Figure 30-2 ■ The position of the hands for deep bimanual palpation.

BOX 30-4 Characteristics of Masses

<i>Location</i> —site on the body, dorsal/ventral surface
<i>Size</i> —length and width in centimeters
<i>Shape</i> —oval, round, elongated, irregular
<i>Consistency</i> —soft, firm, hard
<i>Surface</i> —smooth, nodular
<i>Mobility</i> —fixed, mobile
<i>Pulsatility</i> —present or absent
<i>Tenderness</i> —degree of tenderness to palpation

Deep palpation is usually not done during a routine examination and requires significant practitioner skill. It is performed with extreme caution because pressure can damage internal organs. It is usually not indicated in clients who have acute abdominal pain or pain that is not yet diagnosed.

Deep palpation is done with two hands (bimanually) or one hand. In deep bimanual palpation, the nurse extends the dominant hand as for light palpation, then places the finger pads of the nondominant hand on the dorsal surface of the distal interphalangeal joint of the middle three fingers of the dominant hand (Figure 30-2 ■). The top hand applies pressure while the lower hand remains relaxed to perceive the tactile sensations. For deep palpation using one hand, the finger pads of the dominant hand press over the area to be palpated. Often the other hand is used to support from below (Figure 30-3 ■).

To test skin temperature, it is best to use the dorsum (back) of the hand and fingers, where the examiner's skin is thinnest. To test for vibration, the nurse should use the palmar surface of the hand. General guidelines for palpation include the following:

- The nurse's hands should be clean and warm, and the fingernails short.
- Areas of tenderness should be palpated last.
- Deep palpation should be done after superficial palpation.

The effectiveness of palpation depends largely on the client's relaxation. Nurses can assist a client to relax by (a) gowning and/or draping the client appropriately, (b) positioning the client comfortably, and (c) ensuring that their own hands are warm before beginning. During palpation, the nurse should be sensitive to the client's verbal and facial expressions indicating discomfort.

Figure 30-3 ■ Deep palpation using the lower hand to support the body while the upper hand palpates the organ.

PERCUSSION

Percussion is the act of striking the body surface to elicit sounds that can be heard or vibrations that can be felt. There are two types of percussion: direct and indirect. In *direct percussion*, the nurse strikes the area to be percussed directly with the pads of two, three, or four fingers or with the pad of the middle finger. The strikes are rapid, and the movement is from the wrist. This technique is not generally used to percuss the thorax but is useful in percussing an adult's sinuses (Figure 30-4 ■).

Indirect percussion is the striking of an object (e.g., a finger) held against the body area to be examined. In this technique, the middle finger of the nondominant hand, referred to as the **pleximeter**, is placed firmly on the client's skin. Only the distal phalanx and joint of this finger should be in contact with the skin. Using the tip of the flexed middle finger of the other hand, called the **plexor**, the nurse strikes the pleximeter, usually at the distal interphalangeal joint or a point between the distal and proximal joints (Figure 30-5 ■). The striking motion comes from the wrist; the forearm remains

Figure 30-4 ■ Direct percussion. Using one hand to strike the surface of the body.

Figure 30-5 ■ Indirect percussion. Using the finger of one hand to tap the finger of the other hand.

stationary. The angle between the plexor and the pleximeter should be 90°, and the blows must be firm, rapid, and short to obtain a clear sound.

Percussion is used to determine the size and shape of internal organs by establishing their borders. It indicates whether tissue is fluid filled, air filled, or solid. Percussion elicits five types of sound: flatness, dullness, resonance, hyperresonance, and tympany. **Flatness** is an extremely dull sound produced by very dense tissue, such as muscle or bone. **Dullness** is a thudlike sound produced by dense tissue such as the liver, spleen, or heart. **Resonance** is a hollow sound such as that produced by lungs filled with air. **Hyperresonance** is not produced in the normal body. It is described as booming and can be heard over an emphysematous lung. **Tympany** is a musical or drumlike sound produced from an air-filled stomach. On a continuum, flatness reflects the most dense tissue (the least amount of air) and tympany the least dense tissue (the greatest amount of air). A percussion sound is described according to its intensity, pitch, duration, and quality (Table 30-4).

AUSCULTATION

Auscultation is the process of listening to sounds produced within the body. Auscultation may be direct or indirect. *Direct auscultation* is performed using the unaided ear, for example, to listen to a respiratory wheeze or the grating of a moving joint. *Indirect auscultation* is performed using a stethoscope, which transmits sounds to the nurse's ears. A stethoscope is used primarily to listen to sounds from within the body, such as bowel sounds or valve sounds of the heart and blood pressure.

The stethoscope tubing should be 30 to 35 cm (12 to 14 in.) long, with an internal diameter of about 0.3 cm (1/8 in.). It should have both a flat-disk diaphragm and a bell-shaped amplifier (see Figure 4 in Skill 29-3 on page 493). The diaphragm best transmits high-pitched sounds (e.g., bronchial sounds), and the bell best transmits low-pitched sounds such as some heart sounds. The earpieces of the stethoscope should fit comfortably into the nurse's ears, facing forward. The amplifier of the stethoscope is placed firmly but lightly against the client's skin. If the client has excessive hair, it may be necessary to dampen the hairs with a moist cloth so that they will lie flat against the skin and not interfere with clear sound transmission.

Auscultated sounds are described according to their pitch, intensity, duration, and quality. The **pitch** is the frequency of the vibrations (the number of vibrations per second). Low-pitched sounds, such as some heart sounds, have fewer vibrations per second than high-pitched sounds, such as bronchial sounds. The **intensity** (amplitude) refers to the loudness or softness of a sound. Some body sounds are loud, for example, bronchial sounds heard from the trachea; others are soft, for example, normal breath sounds heard in the lungs. The **duration** of a sound is its length (long or short). The **quality** of sound is a subjective description of a sound, for example, whistling, gurgling, or snapping.

GENERAL SURVEY

Health assessment begins with a general survey that involves observation of the client's general appearance, level of comfort, and mental status, and measurement of vital signs, height, and weight. Many components of the general survey are assessed while taking the client's health history, such as the client's body build, posture, hygiene, and mental status (see Chapter 11 ∞).

Appearance and Mental Status

The general appearance and behavior of an individual must be assessed in relationship to culture, educational level, socioeconomic status, and current circumstances. For example, an individual who has recently experienced a personal loss may appropriately appear depressed (sad expression, slumped posture). The client's age, sex, and race are also useful factors in interpreting findings that suggest increased risk for known conditions. Skill 30-1 describes how to assess general appearance and mental status. Skill 30-17 later in this chapter describes a mental status examination in detail.

TABLE 30-4 Percussion Sounds and Tones

Sound	Intensity	Pitch	Duration	Quality	Example of Location
Flatness	Soft	High	Short	Extremely dull	Muscle, bone
Dullness	Medium	Medium	Moderate	Thudlike	Liver, heart
Resonance	Loud	Low	Long	Hollow	Normal lung
Hyperresonance	Very loud	Very low	Very long	Booming	Emphysematous lung
Tympany	Loud	High (distinguished mainly by musical timbre)	Moderate	Musical	Stomach filled with gas (air)

Assessing Appearance and Mental Status

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of general appearance and mental status is not delegated to unlicensed assistive personnel (UAP). However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

None

IMPLEMENTATION

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Provide for client privacy.

INTERPROFESSIONAL PRACTICE

Assessing appearance and mental status is within the scope of practice of many health care providers other than nurses before, during, and after their treatments. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Assessment	Normal Findings	Deviations from Normal
4. Observe for signs of distress in posture or facial expression.	No distress noted	Bending over because of abdominal pain, wincing, frowning, or labored breathing
5. Observe body build, height, and weight in relation to the client's age, lifestyle, and health.	Proportionate, varies with lifestyle	Excessively thin or obese
6. Observe client's posture and gait, standing, sitting, and walking.	Relaxed, erect posture; coordinated movement	Tense, slouched, bent posture; uncoordinated movement; tremors, unbalanced gait
7. Observe client's overall hygiene and grooming.	Clean, neat	Dirty, unkempt
8. Note body and breath odor.	No body odor or minor body odor relative to work or exercise; no breath odor	Foul body odor; ammonia odor; acetone breath odor; foul breath
9. Note obvious signs of health or illness (e.g., in skin color or breathing).	Well developed, well nourished, intact skin, easy breathing	Pallor (paleness); weakness; lesions, cough
10. Assess the client's attitude (frame of mind).	Cooperative, able to follow instructions	Negative, hostile, withdrawn, anxious
11. Note the client's affect/mood; assess the appropriateness of the client's responses.	Appropriate to situation	Inappropriate to situation, sudden mood change, paranoia
12. Listen for quantity of speech (amount and pace), quality (loudness, clarity, inflection).	Understandable, moderate pace; clear tone and inflection	Rapid or slow pace; overly loud or soft
13. Listen for relevance and organization of thoughts.	Logical sequence; makes sense; has sense of reality	Illogical sequence; flight of ideas; confusion; generalizations; vague
14. Document findings in the client record using printed or electronic forms and checklists supplemented by narrative notes when appropriate. ①		

EVALUATION

- Perform a detailed follow-up examination of specific systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report significant deviations from expected or normal findings to the primary care provider.

Assessing Appearance and Mental Status—continued

SKILL 30-1

Adult Admission Assessment - Sweda, Katherine

*Performed on: 08/21/2014 0655 CDT By: Border, Cathy

Subjective

Assess symptoms relative to any new medications administered for the first time. Evaluate the need to notify the physician for dosage adjustments, discontinuation of the medication, or other interventions.

Pain Present

Unable to assess
 No actual or suspected pain
 Yes actual or suspected pain

General Symptoms

Activity intolerance Edema Nausea
 Anorexia Faintness Weakness
 Confusion/Disorientation Fatigue
 Dizziness Heartburn Other:
 Drooling Itching

Documentation of Activity Intolerance, Confusion/Disorientation, Dizziness, Faintness or Weakness will create an order for Morse Fall Risk Assessment if not done within the last 24 hours

Activity Tolerance

Dyspnea/Fatigue at levels limiting normal person Dyspnea/Fatigue at rest
 Dyspnea/Fatigue with ordinary activity
 Dyspnea/Fatigue with less than ordinary activity

Respiratory Symptoms

Cough Other:
 Denies shortness of breath at rest
 Denies shortness of breath with usual activity
 Drooling
 Shortness of breath

Any of the above symptoms may indicate a problem of Activity Intolerance

Cardiovascular Symptoms

Chest pain/pressure at rest Dizziness Fluid retention
 Chest pain/pressure with activity Edema Palpitations
 Claudication Fatigue Other:

Any of the above symptoms may indicate a problem of Activity Intolerance

Gastrointestinal Symptoms

Abdominal tenderness Constipation Flatulence Impaction Stools, black/bloody Other:
 Anorexia Cramping Heartburn Incontinence Vomiting

In Progress

1 Nursing assessment form.

"Nursing Assessment Form" from Cerner Electronic Health Record. Copyright © by Cerner Corporation. Used by permission of Cerner Corporation.

Vital Signs

Vital signs are measured (a) to establish baseline data against which to compare future measurements and (b) to detect actual and potential health problems. See Chapter 29 ∞ for measurements of temperature, pulse, respirations, blood pressure, and oxygen saturation. See Chapter 46 ∞ for pain assessment.

Height and Weight

In adults, the ratio of weight to height provides a general measure of health. By asking clients about their height and weight before actually measuring them, the nurse obtains some idea of the person's self-image. Excessive discrepancies between the client's responses and the measurements may provide clues to actual or potential problems in self-concept. Take note of any unintentional weight gain or loss lasting or progressing over several weeks.

The nurse measures height with a measuring stick attached to weight scales or to a wall. The client should remove the shoes and stand erect, with heels together, and the heels, buttocks, and back of the head against the measuring stick; eyes should be looking straight ahead. The nurse raises the L-shaped sliding arm until it rests on top of the client's head, or places a small flat object such as a ruler or book on the client's head. The edge of the flat object should be about the measuring guide.

Weight is usually measured when a client is admitted to a health care agency and then often regularly thereafter, for example, each morning before breakfast and after emptying the bladder. Scales measure in pounds (lb) or kilograms (kg), and the nurse may need to convert between the two systems. One kilogram is equal to 2.2 pounds. When accuracy is essential, the nurse should use the same scale each time (because every scale weighs slightly differently), take the measurements at the same time each day, and make sure the client has on a similar kind of clothing and no footwear. The weight is read from a digital display panel or a balancing arm. Clients who cannot stand are weighed on chair (Figure 30-6 ■) or bed scales. The bed scales (Figure 30-7 ■) have canvas straps or a stretcher-like apparatus to support the client. A machine lifts the client above the bed, and the weight is reflected either on a digital display panel or on a balance arm like that of a standing scale. Newer hospital beds have built-in scales.

CLINICAL ALERT!

Review the agency charting form before beginning your assessment to ensure that you know which data you will need to collect, have all the equipment you require, and know how to perform the assessment in a systematic manner.

INTEGUMENT

The integument includes the skin, hair, and nails. The examination begins with a generalized inspection using a good source of lighting, preferably indirect natural daylight.

Skin

Assessment of the skin involves inspection and palpation. The entire skin surface may be assessed at one time or as each aspect of the body

Figure 30-6 ■ Chair scale.
Courtesy DETECTO Scale.

Figure 30-7 ■ Bed scale.

is assessed. In some instances, the nurse may also use the olfactory sense to detect unusual skin odors; these are usually most evident in the skinfolds or in the axillae. Pungent body odor is frequently related to poor hygiene, hyperhidrosis (excessive perspiration), or bromhidrosis (foul-smelling perspiration).

LIFESPAN CONSIDERATIONS General Survey**INFANTS**

- Observation of children's behavior can provide important data for the general survey, including physical development, neuromuscular function, and social and interactional skills.
- It may be helpful to have parents hold older infants and very young children for part of the assessment.
- Measure height of children under age 2 in the supine position with knees fully extended.
- Weigh without clothing.
- Include measurement of head circumference until age 2. Standardized growth charts include head circumference up to age 3.

CHILDREN

- Anxiety in preschool-age children can be decreased by letting them handle and become familiar with examination equipment.

- School-age children may be very modest and shy about exposing parts of the body.
- Adolescents should be examined without parents present.
- Weigh children without shoes and with as little clothing as possible.

OLDER ADULTS

- Allow extra time for clients to answer questions.
- Adapt questioning techniques as appropriate for clients with hearing or visual limitations.
- Older adults can lose several inches in height. Be sure to document height and ask if they are aware of becoming shorter in height.
- When asking about weight loss, be specific about amount and time frame, for example, "Have you lost more than five pounds in the last two months?" "How much did you weigh one year ago?"

Home Care Considerations General Survey**PATIENT-CENTERED CARE**

- Assess the client in private whenever possible. If a family member is needed to assist with recall of events or translation, obtain the client's permission to have the family member present.

- Use your own equipment when possible in measuring vital signs. Bring a tape measure for measuring height. Recognize that the client's home scale for measuring weight may not be accurate.

Pallor is the result of inadequate circulating blood or hemoglobin and subsequent reduction in tissue oxygenation. In clients with dark skin, it is usually characterized by the absence of underlying red tones in the skin and may be most readily seen in the buccal mucosa. In brown-skinned clients, pallor may appear as a yellowish brown tinge; in black-skinned clients, the skin may appear ashen gray. Pallor in all people is usually most evident in areas with the least pigmentation such as the conjunctiva, oral mucous membranes, nail beds, palms of the hand, and soles of the feet.

Cyanosis (a bluish tinge) is most evident in the nail beds, lips, and buccal mucosa. In dark-skinned clients, close inspection of the palpebral conjunctiva (the lining of the eyelids) and palms and soles may also show evidence of cyanosis. **Jaundice** (a yellowish tinge) may first be evident in the sclera of the eyes and then in the mucous membranes and the skin. Nurses should take care not to confuse jaundice with the normal yellow pigmentation in the sclera of a dark-skinned client. If jaundice is suspected, the posterior part of the hard palate should also be inspected for a yellowish color tone. **Erythema** is skin redness associated with a variety of rashes and other conditions.

Localized areas of hyperpigmentation (increased pigmentation) and hypopigmentation (decreased pigmentation) may occur as a result of changes in the distribution of melanin (the dark pigment) or in the function of the melanocytes in the epidermis. An example of hyperpigmentation in a defined area is a birthmark; an example of hypopigmentation is vitiligo. **Vitiligo**, seen as patches of

hypopigmented skin, is caused by the destruction of melanocytes in the area. Albinism is the complete or partial lack of melanin in the skin, hair, and eyes. Other localized color changes may indicate a problem such as edema or a localized infection. Dark-skinned clients normally have areas of lighter pigmentation, such as the palms, lips, and nail beds.

Edema is the presence of excess interstitial fluid. An area of edema appears swollen, shiny, and taut and tends to blanch the skin color or, if accompanied by inflammation, may redden the skin. Generalized edema is most often an indication of impaired venous circulation and in some cases reflects cardiac dysfunction or venous abnormalities.

A skin lesion is an alteration in a client's normal skin appearance. Primary skin lesions are those that appear initially in response to some change in the external or internal environment of the skin (Figure 30-8 ■, 1-8). Secondary skin lesions are those that do not appear initially but result from modifications such as chronicity, trauma, or infection of the primary lesion. For example, a vesicle or blister (primary lesion) may rupture and cause an erosion (secondary lesion). Table 30-5 illustrates secondary lesions. Nurses are responsible for describing skin lesions accurately in terms of location (e.g., face), distribution (i.e., body regions involved), and configuration (the arrangement or position of several lesions) as well as color, shape, size, firmness, texture, and characteristics of individual lesions. Skill 30-2 describes how to assess the skin.

Macule, Patch Flat, unelevated change in color. Macules are 1 mm to 1 cm (0.04 to 0.4 in.) in size and circumscribed. Examples: freckles, measles, petechiae, flat moles. Patches are larger than 1 cm (0.4 in.) and may have an irregular shape. Examples: port wine birthmark, vitiligo (white patches), rubella. ❶

❶ A café-au-lait macule

Nodule, Tumor Elevated, solid, hard mass that extends deeper into the dermis than a papule. Nodules have a circumscribed border and are 0.5 to 2 cm (0.2 to 0.8 in.). Examples: squamous cell carcinoma, fibroma. Tumors are larger than 2 cm (0.8 in.) and may have an irregular border. Examples: malignant melanoma, hemangioma. ❷

❷ Nodules from Recklinghausen's Disease

Papule Circumscribed, solid elevation of skin. Papules are less than 1 cm (0.4 in.). Examples: warts, acne, pimples, elevated moles. ❸

❸ Papular drug eruption

Plaque Plaques are larger than 1 cm (0.4 in.). Examples: psoriasis, rubeola. ❹

❹ Psoriasis

Vesicle, Bulla A circumscribed, round or oval, thin translucent mass filled with serous fluid or blood. Vesicles are less than 0.5 cm (0.2 in.). Examples: herpes simplex, early chicken pox, small burn blister. Bullae are larger than 0.5 cm (0.2 in.). Examples: large blister, second-degree burn, herpes simplex. ❺

Pustule Vesicle or bulla filled with pus. Examples: acne vulgaris, impetigo. ❻

❻ White pustules along with darker healing areas.

❼ Bullous pemphigoid

❽ Digital mucous cyst

Cyst A 1-cm (0.4 in.) or larger, elevated, encapsulated, fluid-filled or semisolid mass arising from the subcutaneous tissue or dermis. Examples: sebaceous and epidermoid cysts, chalazion of the eyelid. ❿

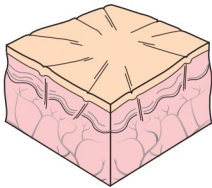

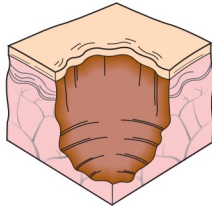

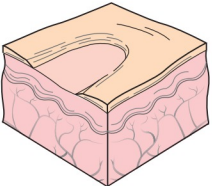

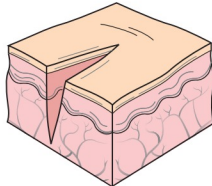

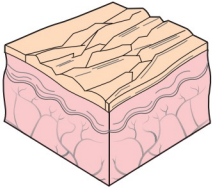

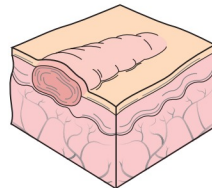

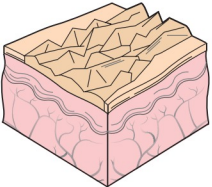

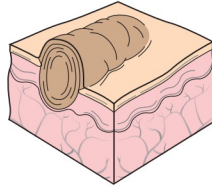

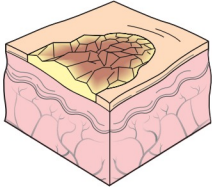

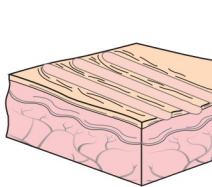

❾ Allergic wheals, urticaria

Wheal A reddened, localized collection of edema fluid; irregular in shape. Size varies. Examples: hives, mosquito bites. ❿

Figure 30–8 ■ Primary skin lesions.

TABLE 30-5 Secondary Skin Lesions

Atrophy	A translucent, dry, paper-like, sometimes wrinkled skin surface resulting from thinning or wasting of the skin due to loss of collagen and elastin.	Ulcer	Deep, irregularly shaped area of skin loss extending into the dermis or subcutaneous tissue. May bleed. May leave scar.
	Examples: striae, aged skin		Examples: pressure ulcers, stasis ulcers, chancres
Erosion	Wearing away of the superficial epidermis causing a moist, shallow depression. Because erosions do not extend into the dermis, they heal without scarring.	Fissure	Linear crack with sharp edges, extending into the dermis.
	Examples: scratch marks, ruptured vesicles		Examples: cracks at the corners of the mouth or in the hands, athlete's foot
Lichenification	Rough, thickened, hardened area of epidermis resulting from chronic irritation such as scratching or rubbing.	Scar	Flat, irregular area of connective tissue left after a lesion or wound has healed. New scars may be red or purple; older scars may be silvery or white.
	Examples: chronic dermatitis		Examples: healed surgical wound or injury, healed acne
Scales	Shedding flakes of greasy, keratinized skin tissue. Color may be white, gray, or silver. Texture may vary from fine to thick.	Keloid	Elevated, irregular, darkened area of excess scar tissue caused by excessive collagen formation during healing. Extends beyond the site of the original injury. Higher incidence in people of African descent.
	Examples: dry skin, dandruff, psoriasis, and eczema		Examples: keloid from ear piercing or surgery
Crust	Dry blood, serum, or pus left on the skin surface when vesicles or pustules burst. Can be red-brown, orange, or yellow. Large crusts that adhere to the skin surface are called scabs.	Excoriation	Linear erosion.
	Examples: eczema, impetigo, herpes, or scabs following abrasion		Examples: scratches, some chemical burns

Assessing the Skin

PLANNING

- Review characteristics of primary and secondary skin lesions if necessary (see Figure 30-8 and Table 30-5).
- Ensure that adequate lighting is available.

DELEGATION

Due to the substantial knowledge and skill required, assessment of the skin is not delegated to UAP. However, the skin is observed during usual care and UAPs should record their findings. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Millimeter ruler
- Clean gloves
- Magnifying glass

INTERPROFESSIONAL PRACTICE

Assessing the skin may be within the scope of practice of many health care providers other than nurses. For example, physical therapists and occupational therapists may notice edema or skin lesions during treatment. Although these other providers may verbally communicate their findings and plan to health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Assessing the Skin—continued

SKILL 30-2

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: pain or itching; presence and spread of lesions, bruises, abrasions, pigmented spots; previous experience with skin problems; associated clinical signs; family history; presence of problems in other family members; related systemic conditions; use of medications,

lotions, home remedies; excessively dry or moist feel to the skin; tendency to bruise easily; association of the problem to season of year, stress, occupation, medications, recent travel, housing, and so on; recent contact with allergens (e.g., metal paint).

CLINICAL ALERT!

If you have not already gathered relevant information about the client's history as it relates to the specific area being assessed, do so before beginning the physical examination. This allows you to focus the examination, customized to the individual client history and current status.

Assessment	Normal Findings	Deviations from Normal
5. Inspect skin color (best assessed under natural light and on areas not exposed to the sun).	Varies from light to deep brown; from ruddy pink to light pink; from yellow overtones to olive	Pallor, cyanosis, jaundice, erythema
6. Inspect uniformity of skin color.	Generally uniform except in areas exposed to the sun; areas of lighter pigmentation (palms, lips, nail beds) in dark-skinned people	Areas of either hyperpigmentation or hypopigmentation
7. Assess edema, if present (i.e., location, color, temperature, shape, and the degree to which the skin remains indented or pitted when pressed by a finger). Measuring the circumference of the extremity with a millimeter tape may be useful for future comparison.	No edema	See the scale for describing edema. 1
8. Inspect, palpate, and describe skin lesions. Apply gloves if lesions are open or draining. Palpate lesions to determine shape and texture. Describe lesions according to location, distribution, color, configuration, size, shape, type, or structure (Box 30-5 on page 527). Use the millimeter ruler to measure lesions. If gloves were applied, remove and discard gloves. Perform hand hygiene.	Freckles, some birthmarks that have not changed since childhood, and some long-standing vascular birthmarks such as strawberry or port-wine hemangiomas, some flat and raised nevi; no abrasions or other lesions	Various interruptions in skin integrity; irregular, multicolored, or raised nevi, some pigmented birthmarks such as melanocystic nevi, and some vascular birthmarks such as cavernous hemangiomas. Even these deviations from normal may not be dangerous or require treatment. Assessment by an advanced-level practitioner is required.
9. Observe and palpate skin moisture.	Moisture in skinfolds and the axillae (varies with environmental temperature and humidity, body temperature, and activity)	Excessive moisture (e.g., in hyperthermia); excessive dryness (e.g., in dehydration)

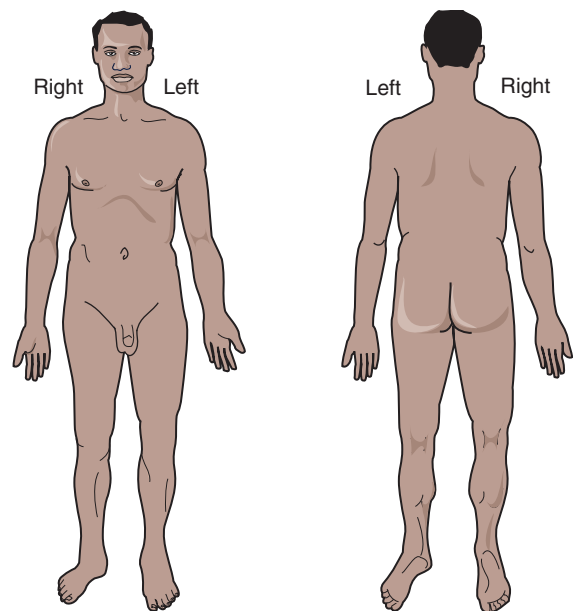

1 Scale for grading edema.

Assessing the Skin—continued

Assessment	Normal Findings	Deviations from Normal
10. Palpate skin temperature. Compare the two feet and the two hands, using the backs of your fingers.	Uniform; within normal range	Generalized hyperthermia (e.g., in fever); generalized hypothermia (e.g., in shock); localized hyperthermia (e.g., in infection); localized hypothermia (e.g., in arteriosclerosis)
11. Note skin turgor (fullness or elasticity) by lifting and pinching the skin on an extremity or on the sternum.	When pinched, skin springs back to previous state (is elastic); may be slower in older adults.	Skin stays pinched or tented or moves back slowly (e.g., in dehydration). Count in seconds how long the skin remains tented. There is no widely accepted time span distinguishing normal from abnormal skin turgor (de Vries Feyens & de Jager, 2011).
12. Remove and discard gloves. <ul style="list-style-type: none"> • Perform hand hygiene. 		
13. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate. Draw location of skin lesions on body surface diagrams. 2		

CLINICAL ALERT!

If agency policy permits and the client agrees, take a digital or instant photograph of significant skin lesions for the client record. Include a measuring guide (ruler or tape) in the picture to demonstrate lesion size.

2 Diagram for charting skin lesions.

EVALUATION

- Compare findings to previous skin assessment data if available to determine if lesions or abnormalities are changing.
- Report significant deviations from expected or normal findings to the primary care provider.

BOX 30-5 Describing Skin Lesions

- *Type or structure.* Skin lesions are classified as primary (those that appear initially in response to some change in the external or internal environment of the skin) and secondary (those that do not appear initially but result from modifications such as chronicity, trauma, or infection of the primary lesion). For example, a vesicle (primary lesion) may rupture and cause an erosion (secondary lesion).
- *Size, shape, and texture.* Note size in millimeters and whether the lesion is circumscribed or irregular; round or oval shaped; flat, elevated, or depressed; solid, soft, or hard; rough or thickened; fluid filled or has flakes.
- *Color.* There may be no discoloration; one discrete color (e.g., red, brown, or black); or several colors, as with ecchymosis (a bruise), in which an initial dark red or blue color fades to a yellow color. When color changes are limited to the edges of a lesion, they are described as *circumscribed*; when spread over a large area, they are described as *diffuse*.
- *Distribution.* Distribution is described according to the location of the lesions on the body and symmetry or asymmetry of findings in comparable body areas.
- *Configuration.* Configuration refers to the arrangement of lesions in relation to each other. Configurations of lesions may be annular (arranged in a circle), clustered together (grouped), linear (arranged in a line), arc or bow shaped, or merged (indiscrete); may follow the course of cutaneous nerves; or may be meshed in the form of a network.

LIFESPAN CONSIDERATIONS Assessing the Skin

INFANTS

- Physiological jaundice may appear in newborns 2 to 3 days after birth and usually lasts about 1 week. Pathologic jaundice, or that which indicates a disease, appears within 24 hours of birth and may last more than 8 days.
- Newborns may have milia (whiteheads), small white nodules over the nose and face, and vernix caseosa (white cheesy, greasy material on the skin).
- Premature infants may have lanugo, a fine downy hair covering their shoulders and back.
- In dark-skinned infants, areas of hyperpigmentation may be found on the back, especially in the sacral area.
- Diaper dermatitis may be seen in infants.
- If a rash is present, inquire in detail about immunization history.
- Assess skin turgor by pinching the skin on the abdomen.

CHILDREN

- Children normally have minor skin lesions (e.g., bruising or abrasions) on arms and legs due to their high activity level. Lesions on other parts of the body may be signs of disease or abuse, and a thorough history should be taken.
- Secondary skin lesions may occur frequently as children scratch or expose a primary lesion to microbes.
- With puberty, oil glands become more productive, and children may develop acne. Most individuals ages 12 to 24 have some acne.
- In dark-skinned children, areas of hyperpigmentation may be found on the back, especially in the sacral area.
- If a rash is present, inquire in detail about immunization history.

OLDER ADULTS

- Changes in lighter colored skin occur at an earlier age than in darker skin.

- The skin loses its elasticity, resulting in wrinkles. Wrinkles first appear on the skin of the face and neck, which are abundant in collagen and elastic fibers.
- The skin appears thin and translucent because of loss of dermis and subcutaneous fat.
- The skin is dry and flaky because sebaceous and sweat glands are less active. Dry skin is more prominent over the extremities.
- The skin takes longer to return to its natural shape after being tented between the thumb and finger.
- Due to the normal loss of peripheral skin turgor in older adults, assess for hydration by checking skin turgor over the sternum or clavicle.
- Flat tan to brown-colored macules, referred to as *senile lentiginos* or *melanotic freckles*, are normally apparent on the back of the hand and other skin areas that are exposed to the sun. These macules may be as large as 1 to 2 cm (0.4 to 0.8 in.).
- Warty lesions (*seborrheic keratosis*) with irregularly shaped borders and a scaly surface often occur on the face, shoulders, and trunk. These benign lesions begin as yellowish to tan and progress to a dark brown or black.
- *Vitiligo* tends to increase with age and is thought to result from an autoimmune response.
- Cutaneous tags (*acrochordons*) are most commonly seen in the neck and axillary regions. These skin lesions vary in size and are soft, often flesh colored, and pedicled.
- Visible, bright red, fine dilated blood vessels (*telangiectasias*) commonly occur as a result of the thinning of the dermis and the loss of support for the blood vessel walls.
- Pink to slightly red lesions with indistinct borders (*actinic keratosis*) may appear at about age 50, often on the face, ears, backs of the hands, and arms. They may become malignant if untreated.

Home Care Considerations Assessing the Skin

PATIENT-CENTERED CARE

- When making a home visit, take a penlight or examination lamp with you in case the home has inadequate lighting.
- If skin lesions are suggestive of physical abuse, follow state regulations for follow-up and reporting. Signs of abuse may include a pattern of bruises, unusual location of burns, or lesions that are not easily explainable. If lesions are present in adults or verbal-age children, conduct the interview and assessment in private.
- Document lesions in the health record by taking a photo (if agency policy permits and client consents). Because digital cameras are common (including on cell phones and tablet

computers), clients can be encouraged to take pictures of their lesions in order to check changes over time or to send to the health care provider.

- Another method that can be used to record lesion size and shape is to lay clean double-thick clear plastic (such as a grocery bag) over the lesion or wound and trace the shape with a permanent marker. Cut away and dispose of the bottom layer that came in contact with the client and place the top layer in the client record. Use this method only if contact with the plastic does not contaminate the wound.

Hair

Assessing a client's hair includes inspecting the hair, considering developmental changes and ethnic differences, and determining the individual's hair care practices and factors influencing them. Much of the information about hair can be obtained by questioning the client.

Normal hair is resilient and evenly distributed. In people with severe protein deficiency (kwashiorkor), the hair color is faded and appears reddish or bleached, and the texture is coarse and dry. Some therapies cause **alopecia** (hair loss), and some disease conditions and medications affect the coarseness of hair.

For example, hypothyroidism can cause very thin and brittle hair. Skill 30–3 describes how to assess the hair.

Nails

Nails are inspected for nail plate shape, angle between the fingernail and the nail bed, nail texture, nail bed color, and the intactness of the tissues around the nails. The parts of the nail are shown in Figure 30–9 ■.

The nail plate is normally colorless and has a convex curve. The angle between the fingernail and the nail bed is normally 160 degrees (Figure 30–10A ■). One nail abnormality is the spoon shape, in which the nail curves upward from the nail bed (Figure 30–10, B).

Assessing the Hair

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the hair is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Clean gloves

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene, apply gloves, and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: recent use of hair dyes, rinses, or curling or straightening preparations; recent chemotherapy (if alopecia is present); presence of disease, such as hypothyroidism, which can be associated with dry, brittle hair.

Assessment	Normal Findings	Deviations from Normal
5. Inspect the evenness of growth over the scalp.	Evenly distributed hair	Patches of hair loss (i.e., alopecia)
6. Inspect hair thickness or thinness.	Thick hair	Very thin hair (e.g., in hypothyroidism)
7. Inspect hair texture and oiliness.	Silky, resilient hair	Brittle hair (e.g., hypothyroidism); excessively oily or dry hair
8. Note presence of infections or infestations by parting the hair in several areas, checking behind the ears and along the hairline at the neck.	No infection or infestation	Flaking, sores, lice, nits (lice eggs), and ringworm
9. Inspect amount of body hair.	Variable	Hirsutism (excessive hairiness) in women; naturally absent or sparse leg hair (poor circulation)
10. Remove and discard gloves. <ul style="list-style-type: none"> • Perform hand hygiene. 		
11. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		

EVALUATION

- Perform a detailed follow-up examination based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report significant deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Hair

INFANTS

- It is normal for infants to have either very little or a great deal of body and scalp hair.

CHILDREN

- As puberty approaches, axillary and pubic hair will appear (see Box 30-9 later in this chapter).

OLDER ADULTS

- Older adults may experience a loss of scalp, pubic, and axillary hair.
- Hairs of the eyebrows, ears, and nostrils become bristle-like and coarse.

Home Care Considerations Assessing the Hair

PATIENT-CENTERED CARE

- When making a home visit, ask to see the products the client usually uses on the hair. Assist the client to determine if the products are appropriate for the client's type of hair and scalp (e.g., for dry or oily hair). Provide education regarding hygiene of the hair and scalp.
- When making a home visit, examine the equipment that the client uses on the hair. Provide client teaching regarding appropriate combs and brushes and regarding safety in using electric hair styling appliances such as hair dryers.

Figure 30-9 ■ The parts of a nail.

Figure 30-10 ■ A, A normal nail, showing the convex shape and the nail plate angle of about 160°; B, a spoon-shaped nail, which may be seen in clients with iron deficiency anemia; C, early clubbing; D, late clubbing (may be caused by long-term oxygen deficit); E, Beau's line on nail (may result from severe injury or illness).

This condition, called koilonychia, may be seen in clients with iron deficiency anemia. **Clubbing** is a condition in which the angle between the nail and the nail bed is 180 degrees, or greater (Figure 30-10C and D). Clubbing may be caused by a long-term lack of oxygen.

Nail texture is normally smooth. Excessively thick nails can appear in older adults, in the presence of poor circulation, or in relation to a chronic fungal infection. Excessively thin nails or the presence of grooves or furrows can reflect prolonged iron deficiency anemia. Beau's lines are horizontal depressions in the nail that can result from injury or severe illness (Figure 30-10E). The nail bed is highly vascular, a characteristic that accounts for its color. A bluish or purplish tint to the nail bed may reflect cyanosis, and pallor may reflect poor arterial circulation. Should the client report a history of

nail fungus (onychomycosis), a referral to a podiatrist or dermatologist for treatment of nail fungus may be appropriate. Symptoms of nail fungus include brittleness, discoloration, thickening, distortion of nail shape, crumbling of the nail, and loosening (detaching) of the nail.

The tissue surrounding the nails is normally intact epidermis. Paronychia is an inflammation of the tissues surrounding a nail. The tissues appear inflamed and swollen, and tenderness is usually present.

A **blanch test** can be carried out to test the capillary refill, that is, peripheral circulation. Normal nail bed capillaries blanch when pressed, but quickly turn pink or their usual color when pressure is released. A slow rate of capillary refill may indicate circulatory problems. Skill 30-4 describes how to assess the nails.

Assessing the Nails

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the nails is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

None

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments. In most situations, clients with artificial nails or polish on fingernails or toenails are not required to remove these for assessment; however, if the assessment cannot

INTERPROFESSIONAL PRACTICE

Assessing the nails is within the scope of practice for many health care providers other than nurses. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

- be conducted due to the presence of polish or artificial nails, document this in the record.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: presence of diabetes mellitus, peripheral circulatory disease, previous injury, or severe illness.

Assessing the Nails—continued

Assessment	Normal Findings	Deviations from Normal
5. Inspect fingernail plate shape to determine its curvature and angle.	Convex curvature; angle of nail plate about 160° (Figure 30-10A)	Spoon nail (Figure 30-10B); clubbing (180° or greater) (Figure 30-10C and D)
6. Inspect fingernail and toenail texture.	Smooth texture	Excessive thickness or thinness or presence of grooves or furrows; Beau's lines (Figure 30-10E); discolored or detached nail
7. Inspect fingernail and toenail bed color.	Highly vascular and pink in light-skinned clients; dark-skinned clients may have brown or black pigmentation in longitudinal streaks	Bluish or purplish tint (may reflect cyanosis); pallor (may reflect poor arterial circulation)
8. Inspect tissues surrounding nails.	Intact epidermis	Hangnails; paronychia (inflammation)
9. Perform blanch test of capillary refill. Press the nails between your thumb and index finger; look for blanching and return of pink color to nail bed. Perform on at least one nail on each hand and foot.	Prompt return of pink or usual color (generally less than 2 seconds)	Delayed return of pink or usual color (may indicate circulatory impairment)
10. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report significant deviations from expected or normal to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Nails

INFANTS

- Newborns nails grow very quickly, are extremely thin, and tear easily.

CHILDREN

- Bent, bruised, or ingrown toenails may indicate shoes that are too tight.
- Nail biting should be discussed with an adult family member because it may be a symptom of stress.

OLDER ADULTS

- The nails grow more slowly and thicken.
- Longitudinal bands commonly develop, and the nails tend to split.
- Bands across the nails may indicate protein deficiency; white spots, zinc deficiency; spoon-shaped nails may indicate iron deficiency.
- Toenail fungus is more common and difficult to eliminate (although not dangerous to health).

Home Care Considerations Assessing the Nails

PATIENT-CENTERED CARE

- If indicated, teach the client or family member about proper nail care including how to trim and shape the nails to avoid paronychia. To avoid cutting the skin accidentally, file infant nails instead of clipping.
- If eyesight, fine motor control, or cognition prevents the client from safely trimming the nails, refer the client to a podiatrist or manicurist if the client requires assistance with nail care.

HEAD

During assessment of the head, the nurse inspects and palpates simultaneously and also auscultates. The nurse examines the skull, face, eyes, ears, nose, sinuses, mouth, and pharynx.

Skull and Face

There is a large range of normal shapes of skulls. A normal head size is referred to as **normocephalic**. If head size appears to be outside of the normal range, the circumference can be compared to standard size tables. Measurements more than two standard deviations from the norm for the age, sex, and race of the client are abnormal and should be reported to the primary care provider. Names of areas of the head are derived from names of the underlying bones: frontal, parietal, occipital, mastoid process, mandible, maxilla, and zygomatic (Figure 30-11 ■).

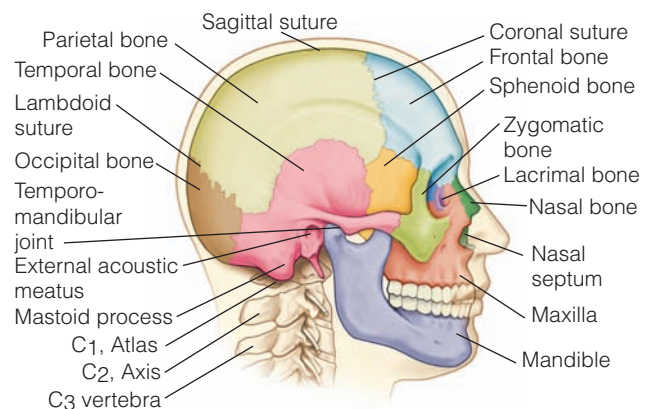

Figure 30-11 ■ Bones of the head.

Many disorders cause a change in facial shape or condition. Kidney or cardiac disease can cause edema of the eyelids. Hyperthyroidism can cause **exophthalmos**, a protrusion of the eyeballs with elevation of the upper eyelids, resulting in a startled or staring expression. Hypothyroidism, or myxedema, can cause a dry, puffy face with dry skin and coarse features and thinning of scalp hair and eyebrows.

Increased adrenal hormone production or administration of steroids can cause a round face with reddened cheeks, referred to as *moon face*, and excessive hair growth on the upper lips, chin, and sideburn areas. Prolonged illness, starvation, and dehydration can result in sunken eyes, cheeks, and temples. Skill 30–5 describes how to assess the skull and face.

Assessing the Skull and Face

SKILL 30–5

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the skull and face is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

None

IMPLEMENTATION Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.

INTERPROFESSIONAL PRACTICE

Assessing the skull and face is within the scope of practice of many health care providers other than nurses. Although these other providers may verbally communicate their findings and plan to health care team members, the nurse must also know where to locate their documentation in the client's medical record.

3. Provide for client privacy.
4. Inquire if the client has any history of the following: past problems with lumps or bumps, itching, scaling, or dandruff; history of loss of consciousness, dizziness, seizures, headache, facial pain, or injury; when and how any lumps occurred; length of time any other problem existed; any known cause of problem; associated symptoms, treatment, and recurrences.

Assessment	Normal Findings	Deviations from Normal
5. Inspect the skull for size, shape, and symmetry.	Rounded (normocephalic and symmetric, with frontal, parietal, and occipital prominences); smooth skull contour	Lack of symmetry; increased skull size with more prominent nose and forehead; longer mandible (may indicate excessive growth hormone or increased bone thickness)
6. Inspect the facial features (e.g., symmetry of structures and of the distribution of hair).	Symmetric or slightly asymmetric facial features; palpebral fissures equal in size; symmetric nasolabial folds	Increased facial hair; low hair line; thinning of eyebrows; asymmetric features; exophthalmos; myxedema facies; moon face
7. Inspect the eyes for edema or hollowness.	No edema	Periorbital edema; sunken eyes
8. Note symmetry of facial movements. Ask the client to elevate the eyebrows, frown, or lower the eyebrows, close the eyes tightly, puff the cheeks, and smile and show the teeth.	Symmetric facial movements	Asymmetric facial movements (e.g., eye cannot close completely); drooping of lower eyelid and mouth; involuntary facial movements (i.e., tics or tremors)
9. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Skull and Face

INFANTS

- Newborns delivered vaginally can have elongated, molded heads, which take on more rounded shapes after a week or two. Infants born by cesarean section tend to have smooth, rounded heads.
- The posterior fontanel (soft spot) is about 1 cm (0.4 in.) in size and usually closes by 8 weeks. The anterior fontanel is larger, about 2 to 3 cm (0.8 to 1.2 in.) in size. It closes by 18 months.
- Newborns can lift their heads slightly and turn them from side to side. Voluntary head control is well established by 4 to 6 months.

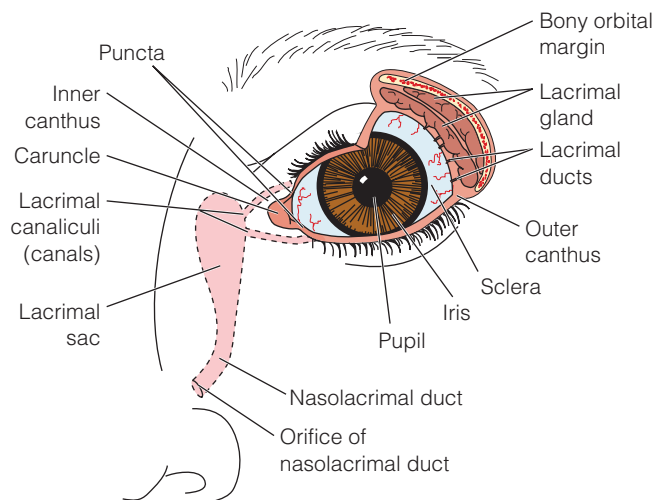

Figure 30-12 ■ The external structures and lacrimal apparatus of the left eye.

Eyes and Vision

To maintain optimum vision, people need to have their eyes examined regularly throughout life. It is recommended that people under age 40 have their eyes tested every 3 to 5 years, or more frequently if there is a family history of diabetes, hypertension, blood dyscrasia, or eye disease (e.g., glaucoma). After age 40, an eye examination is recommended every 2 years.

Examination of the eyes includes assessment of the external structures, **visual acuity** (the degree of detail the eye can discern in an image), ocular movement, and **visual fields** (the area an individual can see when looking straight ahead). Most eye assessment procedures involve inspection. Consideration is also given to developmental changes and to individual hygienic practices, if the client wears contact lenses or has an artificial eye. For the anatomic structures of the eye, see Figure 30-12 ■ and Figure 30-13 ■.

Many people wear eyeglasses or contact lenses to correct common refractive errors of the lens of the eye. These errors include **myopia** (nearsightedness), **hyperopia** (farsightedness), and **presbyopia** (loss of elasticity of the lens and thus loss of ability to see close objects). Presbyopia begins at about 45 years of age. People notice that they have difficulty reading newspaper. When both far

and near vision require correction, two lenses (bifocals) are required. **Astigmatism**, an uneven curvature of the cornea that prevents horizontal and vertical rays from focusing on the retina, is a common problem that may occur in conjunction with myopia and hyperopia. Astigmatism may be corrected with glasses or surgery.

Three types of eye charts are available to test visual acuity (Figure 30-14 ■). People with denominators of 40 or more on the Snellen chart with or without corrective lenses need to be referred to an optometrist or ophthalmologist.

Common inflammatory visual problems that nurses may encounter in clients include conjunctivitis, dacryocystitis, hordeolum, iritis, and contusions or hematomas of the eyelids and surrounding structures. **Conjunctivitis** (inflammation of the bulbar and palpebral conjunctiva) may result from foreign bodies, chemicals, allergenic agents, bacteria, or viruses. Redness, itching, tearing, and mucopurulent discharge occur. During sleep, the eyelids may become encrusted and matted together. **Dacryocystitis** (inflammation of the lacrimal sac) is manifested by tearing and a discharge from the nasolacrimal duct. **Hordeolum (sty)** is a redness, swelling, and tenderness of the hair follicle and glands that empty at the edge of the eyelids. **Iritis** (inflammation of the iris) may be caused by local or systemic infections and results in pain, tearing, and photophobia (sensitivity to light). Contusions or hematomas are “black eyes” resulting from injury.

Cataracts tend to occur in individuals over 65 years old although they may be present at any age. This opacity of the lens or its capsule, which blocks light rays, is frequently removed and replaced by a lens implant. Cataracts may also occur in infants due to a malformation of the lens if the mother contracted rubella in the first trimester of pregnancy. **Glaucoma** (a disturbance in the circulation of aqueous fluid, which causes an increase in intraocular pressure) is the most frequent cause of blindness in people over age 40 although it can occur at younger ages. It can be controlled if diagnosed early. Danger signs of glaucoma include blurred or foggy vision, loss of peripheral vision, difficulty focusing on close objects, difficulty adjusting to dark rooms, and seeing rainbow-colored rings around lights.

Upper eyelids that lie at or below the pupil margin are referred to as ptosis and are usually associated with aging, edema from drug allergy or systemic disease (e.g., kidney disease), congenital lid muscle

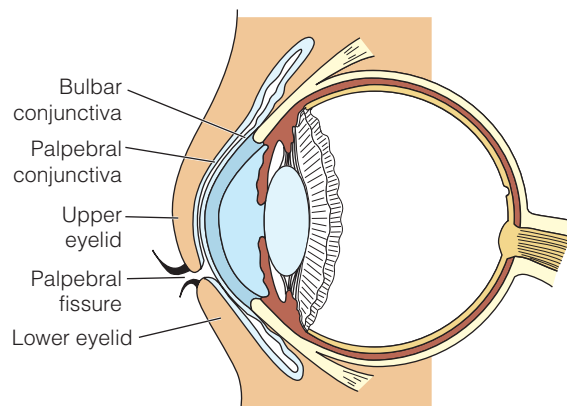

Figure 30-13 ■ Anatomic structures of the right eye, lateral view.

Figure 30-14 ■ Three types of eye charts: *left*, the preschool children’s chart; *center*, the Snellen standard chart; *right*, Snellen E chart for clients unable to read.
right, Roman Sotola/Shutterstock.

dysfunction, neuromuscular disease (e.g., myasthenia gravis), and third cranial nerve impairment. Eversion, an outturning of the eyelid, is called ectropion; inversion, an inturning of the lid, is called entropion. These abnormalities are often associated with scarring injuries or the aging process.

Pupils are normally black, are equal in size (about 3 to 7 mm in diameter), and have round, smooth borders. Cloudy pupils are often indicative of cataracts. **Mydriasis** (enlarged pupils) may indicate injury or glaucoma, or result from certain drugs (e.g., atropine,

cocaine, amphetamines). **Miosis** (constricted pupils) may indicate an inflammation of the iris or result from such drugs as morphine/heroin and other narcotics, barbiturates, or pilocarpine. It is also an age-related change in older adults. **Anisocoria** (unequal pupils) may result from a central nervous system disorder; however, slight variations may be normal. The iris is normally flat and round. A bulging toward the cornea can indicate increased intraocular pressure. Skill 30-6 describes how to assess a client’s eye structures and visual acuity.

Assessing the Eye Structures and Visual Acuity

SKILL 30-6

PLANNING

Place the client in an appropriate room for assessing the eyes and vision. The nurse must be able to control natural and overhead lighting during some portions of the examination.

Equipment

- Millimeter ruler
- Penlight
- Snellen or E chart
- Opaque card

DELEGATION

Due to the substantial knowledge and skill required, assessment of the eyes and vision is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

INTERPROFESSIONAL PRACTICE

Assessing the eyes and vision may be within the scope of practice of other health care providers. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client’s medical record.

Assessing the Eye Structures and Visual Acuity—continued

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene, apply gloves, and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: family history of diabetes, hypertension, blood dyscrasia, or eye disease, injury, or surgery; client's last visit to a provider who specifically assessed the eyes (e.g., ophthalmologist or optometrist); current use of eye medications; use of contact lenses or eye-glasses; hygienic practices for corrective lenses; current symptoms of eye problems (e.g., changes in visual acuity, blurring of vision, tearing, spots, photophobia, itching, or pain).

Assessment	Normal Findings	Deviations from Normal
EXTERNAL EYE STRUCTURES		
5. Inspect the eyebrows for hair distribution and alignment and skin quality and movement (ask client to raise and lower the eyebrows).	Hair evenly distributed; skin intact Eyebrows symmetrically aligned; equal movement	Loss of hair; scaling and flakiness of skin Unequal alignment and movement of eyebrows
6. Inspect the eyelashes for evenness of distribution and direction of curl.	Equally distributed; curled slightly outward	Turned inward
7. Inspect the eyelids for surface characteristics (e.g., skin quality and texture), position in relation to the cornea, ability to blink, and frequency of blinking. Inspect the lower eyelids while the client's eyes are closed.	Skin intact; no discharge; no discoloration Lids close symmetrically	Redness, swelling, flaking, crusting, plaques, discharge, nodules, lesions Lids close asymmetrically, incompletely, or painfully Rapid, monocular, absent, or infrequent blinking
8. Remove and discard gloves. <ul style="list-style-type: none"> • Perform hand hygiene. 	Approximately 15 to 20 involuntary blinks per minute; bilateral blinking When lids open, no visible sclera above corneas, and upper and lower borders of cornea are slightly covered	Ptosis, ectropion, or entropion; rim of sclera visible between lid and iris
EXTERNAL EYE STRUCTURES		
9. Inspect the bulbar conjunctiva (that lying over the sclera) for color, texture, and the presence of lesions.	Transparent; capillaries sometimes evident; sclera appears white (darker or yellowish and with small brown macules in dark-skinned clients)	Jaundiced sclera (e.g., in liver disease); excessively pale sclera (e.g., in anemia); reddened sclera (marijuana use, rheumatoid disease); lesions or nodules (may indicate damage by mechanical, chemical, allergenic, or bacterial agents)
10. Inspect the cornea for clarity and texture. Ask the client to look straight ahead. Hold a penlight at an oblique angle to the eye, and move the light slowly across the corneal surface.	Transparent, shiny, and smooth; details of the iris are visible In older people, a thin, grayish white ring around the margin, called arcus senilis, may be evident	Opaque; surface not smooth (may be the result of trauma or abrasion) Arcus senilis in clients under age 40
11. Inspect the pupils for color, shape, and symmetry of size. Pupil charts are available in some agencies. See 1 for variations in pupil diameters.	Black in color; equal in size; normally 3 to 7 mm in diameter; round, smooth border, iris flat and round	Cloudiness, mydriasis, miosis, anisocoria; bulging of iris toward cornea
		
<p>1 Variations in pupil diameters in millimeters.</p>		
12. Assess each pupil's direct and consensual reaction to light to determine the function of the third (oculomotor) and fourth (trochlear) cranial nerves. <ul style="list-style-type: none"> • Partially darken the room. • Ask the client to look straight ahead. • Using a penlight and approaching from the side, shine a light on the pupil. • Observe the response of the illuminated pupil. It should constrict (direct response). • Shine the light on the pupil again, and observe the response of the other pupil. It should also constrict (consensual response). 	Illuminated pupil constricts (direct response) Nonilluminated pupil constricts (consensual response) Response is brisk	Neither pupil constricts Unequal responses Response is sluggish Absent responses

Assessing the Eye Structures and Visual Acuity—continued

Assessment	Normal Findings	Deviations from Normal
<p>13. Assess each pupil's reaction to accommodation.</p> <ul style="list-style-type: none"> • Hold an object (a penlight or pencil) about 10 cm (4 in.) from the bridge of the client's nose. • Ask the client to look first at the top of the object and then at a distant object (e.g., the far wall) behind the penlight. Alternate the gaze from the near to the far object. Observe the pupil response. • Next, ask the client to look at the near object and then move the penlight or pencil toward the client's nose. 	<p>Pupils constrict when looking at near object; pupils dilate when looking at far object</p> <p>Pupils converge when near object is moved toward nose. To record normal assessment of the pupils, use the abbreviation PERRLA (pupils equally round and react to light and accommodation).</p>	<p>One or both pupils fail to constrict, dilate, or converge</p>

VISUAL FIELDS

14. Assess peripheral visual fields to determine function of the retina and neuronal visual pathways to the brain and second (optic) cranial nerve.
- Have the client sit directly facing you at a distance of 60 to 90 cm (2 to 3 ft).
 - Ask the client to cover the right eye with a card and look directly at your nose.
 - Cover or close your eye directly opposite the client's covered eye (i.e., your left eye), and look directly at the client's nose.
 - Hold an object (e.g., a penlight or pencil) in your fingers, extend your arm, and move the object into the visual field from various points in the periphery. The object should be at an equal distance from the client and yourself. Ask the client to tell you when the moving object is first spotted.
 - To test the temporal field of the left eye, extend and move your right arm in from the client's right periphery.
 - To test the upward field of the left eye, extend and move the right arm down from the upward periphery.
 - To test the downward field of the left eye, extend and move the right arm up from the lower periphery.
 - To test the nasal field of the left eye, extend and move your left arm in from the periphery. ②
 - Repeat the above steps for the right eye, reversing the process.

When looking straight ahead, client can see objects in the periphery

Visual field smaller than normal (possible glaucoma); one-half vision in one or both eyes (possible nerve damage)

Temporally, peripheral objects can be seen at right angles (90°) to the central point of vision.
 The upward field of vision is normally 50°, because the orbital ridge is in the way.
 The downward field of vision is normally 70°, because the cheekbone is in the way.
 The nasal field of vision is normally 50° away from the central point of vision because the nose is in the way.

② Assessing the client's left peripheral visual field.

EXTRAOCULAR MUSCLE TESTS

15. Assess six ocular movements to determine eye alignment and coordination.
- Stand directly in front of the client and hold the penlight at a comfortable distance, such as 30 cm (1 ft) in front of the client's eyes.
 - Ask the client to hold the head in a fixed position facing you and to follow the movements of the penlight with the eyes only.

Both eyes coordinated, move in unison, with parallel alignment

Eye movements not coordinated or parallel; one or both eyes fail to follow a penlight in specific directions, e.g., **strabismus** (cross-eye)

Nystagmus (rapid involuntary rhythmic eye movement) other than at end point may indicate neurologic impairment

Assessing the Eye Structures and Visual Acuity—continued

Assessment

- Move the penlight in a slow, orderly manner through the six cardinal fields of gaze, that is, from the center of the eye along the lines of the arrows in **3** and back to the center.
- Stop the movement of the penlight periodically so that nystagmus can be detected.

16. Assess for location of light reflex by shining penlight on the corneal surface (Hirschberg test).
17. Have client fixate on a near or far object. Cover one eye and observe for movement in the uncovered eye (cover test).

VISUAL ACUITY

18. If the client can read, assess near vision by providing adequate lighting and asking the client to read from a magazine or newspaper held at a distance of 36 cm (14 in.). If the client normally wears corrective lenses, the glasses or lenses should be worn during the test. The document must be in a language the client can read.

CLINICAL ALERT!

A Rosenbaum eye chart may be used to test near vision. It consists of paragraphs of text or characters in different sizes. Be sure the client has a literacy level appropriate for the text used.

19. Assess distance vision by asking the client to wear corrective lenses, unless they are used for reading only (i.e., for distances of only 36 cm [14 in.]).
 - Ask the client to stand or sit 6 m (20 ft) from a Snellen or character chart **4**, cover the eye not being tested, and identify the letters or characters on the chart.
 - Take three readings: right eye, left eye, both eyes.
 - Record the readings of each eye and both eyes (i.e., the smallest line from which the person is able to read one-half or more of the letters).

Normal Findings

Light falls symmetrically (e.g., at “6 o’clock” on both pupils)

Uncovered eye does not move

Able to read newsprint

Deviations from Normal

Light falls off center on one eye

If misalignment is present, when dominant eye is covered, the uncovered eye will move to focus on object

Difficulty reading newsprint unless due to aging process

20/20 vision on Snellen-type chart

4 Testing distance vision.

Denominator of 40 or more on Snellen-type chart with corrective lenses

Continued on page 538

Assessing the Eye Structures and Visual Acuity—continued

Assessment	Normal Findings	Deviations from Normal
<p>At the end of each line of the chart are standardized numbers (fractions). The top line is 20/200. The numerator (top number) is always 20, the distance the person stands from the chart. The denominator (bottom number) is the distance from which the normal eye can read the chart. Therefore, a person who has 20/40 vision can see at 20 feet from the chart what a normal-sighted person can see at 40 feet from the chart. Visual acuity is recorded as “\bar{s}-c” (without correction), or “\bar{c}-c” (with correction). You can also indicate how many letters were misread in the line, e.g., “visual acuity 20/40 – 2 \bar{c}-c” indicates that two letters were misread in the 20/40 line by a client wearing corrective lenses.</p> <p>20. If the client is unable to see even the top line (20/200) of the Snellen-type chart, perform selected vision tests (Box 30–6).</p> <p>21. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>		<p>Limited vision only (e.g., light perception, hand movements, counting fingers at 30 cm (1 ft))</p>
<p>EVALUATION</p> <ul style="list-style-type: none"> Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available. Report deviations from expected or normal findings to the primary care provider. Individuals with denominators of 40 or more on the Snellen or character chart, with or without corrective lenses, may need to be referred to an optometrist or ophthalmologist. 		

LIFESPAN CONSIDERATIONS Assessing the Eyes and Vision

INFANTS

- Infants 4 weeks of age should gaze at and follow objects.
- Ability to focus with both eyes should be present by 6 months of age.
- Infants do not have tears until about 3 months of age.
- Visual acuity is about 20/300 at 4 months and progressively improves.

CHILDREN

- Epicanthal folds, common in individuals of Asian cultures, may cover the medial canthus and cause eyes to appear misaligned. Epicanthal folds may also be seen in young children of any race before the bridge of the nose begins to elevate.
- Preschool children’s acuity can be checked with picture cards or the Snellen E chart. Acuity should approach 20/20 by 6 years of age.
- A cover test and the corneal light reflex (Hirschberg) test should be conducted on young children to detect misalignment early and prevent amblyopia.
- Always perform the acuity test with glasses on if a child has prescription lenses.

- Children should be tested for color vision deficit. From 8% to 10% of Caucasian males and from 0.5% to 1% of Caucasian females have this deficit; it is much less common in non-Caucasian children. The Ishihara or Hardy-Rand-Rittler test can be used.

OLDER ADULTS

Visual Acuity

- Visual acuity decreases as the lens of the eye ages and becomes more opaque and loses elasticity.
- The ability of the iris to accommodate to darkness and dim light diminishes.
- Peripheral vision diminishes.
- The adaptation to light (glare) and dark decreases.
- Accommodation to far objects often improves, but accommodation to near objects decreases.
- Color vision declines; older people are less able to perceive purple colors and to discriminate pastel colors.
- Many older adults wear corrective lenses; they are most likely to have hyperopia. Visual changes are due to loss of elasticity (presbyopia) and transparency of the lens.

LIFESPAN CONSIDERATIONS Assessing the Eyes and Vision—*continued***External Eye Structures**

- The skin around the orbit of the eye may darken.
- The eyeball may appear sunken because of the decrease in orbital fat.
- Skinfolds of the upper lids may seem more prominent, and the lower lids may sag.
- The eyes may appear dry and dull because of the decrease in tear production from the lacrimal glands.
- A thin, grayish white arc or ring (*arcus senilis*) appears around part or all of the cornea. It results from an accumulation of a lipid substance on the cornea. The cornea tends to cloud with age.
- The iris may appear pale with brown discolorations as a result of pigment degeneration.
- The conjunctiva of the eye may appear paler than that of younger adults and may take on a slightly yellow appearance because of the deposition of fat.
- Pupil reaction to light and accommodation is normally symmetrically equal but may be less brisk.
- The pupils can appear smaller in size, unequal, and irregular in shape because of sclerotic changes in the iris.

Home Care Considerations Assessing the Eyes and Vision**PATIENT-CENTERED CARE**

- When making a home visit, take your equipment and charts with you. Also include a tape measure to lay out the 6 meters (20 feet) needed for distance vision testing.
- Use the assessment as an opportunity to reinforce proper eye care and need for regular vision testing.

BOX 30-6 Performing Selected Vision Tests**LIGHT PERCEPTION (LP)**

Shine a penlight into the client's eye from a lateral position, and then turn the light off. Ask the client to tell you when the light is on or off. If the client knows when the light is on or off, the client has light perception, and the vision is recorded as "LP."

HAND MOVEMENTS (H/M)

Hold your hand 30 cm (1 ft) from the client's face and move it slowly back and forth, stopping it periodically. Ask the client to tell you when your hand stops moving. If the client knows when your hand stops moving, record the vision as "H/M 1 ft."

COUNTING FINGERS (C/F)

Hold up some of your fingers 30 cm (1 ft) from the client's face, and ask the client to count your fingers. If the client can do so, note on the vision record "C/F 1 ft."

Figure 30-15 ■ Anatomic structures of the external, middle, and inner ear.

Ears and Hearing

Assessment of the ear includes direct inspection and palpation of the external ear, inspection of the internal parts of the ear by an **otoscope** (instrument for examining the interior of the ear, especially the eardrum, consisting essentially of a magnifying lens and a light), and determination of auditory acuity. The ear is usually assessed during an initial physical examination; periodic reassessments may be necessary for long-term clients or those with hearing problems. In some practice settings, only advanced practice nurses perform otoscopic examinations.

The ear is divided into three parts: external ear, middle ear, and inner ear. Many of the structures discussed next are illustrated in Figure 30-15 ■. The external ear includes the **auricle** or **pinna**, the external auditory canal, and the **tympanic membrane**, or

eardrum. Landmarks of the auricle include the **lobule** (earlobe), **helix** (the posterior curve of the auricle's upper aspect), **antihelix** (the anterior curve of the auricle's upper aspect), **tragus** (the cartilaginous protrusion at the entrance to the ear canal), **triangular fossa** (a depression of the antihelix), and **external auditory meatus** (the entrance to the ear canal). Although not part of the ear, the **mastoid**, a bony prominence behind the ear, is another important landmark. The external ear canal is curved, is about 2.5 cm (1 in.) long in the adult, and ends at the tympanic membrane. It is covered with skin that has many fine hairs, glands, and nerve endings. The glands secrete **cerumen** (earwax), which lubricates and protects the canal.

The curvature of the external ear canal differs with age. In the infant and toddler, the canal has an upward curvature. By age 3, the ear canal assumes the more downward curvature of adulthood.

The middle ear is an air-filled cavity that starts at the tympanic membrane and contains three **ossicles** (bones of sound transmission): the **malleus** (hammer), the **incus** (anvil), and the **stapes** (stirrups). The **eustachian tube**, another part of the middle ear, connects the middle ear to the nasopharynx. The tube stabilizes the air pressure between the external atmosphere and the middle ear, thus preventing rupture of the tympanic membrane and discomfort produced by marked pressure differences.

The inner ear contains the **cochlea**, a seashell-shaped structure essential for sound transmission and hearing, and the **vestibule** and **semicircular canals**, which contain the organs of equilibrium.

Sound transmission and hearing are complex processes. In brief, sound can be transmitted by air conduction or bone conduction. Air-conducted transmission occurs by this process:

1. A sound stimulus enters the external canal and reaches the tympanic membrane.

2. The sound waves vibrate the tympanic membrane and reach the ossicles.
3. The sound waves travel from the ossicles to the opening in the inner ear (oval window).
4. The cochlea receives the sound vibrations.
5. The stimulus travels to the auditory nerve (the eighth cranial nerve) and the cerebral cortex.

Bone-conducted sound transmission occurs when skull bones transport the sound directly to the auditory nerve.

Audiometric evaluations, which measure hearing at various decibels, are recommended for children and older adults. A common hearing deficit with age is loss of ability to hear high-frequency sounds, such as *f*, *s*, *sh*, and *ph*. This neurosensory hearing deficit does not respond well to use of a hearing aid.

Conductive hearing loss is the result of interrupted transmission of sound waves through the outer and middle ear structures. Possible causes are a tear in the tympanic membrane or an obstruction, due to swelling or other causes, in the auditory canal. **Sensorineural hearing loss** is the result of damage to the inner ear, the auditory nerve, or the hearing center in the brain. **Mixed hearing loss** is a combination of conduction and sensorineural loss. Skill 30–7 describes how to assess the ears and hearing.

Assessing the Ears and Hearing

PLANNING

It is important to conduct the ear and hearing examination in an area that is quiet. In addition, the location should allow the client to be positioned sitting or standing at the same level as the nurse.

DELEGATION

Due to the substantial knowledge and skill required, assessment of the ears and hearing is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: family history of hearing problems or loss; presence of ear problems or pain; medication history, especially if there are complaints of ringing in the ears (tinnitus); hearing difficulty: its onset, factors contributing to it, and how it interferes with activities of daily living; use of a corrective hearing device: when and from whom it was obtained.
5. Position the client comfortably, seated if possible.

Equipment

- Otoscope with several sizes of ear specula
- Tuning fork

INTERPROFESSIONAL PRACTICE

Assessing the ears and hearing are within the scope of practice for many health care providers other than nurses. For example, audiologists and physician assistants may check the client's hearing. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Assessing the Ears and Hearing—continued

Assessment	Normal Findings	Deviations from Normal
AURICLES		
<p>6. Inspect the auricles for color, symmetry of size, and position. To inspect position, note the level at which the superior aspect of the auricle attaches to the head in relation to the eye.</p>	<p>Color same as facial skin</p> <p>Symmetrical</p> <p>Auricle aligned with outer canthus of eye, about 10°, from vertical 1</p>	<p>Bluish color of earlobes (e.g., cyanosis); pallor (e.g., frostbite); excessive redness (inflammation or fever)</p> <p>Asymmetry</p> <p>Low-set ears (associated with a congenital abnormality, such as Down syndrome)</p>
		1 Alignment of the ears.
<p>7. Palpate the auricles for texture, elasticity, and areas of tenderness.</p> <ul style="list-style-type: none"> Gently pull the auricle upward, downward, and backward. Fold the pinna forward (it should recoil). Push in on the tragus. Apply pressure to the mastoid process. 	<p>Mobile, firm, and not tender; pinna recoils after it is folded</p>	<p>Lesions (e.g., cysts); flaky, scaly skin (e.g., seborrhea); tenderness when moved or pressed (may indicate inflammation or infection of external ear)</p>
EXTERNAL EAR CANAL AND TYMPANIC MEMBRANE		
<p>8. Inspect the external ear canal for cerumen, skin lesions, pus, and blood.</p>	<p>Distal third contains hair follicles and glands</p> <p>Dry cerumen, grayish-tan color; or sticky, wet cerumen in various shades of brown</p>	<p>Redness and discharge</p> <p>Scaling</p> <p>Excessive cerumen obstructing canal</p>
<p>9. Visualize the tympanic membrane using an otoscope.</p> <ul style="list-style-type: none"> Attach a speculum to the otoscope. Use the largest diameter that will fit the ear canal without causing discomfort. <p>Rationale: This achieves maximum vision of the entire ear canal and tympanic membrane.</p> <ul style="list-style-type: none"> Tip the client's head away from you, and straighten the ear canal. For an adult, straighten the ear canal by pulling the pinna up and back. 2 <p>Rationale: Straightening the ear canal facilitates vision of the ear canal and the tympanic membrane.</p>		2 Straightening the ear canal of an adult by pulling the pinna up and back.

Continued on page 542

Assessing the Ears and Hearing—continued

SKILL 30-7

Assessment

Normal Findings

Deviations from Normal

- Hold the otoscope either (a) right side up, with your fingers between the otoscope handle and the client's head, or (b) upside down, with your fingers and the ulnar surface of your hand against the client's head. 3

Rationale: This stabilizes the head and protects the eardrum and canal from injury if a quick head movement occurs.

- Gently insert the tip of the otoscope into the ear canal, avoiding pressure by the speculum against either side of the ear canal.

Rationale: The inner two thirds of the ear canal is bony; if the speculum is pressed against either side, the client will experience discomfort.

10. Inspect the tympanic membrane for color and gloss.

3 Inserting an otoscope.

Pearly gray color, semitransparent

Pink to red, some opacity
Yellow-amber
White
Blue or deep red
Dull surface

GROSS HEARING ACUITY TESTS

11. Assess client's response to normal voice tones. If client has difficulty hearing the normal voice, proceed with the following tests.

- 11A. Perform the whisper test to assess high-frequency hearing.

- Have the client occlude one ear. Out of the client's sight, at a distance of 0.3 to 0.6 m (1 to 2 ft), whisper a simple phrase such as "The weather is hot today."
- Ask the client to repeat the phrase.
- Repeat with the other ear using a different phrase.

- 11B. **Tuning Fork Tests.** Perform Weber's test to assess bone conduction by examining the lateralization (sideward transmission) of sounds.

- Hold the tuning fork at its base. Activate it by tapping the fork gently against the back of your hand near the knuckles or by stroking the fork between your thumb and index fingers. It should be made to ring softly.
- Place the base of the vibrating fork on top of the client's head 4 and ask where the client hears the noise.

Conduct the Rinne test to compare air conduction to bone conduction.

Normal voice tones audible

Able to repeat the phrases correctly in both ears

Sound is heard in both ears or is localized at the center of the head (Weber negative)

Normal voice tones not audible (e.g., requests nurse to repeat words or statements, leans toward the speaker, turns the head, cups the ears, or speaks in loud tone of voice)
Unable to repeat the phrases in one or both ears

Sound is heard better in impaired ear, indicating a bone-conductive hearing loss; or sound is heard better in ear without a problem, indicating a sensorineural disturbance (Weber positive)

4 Placing the base of the tuning fork on the client's skull (Weber's test).

Assessing the Ears and Hearing—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> Hold the handle of the activated tuning fork on the mastoid process of one ear 5 A until the client states that the vibration can no longer be heard. Immediately hold the still vibrating fork prongs in front of the client's ear canal. 5 B Push aside the client's hair if necessary. Ask whether the client now hears the sound. Sound conducted by air is heard more readily than sound conducted by bone. The tuning fork vibrations conducted by air are normally heard longer. <p>12. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	<p>Air-conducted (AC) hearing is greater than bone-conducted (BC) hearing, i.e., $AC > BC$ (positive Rinne)</p>  <p>A</p>	<p>Bone conduction time is equal to or longer than the air conduction time, i.e., $BC > AC$ or $BC = AC$ (negative Rinne; indicates a conductive hearing loss)</p>  <p>B</p>

5 Rinne test tuning fork placement: A, base of the tuning fork on the mastoid process; B, tuning fork prongs placed in front of client's ear.

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Ears and Hearing

INFANTS

- To assess gross hearing, ring a bell from behind the infant or have the parent call the child's name to check for a response. Newborns will quiet to the sound and may open their eyes wider. By 3 to 4 months of age, the child will turn head and eyes toward the sound.
- All newborns should be assessed for hearing prior to discharge from the hospital. Most states and many countries have a law or regulation requiring universal newborn hearing screening.

CHILDREN

- To inspect the external canal and tympanic membrane in children less than 3 years old, pull the pinna down and back. Insert the speculum only 0.6 to 1.25 cm (0.25 to 0.5 in.).
- Perform routine hearing checks and follow up on abnormal results. In addition to congenital or infection-related causes of hearing loss, noise-induced hearing loss is becoming more common in adolescents and young adults as a result of exposure to loud music and prolonged use of headsets at extremely loud volumes (Weichbold, Holzer, Newesely, & Stephan, 2012).

Teach that music loud enough to prevent hearing a normal conversation can damage hearing.

OLDER ADULTS

- The skin of the ear may appear dry and be less resilient because of the loss of connective tissue.
- Increased coarse and wirelike hair growth occurs along the helix, antihelix, and tragus.
- The pinna increases in both width and length, and the earlobe elongates.
- Earwax is drier.
- The tympanic membrane is more translucent and less flexible. The intensity of the light reflex may diminish slightly.
- Sensorineural hearing loss occurs.
- Generalized hearing loss (presbycusis) occurs in all frequencies, although the first symptom is the loss of high-frequency sounds: the *f*, *s*, *sh*, and *ph* sounds. To such individuals, conversation can be distorted and result in what appears to be inappropriate or confused behavior.

Home Care Considerations Assessing the Ears and Hearing

PATIENT-CENTERED CARE

- Ensure that the examination is conducted in a quiet place. In particular, older adults will have difficulty accurately reporting results of hearing tests if excessive noise is present.
- If necessary, ask the adult present with an infant or child to assist in holding the child still during the examination.

Figure 30-16 ■ The facial sinuses.

Nose and Sinuses

A nurse can inspect the nasal passages very simply with a flashlight. However, a nasal speculum and a penlight or an otoscope with a nasal attachment facilitates examination of the nasal cavity.

Assessment of the nose includes inspection and palpation of the external nose (the upper third of the nose is bone; the remainder is cartilage); patency of the nasal cavities; and inspection of the nasal cavities.

If the client reports difficulty or abnormality in smell, the nurse may test the client’s olfactory sense by asking the client to identify common odors such as coffee or mint. This is done by asking the client to close the eyes and placing vials containing the scent under the client’s nose.

The nurse also inspects and palpates the facial sinuses (Figure 30-16 ■). Skill 30-8 describes how to assess the nose and sinuses.

Assessing the Nose and Sinuses

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the nose and sinuses is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Nasal speculum
- Flashlight/penlight

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client’s identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.

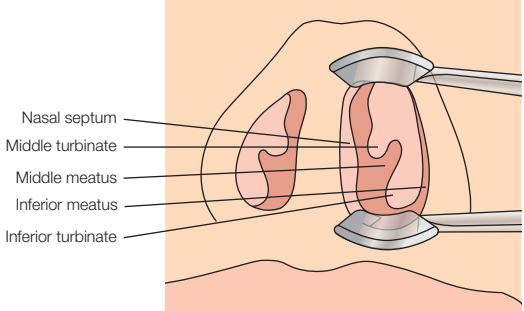

INTERPROFESSIONAL PRACTICE

Assessing the nose and sinuses may be within the scope of practice for health care providers other than nurses, such as physician assistants. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client’s medical record.

3. Provide for client privacy.
4. Inquire if the client has any history of the following: allergies, difficulty breathing through the nose, sinus infections, injuries to nose or face, nosebleeds; medications taken; changes in sense of smell.
5. Position the client comfortably, seated if possible.

Assessment	Normal Findings	Deviations from Normal
NOSE		
6. Inspect the external nose for any deviations in shape, size, or color and flaring or discharge from the nares.	Symmetric and straight No discharge or flaring Uniform color	Asymmetric Discharge from nares Localized areas of redness or presence of skin lesions
7. Lightly palpate the external nose to determine any areas of tenderness, masses, and displacements of bone and cartilage.	Not tender; no lesions	Tenderness on palpation; presence of lesions

Assessing the Nose and Sinuses—continued

Assessment	Normal Findings	Deviations from Normal
<p>8. Determine patency of both nasal cavities. Ask the client to close the mouth, exert pressure on one naris, and breathe through the opposite naris. Repeat the procedure to assess patency of the opposite naris.</p> <p>9. Inspect the nasal cavities using a flashlight or a nasal speculum.</p> <ul style="list-style-type: none"> Hold the speculum in your right hand to inspect the client's left nostril and your left hand to inspect the client's right nostril. Tip the client's head back. Facing the client, insert the tip of the speculum about 1 cm (0.4 in.). Care must be taken to avoid pressure on the sensitive nasal septum. Inspect the lining of the nares and the integrity and the position of the nasal septum. ❶ <p>10. Observe for the presence of redness, swelling, growths, and discharge.</p> <p>11. Inspect the nasal septum between the nasal chambers.</p>	<p>Air moves freely as the client breathes through the nares</p>  <p>❶ The nasal septum, inferior and middle turbinates of the nasal passage.</p> <p>Mucosa pink Clear, watery discharge No lesions Nasal septum intact and in midline</p>	<p>Air movement is restricted in one or both nares</p> <p>Mucosa red, edematous Abnormal discharge (e.g., pus) Presence of lesions (e.g., polyps) Septum deviated to the right or to the left</p>
<p>FACIAL SINUSES</p> <p>12. Palpate the maxillary and frontal sinuses for tenderness.</p> <p>13. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	<p>Not tender</p>	<p>Tenderness in one or more sinuses</p>

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Nose and Sinuses

INFANTS

- A speculum is usually not necessary to examine the septum, turbinates, and vestibule. Instead, push the tip of the nose upward with the thumb and shine a light into the nares.
- Ethmoid and maxillary sinuses are present at birth; frontal sinuses begin to develop by 1 to 2 years of age; and sphenoid sinuses develop later in childhood. Infants and young children have fewer sinus problems than older children and adolescents.

CHILDREN

- A speculum is usually not necessary to examine the septum, turbinates, and vestibule. It might cause the child to be apprehensive. Instead, push the tip of the nose upward with the thumb and shine a light into the nares.

- Ethmoid sinuses continue to develop until age 12.
- Cough and runny nose are the most common signs of sinusitis in preadolescent children.
- Adolescents may have headaches, facial tenderness, and swelling, similar to the signs seen in adults.

OLDER ADULTS

- The sense of smell markedly diminishes because of a decrease in the number of olfactory nerve fibers and atrophy of the remaining fibers. Older adults are less able to identify and discriminate odors.
- Nosebleeds may result from hypertensive disease or other arterial vessel changes.

Mouth and Oropharynx

The mouth and oropharynx are composed of a number of structures: lips, oral mucosa, the tongue and floor of the mouth, teeth and gums, hard and soft palate, uvula, salivary glands, tonsillar pillars, and tonsils. Anatomic structures of the mouth are shown in Figure 30–17. By age 25, most people have all their permanent teeth. For information about structures of the teeth, see Chapter 33.

Normally, three pairs of salivary glands empty into the oral cavity: the parotid, submandibular, and sublingual glands. The *parotid gland* is the largest and empties through Stensen's duct opposite the second molar. The *submandibular gland* empties through Wharton's duct, which is situated on either side of the frenulum on the floor of the mouth. The *sublingual salivary gland* lies in the floor of the mouth and has numerous openings.

Figure 30–17 ■ Anatomic structures of the mouth.

Dental **caries** (cavities) and **periodontal disease** (or **pyorrhea**) are the two problems that most frequently affect the teeth. Both problems are commonly associated with plaque and tartar deposits. **Plaque** is an invisible soft film that adheres to the enamel surface of teeth; it consists of bacteria, molecules of saliva, and remnants of epithelial cells and leukocytes. When plaque is unchecked, tartar (dental calculus) forms. **Tartar** is a visible, hard deposit of plaque and dead bacteria that forms at the gum lines. Tartar buildup can alter the fibers that attach the teeth to the gum and eventually disrupt bone tissue. Periodontal disease is characterized by **gingivitis** (red, swollen gingiva [gum]), bleeding, receding gum lines, and the formation of pockets between the teeth and gums. In advanced periodontal disease, the teeth are loose and pus is evident when the gums are pressed.

Other problems nurses may see are **glossitis** (inflammation of the tongue), **stomatitis** (inflammation of the oral mucosa), and **parotitis** (inflammation of the parotid salivary gland). The accumulation of foul matter (food, microorganisms, and epithelial elements) on the teeth and gums is referred to as **sordes**. Skill 30–9 describes assessment of the mouth and oropharynx.

Assessing the Mouth and Oropharynx

SKILL 30-9

PLANNING

If possible, arrange for the client to sit with the head against a firm surface such as a headrest or examination table. This makes it easier for the client to hold the head still during the examination.

Equipment

- Clean gloves
- Tongue depressor
- 2×2 gauze pads
- Penlight

DELEGATION

Due to the substantial knowledge and skill required, assessment of the mouth and oropharynx is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

INTERPROFESSIONAL PRACTICE

Assessing the mouth and oropharynx is within the scope of practice for many health care providers other than nurses, such as physician assistants. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: routine pattern of dental care, last visit to dentist; length of time ulcers or other lesions have been present; denture discomfort; medications client is receiving.
5. Position the client comfortably, seated if possible.

Assessment

Normal Findings

Deviations from Normal

LIPS AND BUCCAL MUCOSA

- | Assessment | Normal Findings | Deviations from Normal |
|---|--|---|
| <ol style="list-style-type: none"> 6. Inspect the outer lips for symmetry of contour, color, and texture. Ask the client to purse the lips as if to whistle. | Uniform pink color (darker, e.g., bluish hue, in Mediterranean groups and dark-skinned clients)
Soft, moist, smooth texture
Symmetry of contour
Ability to purse lips | Pallor; cyanosis
Blisters; generalized or localized swelling; fissures, crusts, or scales (may result from excessive moisture, nutritional deficiency, or fluid deficit)
Inability to purse lips (may indicate facial nerve damage) |
| <ol style="list-style-type: none"> 7. Inspect and palpate the inner lips and buccal mucosa for color, moisture, texture, and the presence of lesions. <ul style="list-style-type: none"> • Apply clean gloves. | Uniform pink color (freckled brown pigmentation in dark-skinned clients) | Pallor; leukoplakia (white patches), red, bleeding |

Assessing the Mouth and Oropharynx—continued

Assessment

- Ask the client to relax the mouth, and, for better visualization, pull the lip outward and away from the teeth.
- Grasp the lip on each side between the thumb and index finger. ❶

Normal Findings

Moist, smooth, soft, glistening, and elastic texture (drier oral mucosa in older clients due to decreased salivation)

❶ Inspecting the mucosa of the lower lip.

Deviations from Normal

Excessive dryness
Mucosal cysts; irritations from dentures; abrasions, ulcerations; nodules

TEETH AND GUMS

8. Inspect the teeth and gums while examining the inner lips and buccal mucosa.

- Ask the client to open the mouth. Using a tongue depressor, retract the cheek. ❷ View the surface buccal mucosa from top to bottom and back to front. A flashlight or penlight will help illuminate the surface. Repeat the procedure for the other side.
- Examine the back teeth. For proper vision of the molars, use the index fingers of both hands to retract the cheek. ❸ Ask the client to relax the lips and first close, then open, the jaw.

Rationale: *Closing the jaw assists in observation of tooth alignment and loss of teeth; opening the jaw assists in observation of dental fillings and caries.* Observe the number of teeth, tooth color, the state of fillings, dental caries, and tartar along the base of the teeth. Note the presence and fit of partial or complete dentures.

- Inspect the gums around the molars. Observe for bleeding, color, retraction (pulling away from the teeth), edema, and lesions.

32 adult teeth
Smooth, white, shiny tooth enamel

Pink gums (bluish or brown patches in dark-skinned clients)
Moist, firm texture to gums

No retraction of gums

❷ Inspecting the buccal mucosa using a tongue depressor.

❸ Inspecting the back teeth.

Smooth, intact dentures

Missing teeth; ill-fitting dentures
Brown or black discoloration of the enamel (may indicate staining or the presence of caries)
Excessively red gums

Spongy texture; bleeding; tenderness (may indicate periodontal disease)
Receding, atrophied gums; swelling that partially covers the teeth

9. Inspect the dentures. Ask the client to remove complete or partial dentures. Inspect their condition, noting in particular broken or worn areas.

Ill-fitting dentures; irritated and excoriated area under dentures

TONGUE/FLOOR OF THE MOUTH

10. Inspect the surface of the tongue for position, color, and texture. Ask the client to protrude the tongue.

Central position
Pink color (some brown pigmentation on tongue borders in dark-skinned clients); moist; slightly rough; thin whitish coating
Smooth, lateral margins; no lesions
Raised papillae (taste buds)

Deviated from center (may indicate damage to hypoglossal [12th cranial] nerve); excessive trembling
Smooth red tongue (may indicate iron, vitamin B₁₂, or vitamin B₃ deficiency)
Dry, furry tongue (associated with fluid deficit), white coating (may be oral yeast infection)
Nodes, ulcerations, discolorations (white or red areas); areas of tenderness

Assessing the Mouth and Oropharynx—continued

Assessment	Normal Findings	Deviations from Normal
11. Inspect tongue movement. Ask the client to roll the tongue upward and move it from side to side.	Moves freely; no tenderness	Restricted mobility
12. Inspect the base of the tongue, the mouth floor, and the frenulum. Ask the client to place the tip of the tongue against the roof of the mouth.	Smooth tongue base with prominent veins	Swelling, ulceration
PALATES AND UVULA		
13. Inspect the hard and soft palate for color, shape, texture, and the presence of bony prominences. Ask the client to open the mouth wide and tilt the head backward. Then, depress tongue with a tongue depressor as necessary, and use a penlight for appropriate visualization.	Light pink, smooth, soft palate Lighter pink hard palate, more irregular texture	Discoloration (e.g., jaundice or pallor) Palates the same color Irritations Exostoses (bony growths) growing from the hard palate
14. Inspect the uvula for position and mobility while examining the palates. To observe the uvula, ask the client to say “ah” so that the soft palate rises.	Positioned in midline of soft palate, rises during vocalization	Deviation to one side from tumor or trauma; immobility (may indicate damage to trigeminal [5th cranial] nerve or vagus [10th cranial] nerve)
OROPHARYNX AND TONSILS		
15. Inspect the oropharynx for color and texture. Inspect one side at a time to avoid eliciting the gag response. To expose one side of the oropharynx, press a tongue depressor against the tongue on the same side about halfway back while the client tilts the head back and opens the mouth wide. Use a penlight for illumination, if needed.	Pink and smooth posterior wall	Reddened or edematous; presence of lesions, plaques, or drainage
16. Inspect the tonsils (behind the fauces) for color, discharge, and size.	Pink and smooth No discharge Of normal size or not visible • <i>Grade 1 (normal)</i> : The tonsils are behind the tonsillar pillars (the soft structures supporting the soft palate).	Inflamed Presence of discharge Swollen • <i>Grade 2</i> : The tonsils are between the pillars and the uvula. • <i>Grade 3</i> : The tonsils touch the uvula. • <i>Grade 4</i> : One or both tonsils extend to the midline of the oropharynx.
17. Remove and discard gloves. • Perform hand hygiene.		
18. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Mouth and Oropharynx**INFANTS**

- Inspect the palate and uvula for a cleft. A bifid (forked) uvula may indicate an unsuspected cleft palate (i.e., a cleft in the cartilage that is covered by skin).
- Newborns may have a pearly white nodule on their gums, which resolves without treatment.
- The first teeth erupt at about 6 to 7 months of age. Assess for dental hygiene; parents should cleanse the infant's teeth daily with a soft cloth or soft toothbrush.

- Fluoride supplements should be given by 6 months if the child's drinking water contains less than 0.3 parts per million (ppm) fluoride.
- Children should see a dentist by 1 year of age.

CHILDREN

- Tooth development should be appropriate for age.
- White spots on the teeth may indicate excessive fluoride ingestion.

LIFESPAN CONSIDERATIONS Assessing the Mouth and Oropharynx—*continued*

- Drooling is common up to 2 years of age.
- The tonsils are normally larger in children than in adults and commonly extend beyond the palatine arch until the age of 11 or 12 years.

OLDER ADULTS

- The oral mucosa may be drier than that of younger people because of decreased salivary gland activity. Decreased salivation occurs in older people taking prescribed medications such as antidepressants, antihistamines, decongestants, diuretics, antihypertensives, tranquilizers, antispasmodics, and antineoplastics. Extreme dryness is associated with dehydration.
- Some receding of the gums occurs, giving an appearance of increased toothiness.
- Taste sensations diminish. Sweet and salty tastes are lost first. Older people may add more salt and sugar to food than they did when they were younger. Diminished taste sensation is due to atrophy of the taste buds and a decreased sense of smell. It indicates diminished function of the fifth and seventh cranial nerves.

- Tiny purple or bluish black swollen areas (varicosities) under the tongue, known as *caviar spots*, are not uncommon.
- The teeth may show signs of staining, erosion, chipping, and abrasions due to loss of dentin. Medicare does not cover dental cleanings or treatments. Older adults with limited incomes may delay or avoid professional dental care.
- Tooth loss occurs as a result of dental disease but is preventable with good dental hygiene.
- Check that full or removable partial dentures fit properly. Bone loss and weight loss or gain can change the way these prosthetics fit.
- The gag response may be slightly sluggish.
- Older adults who are homebound or are in long-term care facilities often have teeth or dentures in need of repair, due to the difficulty of obtaining dental care in these situations. Do a thorough assessment of missing teeth and those in need of repair, whether they are natural teeth or dentures.

Home Care Considerations Assessing the Mouth and Oropharynx**PATIENT-CENTERED CARE**

- Although clients may be sensitive to discussion of their personal hygiene practices, use the assessment as an opportunity to provide teaching regarding appropriate oral and

dental care for the entire family. Refer clients to a dentist if indicated.

NECK

Examination of the neck includes the muscles, lymph nodes, trachea, thyroid gland, carotid arteries, and jugular veins. Areas of the neck are defined by the sternocleidomastoid muscles, which divide each side of the neck into two triangles: the anterior and posterior (Figure 30–18 ■). The trachea, thyroid gland, anterior cervical nodes, and carotid artery lie within the anterior triangle (Figure 30–19 ■); the carotid artery runs parallel and anterior to the sternocleidomastoid muscle. The posterior lymph nodes lie within the posterior triangle (Figure 30–20 ■).

Each sternocleidomastoid muscle extends from the upper sternum and the medial third of the clavicle to the mastoid process of the temporal bone behind the ear. These muscles turn and laterally flex the head. Each trapezius muscle extends from the occipital bone of the skull to the lateral third of the clavicle. These muscles draw the head to the side and back, elevate the chin, and elevate the shoulders to shrug them.

Lymph nodes in the neck that collect lymph from the head and neck structures are grouped serially and referred to as *chains*. See Figure 30–20 and Table 30–6. The deep cervical

Figure 30–18 ■ Major muscles of the neck.

Figure 30–19 ■ Structures of the neck.

Figure 30–20 ■ Lymph nodes of the neck.

chain is not shown in Figure 30–20 because it lies beneath the sternocleidomastoid muscle. Skill 30–10 describes how to assess the neck.

THORAX AND LUNGS

Assessing the thorax and lungs is frequently critical to assessing the client’s oxygenation status (also see Chapter 50 ∞). Changes in the respiratory system can occur slowly or quickly. In clients with chronic obstructive pulmonary disease (COPD), such as chronic bronchitis, emphysema, and asthma, changes are frequently gradual. The onset of conditions such as pneumonia or pulmonary embolus is generally more acute or sudden.

Chest Landmarks

Before beginning the assessment, the nurse must be familiar with a series of imaginary lines on the chest wall and be able to locate the position of each rib and some spinous processes. These landmarks help the nurse to identify the position of underlying organs (e.g., lobes of the lung) and to record abnormal assessment findings.

TABLE 30–6 Lymph Nodes of the Head and Neck

Node Center	Location	Area Drained
HEAD		
Occipital	At the posterior base of the skull	The occipital region of the scalp and the deep structures of the back of the neck
Postauricular (mastoid)	Behind the auricle of the ear or in front of the mastoid process	The parietal region of the head and part of the ear
Preauricular	In front of the tragus of the ear	The forehead and upper face
FLOOR OF MOUTH		
Submandibular (submaxillary)	Along the medial border of the mandible, half-way between the angle of the jaw and the chin	The chin, upper lip, cheek, nose, teeth, eyelids, part of the tongue and floor of the mouth
Submental	Behind the tip of the mandible in the midline, under the chin	The anterior third of the tongue, gums, and floor of the mouth
NECK		
Superficial anterior cervical (tonsillar)	Along the mandible, anterior to the sternocleidomastoid muscle	The skin and neck
Posterior cervical	Along the anterior aspect of the trapezius muscle	The posterior and lateral regions of the neck, occiput, and mastoid
Deep cervical	Under the sternocleidomastoid muscle	The larynx, thyroid gland, trachea, and upper part of the esophagus
Supraclavicular	Above the clavicle, in the angle between the clavicle and the sternocleidomastoid muscle	The lateral regions of the neck and lungs

Assessing the Neck

SKILL 30–10

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the neck is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment
None

INTERPROFESSIONAL PRACTICE

Assessing the neck is within the scope of practice for many health care providers other than nurses, such as physician assistants and physical therapists. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client’s medical record.

Assessing the Neck—continued

IMPLEMENTATION

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Provide for client privacy.
- Inquire if the client has any history of the following: problems with neck lumps; neck pain or stiffness; when and how any lumps occurred; previous diagnoses of thyroid problems; and other treatments provided (e.g., surgery, radiation).

Assessment	Normal Findings	Deviations from Normal
NECK MUSCLES		
<p>5. Inspect the neck muscles (sternocleidomastoid and trapezius) for abnormal swellings or masses. Ask the client to hold the head erect.</p> <p>6. Observe head movement. Ask client to:</p> <ul style="list-style-type: none"> Move the chin to the chest. Rationale: <i>This determines function of the sternocleidomastoid muscle.</i> Move the head back so that the chin points upward. Rationale: <i>This determines function of the trapezius muscle.</i> Move the head so that the ear is moved toward the shoulder on each side. Rationale: <i>This determines function of the sternocleidomastoid muscle.</i> Turn the head to the right and to the left. Rationale: <i>This determines function of the sternocleidomastoid muscle.</i> <p>7. Assess muscle strength.</p> <ul style="list-style-type: none"> Ask the client to turn the head to one side against the resistance of your hand. Repeat with the other side. Rationale: <i>This determines the strength of the sternocleidomastoid muscle.</i> Ask the client to shrug the shoulders against the resistance of your hands. Rationale: <i>This determines the strength of the trapezius muscles.</i> 	<p>Muscles equal in size; head centered</p> <p>Coordinated, smooth movements with no discomfort Head flexes 45°</p> <p>Head hyperextends 60°</p> <p>Head laterally flexes 40°</p> <p>Head laterally rotates 70°</p> <p>Equal strength</p> <p>Equal strength</p>	<p>Unilateral neck swelling; head tilted to one side (indicates presence of masses, injury, muscle weakness, shortening of sternocleidomastoid muscle, scars) Muscle tremor, spasm, or stiffness</p> <p>Limited range of motion; painful movements; involuntary movements (e.g., up-and-down nodding movements associated with Parkinson's disease) Head hyperextends less than 60°</p> <p>Head laterally flexes less than 40°</p> <p>Head laterally rotates less than 70°</p> <p>Unequal strength</p> <p>Unequal strength</p>
LYMPH NODES		
<p>8. Palpate the entire neck for enlarged lymph nodes.</p> <ul style="list-style-type: none"> Face the client, and bend the client's head forward slightly or toward the side being examined. Rationale: <i>This relaxes the soft tissue and muscles.</i> Palpate the nodes using the pads of the fingers. Move the fingertips in a gentle rotating motion. When examining the submental and submandibular nodes, place the fingertips under the mandible on the side nearest the palpating hand, and pull the skin and subcutaneous tissue laterally over the mandibular surface so that the tissue rolls over the nodes. 	<p>Not palpable</p>	<p>Enlarged, palpable, possibly tender (associated with infection and tumors)</p>

Assessing the Neck—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> When palpating the supraclavicular nodes, have the client bend the head forward to relax the tissues of the anterior neck and to relax the shoulders so that the clavicles drop. Use your hand nearest the side to be examined when facing the client (i.e., your left hand for the client's right nodes). Use your free hand to flex the client's head forward if necessary. Hook your index and third fingers over the clavicle lateral to the sternocleidomastoid muscle. ❶ When palpating the anterior cervical nodes and posterior cervical nodes, move your fingertips slowly in a forward circular motion against the sternocleidomastoid and trapezius muscles, respectively. To palpate the deep cervical nodes, bend or hook your fingers around the sternocleidomastoid muscle. 		<p>❶ Palpating the supraclavicular lymph nodes.</p>
<p>TRACHEA</p> <p>9. Palpate the trachea for lateral deviation. Place your fingertip or thumb on the trachea in the suprasternal notch (see Figure 30-19, earlier), and then move your finger laterally to the left and the right in spaces bordered by the clavicle, the anterior aspect of the sternocleidomastoid muscle, and the trachea.</p>	<p>Central placement in midline of neck; spaces are equal on both sides</p>	<p>Deviation to one side, indicating possible neck tumor; thyroid enlargement; enlarged lymph nodes</p>
<p>THYROID GLAND</p> <p>10. Inspect the thyroid gland.</p> <ul style="list-style-type: none"> Stand in front of the client. Observe the lower half of the neck overlying the thyroid gland for symmetry and visible masses. Ask the client to extend the head and swallow. If necessary, offer a glass of water to make it easier for the client to swallow. <p>Rationale: <i>This action determines how the thyroid and cricoid cartilages move and whether swallowing causes a bulging of the gland.</i></p> <p>11. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	<p>Not visible on inspection</p> <p>Gland ascends during swallowing but is not visible</p>	<p>Visible diffuseness or local enlargement</p> <p>Gland is not fully movable with swallowing</p>
<p>EVALUATION</p> <ul style="list-style-type: none"> Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available. Report deviations from expected or normal findings to the primary care provider. 		

LIFESPAN CONSIDERATIONS Assessing the Neck

<p>INFANTS AND CHILDREN</p> <ul style="list-style-type: none"> Examine the neck while the infant or child is lying supine. Lift the head and turn it from side to side to determine neck mobility. 	<ul style="list-style-type: none"> An infant's neck is normally short, lengthening by about age 3 years. This makes palpation of the trachea difficult.
--	--

Figure 30-21 ■ Chest wall landmarks: A, anterior chest; B, lateral chest; C, posterior chest.

Figure 30-21 ■ shows the anterior, lateral, and posterior series of lines. The midsternal line is a vertical line running through the center of the sternum. The midclavicular lines (right and left) are vertical lines from the midpoints of the clavicles. The anterior axillary lines (right and left) are vertical lines from the anterior axillary folds (Figure 30-21A). Figure 30-21B shows the three imaginary lines of the lateral chest. The posterior axillary line is a vertical line from the posterior axillary fold. The midaxillary line is a vertical line from the apex of the axilla. Figure 30-21C shows the posterior chest landmarks. The vertebral line is a vertical line along the spinous processes. The scapular lines (right and left) are vertical lines from the inferior angles of the scapulae.

Locating the position of each rib and certain spinous processes is essential for identifying underlying lobes of the lung.

Figure 30-22A ■, shows an anterior view of the chest and underlying lungs; Figure 30-22B a posterior view; and Figure 30-22C right and left lateral views. Each lung is first divided into the upper and lower lobes by an oblique fissure that runs from the level of the spinous process of the third thoracic vertebra (T_3) to the level of the sixth rib at the midclavicular line. The right upper lobe is abbreviated RUL; the right lower lobe, RLL. Similarly, the left upper lobe is abbreviated LUL; the left lower lobe, LLL. The right lung is further divided by a minor fissure into the right upper lobe and right middle lobe (RML). This fissure runs anteriorly from the right midaxillary line at the level of the fifth rib to the level of the fourth rib.

These specific landmarks (i.e., T_3 and the fourth, fifth, and sixth ribs) are located as follows. The starting point for locating the ribs anteriorly is the **angle of Louis**, the junction between the body of

Figure 30-22 ■ Chest landmarks: A, anterior chest landmarks and underlying lungs; B, posterior chest landmarks and underlying lungs; C, lateral chest landmarks and underlying lungs.

Figure 30-23 ■ Location of the anterior ribs, the angle of Louis, and the sternum.

the **sternum** (breastbone) and the **manubrium** (the handle-like superior part of the sternum that joins with the clavicles). The superior border of the second rib attaches to the sternum at this manubriosternal junction (Figure 30-23 ■). The nurse can identify the manubrium by first palpating the clavicle and following its course to its attachment at the manubrium. The nurse then palpates and counts distal ribs and intercostal spaces (ICSs) from the second rib. It is important to note that an ICS is numbered according to the number of the rib immediately *above* the space. When palpating for rib identification, the nurse should palpate along the midclavicular line rather than the sternal border because the rib cartilages are very close at the sternum. Only the first seven ribs attach directly to the sternum.

The counting of ribs is more difficult on the posterior than on the anterior thorax. For identifying underlying lung lobes, the pertinent landmark is T₃. The starting point for locating T₃ is the spinous process of the seventh cervical vertebra (C₇) (Figure 30-24 ■).

Figure 30-24 ■ Location of the posterior ribs in relation to the spinous processes.

When the client flexes the neck anteriorly, a prominent process can be observed and palpated. This is the spinous process of the seventh cervical vertebra. If two spinous processes are observed, the superior one is C₇, and the inferior one is the spinous process of the first thoracic vertebra (T₁). The nurse then palpates and counts the spinous processes from C₇ to T₃. Each spinous process up to T₄ is adjacent to the corresponding rib number; for example, T₃ is adjacent to the third rib. After T₄, however, the spinous processes project obliquely, causing the spinous process of the vertebra to lie, not over its correspondingly numbered rib, but over the rib below. Thus, the spinous process of T₅ lies over the body of T₆ and is adjacent to the sixth rib.

Chest Shape and Size

In healthy adults, the thorax is oval. Its anteroposterior diameter is half its transverse diameter (Figure 30-25 ■). The overall shape of the thorax is elliptical; that is, its transverse diameter is smaller at the top than at the base. In older adults, kyphosis and osteoporosis alter the size of the chest cavity as the ribs move downward and forward.

There are several deformities of the chest (Figure 30-26 ■). Pigeon chest (*pectus carinatum*), a permanent deformity, may be caused by rickets (abnormal bone formation due to lack of dietary calcium). A narrow transverse diameter, an increased anteroposterior diameter, and a protruding sternum characterize pigeon chest. A funnel chest (*pectus excavatum*), a congenital defect, is the opposite of pigeon chest in that the sternum is depressed, narrowing the anteroposterior diameter. Because the sternum points posteriorly in clients with a funnel chest, abnormal pressure on the heart may result in altered function. A barrel chest, in which the ratio of the anteroposterior to transverse diameter is 1 to 1, is seen in clients with thoracic kyphosis (excessive convex curvature of the thoracic spine) and emphysema (chronic pulmonary condition in which the air sacs, or alveoli, are dilated and distended). Scoliosis is a lateral deviation of the spine.

Figure 30-25 ■ Configuration of the thorax showing oval shape, anteroposterior diameter, and transverse diameter.

Figure 30-26 ■ Chest deformities: A, pigeon chest; B, funnel chest; C, barrel chest; D, kyphosis; E, scoliosis.

TABLE 30-7 Normal Breath Sounds

Type	Description	Location	Characteristics
Vesicular	Soft-intensity, low-pitched, “gentle sighing” sounds created by air moving through smaller airways (bronchioles and alveoli)	Over peripheral lung; best heard at base of lungs	Best heard on inspiration, which is about 2.5 times longer than the expiratory phase (5:2 ratio)
Bronchovesicular	Moderate-intensity and moderate-pitched “blowing” sounds created by air moving through larger airway (bronchi)	Between the scapulae and lateral to the sternum at the first and second intercostal spaces	Equal inspiratory and expiratory phases (1:1 ratio)
Bronchial (tubular)	High-pitched, loud, “harsh” sounds created by air moving through the trachea	Anteriorly over the trachea; not normally heard over lung tissue	Louder than vesicular sounds; have a short inspiratory phase and long expiratory phase (1:2 ratio)

Breath Sounds

Abnormal breath sounds, called **adventitious breath sounds**, occur when air passes through narrowed airways or airways filled with fluid or mucus, or when pleural linings are inflamed. Table 30-7 describes normal breath sounds. Adventitious sounds are often superimposed over normal sounds (Table 30-8). Absence of breath

sounds over some lung areas is also a significant finding that is associated with collapsed and surgically removed lobes or severe pneumonia.

Assessment of the lungs and thorax includes all methods of examination: inspection, palpation, percussion, and auscultation. Skill 30-11 describes how to assess the thorax and lungs.

TABLE 30–8 Adventitious Breath Sounds

Name	Description	Cause	Location
Crackles (rales)	Fine, short, interrupted crackling sounds; alveolar rales are high pitched. Sound can be simulated by rolling a lock of hair near the ear. Best heard on inspiration but can be heard on both inspiration and expiration. May not be cleared by coughing.	Air passing through fluid or mucus in any air passage	Most commonly heard in the bases of the lower lung lobes
Gurgles (rhonchi)	Continuous, low-pitched, coarse, gurgling, harsh, louder sounds with a moaning or snoring quality. Best heard on expiration but can be heard on both inspiration and expiration. May be altered by coughing.	Air passing through narrowed air passages as a result of secretions, swelling, tumors	Loud sounds can be heard over most lung areas but predominate over the trachea and bronchi
Friction rub	Superficial grating or creaking sounds heard during inspiration and expiration. Not relieved by coughing.	Rubbing together of inflamed pleural surfaces	Heard most often in areas of greatest thoracic expansion (e.g., lower anterior and lateral chest)
Wheeze	Continuous, high-pitched, squeaky musical sounds. Best heard on expiration. Not usually altered by coughing.	Air passing through a constricted bronchus as a result of secretions, swelling, tumors	Heard over all lung fields

Assessing the Thorax and Lungs

SKILL 30-11

PLANNING

For efficiency, the nurse usually examines the posterior thorax first, then the anterior thorax. For posterior and lateral thorax examinations, the client is uncovered to the waist and in a sitting position. A sitting or lying position may be used for anterior thorax examination. The sitting position is preferred because it maximizes thorax expansion. Good lighting is essential, especially for thorax inspection.

Equipment

- Stethoscope

DELEGATION

Due to the substantial knowledge and skill required, assessment of the thorax and lungs is not delegated to UAP. However, many aspects of breathing are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

INTERPROFESSIONAL PRACTICE

Assessing the thorax and lungs is within the scope of practice for many health care providers other than nurses before, during, and after their treatments. For example, both physician assistants and respiratory therapists may check the client's lungs. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy. In women, drape the anterior thorax when it is not being examined.
4. Inquire if the client has any history of the following: family history of illness, including cancer, allergies, tuberculosis; lifestyle habits such as smoking and occupational hazards (e.g., inhaling fumes); medications being taken; current problems (e.g., swellings, coughs, wheezing, pain).

Assessment

Normal Findings

Deviations from Normal

POSTERIOR THORAX

- | Assessment | Normal Findings | Deviations from Normal |
|--|--|---|
| 5. Inspect the shape and symmetry of the thorax from posterior and lateral views. Compare the anteroposterior diameter to the transverse diameter. | Anteroposterior to transverse diameter in ratio of 1:2
Thorax symmetric | Barrel chest; increased anteroposterior to transverse diameter
Thorax asymmetric |

Assessing the Thorax and Lungs—continued

Assessment	Normal Findings	Deviations from Normal
<p>6. Inspect the spinal alignment for deformities if the client can stand. From a lateral position, observe the three normal curvatures: cervical, thoracic, and lumbar.</p> <ul style="list-style-type: none"> To assess for lateral deviation of spine (scoliosis), observe the standing client from the rear. Have the client bend forward at the waist and observe from behind. 	<p>Spine vertically aligned</p> <p>Spinal column is straight, right and left shoulders and hips are at same height.</p>	<p>Exaggerated spinal curvatures (kyphosis, lordosis)</p> <p>Spinal column deviates to one side, often accentuated when bending over. Shoulders or hips not even.</p>
<p>7. Palpate the posterior thorax.</p> <ul style="list-style-type: none"> Assess the temperature and integrity of all chest skin. For clients who have respiratory complaints, palpate all thorax areas for bulges, tenderness, or abnormal movements. Avoid deep palpation for painful areas, especially if a fractured rib is suspected. In such a case, deep palpation could lead to displacement of the bone fragment against the lungs. 	<p>Skin intact; uniform temperature</p> <p>Chest wall intact; no tenderness; no masses</p>	<p>Skin lesions; areas of hyperthermia</p> <p>Lumps, bulges; depressions; areas of tenderness; movable structures (e.g., rib)</p>
<p>8. Palpate the posterior thorax for respiratory excursion (thoracic expansion). Place the palms of both your hands over the lower thorax with your thumbs adjacent to the spine and your fingers stretched laterally. ❶ Ask the client to take a deep breath while you observe the movement of your hands and any lag in movement.</p>	<p>Full and symmetric thorax expansion (i.e., when the client takes a deep breath, your thumbs should move apart an equal distance and at the same time; normally the thumbs separate 3 to 5 cm [1.2 to 2 in.] during deep inspiration)</p>	<p>Asymmetric and/or decreased thorax expansion</p>

❶ Position of the nurse's hands when assessing respiratory excursion on the posterior thorax.

9. Palpate the thorax for vocal (tactile) **fremitus**, the faintly perceptible vibration felt through the chest wall when the client speaks.
- Place the palmar surfaces of your fingertips or the ulnar aspect of your hand or closed fist on the posterior thorax, starting near the apex of the lungs (see ❷, position A).
 - Ask the client to repeat such words as “blue moon” or “one, two, three.”
 - Repeat the two steps, moving your hands sequentially to the base of the lungs, through positions B–E in ❷.

Bilateral symmetry of vocal fremitus
Fremitus is heard most clearly at the apex of the lungs

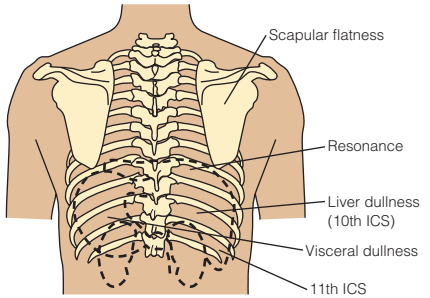

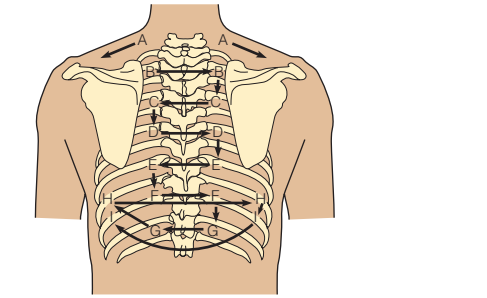

Low-pitched voices of males are more readily palpated than higher pitched voices of females

Decreased or absent fremitus (associated with pneumothorax)
Increased fremitus (associated with consolidated lung tissue, as in pneumonia)

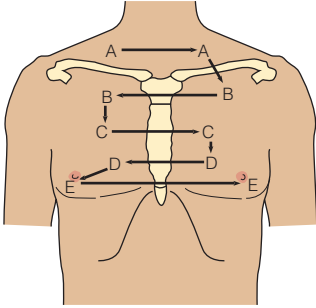

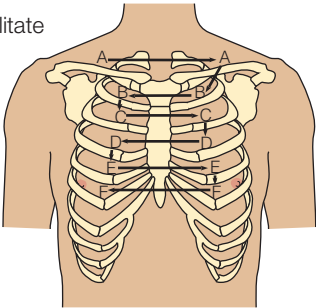

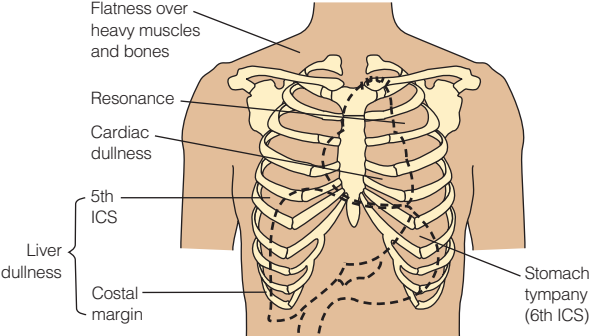

❷ Areas and sequence for palpating tactile fremitus on the posterior thorax.

Assessing the Thorax and Lungs—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> Compare the fremitus on both lungs and between the apex and the base of each lung, using either one hand and moving it from one side of the client to the corresponding area on the other side or using two hands that are placed simultaneously on the corresponding areas of each side of the thorax. 		
<p>10. Percuss the thorax. Percussion of the thorax is performed to determine whether underlying lung tissue is filled with air, liquid, or solid material and to determine the positions and boundaries of certain organs. Because percussion penetrates to a depth of 5 to 7 cm (2 to 3 in.), it detects superficial rather than deep lesions (see 3 and Table 30-4, earlier).</p> <ul style="list-style-type: none"> Ask the client to bend the head and fold the arms forward across the chest. Rationale: <i>This separates the scapula and exposes more lung tissue to percussion.</i> Percuss in the intercostal spaces at about 5-cm (2-in.) intervals in a systematic sequence. 4 Compare one side of the lung with the other. Percuss the lateral thorax every few inches, starting at the axilla and working down to the eighth rib. 	<p>Percussion notes resonate, except over scapula Lowest point of resonance is at the diaphragm (i.e., at the level of the 8th to 10th rib posteriorly) <i>Note:</i> Percussion on a rib normally elicits dullness.</p>	<p>Asymmetry in percussion notes Areas of dullness or flatness over lung tissue (associated with consolidation of lung tissue or a mass)</p>
<p>11. Auscultate the thorax using the flat-disk diaphragm of the stethoscope. Rationale: <i>The diaphragm of the stethoscope is best for transmitting the high-pitched breath sounds.</i></p> <ul style="list-style-type: none"> Use the systematic zigzag procedure used in percussion. Ask the client to take slow, deep breaths through the mouth. Listen at each point to the breath sounds during a complete inspiration and expiration. Compare findings at each point with the corresponding point on the opposite side of the thorax. 	 <p>3 Normal percussion sounds on the posterior thorax.</p>	 <p>4 Sequence for posterior thorax percussion.</p>
<p>ANTERIOR THORAX</p> <p>12. Inspect breathing patterns (e.g., respiratory rate and rhythm).</p> <p>13. Inspect the costal angle (angle formed by the intersection of the costal margins) and the angle at which the ribs enter the spine.</p> <p>14. Palpate the anterior thorax (see posterior thorax palpation).</p> <p>15. Palpate the anterior thorax for respiratory excursion.</p>	<p>Vesicular and bronchovesicular breath sounds (see Table 30-7)</p> <p>Quiet, rhythmic, and effortless respirations (see Chapter 29 ∞, page 496)</p> <p>Costal angle is less than 90°, and the ribs insert into the spine at approximately a 45° angle (see Figure 30-23, earlier)</p> <p>Full symmetric excursion; thumbs normally separate 3 to 5 cm (1.2 to 2 in.)</p>	<p>Adventitious breath sounds (e.g., crackles, gurgles, wheeze, friction rub; see Table 30-8)</p> <p>Absence of breath sounds</p> <p>See Chapter 29 ∞, Box 29-5 on page 498, for abnormal breathing patterns and sounds.</p> <p>Costal angle is widened (associated with chronic obstructive pulmonary disease)</p> <p>Asymmetric and/or decreased respiratory excursion</p>

Assessing the Thorax and Lungs—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> Place the palms of both your hands on the lower thorax, with your fingers laterally along the lower rib cage and your thumbs along the costal margins. 5 Ask the client to take a deep breath while you observe the movement of your hands. 		<p>5 Position of the nurse's hands when assessing respiratory excursion on the anterior thorax.</p>
<p>16. Palpate tactile fremitus in the same manner as for the posterior thorax and using the sequence shown in 6. If the breasts are large and cannot be retracted adequately for palpation, this part of the examination is usually omitted.</p>	<p>Same as posterior vocal fremitus; fremitus is normally decreased over heart and breast tissue</p> 	<p>Same as posterior fremitus</p> <p>6 Areas and sequence for palpating tactile fremitus on the anterior thorax.</p>
<p>17. Percuss the anterior thorax systematically.</p> <ul style="list-style-type: none"> Begin above the clavicles in the supraclavicular space, and proceed downward to the diaphragm. 7 Compare the lung on one side to the lung on the other side. Displace female breasts to facilitate percussion of the lungs. 	<p>Percussion notes resonate down to the sixth rib at the level of the diaphragm but are flat over areas of heavy muscle and bone, dull on areas over the heart and the liver, and tympanic over the underlying stomach. 8</p> 	<p>Asymmetry in percussion notes Areas of dullness or flatness over lung tissue</p> 
<p>18. Auscultate the trachea.</p>	<p>Bronchial and tubular breath sounds (see Table 30-7 on page 555)</p>	<p>Adventitious breath sounds (see Table 30-8 on page 556)</p>
<p>19. Auscultate the anterior thorax. Use the sequence used in percussion 7, beginning over the bronchi between the sternum and the clavicles.</p>	<p>Bronchovesicular and vesicular breath sounds (see Table 30-7)</p>	<p>Adventitious breath sounds (see Table 30-8)</p>
<p>20. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>		

SAMPLE DOCUMENTATION

5/28/15 0830 Lungs clear to auscultation except for fine crackles over both posterior lower lobes, partially cleared after coughing. Rarely moves in bed. Assisted to a chair and reviewed deep-breathing exercises. Effective return demonstration. _____ N. Schmidt, RN

EVALUATION

- Perform a detailed follow-up examination based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Thorax and Lungs

INFANTS

The thorax is rounded; that is, the diameter from the front to the back (anteroposterior) is equal to the transverse diameter (Figure 30–27 ■). It is also cylindrical, having a nearly equal diameter at the top and the base. This makes it harder for infants to expand their thoracic space.

- To assess tactile fremitus, place the hand over the crying infant's thorax.
- Infants tend to breathe using their diaphragm; assess rate and rhythm by watching the abdomen, rather than the thorax, rise and fall.
- The right bronchial branch is short and angles down as it leaves the trachea, making it easy for small objects to be inhaled. Sudden onset of cough or other signs of respiratory distress may indicate the infant has inhaled a foreign object.

CHILDREN

- By about 6 years of age, the anteroposterior diameter has decreased in proportion to the transverse diameter, with a 1:2 ratio present.
- Children tend to breathe more abdominally than thoracically up to age 6.
- During the rapid growth spurts of adolescence, spinal curvature and rotation (scoliosis) may appear. Children should be assessed for scoliosis by age 12 and annually until their growth slows. Curvature greater than 10% should be referred for further medical evaluation.

OLDER ADULTS

- The thoracic curvature may be accentuated (kyphosis) because of osteoporosis and changes in cartilage, resulting in collapse of the vertebrae. This can also compromise and decrease normal respiratory effort.
- Kyphosis and osteoporosis alter the size of the thorax cavity as the ribs move downward and forward.
- The anteroposterior diameter of the thorax widens, giving the person a barrel-chested appearance. This is due to loss of skeletal muscle strength in the thorax and diaphragm and constant lung inflation from excessive expiratory pressure on the alveoli.

Clinical appearance

Figure 30–27 ■ Configuration of the infant's thorax showing round shape, anteroposterior diameter, and transverse diameter.

- Breathing rate and rhythm are unchanged at rest; the rate normally increases with exercise but may take longer to return to the pre-exercise rate.
- Inspiratory muscles become less powerful, and the inspiration reserve volume decreases. A decrease in depth of respiration is therefore apparent.
- Expiration may require the use of accessory muscles. The expiratory reserve volume significantly increases because of the increased amount of air remaining in the lungs at the end of a normal breath.
- Deflation of the lung is incomplete.
- Small airways lose their cartilaginous support and elastic recoil; as a result, they tend to close, particularly in basal or dependent portions of the lung.
- Elastic tissue of the alveoli loses its stretchability and changes to fibrous tissue. Exertional capacity decreases.
- Cilia in the airways decrease in number and are less effective in removing mucus; older clients are therefore at greater risk for pulmonary infections.

CARDIOVASCULAR AND PERIPHERAL VASCULAR SYSTEMS

The cardiovascular system consists of the heart and the central blood vessels (primarily the pulmonary, coronary, and neck arteries and veins). The peripheral vascular system includes those arteries and veins distal to the central vessels, extending all the way to the brain and to the extremities.

Heart

Nurses assess the heart through inspection, palpation, and auscultation, in that sequence. Auscultation is more meaningful when other data are obtained first. The heart is usually assessed during an initial physical assessment; periodic reassessments may be necessary for long-term or at-risk clients or those with cardiac problems. Also see Chapter 51 ∞.

In the average adult, most of the heart lies behind and to the left of the sternum. A small portion (the right atrium) extends to the right of the sternum. The upper portion of the heart (both atria), referred to as its *base*, lies toward the back. The lower portion (the ventricles), referred to as its *apex*, points anteriorly. The apex of the left ventricle

actually touches the chest wall at or medial to the left midclavicular line (MCL) and at or near the fifth left intercostal space (LICS), which is slightly below the left nipple (see Figure 3 on page 494). The point where the apex touches the anterior chest wall and heart movements are most easily observed and palpated is known as the point of maximal impulse (PMI).

CLINICAL ALERT!

Remember that the base of the lungs is the lower (inferior) portion, and the base of the heart is the upper (superior) portion.

The **precordium**, the area of the chest overlying the heart, is inspected and palpated for the presence of abnormal pulsations or lifts or heaves. The terms **lift** and **heave**, often used interchangeably, refer to a rising along the sternal border with each heartbeat. A lift occurs when cardiac action is very forceful. It should be confirmed by palpation with the palm of the hand. Enlargement or overactivity of the left ventricle produces a heave lateral to the apex, whereas enlargement of the right ventricle produces a heave at or near the sternum.

Figure 30-28 ■ Anatomic sites of the precordium.

Heart sounds can be heard by auscultation. The normal first two heart sounds are produced by closure of the valves of the heart. The first heart sound, **S₁**, occurs when the atrioventricular (AV) valves close. These valves close when the ventricles have been sufficiently filled. Although the AV valves do not close simultaneously, the closure occurs closely enough to be heard as one sound. **S₁** is a dull, low-pitched sound described as “lub.” After the ventricles empty the blood into the aorta and pulmonary arteries, the semilunar valves close, producing the second heart sound, **S₂**, described as “dub.” **S₂** has a higher pitch than **S₁** and is shorter in duration. These two sounds, **S₁** and **S₂** (“lub-dub”), occur within 1 second or less, depending on the heart rate.

The two heart sounds are audible anywhere on the precordial area, but they are best heard over the aortic, pulmonic, tricuspid, and mitral areas (Figure 30-28 ■). Each area is associated with the closure of heart valves: the aortic area with the aortic valve (inside the aorta as it arises from the left ventricle); the pulmonic area with the pulmonic valve (inside the pulmonary artery as it arises from the right ventricle); the tricuspid area with the tricuspid valve (between the right atrium and ventricle); and the mitral area (sometimes referred

Figure 30-29 ■ Relationship of heart sounds to systole and diastole.

to as the apical area) with the mitral valve (between the left atrium and ventricle).

Associated with these sounds are systole and diastole. **Systole** is the period in which the ventricles contract. It begins with **S₁** and ends at **S₂**. Systole is normally shorter than diastole. **Diastole** is the period in which the ventricles relax. It starts with **S₂** and ends at the subsequent **S₁**. Normally no sounds are audible during these periods (Figure 30-29 ■). The experienced nurse, however, may perceive extra heart sounds (**S₃** and **S₄**) during diastole. Both sounds are low in pitch and heard best at the apex, with the bell of the stethoscope, and with the client lying on the left side. **S₃** occurs early in diastole right after **S₂** and sounds like “lub-dub-ee” (**S₁**, **S₂**, **S₃**) or “Kentuc-ky.” It often disappears when the client sits up. **S₃** is normal in children and young adults. In older adults, it may indicate heart failure. The **S₄** sound (ventricular gallop) occurs near the very end of diastole just before **S₁** and creates the sound of “dee-lub-dub” (**S₄**, **S₁**, **S₂**) or “Ten-nessee.” **S₄** may be heard in older clients and can be a sign of hypertension.

Normal heart sounds are summarized in Table 30-9. The nurse may also hear abnormal heart sounds, such as clicks, rubs, and murmurs. These are caused by valve disorders or impaired blood flow within the heart and require advanced training to diagnose.

TABLE 30-9 Normal Heart Sounds

Sound or Phase	Description	Area			
		Aortic	Pulmonic	Tricuspid	Mitral
S₁	Dull, low pitched, and longer than S₂ ; sounds like “lub”	Less intensity than S₂	Less intensity than S₂	Louder than or equal to S₂	Louder than or equal to S₂
Systole	Normally silent interval between S₁ and S₂				
S₂	Higher pitch than S₁ ; sounds like “dub”	Louder than S₁	Louder than S₁ ; abnormal if louder than the aortic S₂ in adults over 40 years of age	Less intensity than or equal to S₁	Less intensity than or equal to S₁
Diastole	Normally silent interval between S₂ and next S₁				

Central Vessels

The carotid arteries supply oxygenated blood to the head and neck (Figure 30–30 ■). Because they are the only source of blood to the brain, prolonged occlusion of these arteries can result in serious brain damage. The carotid pulses correlate with central aortic pressure, thus reflecting cardiac function better than the peripheral pulses. When cardiac output is diminished, the peripheral pulses may be difficult or impossible to feel, but the carotid pulse should be felt easily.

The carotid is also auscultated for a bruit. A **bruit** (a blowing or swishing sound) is created by turbulence of blood flow due either to a narrowed arterial lumen (a common development in older people) or to a condition, such as anemia or hyperthyroidism, that elevates cardiac output. If a bruit is found, the carotid artery is then palpated for a thrill. A **thrill**, which frequently accompanies a bruit, is a vibrating sensation like the purring of a cat or water running through a hose. It, too, indicates turbulent blood flow due to arterial obstruction.

The jugular veins drain blood from the head and neck directly into the superior vena cava and right side of the heart. The external jugular veins are superficial and may be visible above the clavicle. The internal jugular veins lie deeper along the carotid artery and may transmit pulsations onto the skin of the neck. Normally, external neck veins are distended and visible when a person lies down; they are flat and not as visible when a person stands up, because gravity encourages venous drainage. By inspecting the jugular veins for pulsations

Figure 30–30 ■ Arteries and veins of the right side of the neck.

and distention, the nurse can assess the adequacy of function of the right side of the heart and venous pressure. Bilateral jugular venous distention (JVD) may indicate right-sided heart failure. Skill 30–12 describes how to assess the heart and central vessels.

Assessing the Heart and Central Vessels

PLANNING

Heart examination is usually performed while the client is in a semi-reclined position. The practitioner usually stands at the client's right side and auscultates and palpates with the right hand but this may be reversed if the nurse is left-handed.

DELEGATION

Due to the substantial knowledge and skill required, assessment of the heart and central vessels is not delegated to UAP. However, many aspects of cardiac function are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any of the following: family history of incidence and age of heart disease, high cholesterol levels, high blood pressure, stroke, obesity, congenital heart disease,

Equipment

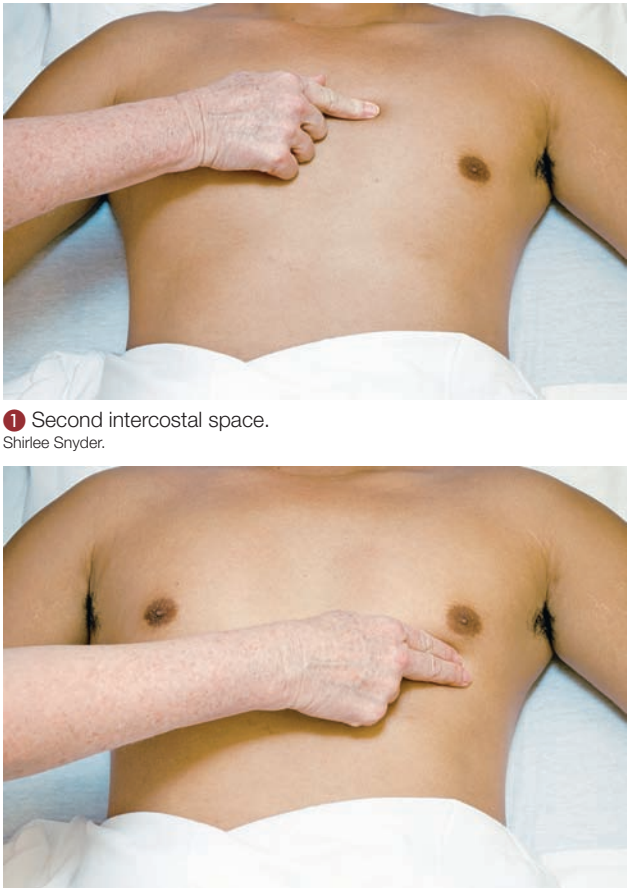

- Stethoscope
- Centimeter ruler

INTERPROFESSIONAL PRACTICE

Assessing the heart and central vessels is within the scope of practice for many health care providers other than nurses. For example, physician assistants may assess the heart and central vessels before, during, and after treatment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

arterial disease, hypertension, and rheumatic fever; client's past history of rheumatic fever, heart murmur, heart attack, varicosities, or heart failure; present symptoms indicative of heart disease (e.g., fatigue, dyspnea, orthopnea, edema, cough, chest pain, palpitations, syncope, hypertension, wheezing, hemoptysis); presence of diseases that affect heart (e.g., obesity, diabetes, lung disease, endocrine disorders); lifestyle habits that are risk factors for cardiac disease (e.g., smoking, alcohol intake, eating and exercise patterns, areas and degree of stress perceived).

Assessing the Heart and Central Vessels—continued

Assessment	Normal Findings	Deviations from Normal
<p>5. Simultaneously inspect and palpate the precordium for the presence of abnormal pulsations, lifts, or heaves. Locate the valve areas of the heart:</p> <ul style="list-style-type: none"> • Locate the angle of Louis. It is felt as a prominence on the sternum. • Move your fingertips down each side of the angle until you can feel the second intercostal spaces. The client's right second intercostal space is the aortic area, and the left second intercostal space is the pulmonic area. ❶ From the pulmonic area, move your fingertips down three left intercostal spaces along the side of the sternum. The left fifth intercostal space close to the sternum is the tricuspid or right ventricular area. • From the tricuspid area, move your fingertips laterally 5 to 7 cm (2 to 3 in.) to the left midclavicular line. ❷ This is the apical or mitral area, or point of maximal impulse (PMI). If you have difficulty locating the PMI, have the client roll onto the left side to move the apex closer to the chest wall. 	 <p>❶ Second intercostal space. Shirlee Snyder.</p> <p>❷ Fifth intercostal space, MCL. Shirlee Snyder.</p>	<p>Pulsations</p> <p>Pulsations Diffuse lift or heave, indicating enlarged or overactive right ventricle</p> <p>PMI displaced laterally or lower indicates enlarged heart Diameter over 2 cm (0.8 in.) indicates enlarged heart or aneurysm Diffuse lift or heave lateral to apex indicates enlargement or overactivity of left ventricle Bounding abdominal pulsations (e.g., aortic aneurysm)</p>
<ul style="list-style-type: none"> • Inspect and palpate the aortic and pulmonic areas, observing them at an angle and to the side, to note the presence or absence of pulsations. Observing these areas at an angle increases the likelihood of seeing pulsations. 	<p>No pulsations</p>	<p>Pulsations</p>
<ul style="list-style-type: none"> • Inspect and palpate the tricuspid area for pulsations and heaves or lifts. 	<p>No pulsations No lift or heave</p>	<p>Pulsations Diffuse lift or heave, indicating enlarged or overactive right ventricle</p>
<ul style="list-style-type: none"> • Inspect and palpate the apical area for pulsation, noting its specific location (it may be displaced laterally or lower) and diameter. If displaced laterally, record the distance between the apex and the MCL in centimeters. 	<p>Pulsations visible in 50% of adults and palpable in most PMI in fifth LICs at or medial to MCL Diameter of 1 to 2 cm (0.4 to 0.8 in.) No lift or heave</p>	<p>PMI displaced laterally or lower indicates enlarged heart Diameter over 2 cm (0.8 in.) indicates enlarged heart or aneurysm Diffuse lift or heave lateral to apex indicates enlargement or overactivity of left ventricle</p>
<ul style="list-style-type: none"> • Inspect and palpate the epigastric area at the base of the sternum for abdominal aortic pulsations. 	<p>Aortic pulsations</p>	<p>Bounding abdominal pulsations (e.g., aortic aneurysm)</p>

Continued on page 564

Assessing the Heart and Central Vessels—continued

Assessment	Normal Findings	Deviations from Normal
<p>6. Auscultate the heart in all four anatomic sites: aortic, pulmonic, tricuspid, and apical (mitral). Auscultation need not be limited to these areas; however, the nurse may need to move the stethoscope to find the most audible sounds for each client.</p> <ul style="list-style-type: none"> Eliminate all sources of room noise. Rationale: <i>Heart sounds are of low intensity, and other noise hinders the nurse's ability to hear them.</i> Keep the client in a supine position with head elevated 15° to 45°. Use both the diaphragm and the bell to listen to all areas. In every area of auscultation, distinguish both S₁ and S₂ sounds. When auscultating, concentrate on one particular sound at a time in each area: the first heart sound, followed by systole, then the second heart sound, then diastole. Systole and diastole are normally silent intervals. Later, reexamine the heart while the client is in the upright sitting position. Rationale: <i>Certain sounds are more audible in certain positions.</i> 	<p>S₁: usually heard at all sites Usually louder at apical area S₂: usually heard at all sites Usually louder at base of heart Systole: silent interval; slightly shorter duration than diastole at normal heart rate (60 to 90 beats/min) Diastole: silent interval; slightly longer duration than systole at normal heart rates</p> <p>S₃ in children and young adults S₄ in many older adults</p>	<p>Increased or decreased intensity Varying intensity with different beats Increased intensity at aortic area Increased intensity at pulmonic area Sharp-sounding ejection clicks</p> <p>S₃ in older adults S₄ may be a sign of hypertension</p>
CAROTID ARTERIES		
<p>7. Palpate the carotid artery, using extreme caution.</p> <ul style="list-style-type: none"> Palpate only one carotid artery at a time. Rationale: <i>This ensures adequate blood flow through the other artery to the brain.</i> Avoid exerting too much pressure or massaging the area. Rationale: <i>Pressure can occlude the artery, and carotid sinus massage can precipitate bradycardia.</i> The carotid sinus is a small dilation at the beginning of the internal carotid artery just above the bifurcation of the common carotid artery, in the upper third of the neck. Ask the client to turn the head slightly toward the side being examined. This makes the carotid artery more accessible. 	<p>Symmetric pulse volumes</p> <p>Full pulsations, thrusting quality Quality remains same when client breathes, turns head, and changes from sitting to supine position Elastic arterial wall</p>	<p>Asymmetric volumes (possible stenosis or thrombosis) Decreased pulsations (may indicate impaired left cardiac output) Increased pulsations</p> <p>Thickening, hard, rigid, beaded, inelastic walls (indicate arteriosclerosis)</p>
<p>8. Auscultate the carotid artery.</p> <ul style="list-style-type: none"> Turn the client's head slightly away from the side being examined. Rationale: <i>This facilitates placement of the stethoscope.</i> Auscultate the carotid artery on one side and then the other. Listen for the presence of a bruit. If you hear a bruit, gently palpate the artery to determine the presence of a thrill. 	<p>No sound heard on auscultation</p>	<p>Presence of bruit in one or both arteries (suggests occlusive artery disease)</p>

Assessing the Heart and Central Vessels—continued

Assessment	Normal Findings	Deviations from Normal
<p>JUGULAR VEINS</p> <p>9. Inspect the jugular veins for distention while the client is placed in the semi-Fowler's position (15° to 45° angle), with the head supported on a small pillow.</p> <p>10. If jugular distention is present, assess the jugular venous pressure (JVP).</p> <ul style="list-style-type: none"> Locate the highest visible point of distention of the internal jugular vein. Although either the internal or the external jugular vein can be used, the internal jugular vein is more reliable. <p>Rationale: <i>The external jugular vein is more easily affected by obstruction or kinking at the base of the neck.</i></p> <ul style="list-style-type: none"> Measure the vertical height of this point in centimeters from the sternal angle, the point at which the clavicles meet. 3 Repeat the preceding steps on the other side. <p>11. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	<p>Veins not visible (indicating right side of heart is functioning normally)</p>	<p>Veins visibly distended (indicating advanced cardiopulmonary disease)</p> <p>Bilateral measurements above 3 to 4 cm (1.2 to 1.6 in.) are considered elevated (may indicate right-sided heart failure)</p> <p>Unilateral distention (may be caused by local obstruction)</p>
<p>3 Assessing the highest point of distention of the jugular vein.</p>		

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Heart and Central Vessels**INFANTS**

- Physiological splitting of the second heart sound (S_2) may be heard when the child takes a deep breath and the aortic valve closes a split second before the pulmonic valve. If splitting of S_2 is heard during normal respirations, it is abnormal and may indicate an atrial-septal defect, pulmonary stenosis, or another heart problem.
- Infants may normally have sinus arrhythmia that is related to respiration. The heart rate slows during expiration and increases when the child breathes in.
- Murmurs may be heard in newborns as the structures of fetal circulation, especially the ductus arteriosus, close.

CHILDREN

- Heart sounds may be louder because of the thinner chest wall.
- A third heart sound (S_3), caused as the ventricles fill, is best heard at the apex, and is present in about one third of all children.

- The PMI is higher and more medial in children under 8 years old.

OLDER ADULTS

- If no disease is present, heart size remains the same size throughout life.
- Cardiac output and strength of contraction decrease, thus lessening the older person's activity tolerance.
- The heart rate returns to its resting rate more slowly after exertion than it did when the individual was younger.
- S_4 heart sound is considered normal in older adults.
- Extra systoles commonly occur. Ten or more systoles per minute are considered abnormal.
- Sudden emotional and physical stresses may result in cardiac arrhythmias and heart failure.

Peripheral Vascular System

Assessing the peripheral vascular system includes measuring the blood pressure, palpating peripheral pulses, and inspecting the skin and tissues to determine **perfusion** (blood supply to an area) to the extremities. Certain aspects of peripheral vascular assessment are often incorporated

into other parts of the assessment procedure. For example, blood pressure is usually measured at the beginning of the physical examination (see the section on assessing blood pressure in Chapter 29 ∞). Pulse sites and pulse assessments are described in Chapter 29 ∞. Skill 30–13 describes how to assess the peripheral vascular system.

Assessing the Peripheral Vascular System

SKILL 30–13

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the peripheral vascular system is not delegated to UAP. However, many aspects of the vascular system are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment
None

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.

INTERPROFESSIONAL PRACTICE

Assessing the peripheral vascular system is within the scope of practice for many health care providers other than nurses. For example, occupational and physical therapists may check the client's pulses before treatment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

3. Provide for client privacy.
4. Inquire if the client has any of the following: past history of heart disorders, varicosities, arterial disease, and hypertension; lifestyle habits such as exercise patterns, activity patterns and tolerance, smoking, and use of alcohol.

Assessment

Normal Findings

Deviations from Normal

PERIPHERAL PULSES

5. Palpate the peripheral pulses on both sides of the client's body individually, simultaneously (except the carotid pulse), and systematically to determine the symmetry of pulse volume. If you have difficulty palpating some of the peripheral pulses, use a Doppler ultrasound probe.

Symmetric pulse volumes
Full pulsations

Asymmetric volumes (indicate impaired circulation)
Absence of pulsation (indicates arterial spasm or occlusion)
Decreased, weak, thready pulsations (indicate impaired cardiac output)
Increased pulse volume (may indicate hypertension, high cardiac output, or circulatory overload)

PERIPHERAL VEINS

6. Inspect the peripheral veins in the arms and legs for the presence and/or appearance of superficial veins when limbs are dependent and when limbs are elevated.
7. Assess the peripheral leg veins for signs of phlebitis.
 - Inspect the calves for redness and swelling over vein sites.
 - Palpate the calves for firmness or tension of the muscles, the presence of edema over the dorsum of the foot, and areas of localized warmth. **Rationale:** *Palpation augments inspection findings, particularly in darker pigmented people in whom redness may not be visible.*
 - Push the calves from side to side to test for tenderness.
 - Firmly dorsiflex the client's foot while supporting the entire leg in extension (Homans' test), or have the person stand or walk.

In dependent position, presence of distention and nodular bulges at calves
When limbs elevated, veins collapse (veins may appear tortuous or distended in older people)

Symmetric in size
Limbs not tender

Distended veins in the thigh and/or lower leg or on posterolateral part of calf from knee to ankle

Swelling of one calf or leg
Tenderness on palpation
Pain in calf muscles with forceful dorsiflexion of the foot (positive Homans' test)
Warmth and redness over vein
No one sign or symptom consistently confirms or excludes the presence of phlebitis or a deep venous thrombosis. Homans' sign has been found to give inconsistent results (D'Amico & Barbarito, 2012).

Assessing the Peripheral Vascular System—continued

Assessment	Normal Findings	Deviations from Normal
PERIPHERAL PERFUSION		
8. Inspect the skin of the hands and feet for color, temperature, edema, and skin changes.	<p>Skin color pink</p> <p>Skin temperature not excessively warm or cold</p> <p>No edema</p> <p>Skin texture resilient and moist</p>	<p>Cyanotic (venous insufficiency)</p> <p>Pallor that increases with limb elevation</p> <p>Dependent rubor, a dusky red color when limb is lowered (arterial insufficiency)</p> <p>Brown pigmentation around ankles (arterial or chronic venous insufficiency)</p> <p>Skin cool (arterial insufficiency)</p> <p>Marked edema (venous insufficiency)</p> <p>Mild edema (arterial insufficiency)</p> <p>Skin thin and shiny or thick, waxy, shiny, and fragile, with reduced hair and ulceration (venous or arterial insufficiency)</p>
9. Assess the adequacy of arterial flow if arterial insufficiency is suspected.		
CAPILLARY REFILL TEST		
<ul style="list-style-type: none"> Press at least one nail on each hand and foot between your thumb and index finger sufficiently to cause blanching (about 5 seconds). Release the pressure, and observe how quickly normal color returns (less than 2 seconds). 	Immediate return of color	Delayed return of color (arterial insufficiency)
OTHER ASSESSMENTS		
<ul style="list-style-type: none"> Inspect the fingernails for changes indicative of circulatory impairment. See the section on assessment of nails earlier in this chapter. See also peripheral pulse assessment earlier. 		
10. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		
	<p>SAMPLE DOCUMENTATION</p> <hr/> <p>5/28/15 0830 Legs mottled red bilaterally toes to mid-calf. States “actually looks a bit better.” Capillary refill 4–5 seconds in toes on both feet. Pedal pulses present but weak. Homans’ test negative. c/o pain in calves after walking 100 feet.</p> <p>_____ N. Schmidt, RN</p> <hr/>	
EVALUATION		
<ul style="list-style-type: none"> Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available. 		<ul style="list-style-type: none"> Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Peripheral Vascular System

INFANTS

- Screen for coarctation of the aorta by palpating the peripheral pulses and comparing the strength of the femoral pulses with the radial pulses and apical pulse. If coarctation is present, femoral pulses will be diminished and radial pulses will be stronger.

CHILDREN

- Changes in the peripheral vasculature, such as bruising, petechiae, and purpura, can indicate serious systemic diseases in children (e.g., leukemia, meningococemia).

OLDER ADULTS

- The overall efficiency of blood vessels decreases as smooth muscle cells are replaced by connective tissue. The lower extremities are more likely to show signs of arterial and venous impairment because of the more distal and dependent position.
- Peripheral vascular assessment should always include upper and lower extremities’ temperature, color, pulses, edema, skin integrity, and sensation. Any differences in symmetry of these findings should be noted.

LIFESPAN CONSIDERATIONS Assessing the Peripheral Vascular System—continued

- Proximal arteries become thinner and dilate.
- Peripheral arteries become thicker and dilate less effectively because of arteriosclerotic changes in the vessel walls.
- Blood vessels lengthen and become more tortuous and prominent. Varicosities occur more frequently.
- In some instances, arteries may be palpated more easily because of the loss of supportive surrounding tissues. Often, however, the most distal pulses of the lower extremities are more difficult to palpate because of decreased arterial perfusion.
- Systolic and diastolic blood pressures increase, but the increase in the systolic pressure is greater. As a result, the pulse pressure widens. Any client with a blood pressure reading above 140/90 mmHg should be referred for follow-up assessments.
- Peripheral edema is frequently observed and is most commonly the result of chronic venous insufficiency or low protein levels in the blood (hypoproteinemia).

Home Care Considerations Assessing the Peripheral Vascular System

PATIENT-CENTERED CARE

- Use the assessment as an opportunity to provide teaching regarding appropriate care of the extremities in those at high risk for or with actual vascular impairment. Educate clients and families regarding skin and nail care, exercise, and positioning to promote circulation.

BREASTS AND AXILLAE

The breasts of men and women need to be inspected and palpated. Men have some glandular tissue beneath each nipple, a potential site for malignancy, whereas mature women have glandular tissue throughout the breast. In females, the largest portion of glandular breast tissue is located in the upper outer quadrant of each breast. A projection of breast tissue from this quadrant extends into the *axilla*, called the *axillary tail of Spence* (Figure 30–31 ■). The majority of breast tumors are located in this upper outer breast quadrant including the tail of Spence. During assessment, the nurse can localize specific findings by dividing the breast into quadrants and the axillary tail. Skill 30–14 describes how to assess the breasts and axillae.

Figure 30–31 ■ The four breast quadrants and the axillary tail of Spence.

Assessing the Breasts and Axillae

SKILL 30–14

PLANNING
DELEGATION

Due to the substantial knowledge and skill required, assessment of the breasts and axillae is not delegated to UAP. However, individuals other than the nurse may record aspects observed during usual care. Abnormal findings must be validated and interpreted by the nurse.

- Equipment**
- Centimeter ruler

IMPLEMENTATION
Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Inquire whether the client has ever had a clinical

INTERPROFESSIONAL PRACTICE

Assessing the breasts and axillae is within the scope of practice for a few health care providers other than nurses. For example, physician assistants may check the client's breasts during their health assessment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

2. Perform hand hygiene and observe other appropriate infection prevention procedures.

Assessing the Breasts and Axillae—continued

3. Provide for client privacy.
4. Inquire if the client has any history of the following: breast masses and what was done about them; pain or tenderness in the breasts and relation to the woman's menstrual cycle; discharge from the nipple; medication history (some medications, e.g., oral contraceptives, steroids, digitalis, and diuretics, may cause nipple discharge; estrogen replacement therapy may be associated with

the development of cysts or cancer); risk factors that may be associated with development of breast cancer (e.g., mother, sister, aunt with breast cancer; alcohol consumption, high-fat diet, obesity, use of oral contraceptives, menarche before age 12, menopause after age 55, age 30 or more at first pregnancy). Inquire if the client performs breast self-examination; technique used and when performed in relation to the menstrual cycle.

Assessment

5. Inspect the breasts for size, symmetry, and contour or shape while the client is in a sitting position.
6. Inspect the skin of the breast for localized discolorations or hyperpigmentation, retraction or dimpling, localized hypervascular areas, swelling or edema. ①

① A lesion causing retraction of the skin.

7. Emphasize any retraction by having the client:
 - Raise the arms above the head.
 - Push the hands together, with elbows flexed. ②
 - Press the hands down on the hips. ③
8. Inspect the areola area for size, shape, symmetry, color, surface characteristics, and any masses or lesions.
9. Inspect the nipples for size, shape, position, color, discharge, and lesions.

Normal Findings

Females: rounded shape; slightly unequal in size; generally symmetric
Males: breasts even with the chest wall; if obese, may be similar in shape to female breasts
 Skin uniform in color (similar to skin of abdomen if not tanned)
 Skin smooth and intact
 Diffuse symmetric horizontal or vertical vascular pattern in light-skinned people
 Striae (stretch marks); moles and nevi

② Pushing the hands together to accentuate retraction of breast tissue.

Deviations from Normal

Recent change in breast size; swellings; marked asymmetry

Localized discolorations or hyperpigmentation
 Retraction or dimpling (result of scar tissue or an invasive tumor)
 Unilateral, localized hypervascular areas (associated with increased blood flow)
 Swelling or edema appearing as pig skin or orange peel due to exaggeration of the pores

③ Pressing the hands down on the hips to accentuate retraction of breast tissue.

Round or oval and bilaterally the same
 Color varies widely, from light pink to dark brown
 Irregular placement of sebaceous glands on the surface of the areola (Montgomery's tubercles)
 Round, everted, and equal in size; similar in color; soft and smooth; both nipples point in same direction (out in young women and men, downward in older women)
 No discharge, except from pregnant or breast-feeding females
 Inversion of one or both nipples that is present from puberty

Any asymmetry, mass, or lesion

Asymmetrical size and color
 Presence of discharge, crusts, or cracks
 Recent inversion of one or both nipples

Continued on page 570

Assessing the Breasts and Axillae—continued

SKILL 30-14

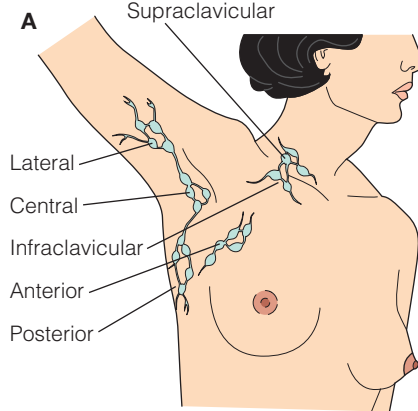

Assessment

10. Palpate the axillary, subclavicular, and supraclavicular lymph nodes 4 while the client sits with the arms abducted and supported on the nurse's forearm. See discussion on palpation of clavicular lymph nodes in Skill 30-10. Use the flat surfaces of all fingertips to palpate the four areas of the axilla:

- The edge of the greater pectoral muscle (musculus pectoralis major) along the anterior axillary line
- The thoracic wall in the midaxillary area
- The upper part of the humerus
- The anterior edge of the latissimus dorsi muscle along the posterior axillary line.

Normal Findings

No tenderness, masses, or nodules

4 Location and palpation of the lymph nodes that drain the lateral breast: A, lymph nodes; B, palpating the axilla.

Deviations from Normal

Tenderness, masses, or nodules

11. Palpate the breast for masses, tenderness, and any discharge from the nipples. Palpation of the breast is generally performed while the client is supine. **Rationale:** *In the supine position, the breasts flatten evenly against the chest wall, facilitating palpation.* For clients who have a past history of breast masses, who are at high risk for breast cancer, or who have pendulous breasts, examination in both a supine and a sitting position is recommended.

No tenderness, masses, nodules, or nipple discharge

Tenderness, masses, nodules, or nipple discharge

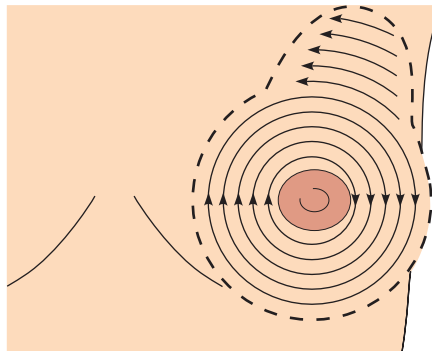

• If you detect a mass, record the following data:

- Location:** the exact location relative to the quadrants and axillary tail, or the clock 5 and the distance from the nipple in centimeters.
- Size:** the length, width, and thickness of the mass in centimeters. If you are able to determine the discrete edges, record this fact.
- Shape:** whether the mass is round, oval, lobulated, indistinct, or irregular.
- Consistency:** whether the mass is hard or soft.
- Mobility:** whether the mass is movable or fixed.
- Skin over the lump:** whether it is reddened, dimpled, or retracted.
- Nipple:** whether it is displaced or retracted.
- Tenderness:** whether palpation is painful.

- If the client reports a breast lump, start with the "normal" breast to obtain baseline data that will serve as a comparison to the reportedly involved breast.
- To enhance flattening of the breast, instruct the client to abduct the arm and place her hand behind her head. Then place a small pillow or rolled towel under the client's shoulder.
- For palpation, use the palmar surface of the middle three fingertips (held together) and make a gentle rotary motion on the breast.
- Choose one of three patterns for palpation:
 - Hands-of-the-clock or spokes-on-a-wheel 5
 - Concentric circles 6
 - Vertical strips pattern. 7
- Start at one point for palpation, and move systematically to the end point to ensure that all breast surfaces are assessed.
- Pay particular attention to the upper outer quadrant area and the tail of Spence.

5 Hands-of-the-clock or spokes-on-a-wheel pattern of breast palpation.

6 Concentric circles pattern of breast palpation.

7 Vertical strips pattern of breast palpation.

Assessing the Breasts and Axillae—continued

Assessment	Normal Findings	Deviations from Normal
<p>12. Palpate the areolae and the nipples for masses. Compress each nipple to determine the presence of any discharge. If discharge is present, milk the breast along its radius to identify the discharge-producing lobe. Assess any discharge for amount, color, consistency, and odor. Note also any tenderness on palpation.</p> <p>13. If the client wishes, teach the technique of breast self-examination (see Chapter 40 ∞).</p> <p>14. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	No tenderness, masses, nodules, or nipple discharge	Tenderness, masses, nodules, or nipple discharge

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Breasts and Axillae

INFANTS

- Newborns up to 2 weeks of age, both boys and girls, may have breast enlargement and white discharge from the nipples (witch's milk).
- Supernumerary ("extra") nipples infrequently are present as small dimples along the mammary chain; these may be associated with renal anomalies.

CHILDREN

- Female breast development begins between 9 and 13 years of age and occurs in five stages (Tanner stages). One breast may develop more rapidly than the other, but at the end of development, they are more or less the same size.
 - Stage 1: prepubertal with no noticeable change
 - Stage 2: breast bud with elevation of nipple and enlargement of the areola
 - Stage 3: enlargement of the breast and areola with no separation of contour
 - Stage 4: projection of the areola and nipple
 - Stage 5: recession of the areola by about age 14 or 15, leaving only the nipple projecting.
- Boys may develop breast buds and have slight enlargement of the areola in early adolescence. Further enlargement of breast tissue (gynecomastia) can occur. This growth is transient,

usually lasting about 2 years, resolving completely by late puberty.

- Axillary hair usually appears in Tanner stages 3 or 4 and is related to adrenal rather than gonadal changes.

PREGNANT FEMALES

- Breast, areola, and nipple size increase.
- The areolae and nipples darken; nipples may become more erect; areolae contain small, scattered, elevated Montgomery's glands.
- Superficial veins become more prominent, and jagged linear stretch marks may develop.
- A thick yellow fluid (colostrum) may be expressed from the nipples after the first trimester.

OLDER ADULTS

- In the postmenopausal female, breasts change in shape and often appear pendulous or flaccid; they lack the firmness they had in younger years.
- The presence of breast lesions may be detected more readily because of the decrease in connective tissue.
- General breast size remains the same. Although glandular tissue atrophies, the amount of fat in breasts (predominantly in the lower quadrants) increases in most women.

ABDOMEN

The nurse locates and describes abdominal findings using two common methods of subdividing the abdomen: quadrants and regions. To divide the abdomen into quadrants, the nurse imagines two lines: a vertical line from the xiphoid process to the pubic symphysis, and a horizontal line across the umbilicus

(Figure 30-32 ■). These quadrants are labeled right upper quadrant, left upper quadrant, right lower quadrant, and left lower quadrant. Using the second method, division into nine regions, the nurse imagines two vertical lines that extend superiorly from the midpoints of the inguinal ligaments, and two horizontal lines, one at the level of the edge of the lower ribs

Figure 30-32 ■ The four abdominal quadrants and the underlying organs: *RUQ*, right upper quadrant; *LUQ*, left upper quadrant; *RLQ*, right lower quadrant; *LLQ*, left lower quadrant.

BOX 30-7 Organs in the Four Abdominal Quadrants

RIGHT UPPER QUADRANT

- Liver
- Gallbladder
- Duodenum
- Head of pancreas
- Right adrenal gland
- Upper lobe of right kidney
- Hepatic flexure of colon
- Section of ascending colon
- Section of transverse colon

LEFT UPPER QUADRANT

- Left lobe of liver
- Stomach
- Spleen
- Upper lobe of left kidney
- Pancreas
- Left adrenal gland
- Splenic flexure of colon
- Section of transverse colon
- Section of descending colon

RIGHT LOWER QUADRANT

- Lower lobe of right kidney
- Cecum
- Appendix
- Section of ascending colon
- Right ovary
- Right fallopian tube
- Right ureter

- Part of uterus

LEFT LOWER QUADRANT

- Lower lobe of left kidney
- Sigmoid colon
- Section of descending colon
- Left ovary
- Left fallopian tube
- Left ureter
- Left spermatic cord
- Part of uterus

BOX 30-8 Organs in the Nine Abdominal Regions

RIGHT HYPOCHONDIAC

- Right lobe of liver
- Gallbladder
- Part of duodenum
- Hepatic flexure of colon
- Upper half of right kidney
- Suprarenal gland

UMBILICAL

- Omentum
- Mesentery
- Lower part of duodenum
- Part of jejunum and ileum

RIGHT LUMBAR

- Ascending colon
- Lower half of right kidney
- Part of duodenum and jejunum

HYPOGASTRIC (PUBIC)

- Ileum
- Bladder
- Uterus

RIGHT INGUINAL

- Cecum
- Appendix
- Lower end of ileum
- Right ureter
- Right spermatic cord
- Right ovary

LEFT HYPOCHONDIAC

- Stomach
- Spleen
- Tail of pancreas
- Splenic flexure of colon
- Upper half of left kidney
- Suprarenal gland

EPIGASTRIC

- Aorta
- Pyloric end of stomach
- Part of duodenum
- Pancreas
- Part of liver

LEFT LUMBAR

- Descending colon
- Lower half of left kidney
- Part of jejunum and ileum

LEFT INGUINAL

- Sigmoid colon
- Left ureter
- Left spermatic cord
- Left ovary

Figure 30-33 ■ The nine abdominal regions: epigastric; left and right hypochondriac; umbilical; left and right lumbar; hypogastric; left and right inguinal or iliac.

and the other at the level of the iliac crests (Figure 30-33 ■). Specific organs or parts of organs lie in each abdominal region (Boxes 30-7 and 30-8).

In addition, practitioners often use certain landmarks to locate abdominal signs and symptoms. These are the xiphoid process of the

sternum, the costal margins, the anterosuperior iliac spine, the umbilicus, the inguinal ligaments, and the superior margin of the pubic symphysis (Figure 30-34 ■).

Assessment of the abdomen involves all four methods of examination (inspection, auscultation, palpation, and percussion).

Figure 30-34 ■ Landmarks commonly used to identify abdominal areas.

When assessing the abdomen, the nurse performs inspection first, followed by auscultation, percussion, and/or palpation. Auscultation is done before palpation and percussion because palpation and percussion cause movement or stimulation of the bowel, which can increase bowel motility and thus heighten bowel sounds, creating false results. Skill 30-15 describes how to assess the abdomen.

Assessing the Abdomen

PLANNING

- Ask the client to urinate since an empty bladder makes the assessment more comfortable.
- Ensure that the room is warm since the client will be exposed.

DELEGATION

Due to the substantial knowledge and skill required, assessment of the abdomen is not delegated to UAP. However, signs and symptoms of problems may be observed during usual care and should be recorded by those individuals. Abnormal findings must be validated and interpreted by the nurse.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: incidence of abdominal pain; its location, onset, sequence, and chronology; its quality (description); its frequency; associated symptoms (e.g., nausea, vomiting, diarrhea); incidence of constipation or diarrhea (have client describe what client means by these

Equipment

- Examining light
- Tape measure (metal or unstretchable cloth)
- Skin-marking pen
- Stethoscope

INTERPROFESSIONAL PRACTICE

Assessing the abdomen is within the scope of practice for many health care providers other than nurses. For example, both physician assistants and nutritionists may check the client's abdomen. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

5. Assist the client to a supine position, with the arms placed comfortably at the sides. Place small pillows beneath the knees and the head to reduce tension in the abdominal muscles. Expose the client's abdomen only from the chest line to the pubic area to avoid chilling and shivering, which can tense the abdominal muscles.

Assessment

Normal Findings

Deviations from Normal

INSPECTION OF THE ABDOMEN

6. Inspect the abdomen for skin integrity (refer to the discussion of skin assessment earlier in this chapter).

Unblemished skin
Uniform color

Silver-white striae (stretch marks) or surgical scars

Presence of rash or other lesions
Tense, glistening skin (may indicate ascites, edema)

Purple striae (associated with Cushing's disease or rapid weight gain and loss)

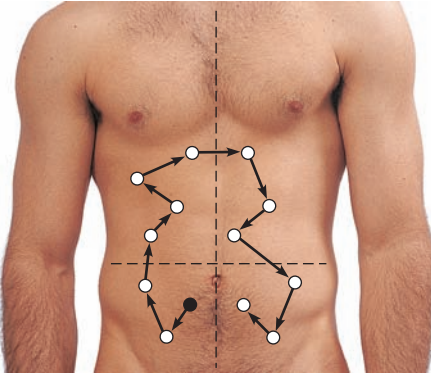

Continued on page 574

Assessing the Abdomen—continued

SKILL 30-15

Assessment	Normal Findings	Deviations from Normal
<p>7. Inspect the abdomen for contour and symmetry:</p> <ul style="list-style-type: none"> Observe the abdominal contour (profile line from the rib margin to the pubic bone) while standing at the client's side when the client is supine. Ask the client to take a deep breath and to hold it. Rationale: <i>This makes an enlarged liver or spleen more obvious.</i> Assess the symmetry of contour while standing at the foot of the bed. If distention is present, measure the abdominal girth by placing a tape around the abdomen at the level of the umbilicus. ❶ If girth will be measured repeatedly, use a skin-marking pen to outline the upper and lower margins of the tape placement for consistency of future measurements. 	<p>Flat, rounded (convex), or scaphoid (concave)</p> <p>No evidence of enlargement of liver or spleen</p> <p>Symmetric contour</p>	<p>Distended</p> <p>Evidence of enlargement of liver or spleen</p> <p>Asymmetric contour, e.g., localized protrusions around umbilicus, inguinal ligaments, or scars (possible hernia or tumor)</p>
<p>8. Observe abdominal movements associated with respiration, peristalsis, or aortic pulsations.</p>	<p>Symmetric movements caused by respiration</p> <p>Visible peristalsis in very lean people</p> <p>Aortic pulsations in thin people at epigastric area</p>	<p>Limited movement due to pain or disease process</p> <p>Visible peristalsis in nonlean clients (possible bowel obstruction)</p> <p>Marked aortic pulsations</p> <p>Visible venous pattern (dilated veins) is associated with liver disease, ascites, and venocaval obstruction</p>
<p>9. Observe the vascular pattern.</p>	<p>No visible vascular pattern</p>	<p>Visible venous pattern (dilated veins) is associated with liver disease, ascites, and venocaval obstruction</p>
<p>AUSCULTATION OF THE ABDOMEN</p>		
<p>10. Auscultate the abdomen for bowel sounds, vascular sounds, and peritoneal friction rubs. Warm the hands and the stethoscope diaphragms. Rationale: <i>Cold hands and a cold stethoscope may cause the client to contract the abdominal muscles, and these contractions may be heard during auscultation.</i></p> <p>For Bowel Sounds</p> <ul style="list-style-type: none"> Use the flat-disk diaphragm. ❷ Rationale: <i>Intestinal sounds are relatively high pitched and best accentuated by the diaphragm.</i> Light pressure with the stethoscope is adequate. 	<p>Audible bowel sounds</p>	<p>Hypoactive, i.e., extremely soft and infrequent (e.g., one per minute). Hypoactive sounds indicate decreased motility and are usually associated with manipulation of the bowel during surgery, inflammation, paralytic ileus, or late bowel obstruction.</p> <p>Hyperactive/increased, i.e., high-pitched, loud, rushing sounds that occur frequently (e.g., every 3 seconds) also known as borborygmi. Hyperactive sounds indicate increased intestinal motility and are usually associated with diarrhea, an early bowel obstruction, or the use of laxatives. True absence of sounds (none heard in 3 to 5 minutes) indicates a cessation of intestinal motility</p>
	 <p>❶ Measuring abdominal girth.</p>	
	 <p>❷ Auscultating the abdomen for bowel sounds.</p>	

Assessing the Abdomen—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> Ask when the client last ate. Rationale: <i>Shortly after or long after eating, bowel sounds may normally increase. They are loudest when a meal is long overdue.</i> Four to 7 hours after a meal, bowel sounds may be heard continuously over the ileocecal valve area (right lower quadrant) while the digestive contents from the small intestine empty through the valve into the large intestine. Place diaphragm of the stethoscope in each of the four quadrants of the abdomen. Listen for active bowel sounds—irregular gurgling noises occurring about every 5 to 20 seconds. The duration of a single sound may range from less than a second to more than several seconds. 		
<p>For Vascular Sounds</p> <ul style="list-style-type: none"> Use the bell of the stethoscope over the aorta, renal arteries, iliac arteries, and femoral arteries. ③ Listen for bruits. 	Absence of arterial bruits	Loud bruit over aortic area (possible aneurysm) Bruit over renal or iliac arteries
<p>Peritoneal Friction Rubs</p> <ul style="list-style-type: none"> Peritoneal friction rubs are rough, grating sounds like two pieces of leather rubbing together. Friction rubs may be caused by inflammation, infection, or abnormal growths. 	Absence of friction rub	Friction rub
<p>PERCUSSION OF THE ABDOMEN</p>	Tympany over the stomach and gas-filled bowels; dullness, especially over the liver and spleen, or a full bladder	Large dull areas (associated with presence of fluid or a tumor)
<p>11. Percuss several areas in each of the four quadrants to determine presence of tympany (sound indicating gas in stomach and intestines) and dullness (decrease, absence, or flatness of resonance over solid masses or fluid). Use a systematic pattern: Begin in the lower right quadrant, proceed to the upper right quadrant, the upper left quadrant, and the lower left quadrant. ④</p>		④ Systematic percussion sites for all four quadrants.

Continued on page 576

Assessing the Abdomen—continued

SKILL 30-15

Assessment

PALPATION OF THE ABDOMEN

12. Perform light palpation first to detect areas of tenderness and/or muscle guarding. Systematically explore all four quadrants. Ensure that the client's position is appropriate for relaxation of the abdominal muscles, and warm the hands. **Rationale:** *Cold hands can elicit muscle tension and thus impede palpatory evaluation.*

Light Palpation

- Hold the palm of your hand slightly above the client's abdomen, with your fingers parallel to the abdomen.
- Depress the abdominal wall lightly, about 1 cm or to the depth of the subcutaneous tissue, with the pads of your fingers. **5**
- Move the finger pads in a slight circular motion.
- Note areas of tenderness or superficial pain, masses, and muscle guarding. To determine areas of tenderness, ask the client to tell you about them and watch for changes in the client's facial expressions.
- If the client is excessively ticklish, begin by pressing your hand on top of the client's hand while pressing lightly. Then slide your hand off the client's and onto the abdomen to continue the examination.

PALPATION OF THE BLADDER

13. Palpate the area above the pubic symphysis if the client's history indicates possible urinary retention. **6**

14. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.

Normal Findings

No tenderness; relaxed abdomen with smooth, consistent tension

5 Light palpation of the abdomen.

Deviations from Normal

Tenderness and hypersensitivity
Superficial masses
Localized areas of increased tension

Not palpable

6 Palpating the bladder.

Distended and palpable as smooth, round, tense mass (indicates urinary retention)

SAMPLE DOCUMENTATION

5/28/15 0945 c/o "gassy" pain LRQ. No BM x 48 hrs. Ate 75% regular diet yesterday. Abdomen flat. Active bowels sounds all 4 quadrants. Tympany above umbilicus, dull below. No masses palpated. 30 mL milk of magnesia given. _____ N. Schmidt, RN

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Abdomen**INFANTS**

- Internal organs of newborns and infants are proportionately larger than those of older children and adults, so their abdomens are rounded and tend to protrude.
- The infant's liver may be palpable 1 to 2 cm (0.4 to 0.8 in.) below the right costal margin.
- Umbilical hernias may be present at birth.

CHILDREN

- Toddlers have a characteristic “potbelly” appearance, which can persist until age 3 to 4 years.
- Late preschool and school-age children are leaner and have a flat abdomen.
- Peristaltic waves may be more visible than in adults.
- Children may not be able to pinpoint areas of tenderness; by observing facial expressions the examiner can determine areas of maximum tenderness.
- The liver is relatively larger than in adults. It can be palpated 1 to 2 cm (0.4 to 0.8 in.) below the right costal margin.
- If the child is ticklish, guarding, or fearful, use a task that requires concentration (such as squeezing the hands together) to distract the child, or have the child place his or her hands on yours as you palpate the abdomen, “helping” you to do the exam.

OLDER ADULTS

- The rounded abdomens of older adults are due to an increase in adipose tissue and a decrease in muscle tone.
- The abdominal wall is slacker and thinner, making palpation easier and more accurate than in younger clients. Muscle wasting and loss of fibroconnective tissue occur.

- The pain threshold in older adults is often higher; major abdominal problems such as appendicitis or other acute emergencies may therefore go undetected.
- Gastrointestinal pain needs to be differentiated from cardiac pain. Gastrointestinal pain may be located in the chest or abdomen, whereas cardiac pain is usually located in the chest. Factors aggravating gastrointestinal pain are usually related to either ingestion or lack of food intake; gastrointestinal pain is usually relieved by antacids, food, or assuming an upright position. Common factors that can aggravate cardiac pain are activity or anxiety; rest or nitroglycerin relieves cardiac pain.
- Stool passes through the intestines at a slower rate in older adults, and the perception of stimuli that produce the urge to defecate often diminishes.
- Fecal incontinence may occur in adults who are confused or have a neurologic impairment.
- Many older adults believe that the absence of a daily bowel movement signifies constipation. When assessing for constipation, the nurse must consider the client's diet, activity, medications, and characteristics and ease of passage of feces as well as the frequency of bowel movements.
- The incidence of colon cancer is higher among older adults than younger adults. Symptoms include a change in bowel function, rectal bleeding, and weight loss. Changes in bowel function, however, are associated with many factors, such as diet, exercise, and medications.
- Decreased absorption of oral medications often occurs with aging.
- In the liver, impaired metabolism of some drugs may occur with aging.

Home Care Considerations Assessing the Abdomen**PATIENT-CENTERED CARE**

- Be sure you have the required equipment on a home visit, including a tape measure and skin-marking pen.
- Use pillows to position the client.
- Undressing the client to perform a complete abdominal examination may not be necessary. Focus the assessment on areas indicated by the history and present complaint.

MUSCULOSKELETAL SYSTEM

The musculoskeletal system encompasses the muscles, bones, and joints. The completeness of an assessment of this system depends largely on the needs and problems of the individual client. The nurse usually assesses the musculoskeletal system for muscle strength, tone, size, and symmetry of muscle development, and for tremors. A **tremor** is an involuntary trembling of a limb or body part. Tremors may involve large groups of muscle fibers or small bundles of muscle fibers. An **intention tremor** becomes more apparent when an individual attempts a voluntary movement, such as

holding a cup of coffee. A **resting tremor** is more apparent when the client is relaxed and diminishes with activity. A **fasciculation** is an abnormal contraction of a bundle of muscle fibers that appears as a twitch.

Bones are assessed for normal form. Joints are assessed for tenderness, swelling, thickening, crepitation (a crackling, grating sound), and range of motion. Body posture is assessed for normal standing and sitting positions. For information about body posture, see Chapter 44 ∞. Skill 30–16 describes how to assess the musculoskeletal system.

Assessing the Musculoskeletal System

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the musculoskeletal system is not delegated to UAP. However, many aspects of its functioning are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Goniometer
- Tape measure

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.

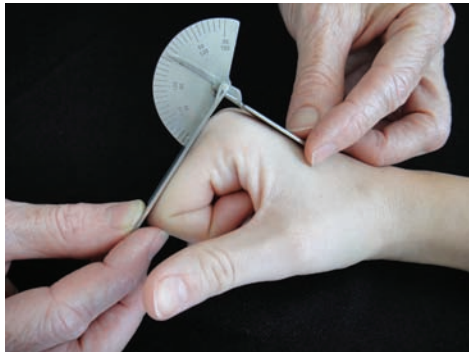

INTERPROFESSIONAL PRACTICE

Assessing the musculoskeletal system is within the scope of practice for many health care providers other than nurses. For example, both physical therapists and occupational therapists assess the musculoskeletal system as an integral part of their work. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

3. Provide for client privacy.
4. Inquire if the client has any history of the following: muscle pain: onset, location, character, associated phenomena (e.g., redness and swelling of joints), and aggravating and alleviating factors; limitations to movement or inability to perform activities of daily living; previous sports injuries; loss of function without pain.

Assessment	Normal Findings	Deviations from Normal
MUSCLES		
5. Inspect the muscles for size. Compare the muscles on one side of the body (e.g., of the arm, thigh, and calf) to the same muscle on the other side. For any discrepancies, measure the muscles with a tape.	Equal size on both sides of body	Atrophy (a decrease in size) or hypertrophy (an increase in size), asymmetry
6. Inspect the muscles and tendons for contractures (shortening).	No contractures	Malposition of body part, e.g., foot drop (foot flexed downward)
7. Inspect the muscles for tremors, for example by having the client hold the arms out in front of the body.	No tremors	Presence of tremor
8. Test muscle strength. Compare the right side with the left side. <i>Sternocleidomastoid:</i> Client turns the head to one side against the resistance of your hand. Repeat with the other side. <i>Trapezius:</i> Client shrugs the shoulders against the resistance of your hands. <i>Deltoid:</i> Client holds arm up and resists while you try to push it down. <i>Biceps:</i> Client fully extends each arm and tries to flex it while you attempt to hold arm in extension. <i>Triceps:</i> Client flexes each arm and then tries to extend it against your attempt to keep arm in flexion. <i>Wrist and finger muscles:</i> Client spreads the fingers and resists as you attempt to push the fingers together. <i>Grip strength:</i> Client grasps your index and middle fingers while you try to pull the fingers out. <i>Hip muscles:</i> Client is supine, both legs extended; client raises one leg at a time while you attempt to hold it down.	Equal strength on each body side	Grading Muscle Strength 0: 0% of normal strength; complete paralysis 1: 10% of normal strength; no movement, contraction of muscle is palpable or visible 2: 25% of normal strength; full muscle movement against gravity, with support 3: 50% of normal strength; normal movement against gravity 4: 75% of normal strength; normal full movement against gravity and against minimal resistance 5: 100% of normal strength; normal full movement against gravity and against full resistance

Assessing the Musculoskeletal System—continued

Assessment	Normal Findings	Deviations from Normal
<p><i>Hip abduction:</i> Client is supine, both legs extended. Place your hands on the lateral surface of each knee; client spreads the legs apart against your resistance.</p> <p><i>Hip adduction:</i> Client is in same position as for hip abduction. Place your hands between the knees; client brings the legs together against your resistance.</p> <p><i>Hamstrings:</i> Client is supine, both knees bent. Client resists while you attempt to straighten the legs.</p> <p><i>Quadriceps:</i> Client is supine, knee partially extended; client resists while you attempt to flex the knee.</p> <p><i>Muscles of the ankles and feet:</i> Client resists while you attempt to dorsiflex the foot and again resists while you attempt to flex the foot.</p>		
BONES		
9. Inspect the skeleton for structure.	No deformities	Bones misaligned
10. Palpate the bones to locate any areas of edema or tenderness.	No tenderness or swelling	Presence of tenderness or swelling (may indicate fracture, neoplasms, or osteoporosis)
JOINTS		
11. Inspect the joint for swelling. Palpate each joint for tenderness, smoothness of movement, swelling, crepitation, and presence of nodules.	No swelling No tenderness, swelling, crepitation, or nodules Joints move smoothly	One or more swollen joints Presence of tenderness, swelling, crepitation, or nodules
12. Assess joint range of motion. See Chapter 44  for the types of joint movements.	Varies to some degree in accordance with person's genetic makeup and degree of physical activity	Limited range of motion in one or more joints
<ul style="list-style-type: none"> Ask the client to move selected body parts. The amount of joint movement can be measured by a goniometer, a device that measures the angle of a joint in degrees.  		
		 A goniometer is used to measure joint angle.
13. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		
EVALUATION		
<ul style="list-style-type: none"> Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available. 		<ul style="list-style-type: none"> Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Musculoskeletal System**INFANTS**

- Palpate the clavicles of newborns. A mass and crepitus may indicate a fracture experienced during vaginal delivery. The newborn may also have limited movement of the arm and shoulder on the affected side.
- When the arms and legs of newborns are pulled to extension and released, newborns naturally return to the flexed fetal position.
- Check muscle strength by holding the infant lightly under the arms with feet placed lightly on a table. Infants should not fall through the hands and should be able to bear body weight on their legs if normal muscle strength is present.
- Check infants for developmental dysplasia of the hip (congenital dislocation) by examining for asymmetric gluteal folds, asymmetric abduction of the legs (Ortolani and Barlow tests), or apparent shortening of the femur.
- Infants should be able to sit without support by 8 months of age, crawl by 7 to 10 months, and walk by 12 to 15 months.
- Observe for symmetry of muscle mass, strength, and function.

CHILDREN

- Pronation and “toeing in” of the feet are common in children between 12 and 30 months of age.
- Genu varum (bowleg) is normal in children for about 1 year after beginning to walk.
- Genu valgus (knock-knee) is normal in preschool and early school-age children.
- Lordosis (swayback) is common in children before age 5.
- Observe the child in normal activities to determine motor function.

- During the rapid growth spurts of adolescence, spinal curvature and rotation (scoliosis) may appear. Children should be assessed for scoliosis by age 12 and annually until their growth slows. Curvature greater than 10% should be referred for further medical evaluation.
- Muscle mass increases in adolescence, especially as children engage in strenuous physical activity, and requires increased nutritional intake.
- Children are at risk for injury related to physical activity and should be assessed for nutritional status, physical conditioning, and safety precautions in order to prevent injury.
- Adolescent girls who participate extensively in strenuous athletic activities are at risk for delayed menses, osteoporosis, and eating disorders; assessment should include a history of these factors.

OLDER ADULTS

- Muscle mass decreases progressively with age, but wide variations are seen among different individuals.
- The decrease in speed, strength, resistance to fatigue, reaction time, and coordination in the older person is due to a decrease in nerve conduction and muscle tone.
- The bones become more fragile and osteoporosis leads to a loss of total bone mass. As a result, older adults are predisposed to fractures and compressed vertebrae.
- In most older adults, osteoarthritic changes in the joints can be observed.
- Note any surgical scars from joint replacement surgeries.

Home Care Considerations Assessing the Musculoskeletal System**PATIENT-CENTERED CARE**

- When making a home visit, observe the client in natural movement around the living area. To assess children, have them remove their clothes down to the underwear.
- A complete examination of joints, bone, and muscles may not be necessary. Focus the assessment on areas indicated by the history and present complaint.

NEUROLOGIC SYSTEM

A thorough neurologic examination may take 1 to 3 hours; however, routine screening tests are usually done first. If the results of these tests raise questions, more extensive evaluations are made. Three major considerations determine the extent of a neurologic exam: (1) the client's chief complaints, (2) the client's physical condition (i.e., level of consciousness and ability to ambulate) because many parts of the examination require movement and coordination of the extremities, and (3) the client's willingness to participate and cooperate.

Examination of the neurologic system includes assessment of (a) mental status including level of consciousness, (b) the cranial nerves, (c) reflexes, (d) motor function, and (e) sensory function. Parts of the neurologic assessment are performed throughout the health examination. For example, the nurse performs a large part of the mental status assessment during the taking of the history and when observing the client's general appearance. Also, the nurse assesses the function of cranial nerves. Cranial nerves II, III, IV, V, and VI (ophthalmic branch) are assessed with the eyes and vision, and cranial nerve VIII (cochlear branch) is assessed with the ears and hearing.

Mental Status

Assessment of mental status reveals the client's general cerebral function. These functions include intellectual (cognitive) as well as emotional (affective) functions.

If problems with use of language, memory, concentration, or thought processes are noted during the nursing history, a more extensive examination is required during neurologic assessment. Major areas of mental status assessment include language, orientation, memory, and attention span and calculation.

LANGUAGE

Any defects in or loss of the power to express oneself by speech, writing, or signs, or to comprehend spoken or written language due to disease or injury of the cerebral cortex, is called **aphasia**. Aphasias can be categorized as sensory or receptive aphasia, and motor or expressive aphasia.

Sensory or receptive aphasia is the loss of the ability to comprehend written or spoken words. Two types of sensory aphasia are auditory (or acoustic) aphasia and visual aphasia. Clients with auditory

aphasia have lost the ability to understand the symbolic content associated with sounds. Clients with visual aphasia have lost the ability to understand printed or written figures.

Motor or expressive aphasia involves loss of the power to express oneself by writing, making signs, or speaking. Clients may find that even though they can recall words, they have lost the ability to combine speech sounds into words.

ORIENTATION

This aspect of the assessment determines the client's ability to recognize other people (*person*), awareness of when and where they presently are (*time* and *place*), and who they, themselves, are (*self*). The terms *disorientation* and *confusion* are often used synonymously although there are differences. It is always preferable to describe the client's actions or statements rather than to label them.

CLINICAL ALERT!

Nurses often chart that the client is "awake, alert, & oriented x3" (or "times three"). This refers to accurate awareness of persons, time, and place. Remember, "person" indicates that the client recognizes others, not that the client can state what his or her own name is.

MEMORY

The nurse assesses the client's recall of information presented seconds previously (immediate recall), events or information from earlier in the day or examination (recent memory), and knowledge recalled from months or years ago (remote or long-term memory).

ATTENTION SPAN AND CALCULATION

This component determines the client's ability to focus on a mental task that is expected to be able to be performed by individuals of normal intelligence.

Level of Consciousness

Level of consciousness (LOC) can lie anywhere along a continuum from a state of alertness to coma. A fully alert client responds to questions spontaneously; a comatose client may not respond to verbal stimuli. The Glasgow Coma Scale was originally developed to predict recovery from a head injury; however, it is used by many professionals to assess LOC. It tests in three major areas: eye response, motor response, and verbal response. An assessment totaling 15 points indicates the client is alert and completely oriented. A comatose client scores 7 or less (see Table 30–10).

Cranial Nerves

The nurse needs to be aware of specific nerve functions and assessment methods for each cranial nerve to detect abnormalities. In some cases, each nerve is assessed; in other cases only selected nerve functions are evaluated.

Reflexes

A **reflex** is an automatic response of the body to a stimulus. It is not voluntarily learned or conscious. The deep tendon reflex (DTR) is

TABLE 30–10 Levels of Consciousness: Glasgow Coma Scale

Faculty Measured	Response	Score
Eye opening	Spontaneous	4
	To verbal command	3
	To pain	2
	No response	1
Motor response	To verbal command	6
	To localized pain	5
	Flexes and withdraws	4
	Flexes abnormally	3
	Extends abnormally	2
	No response	1
Verbal response	Oriented, converses	5
	Disoriented, converses	4
	Uses inappropriate words	3
	Makes incomprehensible sounds	2
	No response	1

activated when a tendon is stimulated (tapped) and its associated muscle contracts. The quality of a reflex response varies among individuals and by age. As a person ages, reflex responses may become less intense.

Reflexes are tested using a percussion hammer. The response is described on a scale of 0 to 4. Experience is necessary to determine appropriate scoring for an individual. Generalist nurses do not commonly assess each of the deep tendon reflexes except for possibly the plantar (Babinski) reflex, indicative of possible spinal cord injury.

Motor Function

Neurologic assessment of the motor system evaluates proprioception and cerebellar function. Structures involved in proprioception are the proprioceptors, the posterior columns of the spinal cord, the cerebellum, and the vestibular apparatus (which is innervated by cranial nerve VIII) in the labyrinth of the internal ear.

Proprioceptors are sensory nerve terminals that occur chiefly in the muscles, tendons, joints, and internal ear. They give information about movements and the position of the body. Stimuli from the proprioceptors travel through the posterior columns of the spinal cord. Deficits of function of the posterior columns of the spinal cord result in impairment of muscle and position sense. Clients with such impairment often must watch their own arm and leg movements to ascertain the position of the limbs.

The cerebellum (a) helps to control posture, (b) acts with the cerebral cortex to make body movements smooth and coordinated, and (c) controls skeletal muscles to maintain equilibrium.

Sensory Function

Sensory functions include touch, pain, temperature, position, and tactile discrimination. The first three are routinely tested.

Generally, the face, arms, legs, hands, and feet are tested for touch and pain, although all parts of the body can be tested. If the client complains of numbness, peculiar sensations, or paralysis, the practitioner should check sensation more carefully over flexor and extensor surfaces of limbs, mapping out clearly any abnormality of touch or pain by examining responses in the area about every 2 cm (1 in.). This is a lengthy procedure and may be performed by a specialist. Abnormal responses to touch stimuli include loss of sensation (anesthesia); more than normal sensation (hyperesthesia); less than normal sensation (hypoesthesia); or an abnormal sensation such as burning, pain, or an electric shock (paresthesia).

A variety of common health conditions, including diabetes and arteriosclerotic heart disease, result in loss of the protective sensation in the lower extremities. This loss can lead to severe tissue damage. In efforts to identify clients at increased risk for damage to the feet, the Bureau of Primary Health Care of the U.S.

government has established the Lower Extremity Amputation Prevention (LEAP) program. The most important aspect of LEAP is assessment of sensation using a special monofilament that delivers 10 grams of force. Health care providers should perform an initial foot screen on all clients with diabetes and at least annually thereafter. Clients who are at risk should have their feet and shoes evaluated at least four times a year to help prevent foot problems from occurring.

A detailed neurologic examination includes position sense, temperature sense, and tactile discrimination. Three types of tactile discrimination are generally tested: **one- and two-point discrimination**, the ability to sense whether one or two areas of the skin are being stimulated by pressure; **stereognosis**, the act of recognizing objects by touching and manipulating them; and **extinction**, the failure to perceive touch on one side of the body when two symmetric areas of the body are touched simultaneously. Skill 30–17 describes how to assess the neurologic system.

Assessing the Neurologic System

PLANNING

If possible, determine whether a screening or full neurologic examination is indicated. This impacts preparation of the client, equipment, and timing.

DELEGATION

Due to the substantial knowledge and skill required, assessment of the neurologic system is not delegated to UAP. However, many aspects of neurologic behavior are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Inquire if the client has any history of the following: presence of pain in the head, back, or extremities, as well as onset and aggravating and alleviating factors; disorientation to time, place, or person; speech disorder; loss of consciousness, fainting, convulsions, trauma, tingling or numbness, tremors or tics, limping, paralysis, uncontrolled muscle movements, loss of memory, mood swings; or problems with smell, vision, taste, touch, or hearing.

Equipment (Depending on Components of Examination)

- Percussion hammer
- Wisps of cotton to assess light-touch sensation
- Sterile safety pin for tactile discrimination

INTERPROFESSIONAL PRACTICE

Assessing the neurologic system is within the scope of practice for many health care providers other than nurses. For example, physical therapists, occupational therapists, and physician assistants will assess those aspects of the client's neurologic functioning relevant to their plan of care. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

CLINICAL ALERT!

All questions and tests used in a neurologic examination must be age, language, education level, and culturally appropriate. Individualize questions and tests before using them.

Language

5. If the client displays difficulty speaking:
 - Point to common objects, and ask the client to name them.
 - Ask the client to read some words and to match the printed and written words with pictures.
 - Ask the client to respond to simple verbal and written commands (e.g., "point to your toes" or "raise your left arm").

Assessing the Neurologic System—continued

Orientation

6. Determine the client's orientation to *time*, *place*, and *person* by tactful questioning. Ask the client the time of day, date, day of the week, duration of illness, city and state of residence, and names of family members.

Ask the client why he or she is seeing a health care provider. Orientation is lost gradually, and early disorientation may be very subtle. "Why" questions may elicit a more accurate clinical picture of the client's orientation status than questions directed to time, place, and person. To evaluate the response, you must know the correct answer.

More direct questioning may be necessary for some people (e.g., "Where are you now?" "What day is it today?") Most people readily accept these questions if initially the nurse asks, "Do you get confused at times?" If the client cannot answer these questions accurately, also include assessment of the *self* by asking the client to state his or her full name.

Memory

7. Listen for lapses in memory. Ask the client about difficulty with memory. If problems are apparent, three categories of memory are tested: immediate recall, recent memory, and remote memory.

To Assess Immediate Recall

- Ask the client to repeat a series of three digits (e.g., 7-4-3), spoken slowly.
- Gradually increase the number of digits (e.g., 7-4-3-5, 7-4-3-5-6, and 7-4-3-5-6-7-2) until the client fails to repeat the series correctly.
- Start again with a series of three digits, but this time ask the client to repeat them backward. The average person can repeat a series of five to eight digits in sequence and four to six digits in reverse order.

To Assess Recent Memory

- Ask the client to recall the recent events of the day, such as how the client got to the clinic. This information must be validated, however.
- Ask the client to recall information given early in the interview (e.g., the name of a doctor).
- Provide the client with three facts to recall (e.g., a color, an object, and an address) or a three-digit number, and ask the client to repeat all three. Later in the interview, ask the client to recall all three items.

To Assess Remote Memory

- Ask the client to describe a previous illness or surgery (e.g., 5 years ago) or a birthday or anniversary. Generally remote memory will be intact until late in neurologic pathology. It is least useful in assessing acute neurologic problems.

Attention Span and Calculation

8. Test the ability to concentrate or maintain *attention span* by asking the client to recite the alphabet or to count backward from 100. Test the ability to calculate by asking the client to subtract 7 or 3 progressively from 100 (i.e., 100, 93, 86, 79, or 100, 97, 94, 91), a task that is referred to as *serial sevens* or *serial threes*. Normally, an adult can complete the serial sevens test in about 90 seconds with three or fewer errors. Because educational level, language, or cultural differences

- 1 Cranial nerves by the numbers. The next time you're trying to remember the locations and functions of the cranial nerves, picture this drawing. All the cranial nerves are represented, though some may be a little harder to spot than others. For example, the shoulders are formed by the number "11" because cranial nerve XI controls neck and shoulder movement. If you immediately recognize that the sides of the face and the top of the head are formed by the number "7" you're well on your way to using this memory device.

affect calculating ability, this test may be inappropriate for some people.

Level of Consciousness

9. Apply the Glasgow Coma Scale (see Table 30-10 on page 581): eye response, motor response, and verbal response. An assessment totaling 15 points indicates the client is alert and completely oriented. A comatose client scores 7 or less.

Cranial Nerves

10. For the specific functions and assessment methods of each cranial nerve, see Table 30-11 on page 590. Test each nerve not already evaluated in another component of the health assessment. A quick way to remember which cranial nerves are assessed in the face is shown in 1.

CLINICAL ALERT!

The names and order of the cranial nerves can be recalled by a mnemonic device such as "On old Olympus's treeless top, a Finn and German viewed a hop." The first letter of each word in the sentence is the same as the first letter of the name of the cranial nerve, in order.

Assessing the Neurologic System – continued

Reflexes

11. Test reflexes using a percussion hammer, comparing one side of the body with the other to evaluate the symmetry of response.

- 0 No reflex response
- +1 Minimal activity (hypoactive)
- +2 Normal response
- +3 More active than normal
- +4 Maximal activity (hyperactive)

Plantar (Babinski) Reflex The plantar, or Babinski, reflex is superficial. It may be absent in adults without pathology or overridden by voluntary control.

- Use a moderately sharp object, such as the handle of the percussion hammer, a key, or an applicator stick.
- Stroke the lateral border of the sole of the client’s foot, starting at the heel, continuing to the ball of the foot, and then proceeding across the ball of the foot toward the big toe. ②
- Observe the response. Normally, all five toes bend downward; this reaction is negative Babinski. In an abnormal (positive) Babinski response, the toes spread outward and the big toe moves upward.

② Testing the plantar (Babinski) reflex.

MOTOR FUNCTION

Assessment	Normal Findings	Deviations from Normal
<p>12. Gross Motor and Balance Tests Generally, the Romberg test and one other gross motor function and balance tests are used.</p> <p>WALKING GAIT Ask the client to walk across the room and back, and assess the client’s gait.</p> <p>ROMBERG TEST Ask the client to stand with feet together and arms resting at the sides, first with eyes open, then closed. Stand close during this test. Rationale: <i>This prevents the client from falling.</i></p> <p>STANDING ON ONE FOOT WITH EYES CLOSED Ask the client to close the eyes and stand on one foot. Repeat on the other foot. Stand close to the client during this test.</p>	<p>Has upright posture and steady gait with opposing arm swing; walks unaided, maintaining balance</p> <p>Negative Romberg: may sway slightly but is able to maintain upright posture and foot stance</p> <p>Maintains stance for at least 5 seconds</p>	<p>Has poor posture and unsteady, irregular, staggering gait with wide stance; bends legs only from hips; has rigid or no arm movements</p> <p>Positive Romberg: cannot maintain foot stance; moves the feet apart to maintain stance If client cannot maintain balance with the eyes shut, client may have sensory ataxia (lack of coordination of the voluntary muscles) If balance cannot be maintained whether the eyes are open or shut, client may have cerebellar ataxia</p> <p>Cannot maintain stance for 5 seconds</p>

Assessing the Neurologic System—continued

Assessment	Normal Findings	Deviations from Normal
<p>HEEL-TOE WALKING</p> <p>Ask the client to walk a straight line, placing the heel of one foot directly in front of the toes of the other foot. ③</p>	<p>Maintains heel-toe walking along a straight line</p>  <p>③ Heel-toe walking test.</p>	<p>Assumes a wider foot gait to stay upright</p>
<p>TOE OR HEEL WALKING</p> <p>Ask the client to walk several steps on the toes and then on the heels.</p>	<p>Able to walk several steps on toes or heels</p>	<p>Cannot maintain balance on toes and heels</p>
<p>13. Fine Motor Tests for the Upper Extremities</p>		
<p>FINGER-TO-NOSE TEST</p> <p>Ask the client to abduct and extend the arms at shoulder height and then rapidly touch the nose alternately with one index finger and then the other. The client repeats the test with the eyes closed if the test is performed easily. ④</p>	<p>Repeatedly and rhythmically touches the nose</p>  <p>④ Finger-to-nose test.</p>	<p>Misses the nose or gives slow response</p>

Continued on page 586

Assessing the Neurologic System—continued

SKILL 30-17

Assessment	Normal Findings	Deviations from Normal
<p>ALTERNATING SUPINATION AND PRONATION OF HANDS ON KNEES Ask the client to pat both knees with the palms of both hands and then with the backs of the hands alternately at an ever-increasing rate. 5</p>	<p>Can alternately supinate and pronate hands at rapid pace</p>	<p>Performs with slow, clumsy movements and irregular timing; has difficulty alternating from supination to pronation</p>
		
	<p>5 Alternating supination and pronation of hands on knees test.</p>	
<p>FINGER-TO-NOSE AND TO THE NURSE'S FINGER Ask the client to touch the nose and then your index finger, held at a distance of about 45 cm (18 in.), at a rapid and increasing rate. 6</p>	<p>Performs with coordination and rapidity</p>	<p>Misses the finger and moves slowly</p>
		
	<p>6 Finger-to-nose and to the nurse's finger test.</p>	
<p>FINGERS-TO-FINGERS Ask the client to spread the arms broadly at shoulder height and then bring the fingers together at the midline, first with the eyes open and then closed, first slowly and then rapidly. 7</p>	<p>Performs with accuracy and rapidity</p>	<p>Moves slowly and is unable to touch fingers consistently</p>
		
	<p>7 Fingers-to-fingers test.</p>	

Assessing the Neurologic System—continued

Assessment

FINGERS-TO-THUMB (SAME HAND)

Ask the client to touch each finger of one hand to the thumb of the same hand as rapidly as possible. **8**

Normal Findings

Rapidly touches each finger to thumb with each hand

8 Fingers-to-thumb (same hand) test.

Deviations from Normal

Cannot coordinate this fine discrete movement with either one or both hands

**14. Fine Motor Tests for the Lower Extremities**

Ask the client to lie supine and to perform these tests.

HEEL DOWN OPPOSITE SHIN

Ask the client to place the heel of one foot just below the opposite knee and run the heel down the shin to the foot. Repeat with the other foot. The client may also use a sitting position for this test. **9**

Demonstrates bilateral equal coordination

9 Heel down opposite shin test.

Has tremors or is awkward; heel moves off shin

TOE OR BALL OF FOOT TO THE NURSE'S FINGER

Ask the client to touch your finger with the large toe of each foot. **10**

Moves smoothly, with coordination

10 Toe or ball of foot to nurse's finger test.

Misses your finger; cannot coordinate movement

**15. Light-Touch Sensation**

Compare the light-touch sensation of symmetric areas of the body. **Rationale:** *Sensitivity to touch varies among different skin areas.*

- Ask the client to close the eyes and to respond by saying “yes” or “now” whenever the client feels the cotton wisp touching the skin.

Light tickling or touch sensation

Anesthesia, hyperesthesia, hypoesthesia, or paresthesia

Assessing the Neurologic System—continued

Assessment	Normal Findings	Deviations from Normal
<ul style="list-style-type: none"> With a wisp of cotton, lightly touch one specific spot and then the same spot on the other side of the body. 11 Test areas on the forehead, cheek, hand, lower arm, abdomen, foot, and lower leg. Check a distal area of the limb first (i.e., the hand before the arm and the foot before the leg). Rationale: <i>The sensory nerve may be assumed to be intact if sensation is felt at its most distal part.</i> If areas of sensory dysfunction are found, determine the boundaries of sensation by testing responses about every 2.5 cm (1 in.) in the area. Make a sketch of the sensory loss area for recording purposes. 		
<p>16. Pain Sensation Assess pain sensation as follows:</p> <ul style="list-style-type: none"> Ask the client to close the eyes and to say “sharp,” “dull,” or “don’t know” when the sharp or dull end of a safety pin is felt. Alternately, use the sharp and dull end to lightly prick designated anatomic areas at random (e.g., hand, forearm, foot, lower leg, abdomen). <i>Note:</i> The face is not tested in this manner. Allow at least 2 seconds between each test to prevent summation effects of stimuli (i.e., several successive stimuli perceived as one stimulus). 	<p>Able to discriminate “sharp” and “dull” sensations</p>	<p>Areas of reduced, heightened, or absent sensation (map them out for recording purposes)</p>
<p>17. Position or Kinesthetic Sensation Commonly, the middle fingers and the large toes are tested for the kinesthetic sensation (sense of position).</p> <ul style="list-style-type: none"> To test the fingers, support the client’s arm and hand with one hand. To test the toes, place the client’s heels on the examining table. Ask the client to close the eyes. Grasp a middle finger or a big toe firmly between your thumb and index finger, and exert the same pressure on both sides of the finger or toe while moving it. 12 Move the finger or toe until it is up, down, or straight out, and ask the client to identify the position. Use a series of brisk, gentle up-and-down movements before bringing the finger or toe suddenly to rest in one of the three positions. 	<p>Can readily determine the position of fingers and toes</p> 	<p>Unable to determine the position of one or more fingers or toes</p>
<p>18. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate. Describe any abnormal findings in objective terms, for example, “When asked to count backwards by threes, client made seven errors and completed the task in 4 minutes.”</p>	<p>12 Position or kinesthetic sensation.</p>	

LIFESPAN CONSIDERATIONS Assessing the Neurologic System**INFANTS**

- Reflexes commonly tested in newborns include:
 - *Rooting*: Stroke the side of the face near mouth; infant opens mouth and turns to the side that is stroked.
 - *Sucking*: Place nipple or finger 3 to 4 cm (1.2 to 1.6 in.) into mouth; infant sucks vigorously.
 - *Tonic neck*: Place infant supine, turn head to one side; arm on side to which head is turned extends; on opposite side, arm curls up (fencer's pose).
 - *Palmar grasp*: Place finger in infant's palm and press; infant curls fingers around.
 - *Stepping*: Hold infant as if weight bearing on surface; infant steps along, one foot at a time.
 - *Moro*: Present loud noise or unexpected movement; infant spreads arms and legs, extends fingers, then flexes and brings hands together; may cry.
- Most of these reflexes disappear between 4 and 6 months of age.

CHILDREN

- Present the procedures as games whenever possible.
- Positive Babinski reflex is abnormal after the child ambulates or at age 2.
- For children under age 5, the Denver Developmental Screening Test II provides a comprehensive neurologic evaluation, particularly for motor function.
- Note the child's ability to understand and follow directions.
- Assess immediate recall or recent memory by using names of cartoon characters. Normal recall in children is one less than age in years.
- Assess for signs of hyperactivity or abnormally short attention span.
- Children should be able to walk backward by age 2, balance on one foot for 5 seconds by age 4, heel-toe walk by age 5, and heel-toe walk backward by age 6.
- Use of the Romberg test is appropriate for children ages 3 and older.

OLDER ADULTS

- Because older adults tire more easily than younger clients, a total neurologic assessment is often done at a different time than the other parts of the physical assessment.

- A full neurologic assessment can be lengthy. Conduct in several sessions if indicated, and cease the tests if the client is noticeably fatigued.
- A decline in mental status is not a normal result of aging. Changes are more the result of physical or psychological disorders (e.g., fever, fluid and electrolyte imbalances, medications). Acute, abrupt-onset mental status changes are usually caused by delirium. These changes are often reversible with treatment. Chronic subtle insidious mental health changes are usually caused by dementia and are usually irreversible.
- Intelligence and learning ability are unaltered with age. Many factors, however, inhibit learning (e.g., anxiety, illness, pain, cultural barrier).
- Short-term memory is often less efficient. Long-term memory is usually unaltered.
- Because old age is often associated with loss of support persons, depression can occur. Mood changes, weight loss, anorexia, constipation, and early morning awakening may be symptoms of depression.
- The stress of being in unfamiliar situations can cause confusion in older adults.
- As a person ages, reflex responses may become less intense.
- Although there is a progressive decrease in the number of functioning neurons in the central nervous system and in the sense organs, older adults usually function well because of the abundant reserves in the number of brain cells.
- Impulse transmission and reaction to stimuli are slower.
- Many older adults have some impairment of hearing, vision, smell, temperature and pain sensation, memory, or mental endurance.
- Coordination changes and includes slower fine finger movements. Standing balance remains intact, and Romberg's test remains negative.
- Reflex responses may slightly increase or decrease. Many show loss of Achilles reflex, and the plantar reflex may be difficult to elicit.
- When testing sensory function, the nurse needs to give older adults time to respond. Normally, older adults have unaltered perception of light touch and superficial pain, decreased perception of deep pain, and decreased perception of temperature stimuli. Many also reveal a decrease or absence of position sense in the large toes.

FEMALE GENITALS AND INGUINAL AREA

The examination of the genitals and reproductive tract of women includes assessment of the inguinal lymph nodes and inspection and palpation of the external genitals. Completeness of the assessment of the genitals and reproductive tract depends on the needs and problems of the individual client. In most practice settings, generalist nurses perform only inspection of the external genitals and palpation of the inguinal lymph nodes.

For sexually active adolescent and adult women, a Papanicolaou test (Pap test) is used to detect cancer of the cervix. If there is an increased or abnormal vaginal discharge, specimens should be taken to check for a sexually transmitted infection.

Examination of the genitals usually creates uncertainty and apprehension in women, and the lithotomy position required for

an internal examination can cause embarrassment. The nurse must explain each part of the examination in advance and perform the examination in an objective, supportive, and efficient manner. Not all agencies permit male practitioners to examine the female genitals. Some agencies may require the presence of another woman during the examination so that there is no question of unprofessional behavior. Most female clients accept examination by a male, especially if he is emotionally comfortable about performing it and does so in a matter-of-fact and competent manner. If the male nurse does not feel comfortable about this part of the examination or if the client is reluctant to be examined by a man, the nurse should refer this part of the examination to a female practitioner. Skill 30-18 describes how to assess the female genitals and inguinal area.

TABLE 30–11 Cranial Nerve Functions and Assessment Methods

Cranial Nerve	Name	Type	Function	Assessment Method
I	Olfactory	Sensory	Smell	Ask client to close eyes and identify different mild aromas, such as coffee, vanilla, peanut butter, orange/lemon, chocolate.
II	Optic	Sensory	Vision and visual fields	Ask client to read Snellen-type chart; check visual fields by confrontation; and conduct an ophthalmoscopic examination (see Skill 30–6).
III	Oculomotor	Motor	Extraocular eye movement (EOM); movement of sphincter of pupil; movement of ciliary muscles of lens	Assess six ocular movements and pupil reaction (see Skill 30–6).
IV	Trochlear	Motor	EOM; specifically, moves eyeball downward and laterally	Assess six ocular movements (see Skill 30–6).
V	Trigeminal Ophthalmic branch	Sensory	Sensation of cornea, skin of face, and nasal mucosa	While client looks upward, lightly touch the lateral sclera of the eye with sterile gauze to elicit blink reflex. To test light sensation, have client close eyes, wipe a wisp of cotton over client's forehead and paranasal sinuses. To test deep sensation, use alternating blunt and sharp ends of a safety pin over same areas.
	Maxillary branch	Sensory	Sensation of skin of face and anterior oral cavity (tongue and teeth)	Assess skin sensation as for ophthalmic branch above.
	Mandibular branch	Motor and sensory	Muscles of mastication; sensation of skin of face	Ask client to clench teeth.
VI	Abducens	Motor	EOM; moves eyeball laterally	Assess directions of gaze.
VII	Facial	Motor and sensory	Facial expression; taste (anterior two thirds of tongue)	Ask client to smile, raise the eyebrows, frown, puff out cheeks, close eyes tightly. Ask client to identify various tastes placed on tip and sides of tongue: sugar (sweet), salt, lemon juice (sour), and quinine (bitter); identify areas of taste.
VIII	Auditory			
	Vestibular branch	Sensory	Equilibrium	Romberg test (see page 584).
	Cochlear branch	Sensory	Hearing	Assess client's ability to hear spoken word and vibrations of tuning fork.
IX	Glossopharyngeal	Motor and sensory	Swallowing ability, tongue movement, taste (posterior tongue)	Apply tastes on posterior tongue for identification. Ask client to move tongue from side to side and up and down.
X	Vagus	Motor and sensory	Sensation of pharynx and larynx; swallowing; vocal cord movement	Assessed with cranial nerve IX; assess client's speech for hoarseness.
XI	Accessory	Motor	Head movement; shrugging of shoulders	Ask client to shrug shoulders against resistance from your hands and turn head to side against resistance from your hand (repeat for other side).
XII	Hypoglossal	Motor	Protrusion of tongue; moves tongue up and down and side to side	Ask client to protrude tongue at midline, then move it side to side.

Assessing the Female Genitals and Inguinal Area

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the female genitals and inguinal lymph nodes is not delegated to UAP. However, individuals other than the nurse may record any aspect that is observed during usual care. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Clean gloves
- Drape
- Supplemental lighting, if needed

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene, apply gloves, and observe other appropriate infection prevention procedures.
3. Provide for client privacy. Request the presence of another health care provider if desired, required by agency policy, or requested by the client.
4. Inquire about the following: age of onset of menstruation, last menstrual period (LMP), regularity of cycle, duration, amount of daily flow, and whether menstruation is painful; incidence of pain during intercourse; vaginal discharge; number of pregnancies, number of live births, labor or delivery complications; urgency and frequency of urination at night; blood in urine, painful urination, incontinence; history of sexually transmitted infection, past and present.
5. Cover the pelvic area with a sheet or drape at all times when the client is not actually being examined. Position the client supine.

Assessment	Normal Findings	Deviations from Normal
6. Inspect the distribution, amount, and characteristics of pubic hair.	There are wide variations; generally kinky in the menstruating adult, thinner and straighter after menopause Distributed in the shape of an inverse triangle	Scant pubic hair (may indicate hormonal problem) Hair growth should not extend over the abdomen
7. Inspect the skin of the pubic area for parasites, inflammation, swelling, and lesions. To assess pubic skin adequately, separate the labia majora and labia minora.	Pubic skin intact, no lesions Skin of vulva area slightly darker than the rest of the body Labia round, full, and relatively symmetric in adult females	Lice, lesions, scars, fissures, swelling, erythema, excoriations, varicosities, or leukoplakia
8. Inspect the clitoris, urethral orifice, and vaginal orifice when separating the labia minora.	Clitoris does not exceed 1 cm (0.4 in.) in width and 2 cm (0.8 in.) in length Urethral orifice appears as a small slit and is the same color as surrounding tissues No inflammation, swelling, or discharge	Presence of lesions Presence of inflammation, swelling, or discharge
9. Palpate the inguinal lymph nodes. 1 Use the pads of the fingers in a rotary motion, noting any enlargement or tenderness.	No enlargement or tenderness	Enlargement and tenderness

1 Lymph nodes of the groin area.

INTERPROFESSIONAL PRACTICE

Assessing the female genitals and inguinal area is also within the scope of practice for health care providers other than nurses, specifically physician assistants conducting their own health assessment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Assessing the Female Genitals and Inguinal Area—continued

10. Remove and discard gloves. Perform hand hygiene.
11. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Significant deviations from normal indicate the need for an internal vaginal examination.

LIFESPAN CONSIDERATIONS Assessing the Female Genitals and Inguinal Area

INFANTS

- Infants can be held in a supine position on the parent's lap with the knees supported in a flexed position and separated.
- In newborns, because of maternal estrogen, the labia and clitoris may be edematous and enlarged, and there may be a small amount of white or bloody vaginal discharge.
- Assess the mons and inguinal area for swelling or tenderness that may indicate presence of an inguinal hernia.

CHILDREN

- Ensure that you have the parent or guardian's approval to perform the examination and then tell the child what you are going to do. Preschool children are taught not to allow others to touch their "private parts."
- Girls should be assessed for Tanner staging of pubertal development (Box 30-9).
- Girls should have a Papanicolaou (Pap) test done if sexually active, or by age 18 years.
- The clitoris is a common site for syphilitic chancres in younger females.

OLDER ADULTS

- Labia are atrophied and flattened.
- The clitoris is a potential site for cancerous lesions.
- The vulva atrophies as a result of a reduction in vascularity, elasticity, adipose tissue, and estrogen levels. Because the vulva is more fragile, it is more easily irritated.
- The vaginal environment becomes drier and more alkaline, resulting in an alteration of the type of flora present and a predisposition to vaginitis. Dyspareunia (difficult or painful intercourse) is also a common occurrence.
- The cervix and uterus decrease in size.
- The fallopian tubes and ovaries atrophy.
- Ovulation and estrogen production cease.
- Vaginal bleeding unrelated to estrogen therapy is abnormal in older women.
- Prolapse of the uterus can occur in older females, especially those who have had multiple pregnancies.

BOX 30-9 Five Stages of Pubic Hair Development in Females

Stage 1: Preadolescence. No pubic hair except for fine body hair.

Stage 2: Usually occurs at ages 11 and 12. Sparse, long, slightly pigmented curly hair develops along the labia.

Stage 3: Usually occurs at ages 12 and 13. Hair becomes darker in color and curlier and develops over the pubic symphysis.

Stage 4: Usually occurs between ages 13 and 14. Hair assumes the texture and curl of the adult but is not as thick and does not appear on the thighs.

Stage 5: Sexual maturity. Hair assumes adult appearance and appears on the inner aspect of the upper thighs (Figure 30-35 ■).

Figure 30-35 ■ Stages of female pubic hair development.

Figure 30-36 ■ Different sizes of metal vaginal specula.

In many agencies only nurse practitioners examine the internal genitals. However, generalist nurses often assist with this examination and need to be familiar with the procedure. Examination of the internal genitals involves (a) palpating Skene's and Bartholin's glands, (b) assessing the pelvic musculature, (c) inserting a vaginal speculum to inspect the cervix and vagina, and (d) obtaining a Papanicolaou smear.

The speculum examination of the vagina involves the insertion of a plastic or metal speculum that consists of two blades and an adjustable thumb screw. Various sizes are available (small, medium, and large); the appropriate size needs to be selected for each client (Figure 30-36 ■). The speculum may be lubricated with water-soluble lubricant if specimens are not being collected. Most examiners lubricate the speculum with warm water. After visualizing the cervix, the examiner takes smear specimens from one or more of the sites.

The nurse's responsibilities when assisting with an examination of the internal female genitals include the following:

1. **Assembling equipment.** These include drapes, gloves, vaginal speculum, warm water or lubricant, and supplies for cytology and culture studies.
2. **Preparing the client.** Advise the client not to douche prior to the procedure. Explain the procedure. It should take only 5 minutes and is normally not painful. Assist the client to a lithotomy position as needed, and drape her appropriately.
3. **Supporting the client during the procedure.** This involves explaining the procedure as needed, and encouraging the client to take deep breaths that will help the pelvic muscles relax.
4. **Monitoring and assisting the client after the procedure.** Assist the client from the lithotomy position and with perineal care as needed.
5. **Documenting the procedure.** Include the date and time it was performed, the name of the examiner, and any nursing assessments and interventions.

Figure 30-37 ■ The male urogenital tract.

MALE GENITALS AND INGUINAL AREA

In adult men, a complete examination includes assessment of the external genitals and prostate gland, and for the presence of any hernias. Nurses in some practice settings performing routine assessment of clients may assess only the external genitals. The male reproductive and urinary systems (Figure 30-37 ■) share the urethra, which is the passageway for both urine and semen. Therefore, in physical assessment of the male these two systems are frequently assessed together.

Examination of the male genitals by a female practitioner is becoming increasingly common, although not all agencies permit a female practitioner to examine the male genitals. Some agencies may require the presence of another person during the examination so that there is no question of unprofessional behavior. Most male clients accept examination by a female, especially if she is emotionally comfortable about performing it and does so in a matter-of-fact and competent manner. If the female nurse does not feel comfortable about this part of the examination or if the client is reluctant to be examined by a woman, the nurse should refer this part of the examination to a male practitioner.

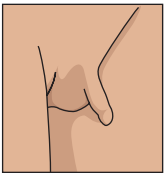

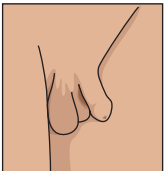

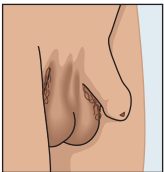

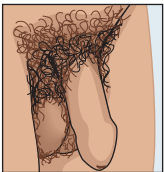

Development of secondary sex characteristics is assessed in relationship to the client's age. See Table 30-12 for the five Tanner stages of the development of pubic hair, the penis, and the testes and scrotum during puberty.

All male clients should be screened for the presence of inguinal or femoral hernias. A **hernia** is a protrusion of the intestine through the inguinal wall or canal. Cancer of the prostate gland is the most common cancer in adult men and occurs primarily in men over age 50. Examination of the prostate gland is performed with the examination of the rectum and anus (see Skill 30-20).

Testicular cancer is much rarer than prostate cancer and occurs primarily in young men ages 15 to 35. Testicular cancer is most commonly found on the anterior and lateral surfaces of the testes. Testicular self-examination should be conducted monthly (see Chapter 40 ∞).

The techniques of inspection and palpation are used to examine the male genitals. Skill 30-19 describes how the nurse can conduct an assessment of the male genitals and inguinal area.

TABLE 30–12 Tanner Stages of Male Pubic Hair and External Genital Development (12 to 16 Years)

Stage	Pubic Hair	Penis	Testes/Scrotum
1 	None, except for body hair like that on the abdomen	Size is relative to body size, as in childhood	Size is relative to body size, as in childhood
2 	Scant, long, slightly pigmented at base of penis	Slight enlargement occurs	Becomes reddened in color and enlarged
3 	Darker, begins to curl and becomes more coarse; extends over pubic symphysis	Elongation occurs	Continuing enlargement
4 	Continues to darken and thicken; extends on the sides, above and below	Increase in both breadth and length; glans develops	Continuing enlargement; color darkens
5 	Adult distribution that extends to inner thighs, umbilicus, and anus	Adult appearance	Adult appearance

Assessing the Male Genitals and Inguinal Area

PLANNING DELEGATION

Due to the substantial knowledge and skill required, assessment of the male genitals and inguinal area is not delegated to UAP. However, individuals other than the nurse may record any aspect that is observed during usual care. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Clean gloves

INTERPROFESSIONAL PRACTICE

Assessing the male genitals and inguinal area is within the scope of practice for health care providers other than nurses, specifically physician assistants conducting their own health assessment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Assessing the Male Genitals and Inguinal Area—continued

IMPLEMENTATION

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he can participate. Discuss how the results will be used in planning further care or treatments.
- Perform hand hygiene, apply gloves, and observe other appropriate infection prevention procedures.
- Provide for client privacy. Request the presence of another health care provider if desired, required by agency policy, or requested by the client.
- Inquire about the following: usual voiding patterns and changes, bladder control, urinary incontinence, frequency, urgency, abdominal pain; symptoms of sexually transmitted infection; swellings that could indicate presence of hernia; family history of nephritis, malignancy of the prostate, or malignancy of the kidney.
- Cover the pelvic area with a sheet or drape at all times when not actually being examined.

Assessment	Normal Findings	Deviations from Normal
PUBIC HAIR		
6. Inspect the distribution, amount, and characteristics of pubic hair.	Triangular distribution, often spreading up the abdomen	Scant amount or absence of hair
PENIS		
7. Inspect the penile shaft and glans penis for lesions, nodules, swellings, and inflammation.	Penile skin intact Appears slightly wrinkled and varies in color as widely as other body skin Foreskin easily retractable from the glans penis Small amount of thick white smegma between the glans and foreskin	Presence of lesions, nodules, swellings, or inflammation Foreskin not retractable Large amount, discolored, or malodorous substance
8. Inspect the urethral meatus for swelling, inflammation, and discharge.	Pink and slitlike appearance Positioned at the tip of the penis	Inflammation; discharge Variation in meatal locations (e.g., hypospadias, on the underside of the penile shaft, and epispadias, on the upper side of the penile shaft)
SCROTUM		
9. Inspect the scrotum for appearance, general size, and symmetry. <ul style="list-style-type: none"> Inspect all skin surfaces by spreading the rugated surface skin and lifting the scrotum as needed to observe posterior surfaces. 	Scrotal skin is darker in color than that of the rest of the body and is loose Size varies with temperature changes (the dartos muscles contract when the area is cold and relax when the area is warm) Scrotum appears asymmetric (left testis is usually lower than right testis)	Discolorations; any tightening of skin (may indicate edema or mass) Marked asymmetry in size
INGUINAL AREA		
10. Inspect both inguinal areas for bulges while the client is standing, if possible. <ul style="list-style-type: none"> First, have the client remain at rest. Next, have the client hold his breath and strain or bear down as though having a bowel movement. Bearing down may make the hernia more visible. 	No swelling or bulges	Swelling or bulge (possible inguinal or femoral hernia)
11. Remove and discard gloves. Perform hand hygiene.		
12. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.		

EVALUATION

- Perform a detailed follow-up examination of other systems based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Male Genitals and Inguinal Area**INFANTS**

- The foreskin of the uncircumcised infant is normally tight at birth and should not be retracted. It will gradually loosen as the baby grows and is usually fully retractable by 2 to 3 years of age. Assess for cleanliness, redness, or irritation.
- Assess for placement of the urethral meatus.
- Palpate the scrotum to determine if the testes are descended; in the newborn and infant, the testes may retract into the inguinal canal, especially with stimulation of the cremasteric reflex.
- Assess the inguinal area for swelling or tenderness that may indicate the presence of an inguinal hernia.

CHILDREN

- Ensure that you have the parent or guardian's approval to perform the examination and then tell the child what you are going to do. Preschool children are taught to not allow others to touch their "private parts."

- In young boys, the cremasteric reflex can cause the testes to ascend into the inguinal canal. If possible have the boy sit cross-legged, which stretches the muscle and decreases the reflex.
- Table 30–12 on page 594 shows the five Tanner stages of development of pubic hair, penis, and testes/scrotum.

OLDER ADULTS

- The penis decreases in size with age; the size and firmness of the testes decrease.
- Testosterone is produced in smaller amounts.
- More time and direct physical stimulation are required for an older man to achieve an erection, but he may have less premature ejaculation than he did at a younger age.
- Seminal fluid is reduced in amount and viscosity.
- Urinary frequency, nocturia, dribbling, and problems with beginning and ending the stream are usually the result of prostatic enlargement.

ANUS

For the generalist nurse, anal examination, an essential part of every comprehensive physical examination, involves only

inspection. Skill 30–20 describes how to assess the rectum and anus.

Assessing the Anus**PLANNING**
DELEGATION

Due to the substantial knowledge and skill required, assessment of the anus is not delegated to UAP. However, many aspects are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse.

Equipment

- Clean gloves

IMPLEMENTATION**Performance**

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene, apply gloves, and observe other appropriate infection prevention procedures for all rectal examinations.
3. Provide for client privacy. Drape the client appropriately to prevent undue exposure of body parts.
4. Inquire if the client has any history of the following: bright blood in stools, tarry black stools, diarrhea, constipation, abdominal

INTERPROFESSIONAL PRACTICE

Assessing the anus is within the scope of practice for health care providers other than nurses, specifically physician assistants conducting their own health assessment. Although these providers may verbally communicate their findings and plan to other health care team members, the nurse must also know where to locate their documentation in the client's medical record.

5. Position the client. In adults, a left lateral or Sims' position with the upper leg acutely flexed is required for the examination. A dorsal recumbent position with hips externally rotated and knees flexed or a lithotomy position may be used. ① For males, a standing position while the client bends over the examining table may also be used.

Assessing the Anus—continued

Position

Sims'

Description

Side-lying position with lowermost arm behind the body, uppermost leg flexed at hip and knee, upper arm flexed at shoulder and elbow.

Lithotomy

Back-lying position with feet supported in stirrups; the hips should be in line with the edge of the table.

Dorsal recumbent

Back-lying position with knees flexed and hips externally rotated small pillow under the head; soles of feet on the surface.

1 Left Sims', lithotomy, and dorsal recumbent positions.

Assessment	Normal Findings	Deviations from Normal
<p>6. Inspect the anus and surrounding tissue for color, integrity, and skin lesions. Then, ask the client to bear down as though defecating. Bearing down creates slight pressure on the skin that may accentuate rectal fissures, rectal prolapse, polyps, or internal hemorrhoids. Describe the location of all abnormal findings in terms of a clock, with the 12 o'clock position toward the pubic symphysis.</p> <p>7. Remove and discard gloves. Perform hand hygiene.</p> <p>8. Document findings in the client record using printed or electronic forms or checklists supplemented by narrative notes when appropriate.</p>	<p>Intact perianal skin; usually slightly more pigmented than the skin of the buttocks Anal skin is normally more pigmented, coarser, and moister than perianal skin and is usually hairless</p>	<p>Presence of fissures (cracks), ulcers, excoriations, inflammations, abscesses, protruding hemorrhoids (dilated veins seen as reddened protrusions of the skin), lumps or tumors, fistula openings, or rectal prolapse (varying degrees of protrusion of the rectal mucous membrane through the anus)</p>

EVALUATION

- Perform a detailed follow-up examination based on findings that deviated from expected or normal for the client. Relate findings to previous assessment data if available.
- Report deviations from expected or normal findings to the primary care provider.

LIFESPAN CONSIDERATIONS Assessing the Anus

INFANTS

- Lightly touching the anus should result in a brief anal contraction ("wink" reflex).

CHILDREN

- Erythema and scratch marks around the anus may indicate a pinworm parasite. Children with this condition may be disturbed by itching during sleep.

OLDER ADULTS

- Chronic constipation and straining at stool cause an increase in the frequency of hemorrhoids and rectal prolapse.

Critical Thinking Checkpoint

A 75-year-old woman is admitted to your unit for evaluation after being found unconscious on the floor of her apartment. She is now awake but moving slowly. Her vital signs are within normal limits.

- In the hospital, it is unrealistic to expect to be able to spend an uninterrupted 30 to 60 minutes with a single client performing an admission assessment. Which three systems would have top priority for her initial assessment and why?
- While gathering relevant history data, what should you do if the client answers with simple one-word answers or gestures?
- Because the client may be in significant discomfort from her fall, it is not easy for her to move about for the examination. How might you organize your assessment to minimize her need to change positions frequently?
- If the client is unable to provide a detailed recent history, what other sources of these data could you consider?

See Critical Thinking Possibilities on student resource website.

Chapter 30 Review

CHAPTER HIGHLIGHTS

- The health examination is conducted to assess the function and integrity of the client's body parts. Initial findings provide baseline data against which subsequent assessment findings are compared.
- The health examination may entail a complete head-to-toe assessment or individual assessment of a body system or body part.
- The health assessment is conducted in a systematic manner that requires the fewest position changes for the client.
- Data obtained in the physical health examination supplement, confirm, or refute data obtained during the nursing history.
- Aspects of the physical assessment procedures should be incorporated in the assessment, intervention, and evaluation phases of the nursing process.
- Nursing history data help the nurse focus on specific aspects of the physical health examination.
- Data obtained in the physical health examination help the nurse establish nursing diagnoses, plan the client's care, and evaluate the outcomes of nursing care.
- Skills in inspection, palpation, percussion, and auscultation are required for the physical health examination; these skills are used in that order throughout the examination except during abdominal assessment, when auscultation follows inspection and precedes percussion and palpation.
- Knowledge of the normal structure and function of body parts and systems is an essential requisite to conducting physical assessment.

TEST YOUR KNOWLEDGE

- Which is a normal finding on auscultation of the lungs?
 - Tympany over the right upper lobe
 - Resonance over the left upper lobe
 - Hyperresonance over the left lower lobe
 - Dullness above the left 10th intercostal space
- The nurse positions the client sitting upright during palpation of which area?
 - Abdomen
 - Genitals
 - Breast
 - Head and neck
- After auscultating the abdomen, the nurse should report which finding to the primary care provider?
 - Bruit over the aorta
 - Absence of bowel sounds for 60 seconds
 - Continuous bowel sounds over the ileocecal valve
 - A completely irregular pattern of bowel sounds
- If unable to locate the client's popliteal pulse during a routine examination, what should the nurse do next?
 - Check for a pedal pulse.
 - Check for a femoral pulse.
 - Take the client's blood pressure on that thigh.
 - Ask another nurse to try to locate the pulse.
- Which of the following is an expected finding during assessment of the older adult?
 - Facial hair that becomes finer and softer
 - Decreased peripheral, color, and night vision
 - Increased sensitivity to odors
 - An irregular respiratory rate and rhythm at rest
- List five aspects of the skin that the nurse assesses during a routine examination.
 -
 -
 -
 -
 -

7. If the client reports loss of short-term memory, the nurse would assess this using which one of the following?
1. Have the client repeat a series of three numbers, increasing to eight if possible.
 2. Have the client describe his or her childhood illnesses.
 3. Ask the client to describe how he or she arrived at this location.
 4. Ask the client to count backward from 100 subtracting seven each time.
8. Refer back to Figure 30–14. If the client can accurately read only the top three lines, what would be an appropriate nursing diagnosis?
1. *Deficient Knowledge*
 2. *Impaired Memory*
 3. *Ineffective Tissue Perfusion*
 4. *Risk for Injury*
9. To palpate lymph nodes, the nurse uses which technique?
1. Use the flat of all four fingers in a vertical and then side-to-side motion.
 2. Use the back of the hand and feel for temperature variation between the right and left sides.
 3. Use the pads of two fingers in a circular motion.
 4. Compress the nodes between the index fingers of both hands.
10. For a client whose assessment of the musculoskeletal system is normal, which does the nurse check on the medical record? (Select all that apply.)
1. Atrophied
 2. Contractured
 3. Crepitation
 4. Equal
 5. Firm
 6. Flaccid
 7. Hypertrophied
 8. Spastic
 9. Symmetrical
 10. Tremor

See Answers to Test Your Knowledge in Appendix A.

Because individuals with a mental illness are more likely to experience poor physical health than the general population, the nurse should conduct a detailed physical health assessment in this population. This paper reviews existing evidence relating to lifestyle factors among the mentally ill such as low exercise levels, poor diet and nutrition, high cholesterol levels, tobacco smoking and poor dental care, contributing to poor physical health such as a higher incidence of cardiovascular disease and type 2 diabetes.

Meeting the Standards

Vital Signs and Health Assessment, the chapters in Unit 7 of *Fundamentals of Nursing: Concepts, Process, and Practice*, cover the most common knowledge, skills, and attitudes required of every registered nurse. Although the nurse does not perform the full spectrum of these activities during each encounter, at least some of the assessments are always essential in providing professional nursing care. Many other practitioners also perform the techniques of gathering the available data regarding clients' temperature, pulses, respirations, blood pressure, oxygen saturation, and systems functioning. However, it is the nurse's interpretation and responses to the data that have an impact on the client's health.

Scenario: Imagine that you are working the evening shift in a hospital on a general medical unit. As the registered nurse, you share an assignment of clients with an unlicensed nursing assistant. You have worked with this assistant previously and know that she does her work in an efficient and accurate manner. You are able to communicate effectively with her because she asks questions when she needs clarification and she reports relevant client data as indicated.

Among the clients you and the assistant are caring for are a female adult receiving intravenous chemotherapy for lung cancer, a female adult with a possible deep venous thrombosis, and a male adult who has chronic obstructive lung disease (COPD).

Questions

American Nurses Association Standard of Professional Performance #10 is Quality of Practice: *The registered nurse systematically enhances the quality and effectiveness of nursing practice. This involves documenting the nursing process, and using creativity and quality improvement strategies to enhance client care.*

When you auscultate the lungs of the client with lung disease, you hear bronchovesicular sounds in the upper and middle lobes and adventitious sounds in both left and right lower lobes. The client reports no significant changes in the previous 24 hours and vital signs are substantially the same as previously. The day shift nurse had reported that the client's lungs were clear throughout, and the previous night shift nurse did not record the results of auscultated lung sounds in the client record.

1. How does this situation relate to Standard #10? Do you see opportunities to improve the quality of practice? Beyond the care of this individual client, what might you do to ensure that the nurses on this unit meet the competencies of the standard?

American Nurses Association Standard of Professional Performance #14 is Professional Practice Evaluation: *The registered nurse evaluates one's own nursing practice in relation to professional practice standards and guidelines, relevant statutes, rules, and regulations. This evaluation includes providing care that is appropriate for clients of different ages, cultures, and ethnicities; uses peer feedback; and incorporates evidence-based actions as part of the evaluation process.*

2. Imagine that when you assess the peripheral pulses of the client with a suspected thrombus, you have difficulty feeling the

dorsalis pedis or posterior tibial pulses on either leg. Considering the standard, what actions would be consistent with professional practice evaluation? Would your actions differ if this was the first time you had such difficulty or if you frequently find you are unable to palpate pedal pulses?

American Nurses Association Standard of Professional Performance #15 is Resource Utilization: *The registered nurse utilizes appropriate resources to plan and provide nursing services that are safe, effective, and financially responsible. This standard holds the registered nurse accountable for assessing client needs, allocating resources based on client needs, delegating care to others, and modifying practice as needed.*

In the scenario described, you will likely do all of those things. You have delegated the measurement of vital signs for all three clients to the assistant.

3. The assistant measures vital signs at 1600 and reports to you immediately that the client receiving chemotherapy has an oral temperature of 40°C (104°F). Describe your thinking in interpreting this data. What would be your response/next steps? List at least four things you would do and explain why they are necessary and appropriate.
4. In retrospect, do you think you should not have delegated measuring the vital signs on this client to the assistant? Why or why not?

American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Author.

-  **37** Perioperative Nursing 865

31 Asepsis

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Explain the concepts of medical and surgical asepsis.
2. Identify signs of localized and systemic infections and inflammation.
3. Identify risks for nosocomial and health care–associated infections.
4. Identify factors influencing a microorganism's ability to produce an infectious process.
5. Identify anatomic and physiological barriers that defend the body against microorganisms.
6. Differentiate active from passive immunity.
7. Identify relevant nursing diagnoses and contributing factors for clients at risk for infection and who have an infection.
8. Identify interventions to reduce risks for infections.
9. Identify measures that break each link in the chain of infection.
10. Compare and contrast category-specific, disease-specific, standard, and transmission-based isolation precaution systems.
11. Verbalize the steps used in:
 - a. Performing hand hygiene.
 - b. Applying and removing a gown, face mask, eyewear, and clean gloves.
 - c. Establishing and maintaining a sterile field.
 - d. Applying and removing sterile gloves by the open method.
 - e. Applying a sterile gown and gloves by the closed method.
12. Recognize when it is appropriate to delegate infection prevention skills to unlicensed assistive personnel.
13. Describe the steps to take in the event of a bloodborne pathogen exposure.

INTRODUCTION

Nurses are directly involved in providing a biologically safe environment. Microorganisms exist everywhere: in water, in soil, and on body surfaces such as the skin, intestinal tract, and other areas open to the outside (e.g., mouth, upper respiratory tract, vagina, and lower urinary tract). Most microorganisms are harmless, and some are even beneficial in that they perform essential functions in the body. Some microorganisms found in the intestines (e.g., enterobacteria) produce substances called *bacteriocins*, which are lethal to related strains of bacteria. Others produce substances that repress the growth of other

microorganisms. Some microorganisms are normal **resident flora** (the collective vegetation in a given area) in one part of the body, yet produce infection in another. For example, *Escherichia coli*, commonly referred to as *E. coli*, is a normal inhabitant of the large intestine but a common cause of infection of the urinary tract. Table 31–1 provides a list of common resident microorganisms.

An **infection** is the growth of microorganisms in body tissue where they are not usually found. Such a microorganism is called an *infectious agent*. If the microorganism produces no clinical evidence of disease, the infection is called *asymptomatic* or *subclinical*. Some

TABLE 31–1 Examples of Common Resident Microorganisms

Body Area	Microorganisms
Skin	<i>Staphylococcus epidermidis</i>
	<i>Propionibacterium acnes</i>
	<i>Staphylococcus aureus</i>
	<i>Corynebacterium xerosis</i>
	<i>Pityrosporum ovale</i> (yeast)
Nasal passages	<i>Staphylococcus aureus</i>
	<i>Staphylococcus epidermidis</i>
Oropharynx	<i>Streptococcus pneumoniae</i>
Mouth	<i>Streptococcus mutans</i>
	<i>Lactobacillus</i>
Intestine	<i>Bacteroides</i>
	<i>Actinomyces</i>
	<i>Bacteroides</i>
	<i>Fusobacterium</i>
	<i>Eubacterium</i>
	<i>Lactobacillus</i>
	<i>Streptococcus</i>
	<i>Enterobacteriaceae</i>
	<i>Shigella</i>
	<i>Escherichia coli</i>
Urethral orifice	<i>Staphylococcus epidermidis</i>
Urethra (lower)	<i>Proteus</i>
Vagina	<i>Lactobacillus</i>
	<i>Bacteroides</i>
	<i>Clostridium</i>
	<i>Candida albicans</i>

subclinical infections can cause considerable damage. For example, cytomegalovirus (CMV) infection in a pregnant woman can lead to significant disease in the unborn child. A detectable alteration in normal tissue function, however, is called **disease**.

Microorganisms vary in their **virulence** (i.e., their ability to produce disease). Microorganisms also vary in the severity of the diseases they produce and their degree of communicability. For example, the common cold virus is less severe but more readily transmitted than the bacillus that causes leprosy (*Mycobacterium leprae*). If the infectious agent can be transmitted to an individual by direct or indirect contact or as an airborne infection, the resulting condition is called a **communicable disease**.

Pathogenicity is the ability to produce disease; thus, a pathogen is a microorganism that causes disease. Many microorganisms that are normally harmless can cause disease under certain circumstances. A “true” pathogen causes disease or infection in a healthy individual. An **opportunistic pathogen** causes disease only in a susceptible individual.

Infectious diseases are a major cause of death worldwide. The control of the spread of microorganisms and the protection of people from communicable diseases and infections are carried out on international, national, state, community, and individual levels. The World Health Organization (WHO) is the major regulatory agency

at the international level. In the United States, the Centers for Disease Control and Prevention (CDC) is the principal national public health agency concerned with disease prevention and control. At the state and county level, health departments track and respond to epidemics and illnesses.

Asepsis is the freedom from disease-causing microorganisms. To decrease the possibility of transferring microorganisms from one place to another, aseptic technique is used. The two basic types of asepsis are medical and surgical. **Medical asepsis** includes all practices intended to confine a specific microorganism to a specific area, limiting the number, growth, and transmission of microorganisms. In medical asepsis, objects are referred to as **clean**, which means the absence of almost all microorganisms, or **dirty** (soiled, contaminated), which means likely to have microorganisms, some of which may be capable of causing infection.

Surgical asepsis, or **sterile technique**, refers to those practices that keep an area or object free of all microorganisms; it includes practices that destroy all microorganisms and spores (microscopic dormant structures formed by some pathogens that are very hardy and often survive common cleaning techniques). Surgical asepsis is used for all procedures involving the sterile areas of the body. **Sepsis** is the condition in which acute organ dysfunction occurs secondary to infection.

TYPES OF MICROORGANISMS THAT CAUSE INFECTIONS

Four major categories of microorganisms cause infection in humans: bacteria, viruses, fungi, and parasites. **Bacteria** are by far the most common infection-causing microorganisms. Several hundred species can cause disease in humans and can live and be transported through air, water, food, soil, body tissues and fluids, and inanimate objects. Most of the microorganisms in Table 31–1 are bacteria. **Viruses** consist primarily of nucleic acid and therefore must enter living cells in order to reproduce. Common virus families include the rhinovirus (causes the common cold), hepatitis, herpes, and human immunodeficiency virus. **Fungi** include yeasts and molds. *Candida albicans* is a yeast considered to be normal flora in the human vagina. **Parasites** live on other living organisms. They include protozoa such as the one that causes malaria, helminths (worms), and arthropods (mites, fleas, ticks).

TYPES OF INFECTIONS

Colonization is the process by which strains of microorganisms become resident flora. In this state, the microorganisms may grow and multiply but do not cause disease. Infection occurs when newly introduced or resident microorganisms succeed in invading a part of the body where the host's defense mechanisms are ineffective and the pathogen causes tissue damage. The infection becomes a disease when the signs and symptoms of the infection are unique and can be differentiated from other conditions.

Infections can be local or systemic. A **local infection** is limited to the specific part of the body where the microorganisms remain. If the microorganisms spread and damage different parts of the body, the infection is a **systemic infection**. When a culture of the person's blood reveals microorganisms, the condition is called **bacteremia**. When bacteremia results in systemic infection, it is referred to as **septicemia**. Unfortunately, septicemia has become more common over time.

There are also **acute** and **chronic infections**. Acute infections generally appear suddenly or last a short time. A chronic infection may occur slowly, over a very long period, and may last months or years.

NOSOCOMIAL AND HEALTH CARE-ASSOCIATED INFECTIONS

Nosocomial infections are classified as infections that originate in the hospital. Nosocomial infections can either develop during a client's stay in a facility or manifest after discharge. Nosocomial microorganisms may also be acquired by personnel working in the facility and can cause significant illness and time lost from work. Nosocomial infections are a subgroup of **health care–associated infections (HAIs)**—those that originate in any health care setting.

HAIs have received increasing attention in recent years and are believed to involve about 2 million clients per year. The Joint Commission (2013) includes reducing the risk of health care–associated infections as one of the National Patient Safety Goals, and funding for plans to reduce HAIs is a component of the American Recovery and Reinvestment Act of 2009. Data are collected on HAIs by the National Healthcare Safety Network. The CDC (2012) reports that central intravenous line–associated bloodstream infections, catheter-associated urinary tract infections, and ventilator-associated pneumonia account for roughly two thirds of all HAIs. The microorganisms that cause nosocomial infections can originate from the clients themselves (an **endogenous** source) or from the hospital environment and hospital personnel (**exogenous** sources). See Table 31–2 for a list of microorganisms and the conditions they cause. Most nosocomial

infections appear to have endogenous sources. *E. coli*, *Staphylococcus aureus*, and enterococci are common infecting microorganisms. *Clostridium difficile* (*C. difficile*), a spore-forming bacillus that infects the gastrointestinal (GI) tract following treatment of other infections with antibiotics, is one of the few HAIs increasing in frequency. *C. difficile* spores are transferred to clients mainly via the hands of health care personnel who have touched a contaminated surface or item.

SAFETY ALERT!

SAFETY

2014 THE JOINT COMMISSION NATIONAL PATIENT SAFETY GOALS (2013)

Goal 7: Reduce the Risk of Health Care–Associated Infections.

- Comply with either the current CDC hand hygiene guidelines or the current WHO hand hygiene guidelines.
Rationale: *Following the best practices identified in these guidelines helps ensure standardized, proven approaches to hand hygiene.*
- Implement evidence-based practices to prevent HAIs due to multidrug-resistant organisms (MDROs) in acute care hospitals.
Rationale: *Each health care agency needs to determine which practices are most appropriate for its unique client population and circumstances that lead to prevalence of particular MDROs.*
- Implement evidence-based practices to prevent central line–associated bloodstream infections.
Note: This requirement covers short- and long-term central venous catheters and peripherally inserted central catheter (PICC) lines.
- Implement evidence-based practices for preventing surgical site infections.

A number of factors contribute to nosocomial infections. **Iatrogenic infections** are the direct result of diagnostic or therapeutic procedures. One example of an iatrogenic infection is bacteremia that results from an intravascular infusion line. Not all nosocomial infections are iatrogenic, nor are all nosocomial infections preventable. Another factor contributing to the development of nosocomial infections is the compromised host, that is, a client whose normal defenses have been lowered by treatments or illness.

The hands of personnel are a common vehicle for the spread of microorganisms. Insufficient hand hygiene is thus an important factor contributing to the spread of nosocomial microorganisms.

SAFETY ALERT!

SAFETY

A person does not need to have an identified infection in order to pass potentially infective microorganisms to another person. Even normal microorganisms for one person can infect another person.

The cost of nosocomial infections to the client, the facility, and funding sources (e.g., insurance companies and federal, state, or local governments) is great. Nosocomial infections extend hospitalization time, increase clients' time away from work, cause disability and discomfort, and even result in loss of life.

CHAIN OF INFECTION

Six links make up the chain of infection (Figure 31–1 ■): the etiologic agent, or microorganism; the place where the organism naturally resides (reservoir); a portal of exit from the reservoir; a method (mode)

TABLE 31–2 Nosocomial Infections

Most Common Microorganisms	Causes
URINARY TRACT	
<i>Escherichia coli</i>	Improper catheterization technique
<i>Enterococcus</i> species	Contamination of closed drainage system
<i>Pseudomonas aeruginosa</i>	Inadequate hand hygiene
SURGICAL SITES	
<i>Staphylococcus aureus</i> (including methicillin-resistant strains—MRSA)	Inadequate hand hygiene
<i>Enterococcus</i> species (including vancomycin-resistant strains—VRE)	Improper dressing change technique
<i>Pseudomonas aeruginosa</i>	
BLOODSTREAM	
Coagulase-negative staphylococci	Inadequate hand hygiene
<i>Staphylococcus aureus</i>	Improper intravenous fluid, tubing, and site care technique
<i>Enterococcus</i> species	
PNEUMONIA	
<i>Staphylococcus aureus</i>	Inadequate hand hygiene
<i>Pseudomonas aeruginosa</i>	Improper suctioning technique
<i>Enterobacter</i> species	

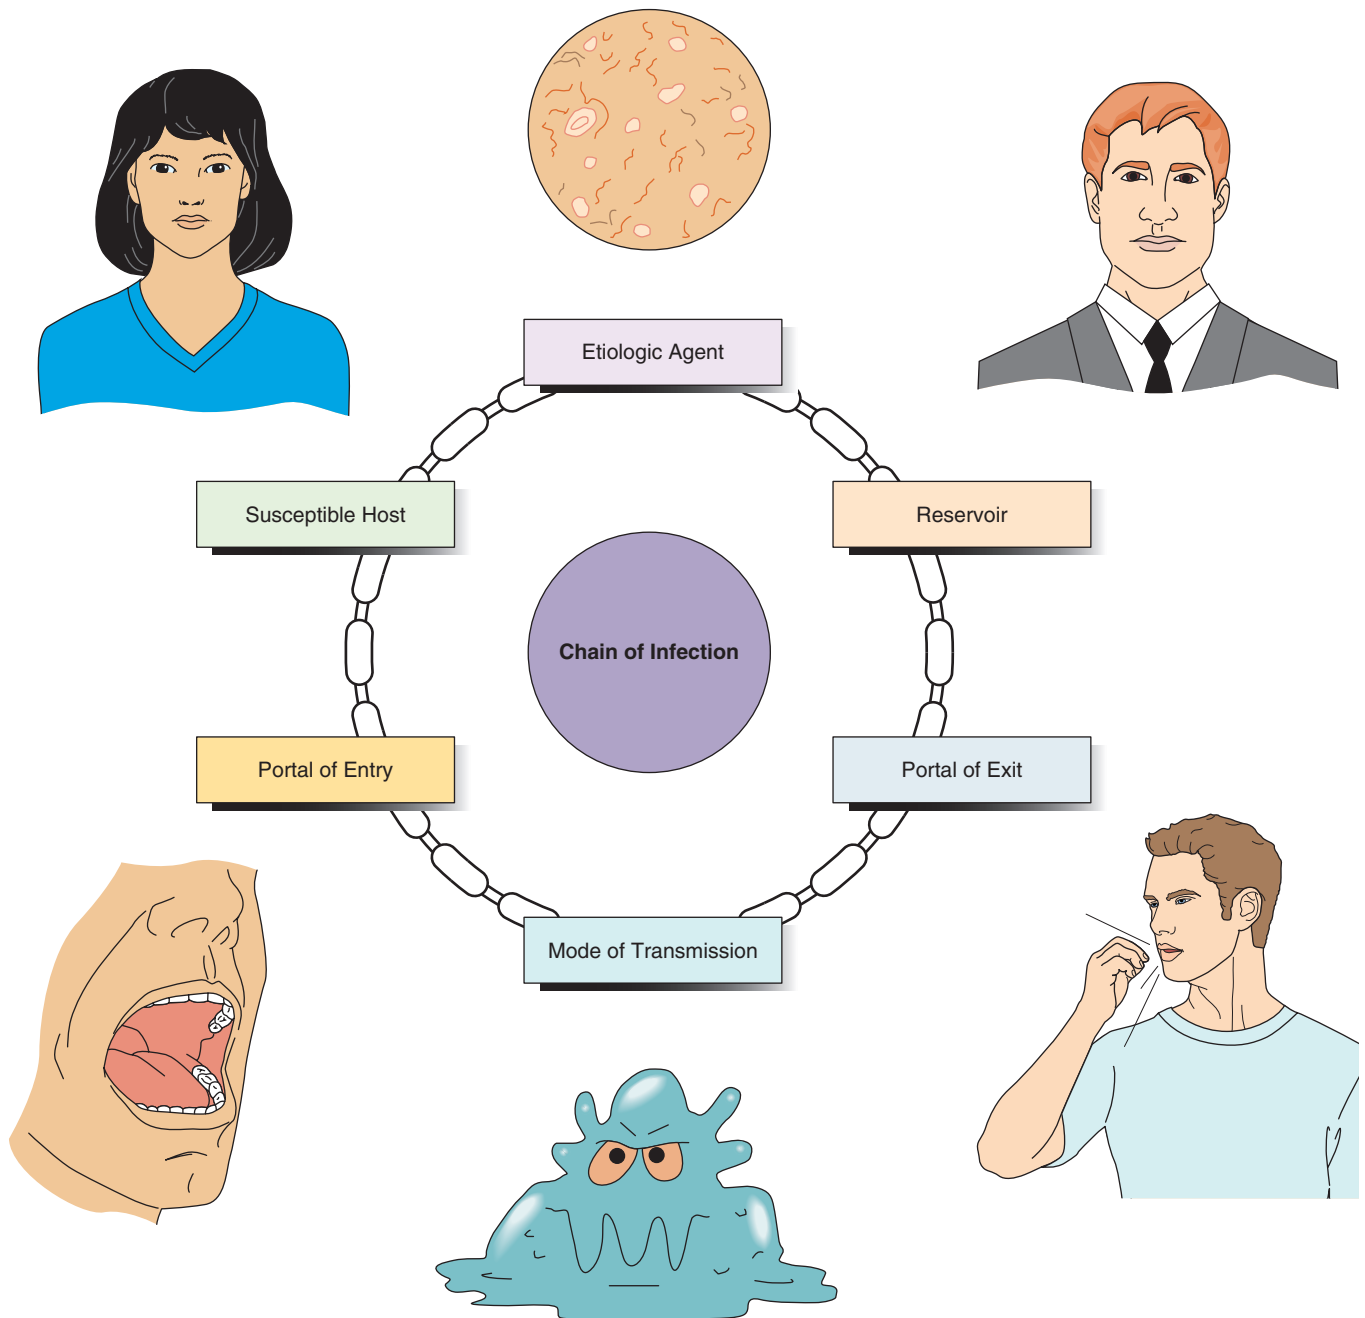

Figure 31-1 ■ The chain of infection.

of transmission; a portal of entry into a host; and the susceptibility of the host.

Etiologic Agent

The extent to which any microorganism is capable of producing an infectious process depends on the number of microorganisms present, the virulence and potency of the microorganisms (pathogenicity), the ability of the microorganisms to enter the body, the susceptibility of the host, and the ability of the microorganisms to live in the host's body.

Some microorganisms, such as the smallpox virus, have the ability to infect almost all susceptible people after exposure. By contrast, microorganisms such as the tuberculosis bacillus infect a relatively

small number of the population who are susceptible and exposed, usually people who are poorly nourished, who are living in crowded conditions, or whose immune systems are less competent (such as older adults or those with HIV or cancer).

Reservoir

There are many **reservoirs**, or sources of microorganisms. Common sources are other humans, the client's own microorganisms, plants, animals, or the general environment. People are the most common source of infection for others and for themselves. For example, the person with an influenza virus frequently spreads it to others. A **carrier** is a person or animal reservoir of a specific infectious agent that usually does not manifest any clinical signs of disease. The *Anopheles* mosquito

TABLE 31–3 Human Body Area Reservoirs, Common Infectious Microorganisms, and Portals of Exit

Body Area Reservoir	Common Infectious Microorganisms	Portals of Exit
Respiratory tract	Parainfluenza virus <i>Mycobacterium tuberculosis</i> <i>Staphylococcus aureus</i>	Nose or mouth through sneezing, coughing, breathing, or talking
Gastrointestinal tract	Hepatitis A virus <i>Salmonella</i> species <i>Clostridium difficile</i>	Mouth: saliva, vomitus Anus: feces Ostomies: feces
Urinary tract	<i>Escherichia coli</i> enterococci <i>Pseudomonas aeruginosa</i>	Urethral meatus and urinary diversion
Reproductive tract	<i>Neisseria gonorrhoeae</i> <i>Treponema pallidum</i> Herpes simplex virus type 2 Hepatitis B virus (HBV)	Vagina: vaginal discharge Urinary meatus: semen, urine

reservoir carries the malaria parasite but is unaffected by it. The carrier state may also exist in individuals with a clinically recognizable disease such as the dog with rabies. Under either circumstance, the carrier state may be of short duration (temporary or transient carrier) or long duration (chronic carrier). Food, water, and feces also can be reservoirs.

Portal of Exit from Reservoir

Before an infection can establish itself in a host, the microorganisms must leave the reservoir. Common human reservoirs and their associated portals of exit are summarized in Table 31–3.

Method of Transmission

After a microorganism leaves its source or reservoir, it requires a means of transmission to reach another person or host through a receptive portal of entry. There are three mechanisms:

- 1. Direct transmission.** Direct transmission involves immediate and direct transfer of microorganisms from person to person through touching, biting, kissing, or sexual intercourse. Droplet spread is also a form of direct transmission but can occur only if the source and the host are within 1 m (3 ft) of each other. Sneezing, coughing, spitting, singing, or talking can project droplet spray into the conjunctiva or onto the mucous membranes of the eye, nose, or mouth of another person.
- 2. Indirect transmission.** Indirect transmission may be either vehicle borne or vector borne:
 - a. Vehicle-borne transmission.** A *vehicle* is any substance that serves as an intermediate means to transport and introduce an infectious agent into a susceptible host through a suitable portal of entry. Fomites (inanimate materials or objects), such as handkerchiefs, toys, soiled clothes, cooking or

eating utensils, and surgical instruments or dressings, can act as vehicles. Water, food, blood, serum, and plasma are other vehicles. For example, food or water may become contaminated by a food handler who carries the hepatitis A virus. The food is then ingested by a susceptible host.

- b. Vector-borne transmission.** A *vector* is an animal or flying or crawling insect that serves as an intermediate means of transporting the infectious agent. Transmission may occur by injecting salivary fluid during biting or by depositing feces or other materials on the skin through the bite wound or a traumatized skin area.
- 3. Airborne transmission.** Airborne transmission may involve droplets or dust. **Droplet nuclei**, the residue of evaporated droplets emitted by an infected host such as someone with tuberculosis, can remain in the air for long periods. Dust particles containing the infectious agent (e.g., *C. difficile*, spores from the soil) can also become airborne. The material is transmitted by air currents to a suitable portal of entry, usually the respiratory tract, of another person.

Portal of Entry to the Susceptible Host

Before a person can become infected, microorganisms must enter the body. The skin is a barrier to infectious agents; however, any break in the skin can readily serve as a portal of entry. Often, microorganisms enter the body of the host by the same route they used to leave the source.

Susceptible Host

A susceptible host is any person who is at risk for infection. A **compromised host** is a person at increased risk, an individual who for one or more reasons is more likely than others to acquire an

infection. Impairment of the body's natural defenses and a number of other factors can affect susceptibility to infection. Examples include age (the very young or the very old); clients receiving immune suppression treatment for cancer, for chronic illness, or following a successful organ transplant; and those with immune deficiency conditions.

BODY DEFENSES AGAINST INFECTION

Individuals have defenses that protect the body from infection. These defenses can be categorized as nonspecific and specific. **Nonspecific defenses** protect the person against all microorganisms, regardless of prior exposure. **Specific (immune) defenses**, by contrast, are directed against identifiable bacteria, viruses, fungi, or other infectious agents.

Nonspecific Defenses

Nonspecific body defenses include anatomic and physiological barriers and the inflammatory response.

ANATOMIC AND PHYSIOLOGICAL BARRIERS

Intact skin and mucous membranes are the body's first line of defense against microorganisms. Unless the skin and mucosa become broken, they are an effective barrier against bacteria. Fungi can live on the skin, but they cannot penetrate it. The dryness of the skin also is a deterrent to bacteria. Bacteria are most plentiful in moist areas of the body, such as the perineum and axillae. Resident bacteria of the skin also prevent other bacteria from multiplying. They use up the available nourishment, and the end products of their metabolism inhibit other bacterial growth. Normal secretions make the skin slightly acidic; acidity also inhibits bacterial growth.

The nasal passages have a defensive function. As entering air follows the tortuous route of the passage, it comes in contact with moist mucous membranes and cilia. These trap microorganisms, dust, and foreign materials. The lungs have alveolar macrophages (large phagocytes). Phagocytes are cells that ingest microorganisms, dead cells, and foreign particles.

Each body orifice also has protective mechanisms. The oral cavity regularly sheds mucosal epithelium to rid the mouth of colonizers. The flow of saliva and its partial buffering action help prevent infections. Saliva contains microbial inhibitors, such as lactoferrin, lysozyme, and secretory IgA.

The eye is protected from infection by tears, which continually wash microorganisms away and contain inhibiting lysozyme. The GI tract also has defenses against infection. The high acidity of the stomach normally prevents microbial growth. The resident flora of the large intestine help prevent the establishment of disease-producing microorganisms. Peristalsis also tends to move microbes out of the body.

The vagina also has natural defenses against infection. When a girl reaches puberty, lactobacilli ferment sugars in the vaginal secretions, creating a vaginal pH of 3.5 to 4.5. This low pH inhibits the growth of many disease-producing microorganisms. The entrance to the urethra normally harbors many microorganisms. These include *Staphylococcus epidermidis coagulase* (from the skin) and *E. coli* (from feces). Urine flow has a flushing and bacteriostatic action that keeps the bacteria from ascending the urethra. An intact mucosal surface also acts as a barrier.

INFLAMMATORY RESPONSE

Inflammation is a local and nonspecific defensive response of the tissues to an injurious or infectious agent. It is an adaptive mechanism that destroys or dilutes the injurious agent, prevents further spread of the injury, and promotes the repair of damaged tissue. It is characterized by five signs: (1) pain, (2) swelling, (3) redness, (4) heat, and (5) impaired function of the part, if the injury is severe. Commonly, words with the suffix *-itis* describe an inflammatory process. For example, *appendicitis* means inflammation of the appendix; *gastritis* means inflammation of the stomach.

CLINICAL ALERT!

An easy way to remember the signs of inflammation are the rhyming Latin words: *rubor* (redness), *tumor* (swelling), *color/calor* (heat), and *dolor* (pain).

Injurious agents can be categorized as physical agents, chemical agents, and microorganisms. *Physical agents* include mechanical objects causing trauma to tissues, excessive heat or cold, and radiation. *Chemical agents* include external irritants (e.g., strong acids, alkalis, poisons, and irritating gases) and internal irritants (substances manufactured within the body such as excessive hydrochloric acid in the stomach). *Microorganisms* include the broad groups of bacteria, viruses, fungi, and parasites.

A series of dynamic events is commonly referred to as the three stages of the inflammatory response:

First stage: vascular and cellular responses

Second stage: exudate production

Third stage: reparative phase.

VASCULAR AND CELLULAR RESPONSES At the start of the first stage of inflammation, blood vessels at the site of injury constrict. This is rapidly followed by dilation of small blood vessels (occurring as a result of histamine released by the injured tissues). Thus, more blood flows to the injured area. This marked increase in blood supply is referred to as hyperemia and is responsible for the characteristic signs of redness and heat.

Vascular permeability increases at the site with dilation of the vessels in response to cell death, the release of chemical mediators (e.g., bradykinin, serotonin, and prostaglandin), and the release of histamine. Fluid, proteins, and **leukocytes** (white blood cells) leak into the interstitial spaces, and the signs of inflammation—swelling (edema) and pain—appear. Pain is caused by the pressure of accumulating fluid on nerve endings and the irritating chemical mediators. Fluid pouring into areas such as the pleural or pericardial cavity can seriously affect organ function. In other areas, such as joints, mobility is impaired.

In response to the exit of leukocytes from the blood, the bone marrow produces large numbers of leukocytes and releases them into the bloodstream. This is called **leukocytosis**. A normal leukocyte count of 4,500 to 11,000 per cubic millimeter of blood can rise to 20,000 or more when inflammation occurs.

EXUDATE PRODUCTION In the second stage of inflammation, the inflammatory **exudate** is produced, consisting of fluid that escaped from the blood vessels, dead phagocytic cells, and dead tissue cells and products that they release. The plasma protein fibrinogen

TABLE 31–4 Types of Immunity

Type	Antigen or Antibody Source	Duration
1. Active	Antibodies are produced by the body in response to an antigen.	Long
a. Natural	Antibodies are formed in the presence of active infection in the body.	Lifelong
b. Artificial	Antigens (vaccines or toxoids) are administered to stimulate antibody production.	Many years; the immunity must be reinforced by booster
2. Passive (acquired)	Antibodies are produced by another source, animal or human.	Short
a. Natural	Antibodies are transferred naturally from an immune mother to her baby through the placenta or in colostrum.	6 months to 1 year
b. Artificial	Immune serum (antibody) from an animal or another human is injected.	2–3 weeks

(which is converted to fibrin when it is released into the tissues), thromboplastin (released by injured tissue cells), and platelets together form an interlacing network to wall off the area, and prevent spread of the injurious agent. During this stage, the injurious agent is overcome, and the exudate is cleared away by lymphatic drainage.

The nature and amount of exudate vary according to the tissue involved and the intensity and duration of the inflammation. The major types of exudate are serous, purulent, and hemorrhagic (sanguineous). Descriptions of these exudates are provided in Chapter 36.

REPARATIVE PHASE The third stage of the inflammatory response involves the repair of injured tissues by regeneration or replacement with fibrous tissue (scar) formation. **Regeneration** is the replacement of destroyed tissue cells by cells that are identical or similar in structure and function. Damaged cells are replaced one by one, but the cells are also organized so that the architectural pattern and function of the tissue are restored. The ability to regenerate cells varies considerably from one type of tissue to another. For example, epithelial tissues of the skin and of the digestive and respiratory tracts have a good regenerative capacity if their underlying support structures are intact. The same holds true for osseous, lymphoid, and bone marrow tissues. Tissues that have little regenerative capacity include nervous, muscular, and elastic tissues.

When regeneration is not possible, repair occurs by fibrous (scar) tissue formation. The inflammatory exudate with its interlacing network of fibrin provides the framework for this tissue to develop. Damaged tissues are replaced with the connective tissue elements of collagen, blood capillaries, lymphatics, and other tissue-bound substances. In the early stages of this process, the tissue is called **granulation tissue**. It is a fragile, gelatinous tissue, appearing pink or red because of the many newly formed capillaries. Later in the process, the tissue shrinks (the capillaries are constricted, even obliterated) and the collagen fibers contract, so that a firmer fibrous tissue remains. This is called cicatrix, or scar.

Specific Defenses

Specific defenses of the body involve the immune system. An **antigen** is a substance that induces a state of sensitivity or immune responsiveness (**immunity**). If the proteins originate in a person's own body, the antigen is called an **autoantigen**.

The immune response has two components: antibody-mediated defenses and cell-mediated defenses. These two systems provide distinct but overlapping protection.

ANTIBODY-MEDIATED DEFENSES

Another name for the *antibody-mediated defenses* is **humoral** (or **circulating**) **immunity** because these defenses reside ultimately in the B lymphocytes and are mediated by antibodies produced by B cells. **Antibodies**, also called **immunoglobulins**, are part of the body's plasma proteins. The antibody-mediated responses defend primarily against the extracellular phases of bacterial and viral infections.

The two major types of immunity are active and passive (Table 31–4). In **active immunity**, the host produces antibodies in response to natural antigens (e.g., infectious microorganisms) or artificial antigens (e.g., vaccines). B cells are activated when they recognize the antigen. They then differentiate into plasma cells, which secrete the antibodies and serum proteins that bind specifically to the foreign substance and initiate a variety of elimination responses. The B cell may produce antibody molecules of five classes of immunoglobulins designated by letters and usually written as IgM, IgG, IgA, IgD, and IgE. The presence of IgM in a laboratory analysis shows current infection. Before the antibody response can become effective, the phagocytic cells of the blood bind and ingest foreign substances. The rate of binding and phagocytosis increases if IgG antibodies (which indicate past infection and subsequent immunity) are present. With **passive** (or **acquired**) **immunity**, the host receives natural (e.g., from a nursing mother) or artificial (e.g., from an injection of immune serum) antibodies produced by another source.

CELL-MEDIATED DEFENSES

The **cell-mediated defenses**, or **cellular immunity**, occur through the T-cell system. On exposure to an antigen, the lymphoid tissues release large numbers of activated T cells into the lymph system. These T cells pass into the general circulation. There are three main groups of T cells: (1) helper T cells, which help in the functions of the immune system; (2) cytotoxic T cells, which attack and kill microorganisms and sometimes the body's own cells; and (3) suppressor T cells, which can suppress the functions of the helper T cells and the cytotoxic T cells. When cell-mediated immunity is lost, as occurs with human immunodeficiency virus (HIV) infection, an individual is "defenseless" against most viral, bacterial, and fungal infections.

FACTORS INCREASING SUSCEPTIBILITY TO INFECTION

Whether a microorganism causes an infection or not depends on a number of factors already mentioned. One of the most important factors is host susceptibility, which is affected by age, heredity, level

of stress, nutritional status, current medical therapy, and preexisting disease processes.

Newborns and older adults have reduced defenses against infection. Infections are a major cause of death of newborns, who have immature immune systems and are protected only for the first 2 or 3 months by immunoglobulins passively received from the mother. Between 1 and 3 months of age, infants begin to synthesize their own immunoglobulins. Immunizations against hepatitis B can begin at birth while diphtheria, tetanus, and pertussis are usually started at 2 months, when the infant's immune system can respond. Children who missed immunizations at earlier ages can receive them later. Go to nursing.pearsonhighered.com to download the Recommended Immunization Schedule for Persons Aged 0 Through 18 Years—United States, table. The nurse should also be familiar with data indicating the safety of recommended immunizations (Maglione et al., 2014).

With advancing age, the immune responses again become weak. Although there is still much to learn about aging, it is known that immunity to infection decreases with advancing age. Because of the prevalence of influenza and its potential for causing death, the CDC recommends annual immunization against influenza for older adults and for individuals with chronic cardiac, respiratory, metabolic, and renal disease. Pneumococcal vaccine is recommended for older adults last vaccinated more than 5 years previously. Go to nursing.pearsonhighered.com to download the Recommended Immunizations for Adults by Age and by Medical Condition table.

Heredity influences the development of infection in that some people have a genetic susceptibility to certain infections. For example, some may be deficient in serum immunoglobulins, which play a significant role in the internal defense mechanism of the body.

The nature, number, and duration of physical and emotional stressors can influence susceptibility to infection. Stressors elevate blood cortisone. Prolonged elevation of blood cortisol decreases anti-inflammatory responses, depletes energy stores, leads to a state of exhaustion, and decreases resistance to infection. For example, a person recovering from a major operation or injury is more likely to develop an infection than a healthy person.

Resistance to infection depends on adequate nutritional status. Because antibodies are proteins, the ability to synthesize antibodies may be impaired by inadequate nutrition, especially when protein reserves are depleted (e.g., as a result of injury, surgery, or debilitating diseases such as cancer).

Some medical therapies predispose a person to infection. For example, radiation treatments for cancer destroy not only cancerous cells but also some normal cells, thereby rendering them more vulnerable to infection. Some diagnostic procedures may also predispose the client to an infection, especially when the skin is broken or sterile body cavities are penetrated during the procedure.

Certain medications also increase susceptibility to infection. Antineoplastic (anticancer) medications may depress bone marrow function, resulting in inadequate production of white blood cells necessary to combat infections. Anti-inflammatory medications, such as adrenal corticosteroids, inhibit the inflammatory response, an essential defense against infection. Even some antibiotics used to treat infections can have adverse effects. Antibiotics may kill resident flora, allowing the proliferation of strains that would not grow and multiply in the body under normal conditions.

CLINICAL ALERT!

Some common medications such as aspirin and ibuprofen are analgesic (pain relieving), antipyretic (fever reducing), and anti-inflammatory. Acetaminophen, however, is analgesic and antipyretic, but not anti-inflammatory.

Certain antibiotics can also induce resistance in some strains of organisms. This resistance has become so widespread that the CDC has created a 12-step Campaign to Prevent Antimicrobial Resistance in Healthcare Settings consisting of four strategies: preventing infection, diagnosing and treating infection effectively, using antimicrobials wisely, and preventing transmission.

Any disease that lessens the body's defenses against infection places the client at risk. Examples are chronic pulmonary disease, which impairs ciliary action and weakens the mucous barrier; peripheral vascular disease, which restricts blood flow; burns, which impair skin integrity; chronic or debilitating diseases, which deplete protein reserves; and immune system diseases such as leukemia and aplastic anemia, which alter the production of white blood cells. Diabetes mellitus is a major underlying disease predisposing clients to infection because compromised peripheral vascular status and increased serum glucose levels increase susceptibility.

●○○ NURSING MANAGEMENT

Assessing

During the assessing phase of the nursing process, the nurse obtains the client's history, conducts the physical assessment, and gathers laboratory data.

Nursing History

During the nursing history, the nurse assesses (a) the degree to which a client is at risk of developing an infection and (b) any client complaints suggesting the presence of an infection. To identify clients at risk, the nurse reviews the client's chart and structures the nursing interview to collect data regarding the factors influencing the development of infection, especially existing disease process, history of recurrent infections, current medications and therapeutic measures, current emotional stressors, nutritional status, and history of immunizations (see the Assessment Interview later in this section).

Physical Assessment

Signs and symptoms of an infection vary according to the body area involved. For example, sneezing, watery or mucoid discharge from the nose, and nasal stuffiness commonly occur with an infection of the nose and sinuses; urinary frequency and cloudy or discolored urine often occur with a urinary infection. Commonly the skin and mucous membranes are involved in a local infectious process, resulting in the following:

- Localized swelling
- Localized redness
- Pain or tenderness with palpation or movement
- Palpable heat at the infected area
- Loss of function of the body part affected, depending on the site and extent of involvement.

In addition, open wounds may exude drainage of various colors.

LIFESPAN CONSIDERATIONS Infections**Children**

Infections are an expected part of childhood, with most children experiencing some kind of infection from time to time. The majority of these infections are caused by viruses, and for the most part are transient, relatively benign, and able to be overcome by the body's natural defenses and supportive care. In some cases, severe, even life-threatening infections occur. Considerations related to children include the following:

- Newborns may not be able to respond to infections due to an underdeveloped immune system. As a result, in the first few months of life, infections may not be associated with typical signs and symptoms (e.g., an infant with an infection may not have a fever).
- Newborns are born with some naturally acquired immunity transferred from the mother across the placenta.
- Breast-fed infants experience higher levels of immunity against infections than formula-fed infants.
- Fevers less than 39°C (102.2°F) in children should not be treated, except for comfort of the child.
- Children between 6 months and 5 years are at higher risk for fever-induced (febrile) seizures. Febrile seizures are not associated with neurologic seizure disorders (e.g., epilepsy).
- Children who are immune compromised (e.g., leukemia, HIV) or have a chronic health condition (e.g., cystic fibrosis, sickle cell disease, congenital heart disease) need extra precautions to prevent exposure to infectious agents.
- Hand hygiene, comprehensive immunizations, good nutrition, adequate hydration, and appropriate rest are essential to preventing and/or treating infections in children.
- Hand washing and good hygiene in day care facilities and schools are important to prevent the spread of infections.
- Adolescents are at high risk for sexually transmitted infections and should be well educated about how to prevent them.

OLDER ADULTS

Normal aging may predispose older adults to increased risk of infection and delayed healing. Anatomic and physiological agents that are protective when a person is younger often change in structure

and function with increasing age and then provide a decrease in their protective ability. Changes take place in the skin, respiratory tract, GI system, kidneys, and immune system. If unchallenged, these systems work well to maintain homeostasis for the individual, but if compromised by stress, illness, infections, treatments, or surgeries, they find it difficult to keep up and therefore are not able to provide adequate protection. Considerations for older adults include the following:

- Nutrition is often poor in older adults. Certain components, especially adequate protein, are necessary to build up and maintain the immune system.
- Diabetes mellitus, which occurs more frequently in older adults, increases the risk of infection and delayed healing by causing an alteration in nutrition and impaired peripheral circulation, which decrease oxygen transport to the tissues.
- The immune system reacts slowly to the introduction of antigens, allowing the antigen to reproduce itself several times before it is recognized by the immune system. T-cell effectiveness is often decreased due to immaturity.
- The normal inflammatory response is delayed. This often causes atypical responses to infections. Instead of displaying the redness, swelling, and fever usually associated with infections, atypical symptoms such as confusion and disorientation, agitation, incontinence, falls, lethargy, and general fatigue are often seen first.

Recognizing these changes in older adults is important in early detection and treatment of related potential for infections and delayed healing. Nursing interventions to promote prevention include the following:

- Provide and teach ways to improve nutritional status.
- Use strict aseptic technique to decrease chance of infections (especially nosocomial infections in health care facilities).
- Encourage older adults to have regular immunizations for flu and pneumonia.
- Be alert to subtle atypical signs of infection and act quickly to diagnose and treat.

ASSESSMENT INTERVIEW Client at Risk for Infections

- When were you last immunized for diphtheria, tetanus, poliomyelitis, rubella, measles, influenza, hepatitis, and pneumococcal pneumonia?
- When did you last have a tuberculin skin test?
- What infections have you had in the past, and how were these treated? Have any of these infections recurred?
- Are you taking any antibiotics, anti-inflammatory medications such as aspirin or ibuprofen, or medications for cancer?
- Have you had any recent diagnostic procedure or therapy that penetrated through your skin or a body cavity?
- What past surgeries have you had?

- How would you describe your eating habits? Do you eat a variety of types of foods?
- Do you take vitamins?
- On a scale of 1 to 10, how would you rate the stress you have experienced in the last 6 months?
- Have you experienced any loss of energy, loss of appetite, nausea, headache, or other signs associated with specific body systems (e.g., difficulty urinating, urinary frequency, or a sore throat)?

Note: As with all history taking, the nurse must individualize the specific terms used, examples given to the client, and teaching techniques used to validate agreement on the meaning of words according to the client's culture, language spoken, and education or intellectual abilities.

Signs of systemic infection include the following:

- Fever
- Increased pulse and respiratory rate if the fever is high
- Malaise and loss of energy
- Anorexia and, in some situations, nausea and vomiting
- Enlargement and tenderness of lymph nodes that drain the area of infection.

Laboratory Data

Laboratory data that indicate the presence of an infection include the following:

- Elevated leukocyte (white blood cell or WBC) count (4,500 to 11,000/mL³ is normal).
- Increases in specific types of leukocytes as revealed in the differential WBC count. Specific types of white blood cells are increased

or decreased in certain infections. See Chapter 34 for normal values for the adult.

- Elevated erythrocyte sedimentation rate (ESR). Red blood cells normally settle slowly, but the rate increases in the presence of an inflammatory process.
- Urine, blood, sputum, or other drainage **cultures** (laboratory cultivations of microorganisms in a special growth medium) that indicate the presence of pathogenic microorganisms.

Diagnosing

The NANDA nursing diagnostic label for problems associated with the transmission of microorganisms is *Risk for Infection*, the state in which an individual is at increased risk for being invaded by pathogenic microorganisms.

When using this label, the nurse should identify risk factors:

- *Inadequate primary defenses* such as broken skin, traumatized tissue, decreased ciliary action, stasis of body fluids, change in pH of secretions, or altered peristalsis
- *Inadequate secondary defenses* such as leukopenia, immunosuppression, decreased hemoglobin, or suppressed inflammatory response.

Clients who have or are at risk for an existing infection are prime candidates for other physical and psychological problems. Examples of nursing diagnoses or collaborative problems that may arise from the actual presence of an infection include the following:

- *Potential Complication of Infection: Fever*
- *Imbalanced Nutrition: Less Than Body Requirements* if the client is too ill to eat adequately
- *Acute Pain* if the client is experiencing tissue damage and discomfort
- *Impaired Social Interaction* or *Social Isolation* if the client is required to be separated from others during a contagious episode
- *Anxiety* if the client is apprehensive regarding changes in life activities resulting from the infection or its treatment such as absence from work or inability to perform usual functions.

Planning

The major goals for clients susceptible to infection are to:

- Maintain or restore defenses.

- Avoid the spread of infectious organisms.
- Reduce or alleviate problems associated with the infection.

Desired outcomes depend on the individual client's condition. Nursing strategies to meet the three broad goals generally include using meticulous medical and surgical aseptic techniques to prevent the spread of potentially infectious microorganisms, implementing measures to support the defenses of a susceptible host, and teaching clients about protective measures to prevent infections and the spread of infectious agents when an infection is present.

Planning for Home Care

Clients being discharged following hospital care for an infection often require continued care to completely eliminate the infection or to adapt to a chronic state. In addition, such clients may be at increased risk for reinfection or development of an opportunistic infection following therapy for existing pathogens.

In preparation for discharge, the nurse needs to know the client's and family's risks, needs, strengths, and resources. The Home Care Considerations box describes the specific assessment data required before establishing a discharge plan. Using the data gathered about the home situation, the nurse tailors the teaching plan for the client and family (see Client Teaching: Infection Prevention on page 612).

Implementing

The nurse implements strategies to prevent infection. If infection cannot be prevented, the nurse's goal is to prevent the spread of the infection within and between individuals, and to treat the existing infection. In the sections that follow, nursing activities are described that interfere with the chain of infection to prevent and control transmission of infectious organisms, and that promote care of the infected client. These activities are summarized in Table 31–5.

Preventing Nosocomial Infections

Meticulous use of medical and surgical asepsis is necessary to prevent transport of potentially infectious microorganisms. As discussed previously in this chapter, nosocomial infections are those acquired in relation to health care services. Many nosocomial infections can be prevented by using proper hand hygiene techniques, environmental

Home Care Assessment Infection

PATIENT-CENTERED CARE

CLIENT AND ENVIRONMENT

- *Self-care abilities for hygiene and toileting*: understanding of rationale for hygiene in the home setting; ability to contain potentially infectious material, such as that from coughing or sneezing, and body fluids (urine, stool, drainage); ability to cleanse hands and implement any required isolation practices
- *Self-care abilities for medication administration*: understanding of medication therapy, expected outcomes, and potential side effects; physical dexterity to take pills, administer intravenous antibiotics, and store medications safely
- *Facilities*: presence of running water, trash containers and disposal, bathroom to facilitate wound care and contain potentially infectious materials
- *Self-care abilities for wound care*: understanding of rationale for wound care and of wound care technique; ability to gather and use supplies for clean or aseptic technique to change dressings or care for wounds

FAMILY

- *Caregiver availability, skills, and responses*: understanding of rationale for wound care and of wound care technique; people able to assist with wound care, medication administration, and shopping if client has restricted activity; people able to comprehend infection prevention activities without excessive personal anxiety
- *Other susceptible cohabitants*: presence and immunization status of children, older adults, or others who may be at risk of infection from the client

COMMUNITY

- *Resources*: availability of and familiarity with possible sources of assistance for finances, supplies, and home health aid (such as public health department and visiting nurses)

CLIENT TEACHING Infection Prevention**ENVIRONMENTAL MANAGEMENT**

- Discuss injury-proofing the home to prevent the possibility of further tissue injury (e.g., use of padding, handrails, removal of hazards).
- Explore ways to control the environmental temperature and airflow (especially if the client has an airborne pathogen).
- Determine the advisability of visitors and family members in proximity to the client.
- Describe ways to manipulate the bed, the room, and other household facilities to prevent additional injury or to contain possible cross contamination.
- Instruct to clean obviously soiled linen separately from other laundry. Rinse in cold water, wash in hot water if possible, and add a cup of bleach or phenol-based disinfectant such as Lysol concentrate to the wash.

INFECTION CONTROL

- Based on assessment of client and family knowledge, teach proper hand hygiene (e.g., before handling foods, before eating, after toileting, before and after any required home care treatment, and after touching any body substances such as wound drainage) and related hygienic measures to all family members.
- Promote nail care: keep fingernails short, clean, and well manicured to eliminate rough edges or hangnails, which can harbor microorganisms.
- Instruct not to share personal care items such as toothbrushes, washcloths, and towels. Describe the rationale of how infections can be transmitted from shared personal items.
- Discuss antimicrobial soaps and effective disinfectants.
- Ensure access to and proper use of gloves and other barriers as indicated by the type of infection or risk.
- Discuss the relationship between hygiene, rest, activity, and nutrition in the chain of infection.
- Instruct about proper administration of medication.
- Instruct about cleaning reusable equipment and supplies. Use soap and water, and disinfect with a chlorine bleach solution.

INFECTION PREVENTION

- Teach the client and family members the signs and symptoms of infection, and when to contact a health care provider. After each teaching session, determine the level of understanding on the topic by verbal questioning.
- Teach the client and family members how to avoid infections. Include information on the importance of adequate nutrition in supporting the body's ability to resist infection (see Chapter 47).
- Suggest techniques for safe food preservation and preparation (e.g., wash raw fruits and vegetables before eating them, refrigerate all opened and unpackaged foods).
- Remind to avoid coughing, sneezing, or breathing directly on others. Cover the mouth and nose to prevent the transmission of airborne microorganisms.
- Inform of the importance of maintaining sufficient fluid intake to promote urine production and output. This helps flush the bladder and urethra of microorganisms.
- Emphasize the need for proper immunizations of all family members.

WOUND CARE

- Teach the client and family the signs of wound healing and wound infection and why monitoring of the wound is important.
- Delineate factors that promote wound healing.
- Explain the proper technique for changing the dressing and disposing of the soiled one. Reinforce the need to place contaminated dressings and other disposable items containing body fluids in moisture-proof plastic bags.
- Advise to put used needles in a puncture-resistant container. Label so as not to discard in the garbage.
- Have client or family repeat instructions and demonstrate skills.

REFERRALS

- Provide appropriate information regarding how to access community resources, home care agencies, sources of supplies, and community or public health departments for immunizations.

controls, sterile technique when warranted, and identification and management of clients at risk for infections.

Hand Hygiene

Hand hygiene is important in every setting, including hospitals. It is considered one of the most effective infection prevention measures. Any client may harbor microorganisms that are currently harmless to the client yet potentially harmful to another person or to the same client if they find a portal of entry. It is important for both the nurses' and the clients' hands to be cleansed at the following times to prevent the spread of microorganisms: before eating, after using the bedpan or toilet, and after the hands have come in contact with any body substances, such as sputum or drainage from a wound. In addition, health care workers should cleanse their hands before and after giving care of any kind.

Because hand hygiene is performed so frequently, it provides a good opportunity for the nurse to take a moment to breathe and prepare for the next client encounter. By allowing a full, quiet breath in and a slow, complete exhalation, the nurse can focus his or her attention and intention to remain mindful. This mindful attitude enhances the nurse's therapeutic presence and increases the effectiveness and safety of care.

For routine client care, vigorous hand washing under a stream of water for 15 to 20 seconds using granular soap, soap-filled sheets, or liquid soap at the beginning of the nurse's shift, when hands are visibly soiled, and after using the toilet is recommended (WHO, 2009). Antimicrobial soaps are usually provided in high-risk areas (e.g., the newborn nursery). In the following situations, the CDC recommends antimicrobial hand hygiene agents:

- When there are known multiple resistant bacteria
- Before invasive procedures
- In special care units, such as nurseries and intensive care units (ICUs)
- Before caring for severely immunocompromised clients.

CLINICAL ALERT!

Cases of MRSA are increasing dramatically in hospital and community settings. Nurses must be vigilant about hand hygiene to reduce this threat.

Hand washing with soap and water may be inadequate to sufficiently remove pathogens, particularly because health care personnel tend to not wash thoroughly. After the initial soap and water

TABLE 31–5 Nursing Interventions That Break the Chain of Infection

Link	Interventions	Rationales
Etiologic agent (microorganism)	Ensure that articles are correctly cleaned and disinfected or sterilized before use. Educate clients and support people about appropriate methods for cleaning, disinfecting, and sterilizing articles.	Correct cleaning, disinfecting, and sterilizing reduce or eliminate microorganisms. Knowledge of ways to reduce or eliminate microorganisms reduces the likelihood of transmission.
Reservoir (source)	Change dressings and bandages when they are soiled or wet. Assist clients to carry out appropriate skin and oral hygiene. Dispose of damp, soiled linens appropriately. Dispose of feces and urine in appropriate receptacles. Ensure that all fluid containers, such as bedside water jugs and suction and drainage bottles, are covered or capped. Empty suction and drainage bottles at the end of each shift or before they become full, or according to agency policy.	Moist dressings are ideal environments for microorganisms to grow and multiply. Hygienic measures reduce the numbers of resident and transient microorganisms and the likelihood of infection. Damp, soiled linens harbor more microorganisms than dry linens. Urine and feces in particular contain many microorganisms. Prolonged exposure increases the risk of contamination and promotes microbial growth. Drainage harbors microorganisms that, if left for long periods, proliferate and can be transmitted to others.
Portal of exit from the reservoir	Avoid talking, coughing, or sneezing over open wounds or sterile fields, and cover the mouth and nose when coughing and sneezing.	These measures limit the number of microorganisms that escape from the respiratory tract.
Method of transmission	Cleanse hands between client contacts, after touching body substances, and before performing invasive procedures or touching open wounds. Instruct clients and support people to cleanse hands before handling food or eating, after eliminating, and after touching infectious material. Wear gloves when handling secretions and excretions. Wear gowns if there is danger of soiling clothing with body substances. Place discarded soiled materials in moisture-proof refuse bags. Hold used bedpans steadily to prevent spillage, and dispose of urine and feces in appropriate receptacles. Initiate and implement infection prevention strategies for all clients. Wear mask and eye protection when in close contact with clients who have infections transmitted by droplets from the respiratory tract. Wear mask and eye protection when sprays of body fluid are possible (e.g., during irrigation procedures).	Hand hygiene is an important means of controlling and preventing the transmission of microorganisms. Hand hygiene helps prevent transfer of microorganisms from one person to another. Gloves prevent soiling of the hands. Gowns prevent soiling of the clothing. Moisture-proof bags prevent the spread of microorganisms to others. Feces in particular contain many microorganisms. All clients may harbor potentially infectious microorganisms that can be transmitted to others. Masks and eyewear reduce the spread of droplet-transmitted microorganisms. Masks and eye protection provide protection from microorganisms in clients' body substances.
Portal of entry to the susceptible host	Use aseptic technique for invasive procedures (e.g., injections, catheterizations). Use sterile technique when exposing open wounds or handling dressings. Place used disposable needles and syringes in puncture-resistant containers for disposal. Provide all clients with their own personal care items.	Invasive procedures penetrate the body's natural protective barriers to microorganisms. Open wounds are vulnerable to microbial infection. Injuries from needles contaminated by blood or body fluids from an infected client or carrier are a primary cause of HBV and HIV transmission to health care workers. People have less resistance to another person's microorganisms than to their own.
Susceptible host	Maintain the integrity of the client's skin and mucous membranes. Ensure that the client receives a balanced diet. Educate the public about the importance of immunizations. Encourage deep, slow, full breathing, ambulation, and movement. Offer stress management strategies and encourage healthy relationships.	Intact skin and mucous membranes protect against invasion by microorganisms. A balanced diet supplies proteins and vitamins necessary to build or maintain body tissues. Certain immunizations may protect people against virulent infectious diseases. These actions enhance ventilation and circulation throughout the body. Tap into the mind–body connection to enhance healing.

hand washing, the CDC recommends the use of alcohol-based anti-septic hand rubs (rinses, gels, or foams) before and after each direct client contact. If there is visible dirt or matter, or if *C. difficile* may be present, alcohol-based rubs will not be sufficient, and soap and water washing is necessary (WHO, 2009). Even if soap and water or alcohol-based rubs are used appropriately, gloves are still required in some situations such as when caring for clients with *C. difficile* (Hand washing ineffective, gloves must be used, 2013).

The CDC promotes the use of alcohol-based hand rubs (foam or gel) because:

- They kill bacteria more effectively and more quickly than hand washing with soap and water.
- They are less damaging to skin than soap and water, resulting in less dryness and irritation.
- They require less time than hand washing with soap and water.
- Bottles/dispensers can be placed at the point of care so they are more accessible.

Proper use of alcohol-based products includes following these steps:

- Apply a palmful of product into cupped hand—enough to cover all surfaces of both hands.
- Rub palms against palms.

- Interlace fingers palm to palm.
- Rub palms to back of hands.
- Rub all surfaces of each finger with opposite hand.
- Continue until product is dry—about 20 to 30 seconds.

CLINICAL ALERT!

Although some religions prohibit drinking alcohol, all accept the value of using alcohol-based hand rubs in health care settings (Longtin, Sax, Allegranzi, Schneider, & Pittet, 2011).

It is important to recognize that performing hand hygiene with either soap or alcohol-based cleansers can damage the skin through the drying effect of the detergents or chemicals. If the nurse develops dermatitis, the client may be at higher risk because hand washing does not decrease bacterial counts on skin with dermatitis. The nurse is also at higher risk because the normal skin barrier has been broken. Although lotions, moisturizers, and emollients have been tried, no research has yet confirmed their effectiveness in decreasing the damage.

Skill 31–1 describes proper hand hygiene techniques using soap and water.

Performing Hand Hygiene

PURPOSES

- To reduce the number of microorganisms on the hands
- To reduce the risk of transmission of microorganisms to clients
- To reduce the risk of cross contamination among clients
- To reduce the risk of transmission of infectious organisms to oneself

ASSESSMENT

Determine the client's:

- Presence of factors increasing susceptibility to infection and possibility of undiagnosed infection (e.g., HIV)
- Use of immunosuppressive medications
- Recent diagnostic procedures or treatments that penetrated the skin or a body cavity
- Current nutritional status
- Signs and symptoms indicating the presence of an infection:
 - *Localized signs:* swelling, redness, pain or tenderness with palpation or movement, palpable heat at site, loss of function of affected body part, presence of exudate
 - *Systemic indications:* fever, increased pulse and respiratory rates, lack of energy, anorexia, enlarged lymph nodes

PLANNING

Determine the location of running water and soap or soap substitutes.

DELEGATION

The skill of hand hygiene is identical for all health care providers, including unlicensed assistive personnel (UAP). Health care team members are accountable for themselves and others to implement appropriate hand washing procedures.

INTERPROFESSIONAL PRACTICE

Hand washing is an essential skill for all health care providers.

Equipment

- Soap
- Warm running water
- Paper towels

IMPLEMENTATION

Preparation

Assess the hands:

- Nails should be kept short. Most agencies do not permit health care workers in direct contact with clients to have any form of artificial nails. The CDC guidelines prohibit artificial nails in caring for high-risk clients, and the WHO guidelines prohibit artificial nails in all settings. **Rationale:** *Short, natural nails are less likely to harbor microorganisms, scratch a client, or puncture gloves.*
- Removal of all jewelry is recommended. **Rationale:** *Although the research is controversial, microorganisms can lodge in the settings of jewelry and under rings. Removal facilitates proper cleaning of the hands and arms.*
- Check hands for breaks in the skin, such as hangnails or cuts. **Rationale:** *A nurse who has open sores may require a work assignment with decreased risk for transmission of infectious organisms due to the chance of acquiring or passing on an infection.*

Performing Hand Hygiene—continued

Performance

- If you are washing your hands where the client can observe you, introduce yourself and explain to the client what you are going to do and why it is necessary.
- Turn on the water and adjust the flow.
 - There are five common types of faucet controls:
 - Hand-operated handles.
 - Knee levers.
 - Foot pedals.
 - Elbow controls. Move these with the elbows instead of the hands.
 - Infrared control. Motion in front of the sensor causes water to start and stop flowing automatically.
 - Adjust the flow so that the water is warm. **Rationale:** Warm water removes less of the protective oil of the skin than hot water.
- Wet the hands thoroughly by holding them under the running water and apply soap to the hands.
 - Hold the hands lower than the elbows so that the water flows from the arms to the fingertips. **Rationale:** The water should flow from the least contaminated to the most contaminated area; the hands are generally considered more contaminated than the lower arms. Note that this is a different technique than is used when performing surgical hand washing. Nurses will learn to perform that level of hand washing if they are working in the operating room.
 - If the soap is liquid, apply 4 to 5 mL (1 tsp). If it is bar soap, granules, or sheets, rub them firmly between the hands.
- Thoroughly wash and rinse the hands.
 - Use firm, rubbing, and circular movements to wash the palm, back, and wrist of each hand. Be sure to include the heel of the hand. Interlace the fingers and thumbs, and move the hands back and forth. ❶ The WHO (2009) recommends these steps:
 - Right palm over left dorsum with interlaced fingers and vice versa
 - Palm to palm with fingers interlaced
 - Backs of fingers to opposing palms with fingers interlocked
 - Rotational rubbing of left thumb clasped in right palm and vice versa.
 Continue these motions for about 30 seconds.

Rationale: The circular action creates friction that helps remove microorganisms mechanically. Interlacing the fingers and thumbs cleans the interdigital spaces.

- Rub the fingertips against the palm of the opposite hand. **Rationale:** The nails and fingertips are commonly missed during hand hygiene.
 - Rinse the hands.
- Thoroughly pat dry the hands and arms.
 - Dry hands and arms thoroughly with a paper towel without scrubbing. **Rationale:** Moist skin becomes chapped readily as does dry skin that is rubbed vigorously; chapping produces lesions.
 - Discard the paper towel in the appropriate container.

❶ Hand washing steps.

Performing Hand Hygiene—continued

2 Using a paper towel to grasp the handle of a hand-operated faucet.

6. Turn off the water.

- Use a new paper towel to grasp a hand-operated control.

2 Rationale: This prevents the nurse from picking up microorganisms from the faucet handles.

EVALUATION

- There is no traditional evaluation of the effectiveness of the individual nurse's hand washing practices. Institutional quality control departments monitor the occurrence of client infections and investigate those situations in which health care providers are implicated in the transmission of infectious organisms. Research has repeatedly shown the positive impact of careful hand hygiene on client health associated with prevention of infection (see Readings and References at the end of this chapter). More

Apply hand lotion if desired. Use only agency-approved hand lotions and dispensers. Other lotions may make hand hygiene less effective, cause the breakdown of latex gloves, and become contaminated with bacteria if dispensers are refilled. **Rationale:** Hand lotions are important to prevent skin dryness and irritation.

Variation: Hand Washing Before Performing Sterile Skills

- Apply the soap and wash as described in step 4, but hold the hands higher than the elbows during this hand wash. Wet the hands and forearms under the running water, letting it run from the fingertips to the elbows so that the hands become cleaner than the elbows.

Rationale: In this way, the water runs from the area that now has the fewest microorganisms to areas with a relatively greater number of pathogens.

- After washing and rinsing, use a towel to dry one hand thoroughly in a rotating motion from the fingers to the elbow. Use a new towel to dry the other hand and arm.

Rationale: A clean towel prevents the transfer of microorganisms from one elbow (least clean area) to the other hand (cleanest area).

- Apply sterile gloves before touching any unsterile items (see Skill 31-4).

researchers are focusing on the relationship between quality of hand hygiene products (gentle, nondrying, aromatic) and adherence to recommended protocols.

Note: In some agencies, clients are encouraged to ask the provider if they have cleansed their hands before allowing them to perform procedures (McGuckin & Govednik, 2013).

Home Care Considerations Hand Hygiene

PATIENT-CENTERED CARE

When making a home visit:

- Keep fingernails clean, short, and well trimmed.
- Perform hand hygiene carefully before and after any hands-on care.
- If there is no running water, use commercially available hand hygiene agents that require no water.

- You may wish to bring your own alcohol-based rub or bactericidal soap and paper towels for use when performing hand hygiene.
- Always turn the water off with a dry paper towel.

Supporting Defenses of a Susceptible Host

People are constantly in contact with microorganisms in the environment. Normally a person's natural defenses ward off the development of an infection. *Susceptibility* is the degree to which an individual can be affected, that is, the likelihood of an organism causing an infection in that person. The following measures can reduce a person's susceptibility:

- **Hygiene.** Intact skin and mucous membranes are one barrier against microorganisms entering the body. In addition, good oral care, including flossing the teeth, reduces the likelihood of an oral infection. Regular and thorough bathing and shampooing remove microorganisms and dirt that can result in an infection.
- **Nutrition.** A balanced diet enhances the health of all body tissues, helps keep the skin intact, and promotes the skin's ability to repel microorganisms. Adequate nutrition enables tissues to maintain

and rebuild themselves and helps keep the immune system functioning well.

- **Fluid.** Fluid intake permits fluid output that flushes out the bladder and urethra, removing microorganisms that could cause an infection.
- **Sleep.** Adequate sleep is essential to health and to renewing energy. See Chapter 45.
- **Stress.** Excessive stress predisposes people to infections. Nurses can assist clients to learn stress-reducing techniques. See Chapter 42.
- **Immunizations.** The use of immunizations has dramatically decreased the incidence of infectious diseases. It is recommended that immunizations begin shortly after birth and be completed in early childhood except for boosters. Go to nursing.pearsonhighered.com to download the Recommended Immunization Schedule for Persons Aged 0 Through 18 Years—United States, table.

DRUG CAPSULE

Macrolide Antibiotic Azithromycin (Zithromax)

Macrolide antibiotics prevent bacteria from growing by interfering with their ability to make proteins. Due to the differences in the way proteins are made in bacteria and humans, the macrolide antibiotics do not interfere with humans' ability to make proteins. They are effective against a wide variety of bacterial organisms, including *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Mycoplasma pneumoniae*, *S. aureus*, and *Mycobacterium avium*. Azithromycin is unusual in that it stays in the body for quite a while, allowing for once-a-day dosing and for shorter treatment courses for most infections. It may be prescribed for infections from susceptible microorganisms such as those that occur in the lungs (bronchitis), ears, skin, and throat. A common oral azithromycin treatment consists of a "double dose" of medication on the first day of treatment and then a single dose for an additional 4 or 5 days. This is often dispensed and referred to as a "Z-Pak" that contains all the pills needed for the full course: two tablets on the first day and one tablet once daily for the next 4 or 5 days.

NURSING RESPONSIBILITIES

- Assess the client for any drug allergies—especially to other antibiotics and particularly those from the erythromycin family. Do not administer azithromycin to clients with stated allergies unless the primary care provider has given approval.
- Assess for signs of possible allergic reaction: rash, hives, itching, swelling of the face or mouth, and difficulty breathing

or swallowing. If any are detected, contact the primary care provider immediately—this is an emergency.

- Azithromycin may be given with meals or on an empty stomach.
- It is available in capsule form or as an oral liquid suspension.
- Drug interactions can occur with anticoagulants, digoxin, and several other medications. Always check the list of client medications for possible interactions.
- Adverse effects are generally limited to GI upset.

CLIENT AND FAMILY TEACHING

- Assess and document client's level of understanding related to medication therapy. Develop a teaching plan to augment any lack of knowledge on the part of the client or family caregiver.
- Teach the client to take azithromycin with a full glass of water, with or without food, but at least 2 hours after antacids.
- Teach the client to complete the entire course of therapy. Stress that the client should not stop taking the medication even if he or she feels better before finishing the course of therapy.
- Instruct to store the medication away from heat and moisture—not in the bathroom.
- Be sure the client understands not to keep leftover medication or share it with other individuals.

Note: Prior to administering any medication, review all aspects with a current drug handbook or other reliable source.

Immunizations may be given by injection, inhalation, oral solutions, or nasal sprays. They are frequently given in combination to minimize multiple injections. Because immunization schedules change frequently, they should be updated yearly.

Immunization programs have been developed for high-risk groups such as health care personnel, older adults who are chronically ill, and people traveling to foreign countries. For example, hepatitis B vaccine is recommended for all health care workers.

Disinfecting and Sterilizing

The first links in the chain of infection, the etiologic agent and the reservoir, are interrupted by the use of **antiseptics** (agents that inhibit the growth of some microorganisms) and **disinfectants** (agents that destroy pathogens other than spores) and by sterilization.

Disinfecting

An antiseptic is a chemical preparation used on skin or tissue. A disinfectant is a chemical preparation, such as phenol or iodine compounds, used on inanimate objects. Disinfectants are frequently caustic and toxic to tissues. Antiseptics and disinfectants often have similar chemical components, but the disinfectant is a more concentrated solution.

Both antiseptics and disinfectants are said to have bactericidal or bacteriostatic properties. A *bactericidal* preparation destroys bacteria, whereas a *bacteriostatic* preparation prevents the growth and reproduction of some bacteria. An agent known to be effective against a particular type of bacteria should be selected. Spore-forming bacteria such as *C. difficile*, which is a frequent cause of nosocomial diarrhea, and *Bacillus anthracis* (anthrax) may be

inhibited by only a few of the agents normally effective against other forms of bacteria. Table 31–6 lists commonly used antiseptics and disinfectants.

When disinfecting articles, nurses need to follow agency protocol and consider the following:

1. The type and number of infectious organisms. Some microorganisms are readily destroyed, whereas others require longer contact with the disinfectant.
2. The recommended concentration of the disinfectant and the duration of contact.
3. The presence of soap. Some disinfectants are ineffective in the presence of soap or detergent.
4. The presence of organic materials. The presence of saliva, blood, pus, or excretions can readily inactivate many disinfectants.
5. The surface areas to be treated. The disinfecting agent must come into contact with all surfaces and areas.

Sterilizing

Sterilization is a process that destroys all microorganisms, including spores and viruses. Four commonly used methods of sterilization are moist heat, gas, boiling water, and radiation.

Moist Heat To sterilize with moist heat (such as with an autoclave), steam under pressure is used because it attains temperatures higher than the boiling point.

Gas Ethylene oxide gas destroys microorganisms by interfering with their metabolic processes. It is also effective against spores. Its advantages are good penetration and effectiveness for heat-sensitive items. Its major disadvantage is its toxicity to humans.

TABLE 31-6 Commonly Used Antiseptics and Disinfectants and Their Effectiveness and Use

Agent	Bacteria	Tuberculosis	Effective Against		Viruses	Use on
			Spores	Fungi		
Isopropyl and ethyl alcohol	X	X		X	X	Hands, vial stoppers
Chlorine (bleach)	X	X	X	X	X	Blood spills
Hydrogen peroxide	X	X	X	X	X	Surfaces
Iodophors	X	X	X	X	X	Equipment; intact skin and tissues if diluted
Phenol	X	X		X	X	Surfaces
Chlorhexidine gluconate (Hibiclens)	X				X	Hands
Triclosan (Bacti-Stat)	X					Hands, intact skin

Boiling Water This is the most practical and inexpensive method for sterilizing in the home. The main disadvantage is that spores and some viruses are not killed by this method. Boiling a minimum of 15 minutes is advised for disinfection of articles in the home.

Radiation Both ionizing (such as alpha, beta, and x-rays) and non-ionizing (ultraviolet light) radiation are used for disinfection and sterilization. The main drawback to ultraviolet light is that the rays do not penetrate deeply. Ionizing radiation is used effectively in industry to sterilize foods, drugs, and other items that are sensitive to heat. Its main advantage is that it is effective for items difficult to sterilize; its chief disadvantage is that the equipment is very expensive.

Infection Prevention and Control

Microorganisms occur normally in various locations of the human body such as the surface of the skin and the GI tract. Usually, they do not cause infection in the client. When the microorganisms enter a different part of the client's body, however, or if the client's immune system is suppressed, infection may occur. Also, these same microorganisms could cause infection in another person. Because it is not always possible to know which clients may have infectious organisms, a set of guidelines has been established by the CDC (Siegel, Rhinehart, Jackson, Chiarello, & the Healthcare Infection Control Practices Advisory Committee, 2007) and other organizations outlining steps all health care workers must follow to reduce the chances that organisms in blood (**bloodborne pathogens**) and potentially infectious organisms from other body tissues will be transmitted from the client to other individuals. The isolation guidelines contain a two-tiered approach. The first is **standard precautions (SP)**. Some agencies may use an earlier term—**universal precautions (UP)**—reflecting their applicability in all client care situations.

The CDC-published recommendations reinforce the need for effective hand hygiene, use of personal protective equipment, and environmental controls. They also include **respiratory hygiene/cough etiquette** that calls for covering the mouth and nose when sneezing or coughing, proper disposal of tissues, and separating potentially infected individuals from others by at least 1 m (3 ft) or having them wear a surgical mask. Health care professionals use SP when providing care to all clients. That is, the risk of caregiver exposure to client body tissues and fluids rather than the suspected presence or absence of infectious organisms determines the use of clean gloves, gowns, masks, and eye protection.

If the client is known to have an infection, the CDC's second tier, transmission-based precautions, are used to protect the nurse and others from acquiring the infectious organism. These precautions are used in addition to SP when those precautions do not completely block the chain of infection and the infections are spread in one of three ways: by airborne or droplet transmission or by contact. Transmission-based precautions may be used singly or in combination.

Isolation refers to measures designed to prevent the spread of infections or potentially infectious microorganisms to health personnel, clients, and visitors. Several sets of guidelines have been used in hospitals and other health care settings.

Category-specific isolation precautions use seven categories: strict isolation, contact isolation, respiratory isolation, tuberculosis isolation, enteric precautions, drainage/secretions precautions, and blood/body fluid precautions.

Disease-specific isolation precautions provide precautions for specific diseases. These precautions delineate use of private rooms with special ventilation, having the client share a room with other clients infected with the same organism, and gowning to prevent gross soiling of clothes for specific infectious diseases.

Standard Precautions

Standard precautions are used in the care of all hospitalized individuals regardless of their diagnosis or possible infection status. They are used in any situations involving blood, all body fluids, excretions, and secretions except sweat (whether or not blood is present or visible), nonintact skin, and mucous membranes. SP include (a) hand hygiene; (b) use of **personal protective equipment (PPE)**, which includes gloves, gowns, eyewear, and masks; (c) safe injection practices; (d) safe handling of potentially contaminated equipment or surfaces in the client environment; and (e) respiratory hygiene/cough etiquette.

Transmission-Based Precautions

Transmission-based precautions are used in addition to standard precautions for clients with known or suspected infections that are spread in one of three ways: by airborne or droplet transmission, or by contact. The three types of transmission-based precautions may be used alone or in combination but always in addition to standard precautions. Recommended practices for standard and transmission-based precautions are shown in Box 31-1.

BOX 31-1 Recommended Isolation Precautions in Hospitals**STANDARD PRECAUTIONS**

- Designed for all clients in hospital.
 - These precautions apply to (a) blood; (b) all body fluids, excretions, and secretions except sweat; (c) nonintact (broken) skin; and (d) mucous membranes.
 - Designed to reduce risk of transmission of microorganisms from recognized and unrecognized sources.
1. Perform proper hand hygiene after contact with blood, body fluids, secretions, excretions, and contaminated objects whether or not gloves are worn.
 - a. Perform proper hand hygiene immediately after removing gloves.
 - b. Use a nonantimicrobial product for routine hand hygiene.
 - c. Use an antimicrobial agent or an antiseptic agent for the control of specific outbreaks of infection.
 2. Wear clean gloves when touching blood, body fluids, secretions, excretions, and contaminated items (i.e., soiled gowns).
 - a. Clean gloves can be unsterile unless their use is intended to prevent the entrance of microorganisms into the body. See the discussion of sterile gloves in this chapter.
 - b. Remove gloves before touching noncontaminated items and surfaces.
 - c. Perform proper hand hygiene immediately after removing gloves.
 3. Wear a mask, eye protection, or a face shield if splashes or sprays of blood, body fluids, secretions, or excretions can be expected.
 4. Wear a clean, nonsterile, water-resistant gown if client care is likely to result in splashes or sprays of blood, body fluids, secretions, or excretions. The gown is intended to protect clothing.
 - a. Remove a soiled gown carefully to avoid the transfer of microorganisms to others (i.e., clients or other health care workers).
 - b. Cleanse hands after removing gown.
 5. Handle client care equipment that is soiled with blood, body fluids, secretions, or excretions carefully to prevent the transfer of microorganisms to others and to the environment.
 - a. Make sure reusable equipment is cleaned and reprocessed correctly.
 - b. Dispose of single-use equipment correctly.
 6. Handle all soiled linen as little as possible. Do not shake it. Bundle it up with the clean side out and dirty side in, and hold away from self so that the nurse's uniform or clothing is not contaminated.
 7. Place used needles and other "sharps" directly into puncture-resistant containers as soon as their use is completed. Do not attempt to recap needles or place sharps back in their sheaths using two hands; use the one-handed scoop technique or other safety device. Using two hands can result in a needlestick puncture injury if the nurse accidentally misses the cover.

TRANSMISSION-BASED PRECAUTIONS**Airborne Precautions**

Use standard precautions as well as the following:

1. Place client in an airborne infection isolation room (AIIR). An AIIR is a private room that has negative air pressure, 6 to 12 air

changes per hour, and either discharge of air to the outside or a filtration system for the room air.

2. If a private room is not available, place client with another client who is infected with the same microorganism.
3. Wear an N95 respirator mask when entering the room of a client who is known to have or suspected of having primary tuberculosis. See the Practice Guidelines on applying a respirator mask.
4. Susceptible people should not enter the room of a client who has rubeola (measles) or varicella (chickenpox). If they must enter, they should wear a respirator mask.
5. Limit movement of client outside the room to essential purposes. Place a surgical mask on the client during transport.

Droplet Precautions

Use standard precautions as well as the following:

1. Place client in private room.
2. If a private room is not available, place client with another client who is infected with the same microorganism.
3. Wear a mask if working within 1 m (3 ft) of the client.
4. Limit movement of client outside the room to essential purposes. Place a surgical mask on the client while outside the room.

Contact Precautions

Use standard precautions as well as the following:

1. Place client in private room.
2. If a private room is not available, place client with another client who is infected with the same microorganism.
3. Wear gloves as described in standard precautions.
 - a. Change gloves after contact with infectious material.
 - b. Remove gloves before leaving client's room.
 - c. Cleanse hands immediately after removing gloves. Use an antimicrobial agent. *Note:* If the client is infected with *C. difficile*, do not use an alcohol-based hand rub because it is not effective on these spores. Use soap and water.
 - d. After hand hygiene, do not touch possibly contaminated surfaces or items in the room.
4. Wear a gown (see standard precautions) when entering a room if there is a possibility of contact with infected surfaces or items, or if the client is incontinent, or has diarrhea, a colostomy, or wound drainage not contained by a dressing.
 - a. Remove gown in the client's room.
 - b. Make sure uniform does not contact possible contaminated surfaces.
5. Limit movement of client outside the room.
6. Dedicate the use of noncritical client care equipment to a single client or to clients with the same infecting microorganisms.

Adapted from "2007 Guidelines for Isolation Precautions Preventing Transmission of Infectious Agents in Healthcare Settings," by J. D. Siegel, E. Rhinehart, M. Jackson, L. Chiarello, and the Healthcare Infection Control Practices Advisory Committee, 2007. Retrieved from <http://www.cdc.gov/ncidod/dhqp/pdf/isolation2007.pdf>.

Airborne precautions are used for clients known to have or suspected of having serious illnesses transmitted by airborne droplet nuclei smaller than 5 microns. Examples of such illnesses include measles (rubeola), varicella (including disseminated zoster), and tuberculosis. The CDC has prepared special guidelines for preventing

the transmission of tuberculosis. The most current information may be found on the CDC Division of Tuberculosis Elimination website.

Droplet precautions are used for clients known to have or suspected of having serious illnesses transmitted by particle droplets larger than 5 microns. Examples of such illnesses are diphtheria

(pharyngeal); mycoplasma pneumonia; pertussis; mumps; rubella; streptococcal pharyngitis, pneumonia, or scarlet fever in infants and young children; and pneumonic plague.

Contact precautions are used for clients known to have or suspected of having serious illnesses easily transmitted by direct client contact or by contact with items in the client's environment. According to the CDC, such illnesses include GI, respiratory, skin, or wound infections or colonization with multidrug-resistant bacteria; specific enteric infections such as *C. difficile* and enterohemorrhagic *E. coli O157:H7*, *Shigella*, and hepatitis A, for diapered or incontinent clients; respiratory syncytial virus, parainfluenza virus, or enteroviral infections in infants and young children; and highly contagious skin infections such as herpes simplex virus, impetigo, pediculosis, and scabies.

Another organism requiring contact precautions is methicillin-resistant *S. aureus* (MRSA). Approximately half of all MRSA infections are acquired in the hospital, one fourth are associated with having received health care but onset is in the community; the remainder are considered community acquired (Jarvis, Jarvis, & Chinn, 2012). Due to aggressive health care emphasis on prevention of MRSA transmission using standard and contact precautions, rates have decreased but are still unacceptably high. More Americans die each year from MRSA than from AIDS (MRSA Research Center, 2013).

In addition to the preceding conditions, special contact precautions are used for vancomycin-resistant enterococci (VRE) infections. The CDC recommends use of an antimicrobial soap for hand washing and no sharing of equipment among clients with and without VRE. The client should have a private room (or a room with other clients who have VRE), and such isolation should continue until at least three cultures taken 1 week apart are negative (Siegel et al., 2007).

Some diseases require a combination of transmission-based precautions. For clients infected with the coronavirus that causes severe acute respiratory syndrome (SARS-CoV), standard (including eye protection), contact, and airborne precautions are indicated (Siegel et al., 2007).

When certain conditions exist, transmission-based precautions are indicated until the presence or absence of the suspected agent has been confirmed. For example, for a generalized petechial rash with fever and a history of travel in an area known to have viral hemorrhagic fever, droplet and contact precautions are used until viruses such as Ebola or Lassa have been ruled out. In contrast, airborne precautions should be initiated if a maculopapular rash with fever, cough, and nasal congestion is present and rubeola has not been eliminated as a possible cause.

Compromised Clients

Compromised clients (those highly susceptible to infection) are often infected by their own microorganisms, by microorganisms on the inadequately cleansed hands of health care personnel, and by nonsterile items (food, water, air, and client-care equipment). Clients who are severely compromised include those who:

- Have diseases, such as leukemia, or treatments such as chemotherapy, that depress the client's resistance to infectious organisms.
- Have extensive skin impairments, such as severe dermatitis or major burns, which cannot be effectively covered with dressings.

The 2007 CDC guidelines (Siegel et al., 2007) for care of severely compromised (immunocompromised) clients include the use of standard precautions as described earlier.

Isolation Practices

Initiation of practices to prevent the transmission of microorganisms is generally a nursing responsibility and is based on a comprehensive assessment of the client. This assessment takes into account the status of the client's normal defense mechanisms, the client's ability to implement necessary precautions, and the source and mode of transmission of the infectious agent. The nurse then decides whether to wear gloves, gowns, masks, and protective eyewear. In all client situations, *nurses must cleanse their hands before and after giving care.*

In addition to the precautions cited within this chapter, the nurse implements aseptic precautions when performing many specific therapies discussed throughout nursing texts. The following are some examples:

- Use strict aseptic technique when performing any invasive procedure (e.g., inserting an intravenous needle or catheter) and when changing surgical dressings.
- Change intravenous tubing and solution containers according to hospital policy (e.g., every 48 to 72 hours).
- Check all sterile supplies for expiration date and intact packaging.
- Prevent urinary infections by maintaining a closed urinary drainage system with a downhill flow of urine. Keep the drainage bag and spout off the floor.
- Implement measures to prevent impaired skin integrity and to prevent accumulation of secretions in the lungs (for example, encourage the client to move, cough, and breathe deeply at least every 2 hours).

Personal Protective Equipment

All health care providers must apply PPE (clean or sterile gloves, gowns, masks, and protective eyewear) according to the risk of exposure to potentially infective materials.

Gloves Gloves are worn for three reasons: First, they protect the hands when the nurse is likely to handle any body substances, for example, blood, urine, feces, sputum, and nonintact skin. Second, gloves reduce the likelihood of nurses transmitting their own endogenous microorganisms to individuals receiving care. Nurses who have open sores or cuts on the hands must wear gloves for protection. Third, gloves reduce the chance that the nurse's hands will transmit microorganisms from one client or an object to another client. In all situations, gloves are changed between client contacts. The hands are cleansed each time gloves are removed for two primary reasons: (1) The gloves may have imperfections or be damaged during wearing so that they could allow microorganism entry and (2) the hands may become contaminated during glove removal.

Some of the gloves used in infection prevention may be made of latex rubber, as are various other items used in health care (catheters, blood pressure cuffs, rubber sheets, intravenous tubing, stockings and binders, adhesive bandages, and dental dams). Because of the frequent use of gloves, clients with chronic illnesses and health care workers have increasingly reported allergic reactions to latex. Latex gloves lubricated with powder or cornstarch are particularly allergenic because the latex allergen adheres to the powder, which

is aerosolized during glove use and inhaled by the user. Latex gloves that are labeled “hypoallergenic” still contain measurable latex and should not be used by or on individuals with known latex sensitivity. Approximately 8% to 12% of health care personnel have latex sensitivity. The people at greatest risk for developing latex allergies are those with other allergies and those who have had frequent or long-term exposure to latex. A newer formulation of latex, aluminum hydroxide–modified natural rubber latex, has been developed that reduces the antigenic protein content while preserving the durability, comfort, fit, tactile sensitivity, and high resistance to punctures and tearing for which latex is known (Doyle, 2011). Nurses may see these latex gloves in use.

Latex allergies can be either local or systemic and may take the form of dermatitis, urticaria (hives), asthma, or anaphylaxis. Clients

and health care workers should be assessed for possible allergies through a thorough history taking. Ask clients if they have had any adverse reactions to items such as balloons, condoms, or dishwashing or utility gloves. Strategies to avoid sensitization or exposure to latex include use of nonlatex products, nonlatex barriers between latex products and the skin, and gloves that are unpowdered or washed before use. People with significant allergies should have no contact with latex products. Most hospitals have eliminated latex products wherever possible and have established a “latex-free environment” goal. Alternatives to latex gloves include both vinyl and nitrile but due to the high failure rate of vinyl gloves, nitrile gloves are preferable for clinical procedures that require manual dexterity and/or will involve more than brief client contact (Siegel et al., 2007).

Skill 31–2 describes application and removal of gloves.

Applying and Removing Personal Protective Equipment (Gloves, Gown, Mask, Eyewear)

PURPOSE

- To protect health care workers and clients from transmission of potentially infective materials

ASSESSMENT

Consider which activities will be required while the nurse is in the client’s room at this time. **Rationale:** *This will determine which equipment is required.*

PLANNING

- Application and removal of PPE can be time consuming. Prioritize care and arrange for personnel to care for your other clients if indicated.
- Determine which supplies are present within the client’s room and which must be brought to the room.
- Consider if special handling is indicated for removal of any specimens or other materials from the room.

DELEGATION

Use of PPE is identical for all health care providers. Clients whose care requires use of PPE may be delegated to UAP. Health care team members are accountable for proper implementation of these procedures by themselves and others.

IMPLEMENTATION

Preparation

Remove or secure all loose items such as name tags or jewelry.

Performance

- Prior to performing the procedure, introduce self and verify the client’s identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
- Perform hand hygiene.
- Apply a clean gown.
 - Pick up a clean gown, and allow it to unfold in front of you without allowing it to touch any area soiled with body substances.
 - Slide the arms and the hands through the sleeves.
 - Fasten the ties at the neck to keep the gown in place.
 - Overlap the gown at the back as much as possible, and fasten the waist ties or belt. **1 Rationale:** *Overlapping securely covers the uniform at the back. Waist ties keep the gown from falling away from the body, which can cause inadvertent soiling of the uniform.*

Equipment

As indicated according to which activities will be performed, ensure that extra supplies are easily available.

- Gown
- Mask
- Eyewear
- Clean gloves

INTERPROFESSIONAL PRACTICE

Proper use of PPE is an essential skill for all health care providers.

- Overlapping the gown at the back to cover the nurse’s uniform.

Applying and Removing Personal Protective Equipment—continued

2 A face mask and eye protection covering the nose, mouth, and eyes. Custom Medical Stock Photo/Custom Medical Stock Photo.

4. Apply the face mask.

- Locate the top edge of the mask. The mask usually has a narrow metal strip along the edge.
- Hold the mask by the top two strings or loops.
- Place the upper edge of the mask over the bridge of the nose, and tie the upper ties at the back of the head or secure the loops around the ears. If glasses are worn, fit the upper edge of the mask under the glasses. **Rationale:** *With the edge of the mask under the glasses, clouding of the glasses is less likely to occur.*
- Secure the lower edge of the mask under the chin, and tie the lower ties at the nape of the neck. 2 **Rationale:** *To be effective, a mask must cover both the nose and the mouth, because air moves in and out of both.*
- If the mask has a metal strip, adjust this firmly over the bridge of the nose. **Rationale:** *A secure fit prevents both the escape and the inhalation of microorganisms around the edges of the mask and the fogging of eyeglasses.*
- Wear the mask only once, and do not wear any mask longer than the manufacturer recommends or once it becomes wet. **Rationale:** *A mask should be used only once because it becomes ineffective when moist.*
- Do not leave a used face mask hanging around the neck.
- The Practice Guidelines provide further instructions on applying a face mask.

5. Apply protective eyewear if it is not combined with the face mask.

6. Apply clean gloves.

- No special technique is required.
- If wearing a gown, pull the gloves up to cover the cuffs of the gown. If not wearing a gown, pull the gloves up to cover the wrists.

7. To remove soiled PPE, remove the gloves first since they are the most soiled.

- If wearing a gown that is tied at the waist in front, undo the ties before removing gloves.
- Remove the first glove by grasping it on its palmar surface, taking care to touch only glove to glove. 3 **Rationale:** *This*

3 Plucking the palmar surface of a contaminated glove.

4 Inserting fingers to remove the second contaminated glove.

keeps the soiled parts of the used gloves from touching the skin of the wrist or hand.

- Pull the first glove completely off by inverting or rolling the glove inside out.
 - Continue to hold the inverted removed glove by the fingers of the remaining gloved hand. Place the first two fingers of the bare hand inside the cuff of the second glove. 4 **Rationale:** *Touching the outside of the second soiled glove with the bare hand is avoided.*
 - Pull the second glove off to the fingers by turning it inside out. This pulls the first glove inside the second glove. **Rationale:** *The soiled part of the glove is folded to the inside to reduce the chance of transferring any microorganisms by direct contact.*
 - Using the bare hand, continue to remove the gloves, which are now inside out, and dispose of them in the refuse container. 5
8. Perform hand hygiene. **Rationale:** *Contact with microorganisms may occur while removing PPE.*
9. Remove protective eyewear and dispose of properly or place in the appropriate receptacle for cleaning.
10. Remove the gown when preparing to leave the room.
- Avoid touching soiled parts on the outside of the gown, if possible. **Rationale:** *The top part of the gown may be soiled, for example, if you have been holding an infant with a respiratory infection.*

Applying and Removing Personal Protective Equipment—continued

5 Holding contaminated gloves that are inside out.

- Grasp the gown along the inside of the neck and pull down over the shoulders. Do not shake the gown.
 - Roll up the gown with the soiled part inside, and discard it in the appropriate container.
11. Remove the mask.
- Remove the mask at the doorway to the client's room. If using a respirator mask, remove it after leaving the room and closing the door.
 - If using a mask with strings, first untie the lower strings of the mask. **Rationale:** *This prevents the top part of the mask from falling onto the chest.*
 - Untie the top strings and, while holding the ties securely, remove the mask from the face. If side loops are present, lift the side loops up and away from the ears and face. Do not touch the front of the mask. **Rationale:** *The front of the mask through which the nurse has been breathing is contaminated.*
 - Discard a disposable mask in the waste container.
 - Perform proper hand hygiene again.

EVALUATION

- Conduct any follow-up indicated during your care of the client. If there has been any failure of the equipment and exposure to potentially infective materials is suspected, follow the procedure in the Practice Guidelines: Steps to Follow After Exposure to Bloodborne Pathogens later in this chapter.
- Ensure that an adequate supply of equipment is available for the next health care provider.

Home Care Considerations Standard Precautions and Personal Protective Equipment

SAFETY

- All aspects of standard precautions apply equally in the home care setting.
- Ensure that the supply of gloves, gowns, masks, and eyewear is adequate.
- Ensure that procedures are in place for removal and disposal of used materials.
- Teach the client and family appropriate aspects of standard precautions.

Gowns Clean or disposable impervious (water-resistant) gowns or plastic aprons are worn during procedures when the nurse's uniform is likely to become soiled. Sterile gowns may be indicated when the nurse changes the dressings of a client with extensive wounds (e.g., burns). *Single-use gown technique* (using a gown only once before it is discarded or laundered) is the usual practice in hospitals. After the gown is worn, the nurse discards it (if it is paper) or places it in a laundry hamper. Skill 31-2 describes the steps for applying and removing a gown. Before leaving the client's room, the nurse cleanses his or her hands.

CLINICAL ALERT!

Wearing a client hospital gown over your uniform serves no infection prevention purpose.

Face Masks Masks are worn to reduce the risk for transmission of organisms by the droplet contact and airborne routes and by splatters of body substances. The CDC recommends that masks be worn:

- By those close to the client if the infection (e.g., measles, mumps, or acute respiratory diseases in children) is transmitted by

large-particle aerosols (droplets). Large-particle aerosols are transmitted by close contact and generally travel short distances (about 1 m, or 3 ft).

- By all individuals entering the room if the infection (e.g., pulmonary tuberculosis and SARS-CoV) is transmitted by small-particle aerosols (droplet nuclei). Small-particle aerosols remain suspended in the air and thus travel greater distances by air. Special masks that provide a tighter face seal and better filtration may be used for these infections.

Various types of masks differ in their filtration effectiveness and fit. Single-use disposable surgical masks are effective for use while the nurse provides care to most clients but should be changed if they become wet or soiled. These masks are discarded in the waste container after use. Disposable particulate respirators of different types may be effective for droplet transmission, splatters, and airborne microorganisms. Some respirators now available are effective in preventing inhalation of tuberculin organisms. The National Institute for Occupational Safety and Health tests and certifies such respirators. Currently, the category "N" respirator at 95% efficiency (referred to as an N95 respirator) meets tuberculosis, SARS, and influenza control criteria.

PRACTICE GUIDELINES

Using an N95 Respirator Mask

- Before handling the respirator, wash hands thoroughly with soap and water.
- If you have used a respirator before that fit you, you should use the same make, model, and size.
- Inspect the respirator for damages. If your respirator has been damaged, **DO NOT USE IT**. Get a new one.
- Anything that comes between the respirator and your face will make the respirator less effective. Do not allow facial hair, hair,

jewelry, glasses, or clothing to come between your face and the respirator or interfere with the placement of the respirator on the face.

If respirators are used for people performing work-related duties, employers must comply with the Occupational Safety and Health Administration’s (OSHA) Respiratory Protection Standard, 29 CFR 1910.134. Consult the OSHA website for more information.

Application

Remove the respirator from its packaging and hold with straps facing upward. Place the bottom strap under the center flaps next to the “WARNING” statement.

Fully open the top and bottom panels, bending the nosepiece around your thumb at center of the foam. Straps should separate when panels are opened. Make certain the bottom panel is unfolded and completely opened.

Place the respirator on your face so that the foam rests on your nose and the bottom panel is securely under your chin.

Pull the top strap over your head and position it high on the back of the head. Then, pull the bottom strap over your head and position it around your neck and below your ears.

Adjust for a comfortable fit by pulling the top panel toward the bridge of your nose and positioning the bottom panel under your chin.

Place fingertips from both hands at the top of your nose and mold the nosepiece around your nose to achieve a secure seal.

Place one or both hands completely over the middle panel. Inhale and exhale sharply. If air leaks around your nose, readjust the nosepiece. If air leaks between the face and faceseal of the respirator, reposition it by adjusting the panels and straps. If you cannot achieve a proper seal, do not enter the contaminated area. See your supervisor.

Please Note:

Check the seal of your three-panel facepiece respirator each time you don the respirator.

Removal

Without touching the respirator, slowly lift the bottom strap from around your neck up over your head.

Lift off the top strap. Do not touch the respirator.

Store or discard according to your facility’s infection control policy.

Evidence-Based Practice Is Wearing Two Pairs of Clean Gloves Better Than Wearing One?

EVIDENCE-BASED PRACTICE

During the removal of PPE after client care, the transfer of virus to the hands and clothing of the health care provider may occur. To determine whether double-gloving reduces virus transfer during removal of contaminated PPE, Casanova, Rutala, Weber, and Sobsey (2012) conducted a study using harmless bacteriophages. They compared the frequency and quantity of viral transfer to hands and clothes during PPE removal with single-gloving and double-gloving techniques. Participants donned PPE (i.e., contact isolation gown, N95 respirator, eye protection, gloves) contaminated with bacteriophages. Participants then removed the PPE, and their hands, face, and scrubs were sampled for virus. Viral transfer to hands during PPE removal was significantly more frequent with single-gloving than with double-gloving. Viral transfer to the uniform was similar during single-gloving and double-gloving.

IMPLICATIONS

The frequency of viral transfer suggests that the correct method of PPE removal should be examined, and providers should be warned that their current practices are likely contaminating their hands and uniforms. A single study, however, is not sufficient to result in a widespread change in practice. It is possible that infectious viral particles do not transfer in the same way as the bacteriophages used in the study. In addition, the study had only 18 participants. Therefore, the study should be replicated with much larger numbers of participants. Even if double-gloving is effective, some areas of the world could not accomplish this intervention due to cost or availability of gloves. In addition, health care providers should be encouraged not to develop a false sense of security based on the possibly erroneous belief that wearing two sets of gloves protects them from contamination.

During certain techniques requiring surgical asepsis (sterile technique), masks are worn (a) to prevent droplet contact transmission of exhaled microorganisms to the sterile field or to a client's open wound and (b) to protect the nurse from splashes of body substances from the client.

Guidelines for applying and removing face masks are shown in Skill 31–2 and in the Practice Guidelines.

Eyewear Protective eyewear (goggles, glasses, or face shields) and masks are indicated in situations where body substances may splatter the face (see Skill 31–2). If the nurse wears prescription eyeglasses, goggles must still be worn over the glasses because the protection must extend around the sides of the glasses.

Disposal of Soiled Equipment and Supplies

Many pieces of equipment are supplied for single use only and are disposed of after use. Some items, however, are reusable. Agencies have specific policies and procedures for handling soiled equipment (e.g., disposal, cleaning, disinfecting, and sterilizing); the nurse needs to become familiar with these practices in the employing agency. Appropriate handling of soiled equipment and supplies is essential for these reasons:

- To prevent inadvertent exposure of health care workers to articles contaminated with body substances
- To prevent contamination of the environment.

Bagging Articles contaminated, or likely to have been contaminated, with infective material such as pus, blood, body fluids, feces, or respiratory secretions need to be enclosed in a sturdy bag impervious to microorganisms before they are removed from the room of any client. Some agencies use labels or bags of a particular color that designate them as infective wastes.

CDC guidelines recommend the following methods:

- A single bag, if it is sturdy and impervious to microorganisms, and if the contaminated articles can be placed in the bag without soiling or contaminating its outside

- Double-bagging if the above conditions are not met.
- Follow agency protocol, or use the following CDC guidelines to handle and bag soiled items:
- Place garbage and soiled *disposable* equipment, including dressings and tissues, in the plastic bag that lines the waste container and tie the bag. If the bag is sturdy and impermeable to microorganisms (waterproof or solid enough to prevent organisms from moving through it even when wet), a single bag is adequate. If not, place the first bag inside another impermeable bag. Some agencies have a particular location where such garbage is to be placed and some use bags of a particular color (e.g., red) to indicate potentially infective waste. Some also separate dry and wet waste material and incinerate dry items, such as paper towels and disposable items. No special precautions are required for disposable equipment that is not contaminated.
- Place *nondisposable* or *reusable* equipment that is visibly soiled in a labeled bag before removing it from the client's room or cubicle, and send it to a central processing area for decontamination. Some agencies may require that glass bottles or jars and metal items be placed in separate bags from rubber and plastic items. Glass and metal can be sterilized in an autoclave, but rubber and plastic are damaged by this process and must be cleaned by other methods, such as gas sterilization.
- Disassemble special procedure trays into component parts. Some components are disposable; others need to be sent to the laundry or central services for cleaning and decontaminating.
- Bag soiled clothing before sending it home or to the agency laundry.

Linens Handle soiled linen as little as possible and with the least agitation possible before placing it in the laundry hamper. This prevents gross microbial contamination of the air and individuals handling the linen. Close the bag before sending it to the laundry in accordance with agency practice.

Laboratory Specimens Laboratory specimens, if placed in a leak-proof container with a secure lid with a biohazard label, need no

special precautions. Use care when collecting specimens to avoid contaminating the outside of the container. Containers that are visibly contaminated on the outside should be placed inside a sealable plastic bag before sending them to the laboratory. This prevents personnel from having hand contact with potentially infective material.

Dishes Dishes require no special precautions. Soiling of dishes can largely be prevented by encouraging clients to cleanse their hands before eating. Some agencies use paper dishes for convenience, which are disposed of in the refuse container.

Blood Pressure Equipment Blood pressure equipment needs no special precautions unless it becomes contaminated with infective material. If it does become contaminated, follow agency policy to decontaminate it. Cleaning procedures vary according to whether it is a wall or portable unit. In some agencies, a disposable cuff is used for clients placed on contact precautions.

Thermometers Nondisposable thermometers are generally disinfected after each use. Check agency policy.

Disposable Needles, Syringes, and Sharps Place needles, syringes, and “sharps” (e.g., lancets, scalpels, and broken glass) into a puncture-resistant container. To avoid puncture wounds, use approved safety or needleless systems and do not detach needles from the syringe or recap the needle before disposal. See Chapter 35 for how to prevent needlestick injuries.

CLINICAL ALERT!

Federal rules protecting the privacy of personal health information may extend to the client labels placed on disposable supplies such as intravenous fluid containers. Agencies may require that these be returned to the pharmacy so that personal information may be removed before disposal. Check agency policy.

Transporting Clients with Infections

Avoid transporting clients with infections outside their own rooms unless absolutely necessary. If a client must be moved, the nurse implements appropriate precautions and measures to prevent contamination of the environment. For example, the nurse ensures that any draining wound is securely covered or places a surgical mask on the client who has an airborne infection. In addition, the nurse notifies personnel at the receiving area of any infection risk so that they can maintain necessary precautions. Follow agency protocol.

Psychosocial Needs of Isolation Clients

Clients requiring isolation precautions can develop several problems as a result of the separation from others and of the special precautions taken in their care. Two of the most common are sensory deprivation and decreased self-esteem related to feelings of inferiority. *Sensory deprivation* occurs when the environment lacks normal stimuli for the client, for example, communication with others. Nurses should therefore be alert to common clinical signs of sensory deprivation: boredom, inactivity, slowness of thought, daydreaming, increased sleeping, thought disorganization, anxiety, hallucinations, and panic.

Chapter 39 provides information on the development of self-esteem and self-esteem disturbances. A client's feeling of inferiority

can be due to the perception of the infection itself or to the required precautions. In North America, many people place a high value on cleanliness, and the idea of being “soiled,” “contaminated,” or “dirty” can give clients the feeling that they have done something bad. The infected individuals may feel “not as good” as others and blame themselves. An appropriate nursing diagnosis may be *Risk for Situational Low Self-Esteem*.

Nurses need to provide care that prevents these two problems or that deals with them positively. Nursing interventions include the following:

1. Assess the individual's need for stimulation.
2. Initiate measures to help meet the need, including regular communication with the client and diversionary activities, such as toys for a child, and telephone, books, television, computer, or radio for an adult; provide a variety of foods to stimulate the client's sense of taste; stimulate the client's visual sense by providing a view or an activity to watch.
3. Explain the infection and the associated procedures to help clients and their support persons understand and accept the situation.
4. Demonstrate warm, accepting behavior. Avoid conveying to the client any sense of annoyance about the precautions or any feelings of revulsion about the infection.
5. Use the least strict precautions indicated by the diagnosis or the client's condition.

Sterile Technique

An object is sterile only when it is free of all microorganisms. It is well known that sterile technique is practiced in operating rooms and special diagnostic areas. Less known perhaps is that sterile technique is also employed for many procedures in general care areas (such as when administering injections, changing wound dressings, performing urinary catheterizations, and administering intravenous therapy). In these situations, all of the principles of surgical asepsis are applied as in the operating or delivery room; however, not all of the sterile techniques that follow are always required. For example, before an operating room procedure, the “scrub nurse” generally puts on a mask and cap, performs a surgical hand scrub, and then applies a sterile gown and gloves. In a general care area, the nurse may only perform hand hygiene and apply sterile gloves. The basic principles of surgical asepsis, and practices that relate to each principle, appear in Table 31–7.

Sterile Field

A **sterile field** is a microorganism-free area. Nurses often establish a sterile field by using the innermost side of a sterile wrapper or by using a sterile drape. When the field is established, sterile supplies and sterile solutions can be placed on it. Sterile forceps are used in many instances to handle and transfer sterile supplies.

So that sterility can be maintained, supplies may be wrapped in a variety of materials. Commercially prepared items are frequently wrapped in plastic, paper, or glass. Sterile liquids (e.g., sterile water for irrigations) are preferably packaged in amounts adequate for one use only because once a container has been opened, there is no assurance that it will remain sterile. Any left-over liquid is discarded.

Skill 31–3 describes how to establish and maintain a sterile field.

TABLE 31-7 Principles and Practices of Surgical Asepsis

Principles	Practices
All objects used in a sterile field must be sterile.	<p>All articles are sterilized appropriately by dry or moist heat, chemicals, or radiation before use.</p> <p>Always check a package containing a sterile object for intactness, dryness, and expiration date. Sterile articles can be stored for only a prescribed time; after that, they are considered unsterile. Any package that appears already open, torn, punctured, or wet is considered unsterile.</p> <p>Storage areas should be clean, dry, off the floor, and away from sinks.</p> <p>Always check chemical indicators of sterilization before using a package. The indicator is often a tape used to fasten the package or contained inside the package. The indicator changes color during sterilization, indicating that the contents have undergone a sterilization procedure. If the color change is not evident, the package is considered unsterile. Commercially prepared sterile packages may not have indicators but are marked with the word <i>sterile</i>.</p>
Sterile objects become unsterile when touched by unsterile objects.	<p>Handle sterile objects that will touch open wounds or enter body cavities only with sterile forceps or sterile gloved hands.</p> <p>Discard or resterilize objects that come into contact with unsterile objects.</p> <p>Whenever the sterility of an object is questionable, assume the article is unsterile.</p>
Sterile objects that are out of sight or below the waist or table level are considered unsterile.	<p>Once left unattended, a sterile field is considered unsterile.</p> <p>Sterile objects are always kept in view. Nurses do not turn their backs on a sterile field.</p> <p>Only the front part of a sterile gown, from shoulder to waist (or table height, whichever is higher), and the cuff of the sleeves to 5 cm (2 in.) above the elbows are considered sterile.</p> <p>Always keep sterile gloved hands in sight and above waist/table level; touch only objects that are sterile.</p> <p>Sterile draped tables in the operating room or elsewhere are considered sterile only at surface level.</p>
Sterile objects can become unsterile by prolonged exposure to airborne microorganisms.	<p>Keep doors closed and traffic to a minimum in areas where a sterile procedure is being performed, because moving air can carry dust and microorganisms.</p> <p>Keep areas in which sterile procedures are carried out as clean as possible by frequent damp cleaning with detergent germicides to minimize contaminants in the area.</p> <p>Keep hair clean and short or enclose it in a net to prevent hair from falling on sterile objects. Microorganisms on the hair can make a sterile field unsterile.</p> <p>Wear surgical caps in operating rooms, delivery rooms, and burn units.</p> <p>Refrain from sneezing or coughing over a sterile field. This can make it unsterile because droplets containing microorganisms from the respiratory tract can travel 1 m (3 ft). Some agencies recommend that masks covering the mouth and the nose be worn by anyone working over a sterile field or an open wound.</p> <p>When working over a sterile field, keep talking to a minimum.</p> <p>To prevent microorganisms from falling over a sterile field, refrain from reaching over a sterile field unless sterile gloves are worn and refrain from moving unsterile objects over a sterile field.</p>
Fluids flow in the direction of gravity.	<p>Unless gloves are worn, always hold wet forceps with the tips below the handles. When the tips are held higher than the handles, fluid can flow onto the handle and become contaminated by the hands. When the forceps are again pointed downward, the contaminated fluid flows back down and contaminates the tips.</p> <p>During a surgical hand wash, hold the hands higher than the elbows to prevent contaminants from the forearms from reaching the hands.</p>
Moisture that passes through a sterile object draws microorganisms from unsterile surfaces above or below to the sterile surface by capillary action.	<p>Sterile moisture-proof barriers are used beneath sterile objects. Liquids are frequently poured into containers on a sterile field. If they are spilled onto the sterile field, the barrier keeps the liquid from seeping beneath it.</p> <p>Keep the sterile covers on sterile equipment dry. Damp surfaces can attract microorganisms in the air.</p> <p>Replace sterile drapes that do not have a sterile barrier underneath when they become moist.</p>
The edges of a sterile field are considered unsterile.	<p>A 2.5-cm (1-in.) margin at each edge of an opened drape is considered unsterile because the edges are in contact with unsterile surfaces.</p> <p>Place all sterile objects more than 2.5 cm (1 in.) inside the edges of a sterile field.</p> <p>Any article that falls outside the edges of a sterile field is considered unsterile.</p>
The skin cannot be sterilized and is unsterile.	<p>Use sterile gloves or sterile forceps to handle sterile items.</p> <p>Prior to a surgical aseptic procedure, cleanse the hands to reduce the number of microorganisms on them.</p>
Conscientiousness, alertness, and honesty are essential qualities in maintaining surgical asepsis.	<p>When a sterile object becomes unsterile, it does not necessarily change in appearance.</p> <p>The person who sees a sterile object become contaminated must correct or report the situation.</p> <p>Do not set up a sterile field ahead of time for future use.</p>

Establishing and Maintaining a Sterile Field

PURPOSE

- To ensure that sterile items remain sterile

ASSESSMENT

Review the client's record or discuss with the client exactly what procedure will be performed that requires a sterile field. Assess the client

for the presence of or risk for infection and ability to participate with the procedure.

PLANNING

Determine, if possible, what supplies and techniques have been used in the past to perform the sterile procedure for this client. Also, attempt to determine if the procedure will be performed again in the future, so you can conduct appropriate client teaching and ensure that adequate supplies will be available.

Schedule the procedure at a time consistent with the primary care provider's order, the need for the procedure, and the client's other activities.

DELEGATION

Sterile procedures are not delegated to UAP.

INTERPROFESSIONAL PRACTICE

Sterile fields and procedures may be within the scope of practice for many health care providers. These providers may perform the procedure independently or with a nurse or other provider. Although these providers may verbally communicate about the procedure to health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Equipment

- Package containing a sterile drape
- Sterile equipment as needed (e.g., wrapped sterile gauze, wrapped sterile bowl, antiseptic solution, sterile forceps)

IMPLEMENTATION

Preparation

- Ensure that the package is clean and dry; if moisture is noted on the inside of a plastic-wrapped package or the outside of a cloth-wrapped package, it is considered contaminated and must be discarded.
- Check the sterilization expiration dates on the package, and look for any indications that it has been previously opened. Spots or stains on cloth or paper-wrapped objects may indicate contamination, and the objects should not be used.
- Follow agency practice for disposal of possibly contaminated packages.

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
- Perform hand hygiene and observe other appropriate infection prevention procedures (see Skills 31-1 and 31-2).
- Provide for client privacy.
- Open the package. If the package is inside a plastic cover, remove the cover.

To Open a Wrapped Package on a Surface

- Place the package in the work area so that the top flap of the wrapper opens away from you.
- Reaching around the package (not over it), pinch the first flap on the outside of the wrapper between the thumb and index finger.
 - Rationale:** Touching only the outside of the wrapper maintains the sterility of the inside of the wrapper. Pull the flap open, laying it flat on the far surface.
- Repeat for the side flaps, opening the topmost one first. Use the right hand for the right flap, and the left hand for the left flap.
 - Rationale:** By using both hands, you avoid reaching over the sterile contents.
- Pull the fourth flap toward you by grasping the corner that is turned down.
 -

Variation: Opening a Wrapped Package While Holding It

- Hold the package in one hand with the top flap opening away from you.

1 Opening the first flap of a sterile wrapped package.

2 Opening the second flap to the side.

- Using the other hand, open the package as described above, pulling the corners of the flaps well back.
 - Tuck each of the corners into the hand holding the package so that they do not flutter and contaminate sterile objects. The hands are consid-

Establishing and Maintaining a Sterile Field—continued

3 Pulling the last flap toward oneself by grasping the corner.

6 Opening a sterile package that has a partially sealed edge.

4 Opening a wrapped package while holding it.

7 Allowing a drape to open freely without touching any objects.

5 Opening a sterile package that has an unsealed corner.

ered contaminated, and at no time should they touch the contents of the package.

Variation: Opening Commercially Prepared Packages

- If the flap of the package has an unsealed corner, hold the package in one hand, and pull back on the flap with the other hand. 5
- If the package has a partially sealed edge, grasp both sides of the edge, one with each hand, and pull apart gently. 6

5. Establish a sterile field by using a drape.

- Open the package containing the drape as described above.
- With one hand, pluck the corner of the drape that is folded back on the top touching only one side of the drape.
- Lift the drape out of the cover, and allow it to open freely without touching any objects. 7 **Rationale:** *If the drape touches the outside of the package or any unsterile surface, it is considered contaminated.*
- With the other hand, carefully pick up another corner of the drape, holding it well away from you and, again, touching only the same side of the drape as the first hand.
- Lay the drape on a clean and dry surface, placing the bottom (i.e., the freely hanging side) farthest from you. 8 **Rationale:** *By placing the lowermost side farthest away, you avoid leaning over the sterile field and contaminating it.*

6. Add necessary sterile supplies, being careful not to touch the drape with the hands.

To Add Wrapped Supplies to a Sterile Field

- Open each wrapped package as described in the preceding steps.
- With the free hand, grasp the corners of the wrapper, and hold them against the wrist of the other hand. 9 **Rationale:** *The sterile wrapper now covers the unsterile hand.*

Continued on page 630

Establishing and Maintaining a Sterile Field—continued

8 Placing a drape on a surface.

9 Adding wrapped sterile supplies to a sterile field.

- Place the sterile bowl, drape, or other supply on the sterile field by approaching from an angle rather than holding the arm over the field.
- Discard the wrapper.

Variation: Adding Commercially Packaged Supplies to a Sterile Field

- Open each package as previously described.
- Hold the package 15 cm (6 in.) above the field, and allow the contents to drop on the field. 10 Keep in mind that 2.5 cm (1 in.) around the edge of the field is considered contaminated. **Rationale:** At a height of 15 cm (6 in.), the outside of the package is not likely to touch and contaminate the sterile field.

Adding Solution to a Sterile Bowl

Liquids (e.g., normal saline) may need to be poured into containers within a sterile field. Unwrapped bottles that contain sterile solution are considered sterile on the inside and contaminated on the outside because the bottle may have been handled. Bottles used in an operating room may be sterilized on the outside as well as the inside, however, and these are handled with sterile gloves.

- Obtain the exact amount of solution, if possible. **Rationale:** Once a sterile bottle has been opened, its sterility cannot be ensured for future use. Follow agency policy for reuse of opened sterile solution bottles.
- Before pouring any liquid, read the label three times to make sure you have the correct solution and concentration (strength). Wipe the outside of the bottle with a damp towel to remove any large particles that could fall into the bowl or field.

10 Adding commercially packaged gauze to a sterile field.

11 Adding a liquid to a sterile bowl.

- Remove the lid or cap from the bottle and invert the lid before placing it on a surface that is not sterile. **Rationale:** Inverting the lid maintains the sterility of the inside surface because it is not allowed to touch an unsterile surface.
- Hold the bottle so that the label is against the palm of the hand. **Rationale:** Any solution that flows down the outside of the bottle during pouring will not damage or obliterate the label.
- Hold the bottle of fluid at a height of 10 to 15 cm (4 to 6 in.) over the bowl and to the side of the sterile field so that as little of the bottle as possible is over the field. 11 **Rationale:** At this height, there is less likelihood of contaminating the sterile field by touching the field or by reaching an arm over it.
- Pour the solution gently to avoid splashing the liquid. **Rationale:** If a barrier drape (one that has a water-resistant layer) is not used and the drape is on an unsterile surface, moisture will contaminate the field by wicking microorganisms through the drape.
- Tilt the neck of the bottle back to vertical quickly when done pouring so that none of the liquid flows down the outside of the bottle. **Rationale:** Such drips would contaminate the sterile field if the outside of the bottle is not sterile.
- If the bottle will be used again, replace the lid securely and write on the label the date and time of opening. **Rationale:** Replacing the lid immediately maintains the sterility of the inner aspect of the lid and the solution. Depending on agency policy, a sterile

Establishing and Maintaining a Sterile Field—continued

container of solution that is opened may be used only once and is then discarded (such as in the operating room). In other settings, policy may permit recapped bottles to be reused within 24 hours.

7. Use sterile forceps to handle sterile supplies. Forceps are usually used to move a sterile article from one place to another, for example, transferring sterile gauze from its package to a sterile dressing tray. Forceps may be disposable or resterilized after use. Commonly used forceps include hemostats **12** and tissue forceps **13**.
 - If forceps tips are wet, keep the tips lower than the wrist at all times, unless you are wearing sterile gloves.
 - 14 Rationale:** Gravity prevents liquids on the tips of the forceps from flowing to the unsterile handles and later back to the tips.
 - Hold sterile forceps above waist or table level, whichever is higher. **Rationale:** Items held below waist or table level are considered contaminated.
 - Hold sterile forceps within sight. **Rationale:** While out of sight, forceps may, unknown to the user, become unsterile. Any forceps that go out of sight should be considered unsterile.
 - When using forceps to lift sterile supplies, be sure that the forceps do not touch the edges or outside of the wrapper. **Rationale:** The edges and outside of the sterile field are considered unsterile.
 - When placing forceps whose handles were in contact with the bare hand, position the handles outside the sterile area. **Rationale:** The handles of these forceps harbor microorganisms from the bare hand.

13 Tissue forceps: Left, plain; Right, toothed.

14 Holding forceps with an ungloved hand, keeping the tips lower than the wrist.

12 Hemostats: Left, straight; Right, curved.

- Deposit a sterile item on a sterile field without permitting moist forceps to touch the sterile field when the surface under the absorbent sterile field is unsterile and a barrier drape is not used.
8. Document that sterile technique was used in the performance of the procedure.

EVALUATION

- Conduct any follow-up indicated during your care of the client. Ensure that adequate numbers and types of sterile supplies are available for the next health care provider.

Home Care Considerations Sterile Field

PATIENT-CENTERED CARE

- Clean and wipe dry a flat surface for the sterile field.
- Keep pets and noninvolved small children out of the area when setting up for and performing sterile procedures.
- Dispose of all soiled materials in a waterproof bag. Check with the agency as to how to dispose of medical refuse.
- Remove all instruments from the home or other setting where others might accidentally find them. **Rationale:** New or used

instruments can be sharp or capable of causing injury. Used instruments may transmit infection. Check with the agency for instructions on cleansing of reusable supplies and disposal of single-use instruments.

- If appropriate, teach the client and family members the principles and rationale underlying the use of a sterile field.

Sterile Gloves

Sterile gloves may be applied by the open method or the closed method. The open method is most frequently used outside the operating room because the closed method requires that the nurse wear a sterile gown. Gloves are worn during many procedures to enable the nurse to handle sterile items freely and to prevent clients at risk (e.g., those with open wounds) from becoming infected by microorganisms on unsterile gloves or the nurse's hands.

Sterile gloves are packaged with a cuff of about 5 cm (2 in.) and with the palms facing upward when the package is opened. The package usually indicates the size of the glove (e.g., size 6 or 7 1/2 or small, medium, large).

Sterile gloves are available to protect the nurse from contact with blood and body fluids. Latex and nitrile gloves are more flexible than vinyl, mold to the wearer's hands, and allow freedom of movement. Since latex should be avoided due to possible allergies, wear nitrile gloves when performing tasks (a) that demand flexibility, (b) that place stress on the material (e.g., turning stopcocks, handling sharp instruments or tape), and (c) that involve a high risk of exposure to pathogens. Vinyl gloves should be chosen for tasks unlikely to stress the glove material, requiring minimal precision, and with minimal risk of exposure to pathogens.

Skill 31–4 describes how to apply and remove sterile gloves by the open method.

Applying and Removing Sterile Gloves (Open Method)**PURPOSES**

- To enable the nurse to handle or touch sterile objects freely without contaminating them
- To prevent transmission of potentially infective organisms from the nurse's hands to clients at high risk for infection

ASSESSMENT

Review the client's record and orders to determine exactly what procedure will be performed that requires sterile gloves. Check the client record and ask about latex allergies. Use nonlatex gloves whenever possible.

PLANNING

Think through the procedure, planning which steps need to be completed before the gloves can be applied. Determine what additional supplies are needed to perform the procedure for this client. Always have an extra pair of sterile gloves available.

DELEGATION

Sterile procedures are not delegated to UAP.

IMPLEMENTATION**Preparation**

Ensure the sterility of the package of gloves.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary.
2. Perform hand hygiene and observe other appropriate infection prevention procedures (see Skills 31–1, 31–2, and 31–3).
3. Provide for client privacy.
4. Open the package of sterile gloves.
 - Place the package of gloves on a clean, dry surface.
 - Rationale:** Any moisture on the surface could contaminate the gloves.
 - Some gloves are packed in an inner as well as an outer package. Open the outer package without contaminating the gloves or the inner package. See Skill 31–3.
 - Remove the inner package from the outer package.
 - Open the inner package as in step 4 of Skill 31–3 or according to the manufacturer's directions. Some manufacturers provide a numbered sequence for opening the flaps and folded tabs to grasp for opening the flaps. If no tabs are provided, pluck the flap so that the fingers do not touch the inner surfaces. **Rationale:** The inner surfaces, which are next to the sterile gloves, will remain sterile.
5. Put the first glove on the dominant hand.
 - If the gloves are packaged so that they lie side by side, grasp the glove for the dominant hand by its folded cuff

INTERPROFESSIONAL PRACTICE

Sterile gloves are used by many health care providers. All providers should be comfortable pointing out to each other when any break in sterile technique is detected.

Equipment

- Packages of sterile gloves

edge (on the palmar side) with the thumb and first finger of the nondominant hand. Touch only the inside of the cuff.

1 Rationale: The hands are not sterile. By touching only the inside of the glove, the nurse avoids contaminating the outside.

or

- If the gloves are packaged one on top of the other, grasp the cuff of the top glove as above, using the opposite hand.
- Insert the dominant hand into the glove and pull the glove on. Keep the thumb of the inserted hand against the palm of the hand during insertion. **2 Rationale:** If the thumb is kept

1 Picking up the first sterile glove.

Applying and Removing Sterile Gloves—continued

2 Putting on the first sterile glove.

against the palm, it is less likely to contaminate the outside of the glove.

- Leave the cuff in place once the unsterile hand releases the glove. **Rationale:** Attempting to further unfold the cuff is likely to contaminate the glove.
6. Put the second glove on the nondominant hand.
- Pick up the other glove with the sterile gloved hand, inserting the gloved fingers under the cuff and holding the gloved thumb close to the gloved palm. 3
 - Pull on the second glove carefully. Hold the thumb of the gloved first hand as far as possible from the palm.
- 4 **Rationale:** In this position, the thumb is less likely to touch the arm and become contaminated.
- Adjust each glove so that it fits smoothly, and carefully pull the cuffs up by sliding the fingers under the cuffs.
7. Remove and dispose of used gloves.
- There is no technique for removing sterile gloves that is different from removing unsterile gloves. If they are soiled with secretions, remove them by turning them inside out. See removal of gloves in Skill 31–2 on page 621.
 - Perform hand hygiene.

3 Picking up the second sterile glove.

4 Putting on the second sterile glove.

8. Document that sterile technique was used in the performance of the procedure.

EVALUATION

- Conduct any follow-up indicated during your care of the client. Ensure that adequate numbers and types of sterile supplies are available for the next health care provider.

Sterile Gowns

Sterile gowning and closed gloving are chiefly carried out in operating or delivery rooms, where surgical asepsis is necessary. The closed method of gloving can be used only when a sterile gown is worn because the gloves are handled through the sleeves of the gown. Before

these procedures, the nurse applies a hair cover and a mask, and performs a surgical hand wash.

Skill 31–5 describes the steps in applying a sterile gown and sterile gloves by the closed method.

Applying a Sterile Gown and Gloves (Closed Method)

PURPOSES

- To enable the nurse to work close to a sterile field and handle sterile objects freely
- To protect clients from becoming contaminated with microorganisms on the nurse's hands, arms, and clothing

ASSESSMENT

Review the client's record and orders to determine exactly what procedure will be performed that requires sterile gown and gloves. Check the client record and ask about latex allergies. Use nonlatex gloves whenever possible.

Planning

Think through the procedure, planning which steps need to be completed before the gloves and gown can be applied. Determine what additional supplies are needed to perform the procedure for this client. Always have an extra pair of sterile gloves available.

Applying a Sterile Gown and Gloves—continued

DELEGATION

Sterile procedures are not delegated to UAP. UAP often assist an RN or scrub nurse by preparing the sterile pack containing the sterile gown and gloves.

Equipment

- Sterile pack containing a sterile gown
- Sterile gloves

IMPLEMENTATION

Preparation

Ensure the sterility of the package.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, and why it is necessary.
2. Perform hand hygiene and observe other appropriate infection prevention procedures (see Skills 31-1, 31-2, and 31-3).
3. Provide for client privacy.

Applying a Sterile Gown

4. Open the package of sterile gloves.
 - Remove the outer wrap from the sterile gloves and leave the gloves in their inner sterile wrap on the sterile field.
 - Rationale:** *If the inner wrapper is not touched, it will remain sterile.* See Skill 31-3, step 4.
5. Unwrap the sterile gown pack.
6. Perform proper hand hygiene.

See the *Variation* section at the end of Skill 31-1 and review agency practice.
7. Apply the sterile gown.
 - Grasp the sterile gown at the crease near the neck, hold it away from you, and permit it to unfold freely without touching anything, including your uniform. **Rationale:** *Your gown will be unsterile if its outer surface touches any unsterile objects.*
 - Put your hands inside the shoulders of the gown without touching the outside of the gown. ①
 - Work the hands down the sleeves only to the beginning of the cuffs. ②

or

INTERPROFESSIONAL PRACTICE

Sterile technique using sterile gown and gloves may be within the scope of practice for many health care providers. For example, in addition to nurses, physical therapists may gown and glove when performing sterile procedures such as burn or wound care. Although these other providers may verbally communicate about the procedure to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

- Have a coworker grasp the neck ties without touching the outside of the gown and pull the gown upward to cover the neckline of your uniform in front and back. The coworker ties the neck ties. ③ Gowning continues at step 11.

② Working the hands down the sleeves of a sterile gown.

① Putting on a sterile gown.

③ A coworker ties the neck ties of a sterile gown.

Applying a Sterile Gown and Gloves—continued

Applying Sterile Gloves (Closed Method)

8. Open the sterile glove wrapper while the hands are still covered by the sleeves. **4**
9. Put the glove on the nondominant hand. Figures **5** through **7** show a right-handed person.
 - With the dominant hand, pick up the opposite glove with the thumb and index finger, handling it through the sleeve.
 - Lay the glove on the opposite gown cuff, thumb side down, with the glove opening pointed toward the fingers. **5**
 - Use the nondominant hand to grasp the cuff of the glove through the gown cuff, and firmly anchor it.
 - With the dominant hand working through its sleeve, grasp the upper side of the glove's cuff, and stretch it over the cuff of the gown.
 - Pull the sleeve up to draw the cuff over the wrist as you extend the fingers of the nondominant hand into the glove's fingers. **6**
10. Put the glove on the dominant hand.
 - Place the fingers of the gloved hand under the cuff of the remaining glove.

4 Opening the sterile glove wrapper.

- 5** Positioning the first sterile glove for the nondominant hand.
- Extend the fingers into the glove as you pull the glove up over the cuff of the gown. **7**

Completion of Gowning

11. Complete gowning as follows.
 - Have a coworker hold the long end of the waist tie of your gown, using sterile gloves or a sterile forceps.

6 Pulling on the first sterile glove.

7 Extending the fingers into the second glove of the dominant hand.

Rationale: This approach keeps the ties sterile.

- Turn completely around until the tie the coworker is holding is in front of you. Take that tie and secure it to the short tie in front of the gown.

or

- Have a coworker take the two ties at each side of the gown and tie them at the back of the gown, making sure that your uniform is completely covered.
- When worn, sterile gowns should be considered sterile in front from the waist to the shoulder. Once the nurse approaches a table, the gown is considered contaminated from the waist or table down, whichever is higher. The sleeves should be considered sterile from the cuff to 5 cm (2 in.) above the elbow, since the arms of a scrubbed person must move across a sterile field. Moisture collection and friction areas such as the neckline, shoulders, underarms, back, and sleeve cuffs should be considered unsterile.

12. Remove and dispose of used gown and gloves.
 - If soiled, remove the attire by turning it inside out. See removal of disposable gowns and gloves in Skill 31–2 for the sequence of when to remove the gown.
13. If appropriate, document that sterile technique was used in the performance of the procedure.

EVALUATION

- Conduct any follow-up indicated during your care of the client. Ensure that adequate numbers and types of sterile supplies are available for the next health care provider.

Infection Prevention for Health Care Workers

National Institute for Occupational Safety and Health (NIOSH; part of the CDC and a research agency of the U.S. Department of Health and Human Services) investigates potentially hazardous working conditions and publishes recommendations for preventing workplace illnesses and injuries. For example, NIOSH published a study on preventing needlestick injuries in health care settings in 1999 that found that the majority of needlestick injuries were preventable. This, in part, led to the Needlestick Safety and Prevention Act that went into effect in April 2001.

The Occupational Safety and Health Administration (OSHA), an agency of the U.S. Department of Labor, publishes and enforces regulations to protect health care workers from occupational injuries, including exposure to bloodborne pathogens in the workplace. **Occupational exposure** is defined as skin, eye, mucous membrane, or parenteral contact with blood or other potentially infectious materials that may result from the performance of an employee's duties.

There are three major modes of transmission of infectious materials in the clinical setting:

- Puncture wounds from contaminated needles or other sharps
- Skin contact, which allows infectious fluids to enter through wounds and broken or damaged skin
- Mucous membrane contact, which allows infectious fluids to enter through mucous membranes of the eyes, mouth, or nose.

Using proper precautions with general medical asepsis, appropriately using PPE (gloves, masks, gowns, goggles, special resuscitative

equipment), and avoiding carelessness in the clinical area will place the caregiver at significantly less risk for injury. The chance of a health care worker becoming infected following exposure to pathogens varies widely; estimates range from 6% to 30% for hepatitis B (nonimmune workers), to 1.8% for hepatitis C, to 0.3% for HIV (CDC, 2011). Measures to be taken in case of possible exposure to these viruses are delineated by the CDC and outlined in the accompanying Practice Guidelines. Hepatitis C, a worldwide epidemic greater than HIV, has become a significant concern to all health care workers because no vaccine against the virus or postexposure prophylaxis currently exists. Prevention remains the primary goal.

OSHA requires that health care employers make the hepatitis B vaccine and vaccination series available to all employees. Other vaccinations may also be made available (e.g., nurses working in an obstetric area should be vaccinated against rubella to protect pregnant clients and their fetuses).

SELF-CARE ALERT

The nurse should consider in advance whether he or she would want prophylaxis for HIV exposure since this is optimally begun within hours of exposure.

Role of the Infection Prevention Nurse

All health care organizations must have interdisciplinary infection prevention committees. Representatives from the clinical laboratory, housekeeping, maintenance, dietary, and client care areas are included.

PRACTICE GUIDELINES

Steps to Follow After Exposure to Bloodborne Pathogens

- Report the incident immediately to appropriate personnel within the agency.
- Complete an injury/accident report and an incident report if required by the agency.
- Seek appropriate evaluation and follow-up. This includes:
 - Identification and documentation of the source individual when feasible and legal. Sometimes the source individual is unknown or the individual's identity is protected by law.
 - Testing of the source for hepatitis B, hepatitis C, and HIV when feasible and consent is given.
 - Making results of the test available to the source individual's health care provider.
 - Testing of blood of exposed nurse (with consent) for hepatitis B, hepatitis C, and HIV antibodies.
 - Postexposure prophylaxis if medically indicated.
 - Medical and psychological counseling regarding personal risk of infection or risk of infecting others.
- For a puncture/laceration:
 - Allow some bleeding to drain the site but do not squeeze the tissues.
 - Wash/clean the area with soap and water.
 - Initiate first-aid and seek treatment if indicated.
- For a mucous membrane exposure (eyes, nose, mouth), saline or water flush for 5 to 10 minutes.

POSTEXPOSURE PROTOCOL (PEP)

HIV

- Treatment should be started as soon as possible, preferably within hours after exposure. Treatment may be less effective

when started more than 24 hours after exposure. Starting treatment after a longer period (e.g., 1 week) should be considered for high-risk exposures previously untreated.

- For "high-risk" exposure (high blood volume *and* source with a high HIV titer): three-drug treatment is recommended.
- For "increased risk" exposure (high blood volume *or* source with a high HIV titer): three-drug treatment is recommended.
- For "low-risk" exposure (neither high blood volume nor source with a high HIV titer): two-drug treatment is considered.
- Drug prophylaxis continues for 4 weeks. If the source is determined to be HIV negative, PEP should be discontinued.
- Drug regimens vary and new drugs and regimens are continuously being developed.
- HIV antibody tests should be done shortly after exposure (baseline), and 6 weeks, 3 months, and 6 months afterward.

Hepatitis B

- Anti-HBs testing after last vaccine dose.
- HBIG and/or hepatitis B vaccine within 1 to 7 days following exposure for nonimmune workers.

Hepatitis C

- Anti-HCV and ALT at baseline and 4 to 6 months after exposure.

Critical Thinking Checkpoint

Mrs. Cortez is a 76-year-old woman who is independent, lives alone, and prefers not to rely on others unless absolutely necessary. She was active and healthy until about 6 months ago, at which time she developed a persistent upper respiratory infection. Because she was unable to obtain or prepare foods, she lost weight and became very weak. She finally sought medical attention, but she has not yet fully recovered. Her primary care provider has admitted Mrs. Cortez to the hospital for shortness of breath, productive cough, dehydration, and nutritional deficiency.

1. Mrs. Cortez's primary care provider suspects that Mrs. Cortez has pneumonia. What data support Mrs. Cortez's increased risk for such an infection?
2. What other information or assessment data would be helpful to you when planning care for Mrs. Cortez?

3. You recognize that standard precautions are instituted for all hospitalized clients. Explain why the use of such precautions may not prevent the spread of Mrs. Cortez's respiratory infection to other susceptible clients.
4. What can you do to prevent the spread of Mrs. Cortez's infection to other hospitalized clients and at the same time prevent Mrs. Cortez from getting infections from other clients?
5. You see the nursing assistant leaving Mrs. Cortez's room. The assistant stops to wash her hands. She turns on the water handles and soaps and rubs her hands together under running water for about 5 seconds. She then turns off the faucets with her bare hands and proceeds with drying her hands. Should you intervene and, if so, what should you do?

See Critical Thinking Possibilities on student resource website.

An important member of this committee is the infection prevention nurse. This nurse is specially trained to be knowledgeable about the latest research and practices in preventing, detecting, and treating infections. All infections are reported to the nurse in a manner that allows for recording and analyzing statistics that can assist in improving infection prevention practices. In addition, the infection prevention nurse may be involved in employee education and implementation of the bloodborne pathogen exposure plan mandated by OSHA.

Evaluating

Using data collected during care—vital signs, lung sounds, skin status, characteristics of urine or other drainage, laboratory blood values,

and so on—the nurse judges whether client outcomes have been achieved.

If outcomes have not been achieved, the nurse may need to consider questions such as the following:

- Were appropriate measures implemented to prevent skin breakdown and lung infection?
- Was strict aseptic technique implemented for invasive procedures?
- Are prescribed medications affecting the immune system?
- Is client placement appropriate to reduce the risk of transmission of microorganisms?
- Did the client and family misunderstand or fail to comply with necessary instructions?

Chapter 31 Review

CHAPTER HIGHLIGHTS

- Microorganisms are everywhere. Most are harmless and some are beneficial; however, many can cause infection in susceptible individuals.
- Effective prevention and control of infectious disease is an international, national, community, and individual responsibility.
- Asepsis is the freedom from disease-causing microorganisms.
- Medical aseptic practices limit the number, growth, and transmission of microorganisms.
- Surgical aseptic practices keep an area or objects free of all microorganisms.
- The incidence of health care–associated infections is significant. Major sites for these infections are the respiratory and urinary tracts, the bloodstream, and wounds.
- Factors that contribute to nosocomial and health care–associated infection risks are invasive procedures, medical therapies, the existence of a large number of susceptible individuals, inappropriate use of antibiotics, and insufficient hand hygiene after client contact and after contact with body substances.
- An infection can develop if the links in the chain of infection—etiologic agent, reservoir, portal of exit, mode of transmission, portal of entry, and susceptible host—are not interrupted.
- Intact skin and mucous membranes are the body's first line of defense against microorganisms.
- Some body secretions (e.g., saliva and tears) contain enzymes that act as antibacterial agents.
- The inflammatory response limits physical, chemical, and microbial injury and promotes repair of injured tissue.
- Immunity is the specific resistance of the body to infectious agents.
- Immunity is active or passive and in either case may be naturally or artificially induced.
- Individuals especially at risk of acquiring an infection are the very young or old; those with a deficiency of serum immunoglobulins, multiple stressors, poor nutritional status, or insufficient immunizations; those receiving certain medical therapies; and those who have an existing disease process.

- Preventing infections in healthy or ill persons and preventing the transmission of microorganisms from infected clients to others are major nursing functions.
- All health care providers must apply clean or sterile gloves, gowns, masks, and protective eyewear according to the risk of exposure to potentially infective materials.
- Should a health care worker be exposed to substances with a high risk of transmitting bloodborne pathogens, postexposure practices and consideration of prophylactic treatment must be followed immediately.

TEST YOUR KNOWLEDGE

- The client is a chronic carrier of infection. To prevent the spread of the infection to other clients or health care providers, the nurse emphasizes interventions that do which of the following?
 - Eliminate the reservoir.
 - Block the portal of exit from the reservoir.
 - Block the portal of entry into the host.
 - Decrease the susceptibility of the host.
- Which is the most effective nursing action for preventing and controlling the spread of infection?
 - Thorough hand hygiene
 - Wearing gloves and masks when providing direct client care
 - Implementing appropriate isolation precautions
 - Administering broad-spectrum prophylactic antibiotics
- In caring for a client on contact precautions for a draining infected foot ulcer, which action should the nurse perform?
 - Wear a mask during dressing changes.
 - Provide disposable meal trays and silverware.
 - Follow standard precautions in all interactions with the client.
 - Use surgical aseptic technique for all direct contact with the client.
- When caring for a single client during one shift, it is appropriate for the nurse to reuse only which of the following personal protective equipment?
 - Goggles
 - Gown
 - Surgical mask
 - Clean gloves
- While applying sterile gloves (open method), the cuff of the first glove rolls under itself about 0.5 cm (1/4 in.). What is the best action for the nurse to take?
 - Remove the glove and start over with a new pair.
 - Wait until the second glove is in place and then unroll the cuff with the other sterile hand.
 - Ask a colleague to assist by unrolling the cuff.
 - Leave the cuff rolled under.
- The nurse evaluates the chart of a 65-year-old client with no apparent risk factors and concludes that which immunizations are current? Select all that apply.
 - Last tetanus booster was at age 50
 - Receives a flu shot every year
 - Has not received the hepatitis B vaccine
 - Has not received the hepatitis A vaccine
 - Has not received the herpes zoster vaccine
- A client with poor nutrition enters the hospital for treatment of a puncture wound. An appropriate nursing diagnosis would be _____.
- After teaching a client and family strategies to prevent infection prevention, which statement by the client would indicate effective learning has occurred?
 - “We will use antimicrobial soap and hot water to wash our hands at least three times per day.”
 - “We must wash or peel all raw fruits and vegetables before eating.”
 - “A wound or sore is not infected unless we see it draining pus.”
 - “We should not share toothbrushes but it is OK to share towels and washcloths.”
- Which of the numbered areas is considered sterile on a person in the operating room? You may assume that all articles were sterile when applied.

Dorling Kindersley Media Library.

- The nurse determines that a field remains sterile if which of the following conditions exist?
 - Tips of wet forceps are held upward when held in ungloved hands.
 - The field was set up 1 hour before the procedure.
 - Sterile items are 2 inches from the edge of the field.
 - The nurse reaches over the field rather than around the edges.

See Answers to Test Your Knowledge in Appendix A.

32 Safety

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Discuss factors that affect people's ability to protect themselves from injury.
2. Describe methods to assess a client's risk for injury.
3. Discuss the National Patient Safety Goals.
4. Identify common potential hazards throughout the life span.
5. Plan strategies to maintain safety in the health care setting, home, and community, including prevention strategies across the life span for falls, seizures, thermal injury, fires, carbon monoxide and other types of poisoning, suffocation or choking, excessive noise, electrical hazards, firearms, radiation, and bioterrorism.
6. Explain interventions to prevent falls.
7. Discuss implementation of seizure precautions.
8. Discuss the use and legal implications of restraints.
9. Describe alternatives to restraints.
10. List desired outcomes to use in evaluating the selected strategies for injury prevention.
11. Verbalize the steps for:
 - a. Using a bed or chair exit safety monitoring device.
 - b. Implementing seizure precautions.
 - c. Applying restraints.
12. Recognize when it is appropriate to delegate using a bed or chair exit safety monitoring device, implementing seizure precautions, and applying restraints of clients to unlicensed assistive personnel.
13. Demonstrate appropriate documentation and reporting of using a bed or chair exit safety monitoring device, implementing seizure precautions, and applying restraints.

INTRODUCTION

A fundamental concern of nurses, which extends from the bedside to the home to the community, is preventing injuries and assisting the injured. Motor vehicle crashes, falls, drowning, fire and burns, poisoning, inhalation and ingestion of foreign objects, and firearm use are major causes of injury and death.

Nurses need to be aware of what constitutes a safe environment for a particular person or for a group of people in home and community settings. Injuries are often caused by human conduct and can be prevented.

FACTORS AFFECTING SAFETY

The ability of people to protect themselves from injury is affected by such factors as age and development, lifestyle, mobility and health status, sensory-perceptual alterations, cognitive awareness, emotional state, ability to communicate, safety awareness, and environmental factors. Nurses need to assess each of these factors when they plan care or teach clients to protect themselves.

Age and Development

Through knowledge and accurate assessment of the environment, people learn to protect themselves from many injuries. Children walking to school learn to stop before crossing the street and wait for oncoming traffic. They also learn not to touch a hot stove. For the

very young, learning about the environment is essential. Only through knowledge and experience do children learn what is potentially harmful.

Older adults can have difficulty with movement and diminished sensory-neurologic acuity, which can contribute to the likelihood of injury. Specific age-related potential hazards and preventive measures are discussed later in this chapter. Box 32-1 summarizes selected hazards for each age group.

Lifestyle

Lifestyle factors that place people at risk for injury include unsafe work environments; residence in neighborhoods with high crime rates; access to firearms; insufficient income to purchase safety equipment or make necessary repairs; and access to illicit drugs, which may also be contaminated by harmful additives. Risk-taking behaviors are contributing factors in some accidents.

Mobility and Health Status

Alterations in mobility related to paralysis, muscle weakness, diminished balance, and lack of coordination place clients at risk for injury. Spinal cord injuries or paralysis impair the client's ability to perceive discomfort, increasing the risk for injury or skin breakdown. Clients who have impaired mobility such as hemiplegia or leg casts are prone to falls related to poor balance. Clients weakened by illness or surgery may suffer from impaired levels of alertness, placing them at risk for falls or injury.

BOX 32-1 Selected Safety Hazards Throughout the Life Span*

- *Developing fetus*: exposure to maternal smoking, alcohol consumption, addictive drugs, x-rays (first trimester), certain pesticides
- *Newborns and infants*: falling, suffocation in crib, placement in the prone position, suffocation when entangled in cords, choking from aspirated milk or ingested objects, burns from hot water or other spilled hot liquids, automobile crashes, crib or playpen injuries, electric shock, poisoning
- *Toddlers*: physical trauma from falling, running into objects, aspiration of small toys, getting cut by sharp objects; automobile crashes; burns; poisoning; drowning; and electric shock
- *Preschoolers*: injury from traffic, playground equipment, and other objects; choking, suffocation, and obstruction of airway or ear canal by foreign objects; poisoning; drowning; fire and burns; harm from other people or animals
- *Adolescents*: vehicular (automobile, bicycle) crashes, recreational injuries, firearms, substance abuse
- *Older adults*: falling, burns, and pedestrian and automobile crashes

*Preventive measures are discussed later in this chapter.

LIFESPAN CONSIDERATIONS Preventing Falls

OLDER ADULTS

- Assess for potential personal causes of falls: hypotension, unsteady gait, altered mental status (such as from medications), poor vision, foot pathology, cognitive changes, and fear.
- In the home or community setting, assess for potential environmental causes of falls:
 - *Lighting*: inadequate amount, inaccessible or inconvenient switches
 - *Floors*: presence of electrical cords, loose rugs, clutter, slippery surfaces
 - *Stairs*: absent or unsteady railings, uneven step height or surfaces
 - *Furniture*: unsteady base, lack of armrests, cabinets too high or too low, chairs with wheels
 - *Bathroom*: inappropriate toilet height, slippery floors or tub, absence of grab bars.
- In the home, consider alternatives to hospital or regular bed if client is extremely prone to fall out of bed:
 - Place the mattress directly onto the floor.
 - Place padding on floor next to bed or between client and side rails.

Sensory-Perceptual Alterations

Accurate sensory perception of environmental stimuli is vital to safety. People with impaired touch perception, hearing, taste, smell, and vision are highly susceptible to injury. A person with impaired vision may trip over a toy or not see an electric cord. A person with impaired hearing may not hear a siren in traffic. A person with impaired olfactory sense may not smell burning food or the sulfur aroma of escaping gas.

Cognitive Awareness

Awareness is the ability to perceive environmental stimuli and body reactions and to respond appropriately through thought and action.

Clients with impaired awareness include people lacking sleep; people who are unconscious or semiconscious; disoriented people who may not understand where they are or what to do to help themselves; people who perceive stimuli that do not exist; and people whose judgment is altered by disease or medications, such as narcotics, tranquilizers, hypnotics, and sedatives. Mildly confused clients may momentarily forget where they are, wander from their rooms, misplace personal belongings, and so forth.

Emotional State

Extreme emotional states can alter the ability to perceive environmental hazards. Stressful situations can reduce a person's level of concentration, cause errors of judgment, and decrease awareness of external stimuli. People with depression may think and react to environmental stimuli more slowly than usual.

Ability to Communicate

Individuals with diminished ability to receive and convey information are at risk for injury. They include clients with aphasia, language barriers, or the ability to read. For example, the person unable to interpret the sign "No smoking—oxygen in use" could cause a fire.

Safety Awareness

Information is crucial to safety. Clients in unfamiliar environments frequently need specific safety information. Lack of knowledge about unfamiliar equipment, such as oxygen tanks, intravenous tubing, and hot packs, is a potential hazard. Healthy clients need information about water safety, car safety, fire prevention, ways to prevent the ingestion of harmful substances, and many preventive measures related to specific age-related hazards.

Environmental Factors

Client safety is affected by the health care setting. Depending on the client situation, the nurse may need to assess the environment of the home, workplace, or community. Bioterrorism and natural disasters are national safety concerns.

HEALTH CARE SETTING

In 1999, the Institute of Medicine (IOM) released its first publication on client safety and medical errors: *To Err Is Human: Building a Safer Health System*. This landmark report attracted a great deal of attention when it reported that 98,000 people died in hospitals each year as a result of medical errors, and many more were seriously harmed (Regenstein, 2013). Since this report, organizations such as The Joint Commission and the Agency for Healthcare Research and Quality (AHRQ) developed and/or continued to accelerate work around patient safety. In addition, the Quality and Safety Education for Nurses (QSEN) project developed guidelines that would enable future nurses to have the knowledge, skills, and attitudes necessary to improve the quality and safety of the health care systems within which they work (Sammer & James, 2011). However, it is now more than a decade later and preventable errors continue. For example, Barclay (2013) states that "diagnostic errors result in between 44,000 and 80,000 annual deaths in the United States alone, and bed sores lead to another 68,000 deaths. Thousands more die each year as a result of communication errors or failure to receive evidence-based interventions (para. 3)."

Historically, medical professionals were blamed and punished for errors, which were often unintended. This punitive approach discouraged individuals from reporting errors, which blocked responsibility for client safety. The clear message of the IOM report was that errors were not usually the result of one individual but of a complex system-related problem. IOM recommended that health care organizations create safety systems. As a result, The Joint Commission created the National Patient Safety Goals (NPSGs) program to help organizations target areas most in need of improvement (Shaw & Miller, 2013, p. 19).

It is important for health organizations to create an environment in which safety is a top priority; this is also known as providing a “culture of safety.” The foundation for a culture of safety is a blame-free work environment, transparency, and a process designed to prevent errors. An example is a willingness to share information and learn from errors. This provides opportunities to study serious occurrences but also near misses. AHRQ (n.d.) defines a near miss or a close call as “an event or situation that did not produce client injury, but only because of chance (para. 2).” This near miss might be because of the health of the client (e.g., a client with a penicillin allergy receives penicillin but experiences no reaction) or a timely intervention (e.g., the nurse happens to notice that a health care provider wrote an order in the wrong client’s chart) (AHRQ, n.d.). Near-miss reporting is used in many hospitals and health care agencies. Nurses are educated on the policies of the agency with regard to near-miss errors and their specific protocols.

Another IOM report, *Keeping Patients Safe—Transforming the Work Environment of Nurses* (2004), established a link between nurses’ work environment and client safety. This report found that the usual work environment of nurses is characterized by many serious threats to client safety. Gerwig (2013) states that health care has one of the highest incidents of occupational injury and illness of any industry in the country and that nurses have among the highest rates of low back disorders (p. 333). There is growing evidence that injuries among nurses negatively affect client care, causing a domino effect. For example, nursing injuries cause time lost due to the injury or illness, which subsequently affects the staffing ratio, which influences client safety (Krause & Hidley, 2013). There is a growing awareness of the relationship between improving health care occupational safety and improving client safety (Gerwig, 2013).

WORKPLACE

In the workplace, machinery, industrial belts and pulleys, and chemicals may create danger. Worker fatigue, noise and air pollution, or working at great heights or in subterranean areas may also create occupational hazards. The work environment of the nurse may also be unsafe. The U.S. Bureau of Labor Statistics (2012) reports that nursing has many hazards. Some of the hazards identified were exposure to infectious agents; activities in client care that require lifting, bending, and walking; exposure to hazardous compounds; and needles. Nurses must adhere to standardized guidelines to prevent injury or disease.

HOME

A safe home requires well-maintained flooring and carpets, a non-skid bathtub or shower surface, handrails, functioning smoke alarms that are strategically placed, and knowledge of fire escape routes. Outdoor areas, where steps or stairs increase the risk for falls, may need ramps instead. Swimming pools need to be safely secured and

maintained. Adequate lighting, both inside and out, will minimize the potential for accidents.

COMMUNITY

Adequate street lighting, safe water and sewage treatment, and regulation of sanitation in food buying and handling all contribute to a healthy, hazard-free community. A safe and secure community strives to be free of excess noise, crime, traffic congestion, dilapidated housing, or unprotected creeks and landfills.

BIOTERRORISM

The Centers for Disease Control and Prevention (CDC) (n.d.) defines a **bioterrorism** attack as the “deliberate release of viruses, bacteria, or other germs (agents) used to cause illness or death in people, animals, or plants (para. 1).” Bioterrorism agents are separated into three categories, depending on how easily they can be spread and the severity of illness or death they cause.

Category A agents have the highest risk because they:

- Can be easily spread or transmitted from person to person.
- Result in high death rates and have the potential for major public health impact.
- Might cause public panic and social disruption.
- Require special action for public health preparedness.

Category B agents are the second highest priority because they:

- Are moderately easy to spread.
- Result in moderate illness rates and low death rates.
- Require specific enhancements of CDC’s laboratory capacity and enhanced disease monitoring.

Category C agents include emerging pathogens that could be engineered for mass spread in the future because they:

- Are easily available.
- Are easily produced and spread.
- Have the potential for high morbidity and mortality rates and major health impact.

DISASTER PLANNING

Nursing personnel play a key role in disaster management and client care throughout all aspects of the health care industry. Nurses are employed in acute care facilities, ambulatory care facilities, long-term care facilities, and within community agencies, including home care and public health. The terrorist events of September 11, 2001, and natural disasters such as Hurricane Sandy in 2012 provided the United States with evidence that nursing and health care must address disaster planning head on.

Experts have recognized that health care delivery systems are not well prepared to handle large-scale disasters and have called for a national framework for providing medical care during catastrophes (Murray, 2012, p. 61). As a result, the U.S. Department of Health and Human Services requested IOM to develop guidelines that offer a systems approach to providing disaster response. These guidelines are called *Crisis Standards of Care: A Systems Framework for Catastrophic Disaster Response*. Murray (2012) states that these crisis standards of care (CSC) “help organizations and health care professionals deliver the best possible care in circumstances in which resources are severely limited and health care standards are compromised” (p. 61). For example, during a disaster, the focus of care for the nurse changes

from the individual to the population, and the CSC framework provides guidance to help health care providers make that adjustment, especially when resources are scarce.

Nurses need to be able to respond to disasters in the community as well as keep safe clients who are already in the health care setting. The Joint Commission has standards requiring health care organizations to develop disaster plans (Romer & Hebda, 2013a). The role that nurses play in disaster planning is to know and understand the chain of command. The line of authority during a disaster is different from that of day-to-day operations. For example, the chain of command may be under the control of an outside agency instead of the nurse's health care institution. For the bedside nurse, the client's safety is top priority and it is essential for the nurse to know the organization's disaster response plan. Many organizations conduct disaster drills for this reason.

Nurses must also care for themselves in the event of a disaster. For example, they must be prepared to deal with the stress associated with the disaster, and to be separated from their families for extended periods of time. It is imperative that nurses set up their own emergency action plans with their families. After the disaster, organizations need to provide stress management opportunities to minimize the impact of the stress incurred during the disaster. Post-traumatic stress syndrome has been identified in nurses who provided care during major disasters (Romer & Hebda, 2013b).

Some nurses would like to help out and volunteer their services during a disaster. An important message from the American Nurses Association is that nurses should “never deploy outside of an organized response system” (Stokowski, 2012, para. 6). Organized response registries for health care professionals exist at both state and federal levels. The interested nurse needs to register in advance with one of these response systems to receive appropriate training. Stokowski (2012) lists the following disaster response organizations with which nurses may register: National Disaster Medical System (NDMS), the American Red Cross, the Medical Reserve Corps (MRC), RN Response Network (RNRN), and the Emergency System for Advance Registration of Volunteer Health Professionals (ESAR-VHP). The interested nurse should determine which organization best suits his or her needs and should register with only one system.

●○○ NURSING MANAGEMENT

Assessing

Assessing clients at risk for injury involves (a) noting pertinent indicators in the nursing history and physical examination, (b) using specifically developed risk assessment tools, and (c) evaluating the client's home environment.

Nursing History and Physical Examination

The nursing history and physical examination can reveal considerable data about the client's safety practices and risks for injury. Data include age and developmental level; general health status; mobility status; presence or absence of physiological or perceptual deficits such as olfactory, visual, tactile, taste, or other sensory impairments; altered thought processes or other impaired cognitive or emotional capabilities; substance abuse; any indications of abuse or neglect; and an accident and injury history. A safety history also needs to include the

client's awareness of hazards, knowledge of safety precautions both at home and at work, and any perceived threats to safety (Figure 32–1 ■).

Risk Assessment Tools

Risk assessment tools are available to determine clients at risk both for specific types of injury, such as falls, or for the general safety of the home and health care setting. In general, these tools direct the nurse to appraise the factors affecting safety as previously discussed. The tools summarize specific data contained in the client's nursing history and physical examination. Client risk factors and environmental hazards for falls are discussed later in this chapter (see the *Falls* section).

Home Hazard Appraisal

Hazards in the home are major causes of falls, fire, poisoning, suffocation, and other accidents, such as those caused by improper use of household equipment, tools, and cooking utensils. See Chapter 8 ∞ for a summary of specific data necessary for a home hazard appraisal.

National Patient Safety Goals

As a result of IOM's report *To Err Is Human* (2000), the health care industry and national organizations (e.g., National Patient Safety Foundation) increased their awareness of the need to improve client safety. For example, since 2002, The Joint Commission has required its accredited agencies to meet specific National Patient Safety Goals (NPSGs). The newest goal is to reduce the harm associated with clinical alarm systems. Davis, Lockhart, Landon, and Henry (2014) report that 80 clients died and 13 were severely injured in U.S. hospitals between January 2009 and June 2012 as a result of alarm-related problems (p. 40). There is a high risk of injury if alarms are silenced, turned off, or ignored. Alarms should be checked at the beginning of each shift to ensure that they are functional. See Box 32–2 for The Joint Commission's 2014 National Patient Safety Goals. It is important to remember that the focus of the NPSGs is on system-wide solutions. This is an important change from the traditional method of finding out who made the error (e.g., creating an environment of fear and scapegoating) to analyzing the system to find out why the error was made (e.g., creating an environment of learning and improvement).

Bioterrorism Attacks

Nurses are considered frontline health care providers. As a result, they need education and training to be able to assess and detect potential bioterrorism attacks. The biologic agents that have been identified by the CDC as being of highest concern include anthrax, botulism, plague, viral hemorrhagic fevers, smallpox, and tularemia. See Table 32–1 for additional information on these agents.

Health care workers need to sustain a heightened awareness and alertness to circumstances or patterns that may indicate potential bioterrorism. The CDC (2001, p. 893) provides the following examples of when it is important to become suspicious:

- Is there an unusual geographic clustering of illness (e.g., individuals who attended the same public event)?
- Is the emergency department receiving an increase of clients with similar symptoms that suggests an infectious disease outbreak?
- Is there an unusual age distribution for common diseases (e.g., an increase in chickenpox-like symptoms among adults)?
- Is there a large number of cases of acute flaccid paralysis, suggestive of a release of *botulinum* toxin?

Figure 32-1 ■ Nurses need to teach clients about safety and how to prevent accidents by using infant car seats, guard gates on stairs, and sunburn protection, life jackets, and helmets.

Top left, Ryan Mcvay/Getty Images; top middle, Dana Hoff/Getty Images; top right, Kris Ubach and Quim Roser/Getty Images; bottom left, David Jakle/Getty Images; bottom right, Alistair Haines/Getty Images.

The health problems that nurses and other health care workers are seeing and caring for in one facility may only be one part of the big picture. Calling the local public health department and reporting observations and suspicions may reveal a larger pattern. Early detection and management are needed to help stop a bioterrorism attack.

Diagnosing

Under the domain of Safety/Protection, NANDA International offers a broad diagnostic label related to safety issues:

- *Risk for Injury*: Vulnerable to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health (Herdman & Kamitsuru, 2014, p. 386).

Because this is a broad label, it is suggested that more specific labels be used to provide clearer direction for nursing care. Diagnoses that describe injury more specifically include: *Risk for Falls*; *Latex Allergy Response*; *Risk for Latex Allergy Response*; and *Risk*

for: Infection, Suffocation, Poisoning, Trauma, Vascular Trauma, Aspiration, Adverse Reaction to Iodinated Contrast Media, Impaired Skin Integrity, and Risk for Self-Directed Violence (Wilkinson, 2014, p. 413; Herdman & Kamitsuru, 2014, pp. 375–377). Other diagnoses the nurse may choose to use are

- *Deficient Knowledge (Accident Prevention)*: Absence or deficiency of cognitive information related to a specific topic (e.g., safety of self and others).
- *Readiness for Enhanced Knowledge (Accident Prevention)*: A pattern of cognitive information related to a specific topic, or its acquisition, which can be strengthened (e.g., expresses a desire to enhance learning about accident prevention).

Planning

When planning care to prevent accidents and injury, the nurse considers all factors affecting the client's safety, specifies desired outcomes, and selects nursing activities to meet these outcomes. The major goal

BOX 32–2 The Joint Commission's 2014 National Patient Safety Goals for Hospitals and Long Term Care**Goal: Improve the Accuracy of Patient Identification.**

- Use at least two patient identifiers when providing care, treatment, and services. [Hospital and Long Term Care]
- Eliminate transfusion errors related to patient misidentification. [Hospital]

Goal: Improve the Effectiveness of Communication Among Caregivers.

- Report critical results of tests and diagnostic procedures on a timely basis. [Hospital]

Goal: Improve the Safety of Using Medications.

- Label all medications, medication containers, and other solutions on and off the sterile field in perioperative and other procedural settings. [Hospital]
- Reduce the likelihood of patient harm associated with the use of anticoagulant therapy. [Hospital and Long Term Care]
- Maintain and communicate accurate patient medication information. [Hospital and Long Term Care]

Goal: Reduce the Harm Associated with Clinical Alarm Systems.

- As of July 1, 2014, establish alarm system safety as a hospital priority.
- During 2014, identify the most important alarm signals to manage.
- As of January 2016, establish policies and procedures for managing the alarms.
- As of January 2016, educate staff and licensed independent practitioners about the purpose and proper operation of alarm systems for which they are responsible.

Goal: Reduce the Risk of Health Care–Associated Infections.

- Comply with either the current Centers for Disease Control and Prevention (CDC) hand hygiene guidelines or the current World Health Organization (WHO) hand hygiene guidelines. [Hospital and Long Term Care]
- Implement evidence-based practices to prevent health care–associated infections due to multidrug-resistant organisms in acute care hospitals. [Hospital]

- Implement evidence-based practices to prevent central line–associated bloodstream infections. [Hospital and Long Term Care]
- Implement evidence-based practices for preventing surgical site infections. [Hospital]
- Implement evidence-based practices to prevent indwelling catheter-associated urinary tract infections (CAUTI). [Hospital]

Goal: Prevent Residents from Falling.

- Determine which residents are most likely to fall. [Long Term Care]
- Take action to prevent falls for these residents. [Long Term Care]

Goal: Prevent Health Care–Associated Pressure Ulcers (Decubitus Ulcers).

- Assess and periodically reassess each resident's risk for developing a pressure ulcer and take action to prevent bed sores. [Long Term Care]

Goal: The Organization Identifies Safety Risks Inherent in Its Patient Population.

- Identify patients at risk for suicide. [Hospital]

UNIVERSAL PROTOCOL FOR PREVENTING WRONG SITE, WRONG PROCEDURE [HOSPITALS]

The Universal Protocol applies to all surgical and nonsurgical invasive procedures. Hospitals can enhance safety by correctly identifying the patient, the appropriate procedure, and the correct site of the procedure.

- Conduct a preprocedure verification process.
- Mark the procedure site.
- A time-out is performed before the procedure.

Retrieved from http://www.jointcommission.org/hap_2014_npsgs; and *Long Term Care (Medicare/Medicaid): 2014 National Patient Safety Goals*, The Joint Commission, 2013b. Retrieved from http://www.jointcommission.org/lt2_2014_npsgs.

for clients with safety risks is to prevent accidents and injury. To meet this goal, clients often need to change their health behaviors and may need to modify the environment.

Desired outcomes associated with preventing injury depend on the individual client. Examples of desired outcomes, although established in the planning phase, are provided in the *Evaluating* section on page 666.

Nursing interventions to meet desired outcomes are largely directed toward helping the client and family to accomplish the following:

- Identify environmental hazards in the home and community.
- Demonstrate safety practices appropriate to the home health care agency, community, and workplace.
- Experience a decrease in the frequency or severity of injury.
- Demonstrate safe child-rearing practices or lifestyle practices.

Implementing

Hazards to safety occur at all ages and vary according to the age and development level of the individual.

Promoting Safety Across the Life Span

Measures to ensure the safety of people of all ages focus on (a) observation or prediction of potentially harmful situations so that harm can be avoided and (b) client education that empowers clients to

protect themselves and their families from injury. Safety measures covering the life span from infancy to older adults are listed in the accompanying Client Teaching.

Newborns and Infants

Accidents are a leading cause of death during infancy, especially during the first year of life. Infants are completely dependent on others for care; they are oblivious to such dangers as falling or ingesting harmful substances. Parents need to learn the amount of observation necessary to maintain infant safety. They also need help to identify and remove common hazards in and around the home, and first-aid information that includes cardiopulmonary resuscitation and interventions for airway obstruction. Common accidents during infancy include burns, suffocation or choking, automobile crashes, falls, and poisoning. Education and support of parents can make them more knowledgeable and better prepared to protect their children from accidents and injuries.

Toddlers

Toddlers are curious and like to feel and taste everything. They are fascinated by potential dangers, such as pools and busy streets, so they need constant supervision and protection. Parents prevent many accidents by “toddler-proofing” the home or other setting where the child will be (Figure 32–2 ■). This practice extends to the use of federally approved car restraints and removing or securing all items that

TABLE 32-1 Biologic Pathogens of Highest Concern for Bioterrorism Attacks

Anthrax	Cause	Spore-forming bacterium— <i>Bacillus anthracis</i>
	Transmission	<ul style="list-style-type: none"> • Not known to spread from one person to another • Cutaneous/skin: direct skin contact with spores (most common) • Respiratory: inhalation of aerosolized spores (rare) • GI: consumption of undercooked or raw meat products or dairy products from infected animals (rare)
	Symptoms of cutaneous anthrax	<ul style="list-style-type: none"> • Localized itching followed by a lesion that turns vesicular and subsequent development of black eschar (scab) within 7–10 days of initial lesion • Fever, flulike symptoms, nonproductive cough, sore throat
Botulism	Cause	A toxin made by a bacterium called <i>Clostridium botulinum</i>
	Transmission	<ul style="list-style-type: none"> • Not spread from one person to another • Foodborne—person ingests preformed toxin • Infant—occurs in small number of infants who harbor <i>C. botulinum</i> in their intestinal tract • Wound—occurs when wounds are infected with <i>C. botulinum</i>
	Symptoms of foodborne botulism	Between 12–36 h after eating toxin-containing food: double and blurred vision, slurred speech, difficulty swallowing, muscle weakness that always descends through the body
Plague	Cause	A bacterium found in rodents and their fleas— <i>Yersinia pestis</i>
	Transmission	<ul style="list-style-type: none"> • Bubonic plague is transmitted through the bite of an infected flea or exposure to infected material through a break in the skin. Bubonic plague is not transmitted person to person. • Pneumonic plague is caused by an aerosol attack (bioweapon). Pneumonic plague can be transmitted person to person.
	Symptoms of pneumonic plague	Fever, weakness, rapidly developing pneumonia with dyspnea, chest pain, cough, and sometimes bloody or watery sputum
Viral hemorrhagic fevers (VHFs)	Cause	<ul style="list-style-type: none"> • Virus. Ebola and yellow fever are two examples. • Viruses of most VHFs reside in an animal reservoir host or arthropod host (e.g., rodents are hosts and ticks and mosquitoes can be vectors). However, the hosts of some VHFs (e.g., Ebola and Marburg) are unknown.
	Transmission	Humans are not natural reservoirs for VHFs. People are infected when they come in contact with infected hosts. However, with some VHFs, after the accidental transmission from the host, humans can transmit the virus to one another.
	Symptoms	After an incubation period of 5–10 days: abrupt onset of fever, myalgia, headache, nausea and vomiting, abdominal pain, diarrhea, chest pain. A rash on the trunk develops approximately 5 days after onset. Bleeding (e.g., petechiae, bruises, and hemorrhages) occurs as disease progresses.
Smallpox	Cause	Variola virus
	Transmission	Droplet nuclei expelled from the mouth of an infected person or by aerosol. Contaminated clothing or bed linen could also spread the disease. Humans are the only natural host of variola.
	Symptoms	<ul style="list-style-type: none"> • Incubation period can range from 7–17 days where the person has no symptoms and is not contagious. • Initial symptoms include high fever, head and body aches, and possibly vomiting. These symptoms last 2–4 days and the person may be contagious. • A rash then appears—first on the tongue and in the mouth. These red spots develop into sores that break open and spread large amounts of the virus into the mouth and throat. The person is highly contagious at this point. • The rash then spreads to the entire body. By the third day of the rash, the rash becomes raised bumps, which fill with thick, opaque fluid and have a depression in the center. The bumps become pustules, which begin to form a crust and then scab. • The scabs fall off, leaving pitted scars. The person is contagious until all the scabs have fallen off.
Tularemia	Cause	The bacterium <i>Francisella tularensis</i> found in animals (especially rodents, rabbits, and hares)
	Transmission	Not known to be spread from person to person It is spread in different ways: <ul style="list-style-type: none"> • Being bitten by an infected tick, deer-fly, or other insect • Handling infected animal carcasses • Eating or drinking contaminated food or water • Breathing in/inhaling the <i>F. tularensis</i>
	Symptoms	<ul style="list-style-type: none"> • Sudden fever, chills, headache, diarrhea, muscle aches, joint pain, dry cough, and progressive weakness • If <i>F. tularensis</i> was used as a bioweapon and made airborne for exposure by inhalation, the infected people would experience severe respiratory illness, including life-threatening pneumonia and systemic infection.

CLIENT TEACHING

Safety Measures Throughout the Life Span

NEWBORNS AND INFANTS

- Use a federally approved car seat at all times (including coming home from hospital). It should be in the back seat, facing backward.
- Never leave the infant unattended on a raised surface.
- Check the temperature of the infant's bath water and formula prior to using.
- Hold the infant upright during feeding. Do not prop the bottle. Cut food in small pieces, and do not feed the infant peanuts or popcorn. Slice hot dogs lengthwise in two pieces then into small pieces.
- Investigate the infant's crib for compliance with federal safety regulations: slats no more than 6 cm (2.4 in.) apart, lead-free paint, height of crib sides, tight fit of mattress to crib.
- Use a playpen with sides made of small-size netting. Never leave playpen sides down.
- Provide large soft toys with no small detachable or sharp-edged parts.
- Use guard gates on stairs and screens on windows. Supervise the infant in swings and highchairs.
- Cover electric outlets. Coil cords out of reach.
- Place plants, household cleaners, and wastebaskets out of reach. Lock away potential poisons, such as medicines, paint, and gasoline.

TODDLERS

- Continue to use federally approved car seats at all times. Place children in back seat when traveling in a car.
- Teach children not to put objects in the mouth, including pills (unless given by parent).
- Keep objects with sharp edges (such as furniture and knives) out of children's reach. Keep plastic bags out of reach.
- Place hot pots on back burners with handles turned inward.
- Keep cleaning solutions, insecticides, and medicines in locked cupboards.
- Keep windows and balconies screened.
- Supervise toddlers in the tub.
- Fence in pools, and supervise toddlers at all times when in or near pools. Do not overfill bathtub. Do not let toddlers play near ditches or wells.
- Teach children not to run or ride a tricycle into the street.
- Obtain a low bed when the child begins to climb.
- Cover outlets with safety covers or plugs.

PRESCHOOLERS

- Do not allow children to run with candy or other objects in the mouth.
- Teach children not to put small objects in the mouth, nose, and ears.
- Remove doors from unused equipment such as refrigerators.
- Always supervise preschoolers crossing streets and begin safety teaching about obeying traffic signals and looking both ways.
- Check Halloween treats before allowing children to eat them. Discard loose or open candy.
- Teach children to play in "safe" areas, not on streets and railroad tracks.
- Teach preschoolers the dangers of playing with matches and playing near charcoal, fire, and heating appliances.
- Teach children to avoid strangers and keep parents informed of their whereabouts.
- Teach preschoolers not to walk in front of swings and not to push others off playground equipment.

SCHOOL-AGE CHILDREN

- Teach children safety rules for recreational and sports activities: Never swim alone, always wear a life jacket when in a boat, and wear a protective helmet and knee and elbow pads when needed.
- Supervise contact sports and activities in which children aim at a target.
- Teach children to obey all traffic and safety rules for bicycling, skateboarding, and roller skating.
- Teach children to use light or reflective clothing when walking or cycling at night.
- Teach children safe ways to use the stove, garden tools, and other equipment.
- Supervise children when they use saws, electric appliances, tools, and other potentially dangerous equipment.
- Teach children not to play with fireworks, gunpowder, or firearms. Keep firearms unloaded, locked up, and out of reach.
- Teach children to avoid excavations, quarries, vacant buildings, and playing around heavy machinery.
- Teach children the health hazards of smoking. If you smoke, stop.
- Teach children the effects of drugs and alcohol on judgment and coordination.

ADOLESCENTS

- Have adolescents complete a driver's education course, and take practice drives with them in various types of weather.
- Set firm limits on automobile use, namely, never to drive after drinking or using drugs, and never to ride with a driver who has done so. Encourage adolescents to call home for a ride if they have been drinking, assuring them they can do so without a reprimand.
- Restrict number of passengers in car during the first year of driving.
- Teach adolescents to wear a safety helmet when riding motorcycles, scooters, and other sports vehicles. Teach safety rules for water sports.
- Encourage adolescents to use proper equipment when participating in sports. Schedule a physical examination before participation, and be certain there is medical supervision for all athletic activities.
- Encourage adolescents to swim, jog, and go boating in groups so they can obtain help in case of an accident.
- Teach safety measures for use of power tools.
- Teach rules for hunting and the proper care and use of firearms.
- Inform the adolescent of the dangers of drugs, alcohol, and unprotected sex. Include teaching about date rape prevention and defense.
- Teach dangers of sunbathing and tanning beds, as well as the proper use of sun block and protective clothing when doing outdoor activities.
- Be alert to changes in the adolescent's mood and behavior. Listen to and maintain open communication with the adolescent. Open communication is a powerful preventive measure.
- Set a good example of behavior that the adolescent can follow.

YOUNG ADULTS

- Reinforce motor vehicle safety: Drive defensively, use "designated drivers" if alcohol is consumed, routinely check brakes and tires, and use seat and shoulder belts or car seats for all passengers.
- Remind the young adult to repair potential fire hazards, such as electric wiring.
- Reinforce water safety: Know the depth of a pool or lake before diving; supervise backyard pools and other water activities.

CLIENT TEACHING—continued

- Discuss evaluating the potential for workplace injuries or death when making decisions about a career or occupation. Encourage the young adult to participate actively in programs that reduce occupational hazards.
- Discuss avoiding excessive sun radiation by limiting exposure, using sun-blocking agents, and wearing protective clothing. Explain the skin changes that may indicate a cancerous condition.
- Encourage young adults who are unable to cope with the pressures, responsibilities, and expectations of adulthood to seek counseling.
- Discuss the dangers associated with the Internet and social networking.

MIDDLE-AGED ADULTS

- Reinforce motor vehicle safety: Use seat belts and drive within the speed limit, especially at night. Test visual acuity periodically.
- Make certain stairways are well lighted and uncluttered.
- Equip bathrooms with hand grasps and nonskid bath mats.
- Test carbon monoxide detectors, smoke detectors, and fire alarms regularly.
- Keep all machines and tools in good working condition at work and at home. Follow safety precautions when using machinery.
- Reinforce safety measures taught earlier in life, such as the hazards of excessive sun exposure.

OLDER ADULTS

- Encourage the client to have regular vision and hearing tests.
- Assist the client to have a home hazard appraisal.
- Encourage the client to keep as active as possible.
- Ensure eyeglasses are functional.
- Ensure appropriate lighting.

- Mark doorways and edges of steps as needed.
- Keep the environment tidy and uncluttered.
- Set safe limits to activities.
- Remove unsafe objects.
- Wear shoes or well-fitted slippers with nonskid soles.
- Use ambulatory devices as necessary (cane, crutches, walker, braces, wheelchair).
- Provide assistance with ambulation as needed.
- Monitor gait and balance.
- Adapt living arrangements to one floor if necessary.
- Encourage exercise and activity as tolerated to maintain muscle strength, joint flexibility, and balance.
- Ensure uncluttered environment with securely fastened rugs.
- Encourage the client to request assistance.
- Keep the bed in the low position.
- Install grab bars in the bathroom.
- Provide a raised toilet seat.
- Instruct the client to rise slowly from a lying to sitting to standing position, and to stand in place for several seconds before walking.
- Provide a bedside commode as needed.
- Assist with voiding on a frequent and scheduled basis.
- Encourage the client to summon help.
- Monitor activity tolerance.
- Attach side rails to the bed.
- Keep rails in place when the bed is in the lowest position.
- Monitor orientation and alertness status.
- Encourage annual or more frequent review of all prescribed medications.

Figure 32-2 ■ Promoting safety (e.g., by placing hot pots on back burners with handles turned inward) is required to keep children from injury. Robert Dant/Getty Images.

can pose a safety hazard to the child in any setting. It may be necessary to inspect for and remove sources of lead from the environment. Lead poisoning (plumbism) is a risk for children exposed to lead paint chips, fumes from leaded gasoline, or any “leaded” substances.

The ingestion of lead-based paint chips is the most common cause of lead poisoning in children.

CLINICAL ALERT!

The remodeling and renovation of older homes (e.g., those built before 1978) accounts for most of the lead poisoning seen today. Nurses need to educate families living in older homes about their children’s risk for lead poisoning and provide lead poisoning prevention advice.

Preschoolers

Children of preschool age are active and often very clumsy, making them susceptible to injury. Control of the environment must continue, keeping hazards such as matches, medicines, and other potential poisons out of reach. Safety education for the child must begin now. Education of the preschooler involves learning how to cross streets, what traffic signals mean, and how to ride bicycles and other wheeled toys safely. Caution children to avoid hazards, such as busy streets, swimming pools, and other potentially dangerous areas. Parents must maintain careful surveillance; the developmental level of the preschooler does not allow for self-reliance in matters of safety. Parents must also keep in mind that their child’s cognitive and motor skills increase quickly; hence, safety measures must keep up with the acquisition of new skills.

School-Age Children

By the time children attend school, they are learning to think before they act. They often prefer adult equipment to toys. They want to play with other children in such activities as bicycling, hiking, swimming,

and boating. Although sensitive to peer pressure, the school-age child will respond to rules. Children of this age engage in fantasy and magical thinking. They often imitate the actions of parents and superheroes with whom they identify.

Injuries sustained as a result of accidents are the leading cause of death in school-age children. The most frequent causes of fatalities, in descending order, are motor vehicle crashes, drownings, fires, and firearms. School-age children are also involved in many minor injuries, frequently resulting from outdoor activities and recreational equipment such as swings, bicycles, skateboards, and swimming pools.

Adolescents

Obtaining a driver's license is an important event in the life of an adolescent in the United States, but the privilege is not always wisely handled. Teenagers may use driving as an outlet for stress, as a way to assert independence, or as a way to impress peers. When setting limits on automobile use, parents need to assess the teenager's level of responsibility, common sense, and ability to resist peer pressure. The age of the teenager alone does not determine readiness to handle this responsibility.

Adolescents are at risk for sports injuries because their coordination skills are not fully developed. However, sports activities are important to the adolescent's self-esteem and overall development. In addition to providing beneficial exercise, sports activities enhance social and personal development. They help the adolescent experience competition, teamwork, and conflict resolution.

Suicide and homicide are two leading causes of death among teenagers. Adolescent males commit suicide at a higher rate than adolescent females, and African Americans commit homicide at a higher rate than European Americans. Suicides by firearms, drugs, and automobile exhaust gases are the most common. Factors influencing the high suicide and homicide rates include economic deprivation, family breakup, and the availability of firearms, which are the most frequently used weapons. Cutting or stabbing tools are the next most frequently used weapons.

Young Adults

Motor vehicle crashes are by far the leading cause of mortality for this group; other causes of death for young adults include drowning, fires, burns, and firearms.

One safety hazard for many young adults is exposure to natural radiation from sunbathing or outdoor activities. Exposure to the sun is directly related to skin cancer. Suicide is another leading cause of death in young adults. Many suicides may actually be mistaken for unintentional death (automobile crashes, alcohol intoxication, and drug overdose). In general, suicide results from the young adult's inability to cope with the pressures, responsibilities, and expectations of adulthood.

The nurse's role in the prevention of suicide includes identifying behaviors that may indicate potential problems: depression; a variety of physical complaints including weight loss, sleep disturbances, and digestive disorders; and decreased interest in social and work roles along with an increase in isolation. A young adult identified as at risk for suicide should be referred to a mental health professional or a crisis center. Nurses can also reduce the incidence of suicide by participating in educational programs that provide information about the early signs of suicide.

Middle-Aged Adults

Changing physiological factors, as well as concern over personal and work-related responsibilities, may contribute to the injury rate of middle-aged people. Motor vehicle crashes are the most common cause of accidental death in this age group. Decreased reaction times and visual acuity may make the middle-aged adult prone to accidents. Other unintentional causes of death for middle-aged adults include falls, fires, burns, poisonings, and drownings. Occupational injuries continue to be a significant safety hazard during the middle years.

Older Adults

Injury prevention is a major concern for older adults. Because vision is limited, reflexes are slowed, and bones are brittle, activities such as climbing stairs, driving a car, and even walking require caution. Driving, particularly at night, requires caution because accommodation of the eye to light is impaired and peripheral vision is diminished. Older adults need to learn to turn their head before changing lanes and should not rely on side vision, for example, when crossing a street or changing lanes. Driving in fog or other hazardous conditions should be avoided.

Fires are a hazard for the older person with a failing memory. The older person may forget that the iron or stove has been left on or may not extinguish a cigarette completely. Because of reduced sensitivity to pain and heat, care must be taken to prevent burns when the person bathes or uses heating devices.

Older adults at risk for wandering due to organic brain syndromes need to wear identification devices. They can also be registered with the local Alzheimer's Association's Wanderer's Alert Program.

Because older adults who take analgesics or sedatives may become lethargic or confused, they should be monitored regularly and closely. Other measures to induce sleep should be used whenever possible. Nurses can help older clients make the home environment safe. Specific hazards should be identified and corrected; for example, handrails can be installed on staircases. The nurse teaches the importance of taking only prescribed medications and contacting a health professional at the first indication of medication intolerance.

SAFETY ALERT!

SAFETY

Older adults have trouble seeing the edges of stairs. Painting white stripes on the edges of the steps will help increase contrast and may prevent falls.

The incidence of suicide in older adults is increasing. People ages 65 and older comprise about 13% of the U.S. population; however, they account for over 18% of all suicides (Caruso, n.d.). As people age, they experience both physical and emotional losses. They often develop chronic illnesses, which can lead to functional loss and disability. And, their memory and other cognitive functions often decline. All of these losses make the older adult more susceptible to depression, which is a major risk factor for suicide. Mehra, Gianakos, and Driscoll (2012) report that key risk factors for suicide in older adults include the following:

- **Gender.** The suicide rate for men 75 years and older is almost twice the rate for men of all ages.
- **Rural communities.** Suicide rates are three times higher in rural areas than in urban ones.

- **Depression.** Common symptoms of depression, such as fatigue, sleep problems, and weight loss or gain, may incorrectly be attributed to the older person's existing chronic illness(es). Chronic pain can also worsen depression.
- **Social isolation.** The risk of suicide increases when social isolation is due to bereavement or loss of social support.

Compared with the general population, suicide attempts by older individuals are usually more serious, because of a greater degree of premeditation and planning to end the life, not just to get attention as is often seen in other age groups (Kneisl & Trigoboff, 2013). Also, the method of suicide is generally more violent in the older population. For example, older men are more likely to have access to and use guns as a means of suicide (Tabloski & Connell, 2014).

It is important for nurses to know the signs and symptoms of depression and suicide. Of note is the fact that many older adults have seen a primary care provider or have sought help in an emergency department in the month before their suicide (Kneisl & Trigoboff, 2013; Tabloski & Connell, 2014). Nurses who interact with older adults who seem sad or depressed should ask the client about suicidal intent. Some nurses hesitate to do this thinking that asking will place the idea in the older adult's mind. However, this is rarely, if ever, the case (Tabloski & Connell, 2014). If the older adult responds affirmatively, the nurse should direct the client to the appropriate professional or agency for treatment and counseling.

SAFETY ALERT!

SAFETY

Studies show that many older adults who die by suicide visited a primary care provider within a month before their death. These findings point to the urgency of improving detection and treatment of depression to reduce suicide risk among older adults (National Institute of Mental Health, 2009).

Safety Problems Across the Life Span

Domestic violence is increasing at an alarming rate and involving individuals of all ages. It includes child abuse, intimate partner abuse, and older adult abuse and affects the health and safety of families and the community. Statistics are inaccurate due to the underreporting of incidents. Nurses should be involved in working with all phases of domestic violence: prevention, screening, referrals for treatment, and follow-up care. This usually necessitates collaborative planning with primary care providers, law enforcement agencies, social services, and other community agencies.

Nurses also have the opportunity to become advocates for community support programs for domestic violence and can become involved in educating other professionals regarding prevention, screening, and treatment.

Domestic violence takes on extra importance because it is known that people who were abused as children often display abusive behavior as an adult. This fact points to the need for prevention and early intervention to prevent the cycle from continuing. Nurses can be of assistance in restoring dignity, health, and safety to vulnerable individuals.

Promoting Safety in the Health Care Setting

Client safety in the health care setting is of primary importance. One of the primary interventions health care institutions must enact is a climate of change and trust. There is a need to change the culture in

health care from placing blame to examining how to improve care. Trust needs to be developed and sustained for people to feel open to discuss and share experiences about their safety. Communication is of utmost importance to protect clients from errors and maintain continuity of care. Nurses are the frontline managers of client care and must be actively involved in the priority of client safety and the prevention of medical errors.

Preventing Specific Hazards

Implementing measures to prevent specific hazards or injuries such as burns, fires, falls, seizures, poisoning, suffocation, and so on are critical aspects of nursing care. Teaching clients about safety is another important aspect. Nurses usually have opportunities to teach while providing care.

Falls

People of any age can fall, but infants and older adults are particularly prone to falling and causing serious injury. Falls are the leading cause of injuries among older adults. More than one third of adults ages 65 and older experience falls, and in this group, falls are the leading cause of injury-related deaths and the most common cause of injuries and hospital admissions (Jorgensen, 2011, p. 2). Most falls occur in the home and are a major threat to the independence of older adults. Fear of falling is common in older adults, even in those who have not experienced a fall. This fear is of particular concern for those who live alone and who anticipate being helpless and unable to summon help after a fall. For these individuals the nurse should encourage daily or more frequent contact with a friend or family member, installation of a personal emergency response system, and measures to maintain a physical environment that prevents falls. Risk factors and associated preventive measures are shown in Table 32–2.

CLINICAL ALERT!

Falls can break bones and self-confidence, leading to fear of falling, which can cause a decreased activity level and decreased muscle strength. All increase the risk of falling.

Health care facilities have strong incentives to reduce the number of client falls. As of 2008, the Centers for Medicare and Medicaid Services (CMS) stopped paying for injuries caused by in-hospital falls (Titler, Shever, Kanak, Picone, & Qin, 2011). In 2010, The Joint Commission added two required standards relating to client safety and hospital falls (Jorgensen, 2011): The hospital must (1) assess and manage the client's risks for falls and (2) implement interventions to reduce falls based on the client's assessed risk. Therefore, identifying clients at risk for falling can reduce the number of falls that occur in a hospital.

It is important to assess clients for fall risk on admission, whenever a change in physical or mental status occurs, on transfer, and before discharge (Kulik, 2011, p. 6). Many assessment tools to determine a client's risk of falling are available. Most assess for age, number of diseases, medications, environment, physical ability, vision, and history of falls. Assessing the client for fall risks gives the nurse information needed to develop an individualized care plan.

Older adults experience a decrease in muscle strength as they age that affects their balance and increases their risk of falling. The nurse can complete a 2- to 5-minute assessment tool called the "Timed Up and Go" (TUG) test in a hospital, long-term care, or home setting. This

TABLE 32–2 Risk Factors and Preventive Measures for Falls

Risk Factor	Preventive Measures
Poor vision	Ensure eyeglasses are functional. Ensure appropriate lighting. Mark doorways and edges of steps as needed. Keep the environment tidy.
Cognitive dysfunction (confusion, disorientation, impaired memory, or judgment)	Set safe limits to activities. Remove unsafe objects.
Impaired gait or balance and difficulty walking because of lower extremity dysfunction (e.g., arthritis)	Wear shoes or well-fitted slippers with nonskid soles. Use ambulatory devices as necessary (cane, crutches, walker, braces, wheelchair). Provide assistance with ambulation as needed. Monitor gait and balance. Adapt living arrangements to one floor if necessary. Encourage exercise and activity as tolerated to maintain muscle strength, joint flexibility, and balance. Ensure uncluttered environment with securely fastened rugs.
Difficulty getting in and out of chair or in and out of bed	Encourage client to request assistance. Keep the bed in the low position. Install grab bars in bathroom. Provide a raised toilet seat.
Orthostatic hypotension	Instruct client to rise slowly from a lying to sitting to standing position, and to stand in place for several seconds before walking. Provide a bedside commode.
Urinary frequency or receiving diuretics	Assist with voiding on a frequent and scheduled basis.
Weakness from disease process or therapy	Encourage client to summon help. Monitor activity tolerance.
Current medication regimen that includes sedatives, hypnotics, tranquilizers, narcotic analgesics, diuretics	Attach one-quarter to one-half length side rails to the bed if appropriate. Keep the rails in place when the bed is in the lowest position. Monitor orientation and alertness status. Discuss how alcohol contributes to fall-related injuries. Encourage client not to mix alcohol and medications and to avoid alcohol when necessary. Encourage annual or more frequent review of all medications prescribed.

assessment requires the person to complete a series of tasks that are important for independent mobility: standing, walking, turning, and sitting (Picone, 2013, p. 57). The test consists of asking the person to stand up from a standard chair, walk at a comfortable pace for a distance of 10 feet to a spot marked with a piece of tape, turn, walk back, and sit down. The person is allowed to use their routine walking aid. The person is instructed not to use the arms to stand up from the chair and no physical assistance is given. The time to complete the test is measured with a stopwatch. Usually the test is performed twice and the best time is used. A time of 14 seconds or more indicates a high risk of falling (Herman, Giladi, & Hausdorff, 2011; Picone, 2013). This quick assessment, along with an assessment of the client's environment, can help the nurse recommend safety measures to the client and family.

Health agencies have protocols to help prevent client falls. The AHRQ (2013) strongly encourages health agencies to have “universal fall precautions” as part of their fall prevention programs. Universal fall precautions keep *all* client environments safe (see Box 32–3).

The majority of falls in the acute hospital setting occur in the client's room, generally around the bed and in the bathroom, with the majority of falls not being observed. The major reason for these falls relates to toileting and a client's fear of having “an accident.” Evidence reveals an association between being in a hurry to get to the bathroom and falls. AHRQ (2013) recommends a proactive approach called “scheduled rounding.” This is where the nurse conducts hourly

BOX 32–3 Sample Universal Fall Precautions

- Familiarize the client with the environment.
- Have the client “teach back” how to use the call light.
- Keep the call light within reach at all times.
- Keep the client's personal possessions within safe reach.
- Provide sturdy handrails in client bathrooms, rooms, and hallway.
- Keep the hospital bed in low position with brakes locked when client is resting in bed.
- Provide nonslip, well-fitting footwear.
- Use night-lights or supplemental light.
- Keep floor surfaces clean and dry. Clean up all spills promptly.
- Keep client area uncluttered.

From *Preventing Falls in Hospitals: A Toolkit for Improving Quality of Care*, by AHRQ, 2013. Retrieved from <http://www.ahrq.gov/professionals/systems/long-term-care/resources/injuries/fallpxtoolkit/index.html>; and *Institute for Clinical Systems Improvement: Prevention of Falls (Acute Care)*, by J. Degelau et al., 2012. Retrieved from https://www.icsi.org/_asset/dcn15z/Falls-Interactive0412.pdf#page=19.

visits between 6 AM and 10 PM and visits every 2 hours between 10 PM and 6 AM. The hourly rounding can be alternated between the nurse and unlicensed assistive personnel. The rounding usually includes pain assessment, offering help with toileting, offering hydration or nutrition, positioning the client if needed, making sure clients' call light and personal items are within safe reach, and asking the client/family to use the call light if the client needs to get out of bed. For

PRACTICE GUIDELINES

Preventing Falls in Health Care Agencies

- On admission, orient clients to their surroundings and explain the call system.
- Carefully assess the client's ability to ambulate and transfer. Provide walking aids and assistance as required.
- Closely supervise the clients at risk for falls, especially at night.
- Encourage the client to use the call light to request assistance. Ensure that the light is within easy reach.
- Place bedside tables and overbed tables near the bed or chair so that clients do not overreach and consequently lose their balance.
- Always keep hospital beds in the low position and wheels locked when not providing care so that clients can move in or out of bed easily.
- Encourage clients to use grab bars mounted in toilet and bathing areas and railings along corridors.
- Make sure nonskid bath mats are available in tubs and showers.
- Encourage the client to wear nonskid footwear.
- Keep the environment tidy; keep light cords from underfoot and furniture out of the way.
- Use individualized interventions (e.g., alarm sensitive to client position) rather than side rails for confused clients.
- Use mechanical or electronic ceiling lifts to transfer dependent clients.

information on preventing falls and subsequent injury of clients, see the Practice Guidelines.

CLINICAL ALERT!

When a client falls, the nurse's first duty is to the client. First, assess for injuries. Then, notify the primary care provider.

Although it may seem that raising the side rails on a bed is an effective method of preventing falls, do not routinely raise rails for this purpose. Research has shown that individuals with memory impairment, altered mobility, nocturia, and other sleep disorders are prone to becoming entrapped in side rails and may, in fact, be more likely to fall trying to get out around raised rails (Nowicki, Fulbrook, & Burns, 2010). Clients may even become entrapped between the mattress and side rails, leading to asphyxiation deaths. In some settings, side rails are not used at all. Instead, beds are lowered fully, and long pads are placed on each side of the bed.

Health care environments should be safety oriented with systems in place to allow objective evaluation of outcomes. Environments

should be designed with many safety features to reduce the risk of falls, such as regular toileting and orientation of clients who are confused or impaired; the use of fall risk alerts such as client ID wrist bands of a specific color; railings along corridors; call lights at each bedside; safety bars in toilet areas; locks on beds, wheelchairs, and stretchers; well-maintained and appropriately sized wheelchairs; one-quarter to one-half length side rails on beds or pads beside beds; night-lights; freedom from clutter; and so on.

Electronic **safety monitoring devices** are available to detect when clients are attempting to move or get out of bed. For example, a bed or chair safety monitor has a position-sensitive switch that triggers an audio alarm when the client attempts to get out of the bed or chair. A magnetic box mobility monitor mounted on a bed or chair connects with a clip to clothing. It will pull apart should the client try to move away from the chair or bed, triggering an alarm. There are also dual-sensor systems that have a pressure-sensitive sensor combined with an infrared beam detector. These monitors, however, can alarm with normal position changes, so nurses must be careful to assess whether or not the client is actually trying to exit the bed or chair. Skill 32-1 describes how to use these devices.

Using a Bed or Chair Exit Safety Monitoring Device

PURPOSES

- To alert the nurse that the client is attempting to get out of bed
- To help decrease the risk of client falls

ASSESSMENT**Assess**

- Mobility status
- Judgment about the ability to get out of bed safely
- Client's pattern of exiting the bed (e.g., using upper extremities to pull the body up before lowering the feet to the floor or leaning toward the edge of the bed prior to dropping the legs over the side)
- Proximity of client's room to nurses' station
- Position of side rails
- Functioning status of call light

PLANNING

Determine the best type of device and appropriate location for the device. No matter where the device is applied, choose a location where skin is intact.

Equipment

- Alarm and control device
- Sensor
- Connection to nurse call system

Using a Bed or Chair Exit Safety Monitoring Device—continued

DELEGATION

Risk factors for falls may be observed and recorded by individuals other than the nurse. The nurse is responsible for assessing the client and confirming that there is a risk of the client falling when getting out of a chair or bed unassisted. The nurse develops a plan of care that includes a variety of interventions that will protect the client. If indicated, use of a safety monitoring device may be delegated to unlicensed assistive personnel (UAP) who have been trained in their application and monitoring.

INTERPROFESSIONAL PRACTICE

Assessing a client's risk for falls is within the scope of practice for several health care providers. For example, in addition to nurses, both physical therapists and occupational therapists assess for fall risk. Although these therapists may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to client and family the purpose and procedure of using a safety monitoring device. Explain that the device does not limit mobility in any manner; rather, it alerts the staff when the client is about to get out of bed or a chair. Explain that the nurse must be called when the client needs to get out of bed or a chair.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Test the battery device and alarm sound.

Rationale: *Testing ensures that the device is functioning properly prior to use.*

5. Apply the leg band or sensor pad.
 - Place the leg band according to the manufacturer's recommendation. Place the client's leg in a straight-horizontal position.

Rationale: *The alarm device is position sensitive; that is, when it approaches a near-vertical position (such as in walking, crawling, or kneeling as the client attempts to get out of bed), the audio alarm will be triggered.*
 - For the bed or chair device, the sensor is usually placed under the buttocks area. ①
 - For a bed or chair device, set the time delay from 1 to 12 seconds for determining the client's movement patterns.
 - Connect the sensor pad to the control unit and the nurse call system.
6. Instruct the client to call the nurse when the client wants or needs to get up, and assist as required.
 - When assisting the client up, deactivate the alarm.
 - Assist the client back to the bed or chair, and reattach the alarm device.

7. Ensure client safety with additional safety precautions.
 - Place call light within client reach, lift side rails per agency policy, and lower the bed to its lowest position.

Rationale: *The alarm device is not a substitute for other precautionary measures.*
- Place ambulation monitoring signs on the client's door, chart, and other relevant locations.
- Document the type of alarm used, where it was placed, and its effectiveness in the client record using forms or checklists supplemented by narrative notes when appropriate. Record all additional safety precautions and interventions discussed and employed.

① Placement of a bed exit monitoring device.

Continued on page 654

Using a Bed or Chair Exit Safety Monitoring Device—continued

SAMPLE DOCUMENTATION

7/2/2015 1130 Found out of bed despite frequent reminders given to use call light for assistance. Explained about using a magnetic box mobility alarm to ensure own safety from possible fall. Verbalized agreement. Alarm device applied. Reminded again of importance to call the nurse for assistance. Call light placed within client's reach.
 _____ T. Kyle, RN

EVALUATION

- If the alarm is too sensitive to client movement that is not an attempt to move from bed or chair, reassess and modify alarm controls accordingly.
- Conduct appropriate follow-up relating to effectiveness of safety precautions.
- Report any difficulties using the device or any falls to the primary care provider.

Home Care Considerations Using a Bed or Chair Exit Safety Monitoring Device

SAFETY

If the device is used in the home, instruct caregivers to do the following:

- Test the monitoring device every 12 to 24 hours to ensure that it is working.
- Check the volume of the alarm to ascertain that they can hear it. Use of the device does not take the place of proper supervision of clients at risk for falling. Assessment of the reasons for falling, especially among older adults, can lead to effective prevention.

Seizures

A **seizure** is a single temporary event that consists of uncontrolled electrical neuronal discharge of the brain that interrupts normal brain function (Osborn, Wraa, Watson, & Holleran, 2014, p. 543). The etiology or cause of the seizure can be different based on the age of the client. Trauma during birth is the leading cause of seizures in newborns. Infants and children develop seizures as a result of fever, trauma, and infections of the central nervous system. The development of seizures in the adult population is most commonly related to structural abnormalities of the brain such as tumors, strokes, and trauma.

Seizures are classified into two categories: partial and generalized. Partial seizures (also called focal) involve electrical discharges

from one area of the brain. In contrast, generalized seizures affect the whole brain. Each of these seizure categories includes different types of seizures, depending on the characteristics of the seizure activity (e.g., loss of consciousness versus no impairment to consciousness). Thus, it is important for nurses to thoroughly describe their observations before, during, and after a client's seizure episode. Clients are at risk for injury if they experience seizures that involve the entire body such as *grand mal* (tonic-clonic) seizures or any seizure that includes loss of consciousness. **Seizure precautions** are safety measures taken by the nurse to protect clients from injury should they have a seizure. Skill 32-2 describes how to implement seizure precautions.

Implementing Seizure Precautions

PURPOSE

- To protect the client from injury

ASSESSMENT

Assess the history of seizures during the admission assessment. If the client has experienced a seizure previously, ask for detailed information, including characteristics of an aura or warning symptoms that indicate the seizure is beginning, duration and frequency

of the seizures, consequences of the seizures (e.g., incontinence or difficulty breathing), and actions that should be taken to prevent or reduce seizure activity.

PLANNING

Review emergency procedures because respiratory arrest or other injury can result from a seizure.

Equipment

- Blankets or other linens to pad side rails
- Oral suction equipment
- Oxygen equipment

DELEGATION

UAP should be familiar with establishing and implementing seizure precautions and methods of obtaining assistance during a client's seizure. Care of the client during a seizure, however, is the responsibility of the nurse due to the importance of careful assessment of respiratory status and the potential need for intervention.

Implementing Seizure Precautions—continued

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures. If the client is actively seizing, apply clean gloves in preparation for performing respiratory care measures.
3. Provide for client privacy.
4. Pad the bed of any client who might have a seizure. Secure blankets or other linens around the head, foot, and side rails of the bed. ①
5. Put oral suction equipment in place and test to ensure that it is functional.

Rationale: Suctioning may be needed to prevent aspiration of oral secretions.

6. If a seizure occurs:
 - Remain with the client and call for assistance. Do not restrain the client.

① Padding a bed for seizure precautions.

- If the client is not in bed, assist the client to the floor and protect the client's head by holding it in your lap or on a pillow. Loosen any clothing around the neck and chest.
 - Turn the client to a lateral position if possible.
- Rationale:** Turning to the side allows secretions to drain out of the mouth, decreasing the risk of aspiration, and helps keep the tongue from occluding the airway.
- Move items in the environment to ensure the client does not experience an injury.
 - Do not insert anything into the client's mouth.
 - Time the seizure duration.
 - Observe the progression of the seizure, noting the sequence and type of limb involvement. Observe skin color. When the seizure allows, check pulse and respirations.
 - Apply oxygen via mask or cannula.
 - Use equipment to suction the oral airway if the client vomits or has excessive oral secretions.
 - Administer anticonvulsant or antiepileptic medications, as ordered.
 - When the seizure has subsided, assist client to a comfortable position. Reorient. Explain what happened. Reassure the client. Provide hygiene as necessary. Allow the client to verbalize feelings about the seizure.
 - Status epilepticus clients may stop breathing after the seizure. Begin CPR immediately. Apply oxygen per nasal cannula or mask when breathing resumes.
 - If applied, remove and discard gloves.
 - Perform hand hygiene.

7. Document the event in the client record using forms or checklists supplemented by narrative notes when appropriate.

SAMPLE DOCUMENTATION

7/8/2015 1815 Upon entering room, observed generalized muscle spasms/contractions of arms and legs lasting 25 seconds. Seizure padding previously placed on bed. Incontinent of urine. Cyanotic. Placed on left side. Suctioned. Airway clear. Respirations 14/min with irregular pattern. Oxygen applied at 4 L/min via mask. Oxygen sat 90% on O₂. Not currently responding to verbal stimuli. Dr. Smith notified. Diazepam 10 mg given IV per order. VS taken every 15 min. See neuro flow sheet _____ B. Gill, RN

1835 Respirations 15/min regular. Responding to verbal stimuli. Oriented to person, place, and time. Oxygen saturation 95% on O₂. Oxygen discontinued per doctor's order. VS continue every 15 min. See neuro flow sheet _____ B. Gill, RN

EVALUATION

- Perform a detailed follow-up examination of the client. Administer medications if indicated and ordered.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Implementing Seizure Precautions

CHILDREN

- Seizures occur in about 10% of children. Most seizures are caused by disorders that originate outside of the brain (e.g., infection, head trauma, hypoxia, toxins) (Kyle & Carman, 2013, p. 510).
- Febrile seizures occur more commonly in children than in adults and are usually preventable through the use of antipyretics and tepid baths.
- Determine oxygenation. Apply oxygen if pulse oximetry reading is less than 95% (see Chapter 50 ∞).
- Children who have frequent seizures may need to wear helmets for protection.
- Children on antiepileptic medications should wear a medical identification tag (bracelet or necklace).

Home Care Considerations Implementing Seizure Precautions

SAFETY

- If clients have frequent or recurrent seizures or take anticonvulsant medications, they should wear a medical identification tag (bracelet or necklace) and carry a card delineating any medications they take.
- When making home visits, inspect antiepileptic medications and confirm that clients are taking them correctly. Blood level measurements may be required periodically.
- Assist clients in determining who in the community should or must be informed of their seizure disorder (e.g., employers,

health care providers such as dentists, motor vehicle department if driving, and companions).

- Discuss safety precautions for inside and out of the home. If seizures are not well controlled, activities that may require restriction or direct supervision by others include tub bathing, swimming, cooking, using electric equipment or machinery, and driving.
- Discuss with the client and family factors that may precipitate a seizure.

Scalds and Burns

A **scald** is a burn from a hot liquid or vapor, such as steam. A **burn** results from excessive exposure to thermal, chemical, electric, or radioactive agents.

Common home hazards causing scalds include the following:

- Pot handles that protrude over the edge of a stove
- Electric appliances used to heat liquids or oils, especially those with dangling cords that are within reach of crawling infants and young children
- Excessively hot bath water.

In health care agencies, the risk of scalds and burns is greater for clients whose skin sensitivity to temperature is impaired. Scalds can occur from overly hot bath water, and burns can occur from therapeutic applications of heat (see Chapter 36 ∞). It is important for the nurse to assess how well clients can protect themselves and what special precautions, if any, need to be taken.

Fires

Fires continue to be a constant risk in both health care settings and homes. Agency fires usually result from malfunctioning electric equipment or combustion of anesthetic gas. Home fires most frequently result from careless disposal of burning cigarettes or matches, from grease, or from faulty electric wiring.

Agency Fires In health care agencies, fire is particularly hazardous when people are incapacitated and unable to leave the building without assistance. This incapacity makes it extremely important for nurses to be aware of the fire safety regulations and fire prevention practices of the agencies in which they work. When smoke or fire is detected, two mnemonics can help the nurse remember the steps to follow. First is the RACE protocol:

1. **Rescue:** If the area is safe to enter, protect and evacuate clients who are in immediate danger.
2. **Alarm:** Pull the fire alarm and report the fire details and location to the hospital's fire emergency extension.
3. **Confine:** Contain the fire by closing the doors to all rooms and the fire doors at each entrance to the unit.
4. **Extinguish:** Extinguish the fire. Use the appropriate type of fire extinguisher (see the PASS mnemonic) OR Evacuate the area if the fire is too large for a fire extinguisher.

Extinguishing the fire requires knowledge of three categories of fire, classified according to the type of material that is burning:

Class A: paper, wood, upholstery, rags, ordinary rubbish

Class B: flammable liquids and gases

Class C: electrical.

Figure 32-3 ■ Fire extinguisher.
© Squared Studios/Getty Images.

The right type of extinguisher must be used to fight the fire. Extinguishers have picture symbols showing the type of fire for which they are to be used. Directions for use are also attached. See Figure 32-3 ■. The nurse follows the mnemonic PASS when using a fire extinguisher:

Pull out the extinguisher's safety pin.

Aim the hose at the base of the fire.

Squeeze or press the handle to discharge the material onto the fire.

Sweep the hose from side to side across the base of the fire until the fire appears to be out.

Home Fires Nursing interventions for home fires focus on teaching fire safety. Preventive measures include the following:

- Keep emergency numbers near the telephone, or stored for speed dialing.
- Be sure the smoke alarms are operable and appropriately located.
- Teach clients to change the batteries in their smoke alarms annually on a special day such as a birthday or January 1.
- Have a family fire drill plan. Every member needs to know the plan for the nearest exit from different locations of the home.
- Keep fire extinguishers available and in working order.
- Close windows and doors if possible, cover the mouth and nose with a damp cloth when exiting through a smoke-filled area, and

Figure 32–4 ■ Carbon monoxide detector.
Danny Hooks/Getty Images.

avoid heavy smoke by assuming a bent position with the head as close to the floor as possible.

Carbon Monoxide Poisoning

Carbon monoxide (CO) is an odorless, colorless, tasteless gas that is very toxic. Exposure to CO can cause symptoms that include headaches, dizziness, weakness, nausea, vomiting, or loss of muscle control. Prolonged exposure to CO can lead to unconsciousness, brain damage, or death. Learning the steps to prevent CO exposure is particularly important because all gasoline-powered vehicles, lawn mowers, kerosene stoves, barbecues, and burning wood emit CO. Incomplete or faulty combustion of any fuel, including natural gas used in furnaces, also produces CO. Carbon monoxide detectors are available for the home (Figure 32–4 ■).

Poisoning

Inadequate supervision and improper storage of many household toxic substances are the major reasons for poisoning in children. Implementing poison prevention for children is focused on teaching parents to “childproof” the environment, including disposing of unused medications properly (see Chapter 35 ∞). Adolescent and

adult poisonings are usually caused by insect or snake bites and drugs used for recreation or in suicide attempts. Implementing poison prevention in these age groups focuses on providing information and counseling. Poisoning in older adults usually results from accidental ingestion of a toxic substance (e.g., due to failing eyesight) or an overdose of a prescribed medication (e.g., due to impaired memory). Implementing poison prevention with older adults focuses on safeguarding the environment and monitoring the underlying problems.

In older adults who have dementia, poisoning is often a safety problem. As cognitive abilities deteriorate, the same precautions need to be taken as with children. Older adults who have dementia have the need to feel everything and will put anything in their mouths, including plants, flowers, candles, small objects, and medications. These and other potentially dangerous items need to be locked up or kept out of reach. A telephone number for the nearest poison control center should be readily available. These precautions are important whether the individual with dementia is being cared for at home or in an institution.

In response to the ever-increasing number of poison hazards, many countries have established poison control centers that provide accurate, up-to-date information about potential hazards and recommend treatment as needed. For certain poisons, specific antidotes or treatments are available; for many, there is no specific therapy.

Nurses intervene in community settings by educating the public about what to do in the event of poisoning: Identify the specific poison by searching for an opened container, empty bottle, or other evidence. Contact the poison control center, indicate the exact quantity of poison the person ingested, and state the person’s age and apparent symptoms. Keep the person as quiet as possible and lying on the side or sitting with head placed between the legs to prevent aspiration of vomitus. The Client Teaching feature provides additional guidelines for teaching clients to prevent poisoning.

Suffocation or Choking

Suffocation, or **asphyxiation**, is lack of oxygen due to interrupted breathing. Suffocation occurs when the air source is cut off for any reason. One common reason for choking is that food or a foreign object has become lodged in the throat. The universal sign of distress is the victim’s grasping the anterior neck and being unable to speak or

CLIENT TEACHING

Preventing Poisoning

- Lock potentially toxic agents, including drugs and cleaning agents, in a cupboard, or attach special plastic hooks to the insides of cabinet doors to keep them securely closed. Unlatching these hooks requires firmer thumb pressure than small children can usually exert. Do not let children watch you open the latches. Kids learn fast!
- Avoid storing toxic liquids or solids in food containers, such as soft drink bottles, peanut butter jars, or milk cartons.
- Do not remove container labels or reuse empty containers to store different substances. Laws mandate that the labels of all poisons specify antidotes.
- Do not rely on cooking to destroy toxic chemicals in plants. Never use anything prepared from nature as a medicine or “tea.”
- Teach children never to eat any part of an unknown plant or mushroom and not to put leaves, stems, bark, seeds, nuts, or berries from any plant into their mouths.
- Place poison warning stickers designed for children on containers of bleach, lye, kerosene, solvent, and other toxic substances.
- Do not refer to medicine as candy or pretend false enjoyment when taking medications in front of children; allow them to see the necessity of the medicine without glamorizing it.
- Read and follow label directions on all products before using them.
- Keep syrup of ipecac on hand at all times. Syrup of ipecac is a nonprescription emetic available in single-dose 15-mL vials in all drugstores. Use it only after getting advice from the local poison control center or the family primary care provider.
- Do not keep poisonous plants in the home, and avoid planting poisonous plants in the yard. The cooperative extension agency in your county can provide a list of poisonous plants.
- Display the phone number of the poison control center near or on all telephones in the home so that it is available to babysitters, family, and friends.

Figure 32-5 ■ Performing the Heimlich maneuver.
Science Photo Library/Getty Images.

cough. The emergency response is the **Heimlich maneuver** or abdominal thrust, which can dislodge the foreign object and reestablish an airway. See Figure 32-5 ■.

Other causes of suffocation are drowning, gas or smoke inhalation, accidental coverage of the nose and mouth by a piece of plastic, accidental strangulation by the shoulder harness of a seat belt, and being trapped in a confined space (e.g., a discarded refrigerator). If a person does not receive immediate relief from suffocation, the interrupted breathing leads to respiratory and cardiac arrest and death. Any obstruction to the air passages must be immediately removed and life support measures instituted when an arrest occurs.

Excessive Noise

Excessive noise is a health hazard that can cause hearing loss, depending on (a) the overall level of noise, (b) the frequency range of the noise, and (c) the duration of exposure and individual susceptibility. Sound levels above 120 decibels (dB; units of loudness) are painful and may cause hearing damage even if a person is exposed for only a short period. Exposure to 85 to 95 dB for several hours a day can lead to progressive or permanent hearing loss. Noise levels below 85 dB usually do not affect hearing.

Tolerance of noise is largely individual. The rural dweller may find the city noisy, whereas the city dweller may be oblivious to urban sounds.

When ill or injured, people are frequently sensitive to noises that normally would not disturb them. Loud voices, the clatter of dishes, and even a nearby television can disturb clients, some of whom react angrily. Physiological effects of noise include (a) increased heart and respiratory rates, (b) increased muscular activity, (c) nausea, and (d) hearing loss, if the noise is sufficiently loud.

Noise can be minimized in several ways. Acoustic tiles on ceilings, walls, and floors as well as drapes and carpeting absorb sound. Background music can mask noise and have a calming effect on some people. It is important for nurses to minimize noise in the hospital setting and to encourage clients to protect their hearing as much as possible.

Electrical Hazards

All electric equipment must be properly grounded. The electric plug of grounded equipment has three prongs. The two short prongs transmit the power to the equipment. The third, longer prong is the grounding device, which carries short circuits or stray electric current

Figure 32-6 ■ Three-pronged grounded plug.
Scott Weichert/Getty Images.

to the ground (Figure 32-6 ■). Grounding prongs offer a path of least resistance to stray electric currents.

Faulty equipment such as equipment with a frayed cord presents a danger of electric shock or may start a fire. For example, an electric spark near certain anesthetic gases or a high concentration of oxygen can cause a serious fire. Actions to reduce electrical hazards are described in Client Teaching.

When major electrical injury (macroshock) does occur, the victim may sustain both superficial and deep burns, muscle contractions, and cardiac and respiratory arrest, necessitating cardiopulmonary resuscitation and life support. **Electric shock** occurs when a current travels through the body to the ground rather than through electric wiring, or from static electricity that builds up on the body. Using machines in good repair, wearing shoes with rubber soles, standing on a nonconductive floor, and using nonconductive gloves can prevent macroshock. However, even with such precautions the rescuer must know that the victim is not to be touched until the electricity is shut off or the victim has been removed from contact with the electric current; otherwise the rescuer may also receive electrical injury.

Firearms

Parents who bring a handgun into the home must accept full responsibility for teaching safety rules to any children who have knowledge of the presence of firearms. The following basic firearm safety rules must be implemented for any gun:

- Store all guns in sturdy locked cabinets without glass and make sure the keys are inaccessible to children.
- Store the bullets in a different location from the guns.
- Tell children never to touch a gun or stay in a friend's house where a gun is accessible.
- Teach children never to point the barrel of a gun at anyone.
- Ensure the firearm is unloaded and the action is open when handing it to someone else.

CLIENT TEACHING

Reducing Electrical Hazards

- Check cords for fraying or other signs of damage before using an appliance. Do not use if damage is apparent.
 - Avoid overloading outlets and fuse boxes with too many appliances.
 - Use only grounded outlets and plugs.
 - Always pull a plug from the wall outlet by firmly grasping the plug and pulling it straight out. Pulling a plug by its cord can damage the cord and plug unit.
 - Never use electric appliances near sinks, bathtubs, showers, or other wet areas, because water readily conducts electricity.
 - Keep electric cords and appliances out of the reach of young children.
 - Place protective covers over wall outlets to protect young children.
 - Have all noninsulated wiring in the home altered to meet safety standards.
 - Carefully read instructions before operating electric equipment. Clients who do not understand how to operate the equipment should seek advice.
 - Always disconnect appliances before cleaning or repairing them.
 - Unplug any appliance that has given a tingling sensation or shock and have an electrician evaluate it for stray current.
 - Keep electric cords coiled or taped to the ground away from areas of traffic to prevent others from damaging the cords or tripping over them.
- Do not handle firearms while affected by alcohol or drugs of any kind, including pharmaceuticals.
 - When cleaning or dry firing a firearm, remove all ammunition to another room, and double-check the firearm when you enter the room you will be using to clean the firearm.
 - Have firearms that are regularly used inspected by a qualified gunsmith at least every 2 years.

Radiation

Radiation injury can occur from overexposure to radioactive materials used in diagnostic and therapeutic procedures. Clients being examined using radiography or fluoroscopy generally receive minimal exposure and few precautions are necessary. Nurses need to protect themselves, however, from radiation when some clients are receiving radiation therapy. Exposure to radiation can be minimized by (a) limiting the time near the source, (b) providing as much distance as possible from the source, and (c) using shielding devices such as lead aprons when near the source. Nurses need to become familiar with agency protocols related to radiation therapy.

Bioterrorism Attack

No one knows when a bioterrorism attack will occur. Thus, it is important that health care personnel and facilities plan and prepare for the unknown. The Joint Commission requires its accredited health care organizations to meet established disaster preparedness standards. In 2001, these standards were expanded to introduce the concepts of emergency management and community involvement in the preparedness process. Health care organizations are now expected to address four specific phases of disaster planning—mitigation, preparedness, response, and recovery—as well as to participate annually in at least one community-wide practice drill.

Procedure- and Equipment-Related Accidents

Risk assessment in the health care setting must include risks related to procedures and equipment. Nurses need to follow safeguards to prevent errors or accidents whether giving a medication or assisting a client out of bed. Most health care agencies establish protocols that are designed to prevent accidents. When in doubt about a course of action, the nurse should consult the appropriate written guidelines before proceeding.

When an accident or error does occur, most agencies require that the incident be reported. The nurse completes the report immediately after taking whatever action is required to safeguard the client and notifying the charge nurse. For additional information about incident reports, see Chapter 4 ∞.

Restraining Clients

Restraints are devices used to limit the physical activity of a client or a part of the body. The CMS states “all patients have the right to be free from physical or mental abuse, and corporal punishment. All patients have the right to be free from restraint or seclusion, of any form, imposed as a means of coercion, discipline, convenience, or retaliation by staff. Restraint or seclusion may only be imposed to ensure the immediate physical safety of the patient, a staff member, or others and must be discontinued at the earliest possible time” (2008, p. 83). In general, the shift in attitudes about the use of restraints has been toward using other means for controlling behaviors that may pose a threat to self or others. This desired outcome is referred to as a restraint-free environment.

The decision to use a restraint must be based on a comprehensive, individualized client assessment. This assessment needs to determine whether the use of less restrictive measures is a greater risk than the risk of using a restraint (CMS, 2008, p. 83). Restraints should not be considered a part of routine client care and should not be included in a fall prevention program. A request from a family member to apply a restraint is not sufficient cause to apply a restraint. It should, however, prompt the nurse to assess the client and current situation to determine if a restraint intervention is needed. The assessments and, if a restraint is needed, must be documented. This documentation should reflect that the least restrictive intervention was used (CMS, 2008, p. 86).

Restraints are frequently used for older adults with dementia who are confused and may pose a threat to themselves. It is important to screen such clients on admission using available standardized instruments (e.g., the Mini Cog for cognitive function, the Confusion Assessment Method for level of confusion, and the Katz ADL to assess mobility and transfer ability). Any deviation from the admission baseline signals a need to rescreen the client.

Restraints can be classified as physical or chemical restraints or the use of seclusion. **Physical restraints** include “any manual method, physical or mechanical device, material, or equipment that immobilizes or reduces the ability of a patient to move his or her arms, legs, body, or head freely” (CMS, 2008). Examples can include leather or cloth wrist and ankle restraints, soft belts or vests, hand mitts, pelvic ties, gerichairs, and overchair tables). They cannot be removed easily and they restrict the client’s movement. Generally, if a client can easily remove a device, the device would not be considered a restraint. **Chemical restraints** involve using a medication to control behavior or to restrict the client’s freedom of movement and is *not* a standard treatment for the client’s medical or psychological

condition (CMS, 2008). **Seclusion** is the involuntary confinement of a client alone in a room or area from which the client is physically prevented from leaving (CMS, 2008).

Improper use of restraints and lack of monitoring can lead to injury and death and to psychological harm. Restraints can cause injury to clients through the hazards of immobility (e.g., muscle atrophy, bone loss, contractures, pressure ulcers, constipation, and decreased appetite), confusion, boredom and loneliness, depression, and loss of dignity. Death can result due to strangulation, suffocation, broken necks, burns, pneumonia, and sepsis. Cases in which restrained individuals have not received proper care related to hygiene, skin assessments, hydration, nutritional requirements, elimination, pain assessment, and appropriate assessments and monitoring of vital signs have been documented. The recent focus in health care safety is to explore ways to prevent, reduce, and hopefully eliminate the use of restraints while still protecting a client's safety, rights, and dignity. Attention to the legal and ethical rights of clients has fueled movement toward restraint-free environments.

Legal Implications of Restraints

Increasingly, determining the need for safety measures is viewed as an independent nursing function. However, because restraints restrict the individual's freedom, their use has legal implications. Nurses need to know their agency's policies and the state laws about restraining clients. The CMS revised standards for use of restraints effective January 2007, and these standards apply to all health care organizations (CMS, 2008). See Box 32–4 for standards for use of restraint and seclusion.

The standards address two types of behaviors in which restraints might be necessary: nonviolent, non–self-destructive behavior and violent or self-destructive behavior. For the nonviolent, non–self-destructive behavior, restraints may be necessary to directly support medical healing. For example, a client attempting to seriously interfere with a physical treatment or device (e.g., an IV line, respirator, or a dressing) may require a restraint when less restrictive approaches do not work to prevent this interference. For violent or self-destructive behavior, restraint or seclusion may be used to protect the client from injury to self or others. Seclusion may *only* be used for the

management of violent or self-destructive behavior that jeopardizes the immediate physical safety of the client, a staff member, or others. In both cases, a nurse may apply restraints but a physician or other licensed independent practitioner (LIP) who is responsible for the care of the client must order the use of restraint or seclusion. In addition, there must be a face-to-face evaluation of the client within 1 hour by the physician or LIP, or an RN or physician assistant (PA) who has been trained according to the new requirements (CMS, 2008). If an RN or PA performs the evaluation, the attending physician or LIP responsible for the client's care must be consulted as soon as possible after the evaluation is performed. A written restraint order for an adult with violent or self-destructive behavior, following evaluation, is valid for only 4 hours for up to a total of 24 hours. If the client must be restrained and secluded, there must be continual visual and audio monitoring of the client's status. All orders must be renewed daily. Each order for restraint used to ensure the physical safety of the non-violent or non–self-destructive client is renewed per hospital policy.

Restrained clients must be monitored regularly, and the new standards allow hospital policies to guide staff in determining appropriate intervals for assessment and monitoring. However, in the case of clients in seclusion, continual, ongoing monitoring is required.

Standards require that a primary care provider's order for restraints include delineation of the reason for, specific time frame (only for violent or self-destructive behavior), and type of restraint necessary. Restraint or seclusion must be discontinued at the earliest possible time, regardless of the length of time identified in the order. "As-needed" (prn) orders for restraints are prohibited. *In all cases, restraints should be used only after every other possible means of ensuring safety have been unsuccessful and documented.* See alternatives to the use of restraints in Box 32–5. Restrained clients often become more restless and anxious as a result of the loss of self-control. Nurses must document that the need for the restraint was made clear both to the client and to support people such as family members.

Clients have the right to be free from restraints that are not medically necessary. As a result, there must be justification that the use of restraints will protect the client and that less restrictive measures were attempted and found not effective. Restraints *cannot* be used for staff convenience or client punishment. Given that the above conditions are met and restraints are needed, it is important for the nurse to be able to correctly apply restraints without endangering client safety.

BOX 32–4 Standards for Use of Restraints and Seclusion

- Restraint may be used to ensure the client's immediate physical safety, even if the client is not violent or self-destructive.
- Seclusion may *only* be used for the management of violent or self-destructive behavior that is an immediate threat to the client's physical safety.
- Restraint or seclusion may only be used when less restrictive interventions have been determined to be ineffective to protect the client, a staff member, or others from harm.
- The type or technique of restraint or seclusion used must be the least restrictive intervention that will be effective to protect the client, a staff member, or others from harm.
- The use of restraint or seclusion must be implemented in accordance with safe and appropriate restraint and seclusion techniques per hospital policy.
- Restraint or seclusion must be discontinued at the earliest possible time.

From *Hospitals—Restraint/Seclusion Interpretive Guidelines & Updated State Operations Manual (SOM) Appendix A*, by Centers for Medicare & Medicaid Services, 2008. Retrieved from <https://www.cms.gov/Medicare/Provider-Enrollment-and-Certification/SurveyCertificationGenInfo/downloads/SCLetter08-18.pdf>.

Selecting a Restraint

Before selecting a restraint, nurses need to understand its purpose clearly and measure it against the following five criteria:

1. It restricts the client's movement as little as possible. If a client needs to have one arm restrained, do not restrain the entire body.
2. It is safe for the particular client. Choose a restraint with which the client cannot self-inflict injury. For example, a physically restrained person could incur injury trying to climb out of bed if one wrist is tied to the bed frame. A jacket restraint would restrain the person more safely.
3. It does not interfere with the client's treatment or health problem. If a client has poor blood circulation to the hands, apply a restraint that will not aggravate that circulatory problem.
4. It is readily changeable. Restraints need to be changed frequently, especially if they become soiled. Keeping other guidelines in mind, choose a restraint that can be changed with minimal disturbance to the client.

BOX 32-5 Alternatives to Restraints

- Assess for pain and treat appropriately.
- Ask family members or significant others to stay with the client.
- Reduce stimulation (e.g., noise, lights); play soothing music.
- Assign nurses in pairs to act as “buddies” so that one nurse can observe the client when the other leaves the unit.
- Place unstable clients in an area that is constantly or closely supervised.
- Prepare clients before a move to limit relocation shock and resultant confusion.
- Stay with a client using a bedside commode or bathroom if the client is confused or sedated or has a gait disturbance or a high-risk score for falling.
- Provide frequent toileting, if needed; provide a bedside commode.
- Monitor all the client’s medications and, if possible, attempt to lower or eliminate dosages of sedatives or psychotropics.
- Position beds at their lowest level to facilitate getting in and out of bed.
- Replace full-length side rails with half- or three-quarter-length rails to prevent confused clients from climbing over rails or falling from the end of the bed.
- Use rocking chairs to help confused clients expend some of their energy so that they will be less inclined to wander.
- Wedge pillows or pads against the sides of wheelchairs to keep clients safely positioned.
- Place a removable lap tray on a wheelchair to provide support and help keep the client in place.
- To quiet agitated clients, try a warm beverage, soft lights, a back rub, or a walk.
- Use “environmental restraints,” such as pieces of furniture or large plants as barriers, to keep clients from wandering beyond appropriate areas.
- Place a picture or other personal item on the door to clients’ rooms to help them identify their room.
- Try to determine the causes of the client’s sundowner syndrome (nocturnal wandering and disorientation as darkness falls, associated with dementia). Possible causes include poor hearing, poor eyesight, or pain.
- Allow restless clients to walk after determining the safety of the environment.
- Establish ongoing assessment to monitor changes in physical and cognitive functional abilities and risk factors.

5. It is as discreet as possible. Both clients and visitors are often embarrassed by a restraint, even though they understand why it is being used. The less obvious the restraint, the more comfortable people feel.

Types of Restraints

Several types of restraints are available. Among the most common for adults are jacket or vest restraints, belt restraints, mitt or hand restraints, and limb restraints. Gerichairs, wheelchairs with lap trays, and bed rails can also be considered restraints. When using restraints, the nurse may find the accompanying Practice Guidelines helpful.

When evaluating if a device is a restraint or not, determine the intended use (e.g., physical restriction), its involuntary application, and/or the client need for the restraint. For example, if all of the bed’s side rails are up and restrict the client’s freedom to leave the bed, and the client did not voluntarily request all rails to be up, they are a restraint. If, however, one side rail is up to assist the client to get in and out of the bed, it is not a restraint because it is helping the client to exit the bed. Also, if the client can release or remove a device, it would not be considered a restraint.

There are several types of vest restraints, but all are essentially sleeveless jackets or vests with straps (tails) that can be tied to the bed

Evidence-Based Practice What Factors Are Involved as Nurses Protect the Safety of Older Clients?**EVIDENCE-BASED PRACTICE**

Ludwick, O’Toole, and Meehan (2012) used a grounded theory approach to develop a framework for understanding nurses’ work for maintaining the safety of older clients. In the study, seven nurses were asked to describe a situation where they needed to initiate, maintain, or terminate restraints. The nurses were all females working on a medical-surgical unit in a large, urban hospital in the Midwestern United States. The experience of the group ranged from 2 to 31 years and their ages ranged from 32 to 50. This qualitative research involved collecting the audiotaped interview data followed by subsequent analysis of the data through various coding steps and the development of a conditional/consequential matrix. This matrix was used to trace nurses’ work in maintaining client safety.

All of the nurses described the older client’s mental condition as causing a risk of potential client injury that either led to initiation of restraints or restraint alternatives (i.e., for increasing confusion) or termination of restraints or restraint alternatives (i.e., for improvement of mental status). The nurses discussed in depth how they worked to maintain client safety. It entailed a complex process that involved “adjusting, monitoring, trialing removal, negotiating with clients, and lessening or increasing the amount of restraints or the use of alternative interventions for the client’s safety.” Part of the “safety work” included the nurses’ attempts to correct underlying problems (e.g., negotiating with physicians to determine the original cause of the confusion, such as a urinary tract infection) and discussing with

physicians the option of removing or altering a treatment, such as removing an IV, to reduce the need for restraint. Of interest were the examples of intervening conditions that influenced continued use of restraints. For example, once restraints were initiated, there was a reluctance to discontinue them because of the question of who would be responsible if something happened when they were removed. Also, the hospital policy required that once restraints were removed, the physician’s order was no longer in effect and the nurse would need to obtain another order if needed. Thus, it was easier to leave the restraints on than try a trial period with the client out of restraints. Another intervening condition that was mentioned was staffing numbers and the increased workload involved with use of restraints.

IMPLICATIONS

The authors urge caution in drawing implications due to the small sample size. Further research is needed with a larger group from diverse hospital settings. The study, however, did show how nurses made decisions about the use of restraints and the complex process and additional work involved in maintaining client safety, which should be considered when nurse-to-client ratios are determined. Another implication is the need to reexamine restraint policies to determine if they are limiting nurses’ choices about maintaining and discontinuing restraints.

PRACTICE GUIDELINES

Applying Restraints

- Obtain consent from the client or guardian.
- Ensure that a primary care provider's order has been provided or, in an emergency, obtain one within the time frame specified in agency policy.
- Assure the client and the client's support people that the restraint is temporary and protective. A restraint must never be applied as punishment for any behavior or merely for the nurse's convenience.
- Apply the restraint in such a way that the client can move as freely as possible while remaining safe.
- Ensure that limb restraints are applied securely but not so tightly that they impede blood circulation to any body area or extremity.
- Pad bony prominences (e.g., wrists and ankles) before applying a restraint over them. The movement of a restraint without padding over such prominences can quickly abrade the skin.
- Always tie a limb restraint with a knot (e.g., a clove hitch) that will not tighten when pulled.
- Tie the ends of a body restraint to the part of the bed that moves to elevate the head. Never tie the ends to a side rail or to the fixed frame of the bed if the bed position is to be changed.
- Assess the restraint per agency protocol time frame. Some facilities have specific forms to be used to record ongoing assessment. This may be a visual check to ensure client safety and no signs of injury.
- Assess skin integrity per agency protocol (e.g., every 2 hours), and provide range-of-motion (ROM) exercises (see Chapter 44 ) and skin care when restraints are removed (see Chapter 36 ) .
- Assess and assist with basic needs: nutrition, hydration, hygiene, elimination.
- Reassess the continued need for the restraint. Include an assessment of the underlying cause of the behavior necessitating use of the restraints.
- When a restraint is temporarily removed, do not leave the client unattended.
- Immediately report to the nurse in charge and record on the client's chart any persistent reddened or broken skin areas under the restraint.
- At the first indication of cyanosis or pallor, coldness of a skin area, or a client's complaint of a tingling sensation, pain, or numbness, loosen the restraint and exercise the limb.
- Apply a restraint so that it can be released quickly in case of an emergency and with the body part in a normal anatomic position.
- Provide emotional support verbally and through touch.

frame under the mattress. These body restraints are used to ensure the safety of confused or sedated clients in beds or wheelchairs. The U.S. Food and Drug Administration (FDA) advises that manufacturers place “front” and “back” labels on vest restraints.

Belt or safety strap body restraints are used to ensure the safety of all clients who are being moved on stretchers or in wheelchairs. Some wheelchairs have a soft, padded safety bar that attaches to side brackets that are installed under the arm rests. To prevent the person from slumping forward, the nurse then attaches a shoulder “Y” strap to the bar and over the client's shoulders to the rear handles. Other safety belt models have a three-loop design. One loop surrounds the person's waist and attaches to the rear handles. If such restraints are unavailable, the nurse can place a folded towel or small sheet around the client's waist and fasten it at the back of the wheelchair. Belt restraints may also be used for certain clients confined to bed or to chairs.

A mitt or hand restraint (Figure 32-7 ) is used to prevent clients of any age from using their hands or fingers to scratch and injure themselves. For example, a confused client may need to be prevented from pulling at intravenous tubing or a head bandage following brain

Figure 32-7  A mitt restraint.

surgery. Hand or mitt restraints allow the client to be ambulatory and/or to move the arm freely rather than be confined to a bed or a chair. Mitts need to be removed on a regular basis to permit the client to wash and exercise the hands. The nurse also needs to take off the mitt to check the circulation to the hand.

Limb restraints (Figure 32-8 ) , which are generally made of cloth, may be used to immobilize a limb, primarily for therapeutic reasons (e.g., to maintain an intravenous infusion). Commonly used with children, elbow restraints (e.g., No-No's) prevent flexion of the joint so that tubing, connections, catheters, and bandages cannot be reached. Restraints for infants and children include mummy restraints, elbow restraints, and crib nets (see Lifespan Considerations later in chapter). See Skill 32-3 for applying restraints.

Figure 32-8  A limb restraint.

Applying Restraints

PURPOSES

- To promote safety and prevent injury
- To allow a medical or surgical treatment to proceed without client interference (e.g., to prevent movements that would disrupt therapy to a limb connected to tubes or appliance)

ASSESSMENT

Assess

- The behavior indicating the possible need for a restraint
- Underlying cause for assessed behavior
- What other protective measures may be implemented before applying a restraint
- Status of skin to which restraint is to be applied
- Circulatory status distal to restraints and of extremities
- Effectiveness of other available safety precautions

PLANNING

Review institutional policy for restraints and seek consultation as appropriate before independently deciding to apply a restraint. All other possible interventions that are less restrictive *must* have been tried and their failure documented. The primary care provider must be notified prior to using a restraint, unless there is a danger to self or others. In that case the primary care provider must be notified within the prescribed time frame per the agency protocol.

Equipment

- Appropriate type and size of restraint

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client and family what you are going to do, why it is necessary, and how they can participate. Allow time for the client to express feelings about being restrained. Provide needed emotional reassurance that the restraints will be used only when absolutely necessary and that there will be close contact with the client in case assistance is required.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy if indicated.
4. Apply the selected restraint.

Belt Restraint (Safety Belt)

- Determine that the safety belt is in good order. If a Velcro safety belt is to be used, make sure that both pieces of Velcro are intact.
- If the belt has a long portion and a shorter portion, place the long portion of the belt behind (under) the bedridden client and secure it to the movable part of the bed frame.

Rationale: *The long attached portion will then move up when the head of the bed is elevated and will not tighten around the client.*

Place the shorter portion of the belt around the client's waist, over the gown. There should be a finger's width between the belt and the client.

or

- Attach the belt around the client's waist, and fasten it at the back of the chair.

or

- If the belt is attached to a stretcher, secure the belt firmly over the client's hips or abdomen.

Rationale: *Belt restraints must be applied to all clients on stretchers even when the side rails are up.*

Jacket Restraint

- Place vest on client, with opening at the front or the back, depending on the type.
- Pull the tie on the end of the vest flap across the chest, and place it through the slit in the opposite side of the chest.

DELEGATION

The nurse must make the determination that restraints are appropriate in specific situations, select the proper type of restraints, evaluate the effectiveness of the restraints, and assess for potential complications from their use. Application of ordered restraints and their temporary removal for skin monitoring and care may be delegated to UAP who have been trained in their use.

- Repeat for the other tie.
- Use a half-bow knot (a type of quick-release knot) to secure each tie around the movable bed frame or behind the chair to a chair leg. 1

Rationale: *A half-bow knot does not tighten or slip when the attached end is pulled but unties easily when the loose end is pulled.*

or

- Fasten the ties together behind the chair using a slip or quick-release knot.
- Ensure that the client is positioned appropriately to enable maximum chest expansion for breathing.

- 1 To make a half-bow (quick-release) knot, first place the restraint tie under the side frame of the bed (or around a chair leg). A, Bring the free end up, around, under, and over the attached end of the tie and pull it tight. B, Again take the free end over and under the attached end of the tie, but this time make a half-bow loop. C, Tighten the free end of the tie and the bow until the knot is secure. To untie the knot, pull the end of the tie and then loosen the first cross over the tie.

Applying Restraints—continued

SKILL 32-3

A

B

2 Ensure that two fingers can be inserted between the restraint and **A**, the wrist, or **B**, the chest.

Mitt Restraint

- Apply the commercial thumbless mitt (see Figure 32–7) to the hand to be restrained. Make sure the fingers can be slightly flexed and are not caught under the hand.
- Follow the manufacturer’s directions for securing the mitt.
- If a mitt is to be worn for several days, remove it at regular intervals per agency protocol. Wash and exercise the client’s hand, then reapply the mitt. Check agency policies about recommended intervals for removal.
- Assess the client’s circulation to the hands shortly after the mitt is applied and at regular intervals.

Rationale: *Client complaints of numbness, discomfort, or inability to move the fingers could indicate impaired circulation to the hand.*

Wrist or Ankle Restraint

- Pad bony prominences on the wrist or ankle if needed to prevent skin breakdown.
- Apply the padded portion of the restraint around the ankle or wrist.
- Pull the tie of the restraint through the slit in the wrist portion or through the buckle and ensure that the restraint is not too tight. 2
- Using a half-bow knot, attach the other end of the restraint to the movable portion of the bed frame.

Rationale: *If the ties are attached to the movable portion, the wrist or ankle will not be pulled when the bed position is changed.*

5. Adjust the plan of care as required, for example, to include releasing the restraint, providing skin care, range-of-motion exercises, and attending to the client’s physical needs by providing fluids, nutrition, and toileting.

EVALUATION

- Perform a detailed follow-up of the need for the restraints and the client’s response. Relate these findings to previous data if available.
- Evaluate circulatory status of restrained limbs.
- Evaluate skin status beneath restraints.

6. Document on the client’s chart the behavior(s) indicating the need for the restraint, all other interventions implemented in an attempt to avoid the use of restraints and their outcomes, and the time the primary care provider was notified of the need for restraint. Also record:

- The type of restraint applied, the time it was applied, and the goal for its application
- The client’s response to the restraint, including a rationale for its continued use
- The times that the restraints were removed and skin care given
- Any other assessments and interventions
- Explanations given to the client and significant others.

SAMPLE DOCUMENTATION

7/10/2015 2000 Confused. Disoriented to time and place. Reoriented frequently. Pulling at central IV line, NG tube, and chest tube. Medicated for pain relief. Lights dimmed. _____ C. Murphy, RN
 1245 Continues to pull at IV and tubes. Dr. Jones called. Received an order to apply mitt restraints. Family notified and situation explained. Stated that a family member will come and sit with client. Mitt restraints applied, relaxation music initiated. _____ C. Murphy, RN
 1130 Son arrived and sitting with client. Calm though remains disoriented. Mitts removed, skin intact, hands warm and pink. Vital signs stable. _____ C. Murphy, RN

- Remove the restraints as soon as they are no longer needed and document.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Restraints

INFANTS

Elbow restraints (Figure 32–9 ■) are used to prevent infants or small children from flexing their elbows to touch or reach their face or head, especially after surgery. Ready-made elbow restraints are available commercially.

A mummy restraint (Figure 32–10 ■) is a special folding of a blanket or sheet around an infant to prevent movement during a procedure such as gastric washing, eye irrigation, or collection of a blood specimen.

- Obtain a blanket or sheet large enough so that the distance between opposite corners is about twice the length of the infant's body. Lay the blanket or sheet on a flat, dry surface.
- Fold down one corner, and place the baby on it in the supine position.
- Fold the right side of the blanket over the infant's body, leaving the left arm free (Figure 32–10A). The right arm is in a natural position at the side.
- Fold the excess blanket at the bottom up under the infant (Figure 32–10B, 2).

Figure 32–9 ■ Infant with elbow restraints.

- With the left arm in a natural position at the baby's side, fold the left side of the blanket over the infant, including the arm, and tuck the blanket under the body (Figure 32–10B, 3).
- Remain with the infant who is in a mummy restraint until the specific procedure is completed.

CHILDREN

A crib net is simply a device placed over the top of a crib to prevent active young children from climbing out of the crib. At the same time, it allows them freedom to move about in the crib. The crib net or dome is not attached to the movable parts of the crib so that the caregiver can have access to the child without removing the dome or net.

- Place the net over the sides and ends of the crib.
- Secure the ties to the springs or frame of the crib. The crib sides can then be freely lowered without removing the net.
- Test with your hand that the net will stretch if the child stands against it in the crib.

Figure 32–10 ■ Making a mummy restraint.

Home Care Considerations Applying Restraints

SAFETY

Restraints may be necessary for clients in wheelchairs or in the home. Safety guidelines apply in all cases. Assess the knowledge and skill of all caregivers in the use of restraints and educate as indicated.

- Use means other than restraints as much as possible, and stay with the client.
- Pad bony prominences, such as wrists and ankles, if needed before applying a restraint over them.
- Tie restraints with knots that will not tighten when pulled and to parts of the wheelchair that do not move and release quickly in case of emergency.
- Assess restrained limbs for signs of impaired blood circulation.
- Always stay with a client whose restraint is temporarily removed.

LIFESPAN CONSIDERATIONS Safety

OLDER ADULTS

Some of the changes due to aging that place the older adult at higher risk for safety concerns are:

- Decrease in visual and hearing acuity
- Decrease in response of reflexes
- Fragility of bones and decrease in flexibility of joints and muscles
- Decrease in temperature regulation, increasing the risk of hypothermia and hyperthermia
- Decrease in kidney function, which increases risk of toxicity from medications.

A home environment that was safe when they were younger may need modifications for older adults to decrease the risk of injury. A plan and telephone numbers of those to call in an emergency situation should be available.

Evaluating

To prevent client injury, the nurse's role is largely educative and desired outcomes reflect the client's acquisition of knowledge of hazards, behaviors that incorporate safety practices, and skills to perform in the event of certain emergencies. The nurse needs to individualize these for clients. Examples of desired outcomes include the client being able to do the following:

- Describe methods to prevent specific hazards (e.g., falls, suffocation, choking, fires, drowning, electric shock).
- Report use of home safety measures (e.g., fire safety measures, smoke detector maintenance, fall prevention strategies, burn

prevention measures, poison prevention measures, safe storage of hazardous materials, firearm safety precautions, electrocution prevention, water safety precautions, bicycle safety, motor vehicle safety).

- Alter home physical environment to reduce the risk of injury.
- Describe emergency procedures for poisoning and fire.
- Describe age-specific risks, work safety risks, or community safety risks.
- Demonstrate correct use of child safety seats.
- Demonstrate correct administration of cardiopulmonary resuscitation.

Critical Thinking Checkpoint

Mr. Moore is a 72-year-old widower who is recovering from a fall in which he fractured his hip and underwent surgical repair 1 week ago. He will be staying with his son for 2 weeks after he is discharged from the hospital, but he is eager to return to his own home. Once he is home, his son will visit nightly after work, he will receive Meals-on-Wheels once a day, and a home health care attendant will visit weekly to assist him with hygienic care until he is more independent. Mr. Moore's wife died 3 years ago, but he has remained independent and continued his social functions. He lives in a small single-level house with his dog and cat, and he enjoys gardening. Prior to fracturing his hip he walked his dog daily. You will be his home health care nurse.

1. While hospitalized, Mr. Moore experienced some mild confusion during the night, but his nurses decided not to restrain him. What are the best reasons for avoiding the use of restraints for clients such as Mr. Moore?
2. What are some of the more obvious factors that may affect Mr. Moore's safety as he returns home?
3. What do you need to assess with regard to Mr. Moore's safety and what suggestions can you make for enhancing his safety?
4. What strengths do you note about Mr. Moore that may protect him from injury when he returns home?

See Critical Thinking Possibilities on student resource website.

Chapter 32 Review

CHAPTER HIGHLIGHTS

- Injuries are a major cause of death among individuals of all ages in the United States.
- Nurses need awareness of what constitutes a safe environment for specific individuals and for groups of people in the home, community, and workplace.
- Hazards to safety occur at all ages and vary according to the age and development of the individual.
- Nursing assessment of safety includes assessing factors that can affect safety, for example, age and developmental level, lifestyle, mobility and health status, sensory-perceptual alterations, cognitive awareness, ability to communicate, safety awareness, and environmental factors.
- Nurses assess clients at risk for injury through methods such as nursing history and physical examination, risk assessment tools, and home hazard appraisal.
- The landmark report *To Err Is Human* increased the awareness in the health care industry of the need to improve client safety. As a result, National Patient Safety Goals (NPSG) were initiated and are required to be implemented by The Joint Commission. The QSEN project developed guidelines to help future nurses develop the knowledge, skills, and attitudes required to improve client safety. The foundation for a culture of safety is a blame-free environment, transparency, and a process designed to prevent error.
- Nurses need to sustain a heightened awareness and alertness of circumstances or patterns that may indicate potential bioterrorism. Early detection and management are needed to help stop a bioterrorism attack.
- Major nursing diagnoses for clients at risk for injury can be categorized as *Risk for Injury*, with more specific diagnoses such as: *Risk for Falls*, *Latex Allergy Response*; *Risk for Latex Allergy Response*; *Risk for Infection*, *Risk for Suffocation*; *Risk for Poisoning*; *Risk for Trauma*; *Risk for Vascular Trauma*, *Aspiration*; *Risk for Adverse Reaction to Iodinated Contrast Media*; *Risk for Impaired Skin Integrity* and *Risk for Self-Directed Violence*. Other diagnoses include *Deficient Knowledge (Accident Prevention)* and *Readiness for Enhanced Knowledge (Accident Prevention)*.
- Measures to ensure the safety of people of all ages focus on (a) observation or prediction of situations that are potentially harmful and (b) client education that empowers clients to safeguard themselves and their families from injury.
- Falls are a common cause of injury among older adults.
- Side rails do not protect hospitalized clients from falls. It is more likely the client will fall trying to get out around raised rails.
- Prevention of falls in health care agencies is an ongoing concern.
- Seizure precautions are safety measures taken by the nurse to protect clients from injury should they have a seizure.

- Nurses must be familiar with the fire procedures in the health care agencies where they practice. In the event of a fire, the nurse can use two mnemonics to remember the steps to follow: RACE and PASS.
- Major reasons for poisoning in children are inadequate supervision and improper storage of household toxic substances.
- Suffocation can occur when foreign objects become lodged in the throat, cutting off an individual's oxygen supply.
- Prolonged exposure to excessive noise can cause hearing loss.
- Improper grounding and faulty electric equipment pose health hazards in the hospital and the home. Injuries can be prevented by using grounded outlets and plugs, putting protective covers over outlets, keeping appliances in good repair, and making sure that electric wiring and circuits meet safety standards.
- Firearms pose a risk to individuals of all ages. Adults must take full responsibility for following safety procedures when keeping firearms in the home, including storage of ammunition in a separate location.
- In hospitals, radioactive substances are used for both diagnostic and treatment purposes; agency policy must be followed to safeguard clients and staff from unsafe exposure.
- Various alternatives to restraints must be considered before a restraint is applied.
- Because restraints restrict a client's basic freedom to move, careful assessment and accurate, complete documentation are important when restraints are used.

TEST YOUR KNOWLEDGE

1. A nurse sees smoke emerging from the suction equipment being used. Which is the greatest priority in the event of a fire?
 1. Report the fire.
 2. Extinguish the fire.
 3. Protect the clients.
 4. Contain the fire.
2. A nurse who is teaching a group of adults ages 20 to 40 years old about safety is going to ensure that which topic is a priority?
 1. Automobile crashes
 2. Drowning and firearms
 3. Falls
 4. Suicide and homicide
3. An 87-year-old man is admitted to the hospital for cellulitis of the left arm. He ambulates with a walker and takes a diuretic medication to control symptoms of fluid retention. Which intervention is most important to protect him from injury?
 1. Leave the bathroom light on.
 2. Withhold the client's diuretic medication.
 3. Provide a bedside commode.
 4. Keep the side rails up.
4. A mother and her 3-year-old live in a home built in 1932. Which NANDA nursing diagnosis is most applicable for this child?
 1. *Risk for Suffocation*
 2. *Risk for Injury*
 3. *Risk for Poisoning*
 4. *Risk for Disuse Syndrome*
5. A 75-year-old client, hospitalized with a cerebrovascular accident (stroke), becomes disoriented at times and tries to get out of bed, but is unable to ambulate without help. What is the most appropriate safety measure?
 1. Restrain the client in bed.
 2. Ask a family member to stay with the client.
 3. Check the client every 15 minutes.
 4. Use a bed exit safety monitoring device.
6. A client is being admitted to the hospital because of a seizure that occurred at his home. The client has no previous history of seizures. In planning the client's nursing care, which of the following measures is most essential at this time of admission? Select all that apply.
 1. Place a padded tongue depressor at the head of the bed.
 2. Pad the bed with blankets.
 3. Inform the client about the importance of wearing a medical identification tag.
 4. Teach the client about epilepsy.
 5. Test oral suction equipment.
7. Which nursing intervention is the highest in priority for a client at risk for falls in a hospital setting?
 1. Keep all of the side rails up.
 2. Review prescribed medications.
 3. Complete the "get up and go" test.
 4. Place the bed in the lowest position.
8. Medication errors can place the client at significant risk. Which practice(s) will help decrease the possibility of errors? Select all that apply.
 1. Hire only competent nurses.
 2. Improve the nurse's ability to multitask.
 3. Establish a reporting system for "near misses."
 4. Communicate effectively.
 5. Create a culture of trust.
9. When planning to teach health care topics to a group of male adolescents, which topic should the nurse consider a priority?
 1. Sports contribute to an adolescent's self-esteem.
 2. Sunbathing and tanning beds can be dangerous.
 3. Guns are the most frequently used weapon for adolescent suicide.
 4. A driver's education course is mandatory for safety.
10. The nurse, at change-of-shift report, learns that one of the clients in his care has bilateral soft wrist restraints. The client is confused, is trying to get out of bed, and had pulled out the IV line, which was subsequently reinserted. Which action(s) by the nurse is appropriate? Select all that apply.
 1. Document the behavior(s) that require continued use of the restraints.
 2. Ensure that the restraints are tied to the side rails.
 3. Provide range-of-motion exercises when the restraints are removed.
 4. Orient the client.
 5. Assess the tightness of the restraints.

See Answers to Test Your Knowledge in Appendix A.

READINGS AND REFERENCES

Suggested Readings

- Delamont, A. (2013). How to avoid the top seven nursing errors. *Nursing Made Incredibly Easy!*, 11(2), 8–10. The author succinctly reviews the most common nursing errors and how to prevent them.
- Mazer, S. E. (2012). Creating a culture of safety: Reducing hospital noise. *Biomedical Instrumentation & Technology*, 46(5), 350–355. doi:10.2345/0899-8205-46.5.350
- Noise is the number one complaint from clients. The author increases the reader's awareness of why that is; the effects of noise on clients, families, and health care providers; and steps that can be taken to reduce noise in health care environments.
- Speroni, K. G., Fisher, J., Dennis, M., & Daniel, M. (2013). What causes near-misses and how are they mitigated? *Nursing*, 43(4), 19–24. doi:10.1097/01.NURSE.0000427995.92553.ef
- A near miss is a change in a normal process that, if continued, could have a negative impact on client safety. The researchers for this study wanted to determine the reasons hospital RNs attribute to near misses and the techniques they used to lessen these near misses to prevent a serious event. The authors describe the personal and institutional factors related to near misses.
- Youngberg, B. J. (2013). *Patient safety handbook* (2nd ed.). Burlington, MA: Jones & Bartlett.
- This book provides a comprehensive review beginning with the landmark IOM report *To Err Is Human* and the subsequent work that has been completed during the past 10 years. It also provides specific strategies for making health care systems, health care providers, and clients safer.

33 Hygiene

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Describe hygienic care that nurses provide to clients.
2. Identify factors influencing personal hygiene.
3. Identify normal and abnormal assessment findings while providing hygiene care.
4. Apply the nursing process to common problems related to hygienic care of the:
 - Skin.
 - Feet.
 - Nails.
 - Mouth.
 - Hair.
 - Eyes.
 - Ears.
5. Identify the purposes of bathing.
6. Describe various types of baths.
7. Compare and contrast the task-centered approach and the person-centered approach to bathing.
8. Describe guidelines for bathing individuals with dementia.
9. Discuss the different types of contact lenses.
10. Discuss the different types of hearing aids.
11. Discuss factors that support a positive and safe environment for the client.
12. Identify safety and comfort measures underlying bed-making procedures.
13. Verbalize the steps used in:
 - a. Bathing an adult client.
 - b. Providing perineal-genital care.
 - c. Providing foot care.
 - d. Brushing and flossing the teeth.
 - e. Providing special oral care.
 - f. Providing hair care.
 - g. Removing, cleaning, and inserting a hearing aid.
 - h. Changing an unoccupied bed.
 - i. Changing an occupied bed.
14. Recognize when it is appropriate to delegate hygiene skills for clients to unlicensed assistive personnel.
15. Demonstrate appropriate documentation and reporting of hygiene skills.

sweat glands, 670
tartar, 690
therapeutic baths, 675
ticks, 698
tinea pedis, 685
xerostomia, 695

INTRODUCTION

Hygiene is the science of health and its maintenance. Personal **hygiene** is the self-care by which people attend to such functions as bathing, toileting, general body hygiene, and grooming. Hygiene is a highly personal matter determined by individual values and practices. It involves care of the skin, feet, nails, oral and nasal cavities, teeth, hair, eyes, ears, and perineal-genital areas.

It is important for nurses to know exactly how much assistance a client needs for hygienic care. Clients may require help after urinating or defecating, after vomiting, and whenever they become soiled, for example, from wound drainage or from profuse perspiration. Table 33–1 lists factors that influence hygienic practices.

HYGIENIC CARE

Nurses commonly use the following terms to describe types of hygienic care. *Early morning care* is provided to clients as they awaken in the morning. This care consists of providing a urinal or bedpan to the client confined to bed, washing the face and hands, and giving oral care. *Morning care* is often provided after clients have breakfast, although it may be provided before breakfast. It usually includes providing for elimination needs, a bath or shower, perineal care, back massages, and oral, nail, and hair care. Making the client's bed is part of morning care. *Hour of sleep* or *PM care* is provided to clients before they retire for the night. It usually involves providing for elimination needs, washing face and hands, giving oral care, and giving a back

TABLE 33–1 Factors Influencing Individual Hygienic Practices

Factor	Variables
Culture	North American culture places a high value on cleanliness. Many North Americans bathe or shower once or twice a day, whereas people from some other cultures bathe once a week. Some cultures consider privacy essential for bathing, whereas others practice communal bathing. Body odor is offensive in some cultures and accepted as normal in others.
Religion	Ceremonial washings are practiced by some religions.
Environment	Finances may affect the availability of facilities for bathing. For example, homeless people may not have warm water available; soap, shampoo, shaving lotion, and deodorants may be too expensive for people who have limited resources.
Developmental level	Children learn hygiene in the home. Practices vary according to the individual's age; for example, preschoolers can carry out most tasks independently with encouragement.
Health and energy	Ill people may not have the motivation or energy to attend to hygiene. Some clients who have neuromuscular impairments may be unable to perform hygienic care.
Personal preferences	Some people prefer a shower to a tub bath. The time of bathing varies (e.g., morning versus evening).

massage. *As-needed (prn) care* is provided as required by the client. For example, a client who is diaphoretic (sweating profusely) may need more frequent bathing and a change of clothes and linen.

SKIN

The skin is the largest organ of the body. It serves five major functions:

1. It protects underlying tissues from injury by preventing the passage of microorganisms. The skin and mucous membranes are considered the body's first line of defense.
2. It regulates the body temperature. Cooling of the body occurs through the heat loss processes of evaporation of perspiration, and by radiation and conduction of heat from the body when the blood vessels of the skin are vasodilated. Body heat is conserved through lack of perspiration and vasoconstriction of the blood vessels. See Chapter 29 ∞.
3. It secretes **sebum**, an oily substance that (a) softens and lubricates the hair and skin, (b) prevents the hair from becoming brittle, and (c) decreases water loss from the skin when the external humidity is low. Because fat is a poor conductor of heat, sebum (d) lessens the amount of heat lost from the skin. Sebum (e) also has a **bactericidal** (bacteria-killing) action.
4. It transmits sensations through nerve receptors, which are sensitive to pain, temperature, touch, and pressure.
5. It produces and absorbs vitamin D in conjunction with ultraviolet rays from the sun, which activate a vitamin D precursor present in the skin.

The normal skin of a healthy person has transient and resident microorganisms that are not usually harmful. See Chapter 36 ∞.

Sudoriferous (sweat) glands are on all body surfaces except the lips and parts of the genitals. The body has from 2 to 5 million, which are all present at birth. They are most numerous on the palms of the hands and the soles of the feet. Sweat glands are classified as apocrine and eccrine. The **apocrine glands**, located largely in the axillae and anogenital areas, begin to function at puberty under the influence of androgens. Although they produce sweat almost constantly, apocrine glands are of little use in thermoregulation. The secretion of these glands is odorless, but when decomposed or acted on by bacteria on the skin, it takes on a musky, unpleasant odor. The **eccrine glands** are important physiologically. They are more

numerous than the apocrine glands and are found chiefly on the palms of the hands, soles of the feet, and forehead. The sweat they produce cools the body through evaporation. Sweat is made up of water, sodium, potassium, chloride, glucose, urea, and lactate.

●○● NURSING MANAGEMENT

Assessing

Assessment of the client's skin and hygienic practices includes (a) a nursing health history to determine the client's skin care practices, self-care abilities, and past or current skin problems; and (b) physical assessment of the skin.

Nursing History

Data about the client's skin care practices enable the nurse to incorporate the client's needs and preferences as much as possible in the plan of care. Andrews and Boyle (2012) state that people in most cultures in the United States and Canada try to disguise natural body odors by bathing frequently and using deodorant, cologne, or perfumes. Immigrants from other countries where water is scarce may bathe less often than people from countries where water is more accessible (p. 56).

Assessment of the client's self-care abilities determines the amount of nursing assistance and the type of bath (e.g., bed, tub, or shower) best suited for the client. Important considerations include the client's balance (for tub and shower), ability to sit unsupported (in the tub or bed), activity tolerance, coordination, adequate muscle strength, appropriate joint range of motion, vision, and the client's preferences. Cognition and motivation are also essential. Clients whose cognitive function is impaired or whose illness alters energy levels and motivation will usually need more assistance. It is important for the nurse to determine each client's functional level and to maintain and promote as much client independence as possible. This also enables the nurse to identify a client's potential for growth and rehabilitation. There are several models of functional levels of self-care. One example is shown in Table 33–2.

The presence of past or current skin problems alerts the nurse to specific nursing interventions or referrals the client may require. Many skin care conditions have implications for hygienic care. The client may provide descriptions of these problems during the nursing health history, or the nurse may observe some during the physical examination that follows. Common skin problems and implications for nursing interventions are shown in Table 33–3. Questions to elicit

TABLE 33–2 Definitions and Descriptors for Functional Level

(0) Completely Independent	(+1) Requires Use of Equipment or Device	Semidependent (+2) Requires Help from Another Person for Assistance, Supervision, or Teaching	Moderately Dependent (+3) Requires Help from Another Person and Equipment or Device	Totally Dependent (+4) Does Not Participate in Activity
Bathing		Nurse provides all equipment; positions client in bed/bathroom. Client completes bath, except for back and feet.	Nurse supplies all equipment; positions client; washes back, legs, perineum, and all other parts, as needed. Client can assist.	Client needs complete bath; cannot assist at all.
Oral hygiene		Nurse provides equipment; client does task.	Nurse prepares brush, rinses mouth, positions client.	Nurse completes entire procedure.
Dressing/grooming		Nurse gathers items for client; may button, zip, or tie clothing. Client dresses self.	Nurse combs client's hair, assists with dressing, buttons and zips clothing, ties shoes.	Client needs to be dressed and cannot assist the nurse; nurse combs client's hair.
Toileting		Client can walk to bathroom/commode with assistance; nurse helps with clothing.	Nurse provides bedpan, positions client on or off bedpan, places client on commode.	Client is incontinent; nurse places client on bedpan or commode.

From *Pearson Nursing Diagnosis Handbook*, Coursesmart etextbook, 10th ed. (pp. 629, 633, 641), by J. M. Wilkinson, 2014, Upper Saddle River, NJ: Pearson. Reprinted and Electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

TABLE 33–3 Common Skin Problems

Problem and Appearance	Nursing Implications
<p>ABRASION Superficial layers of the skin are scraped or rubbed away. Area is reddened and may have localized bleeding or serous weeping.</p>	<ol style="list-style-type: none"> 1. Prone to infection; therefore, wound should be kept clean and dry. 2. Do not wear rings or jewelry when providing care to avoid causing abrasions to clients. 3. Lift, do not pull, a client across a bed. 4. Use two or more people for assistance.
<p>EXCESSIVE DRYNESS Skin can appear flaky and rough.</p>	<ol style="list-style-type: none"> 1. Prone to infection if the skin cracks; therefore, provide alcohol-free lotions to moisturize the skin and prevent cracking. 2. Bathe client less frequently; use no soap, or use nonirritating soap and limit its use. Rinse skin thoroughly because soap can be irritating and drying. 3. Encourage increased fluid intake if health permits to prevent dehydration.
<p>AMMONIA DERMATITIS (DIAPER RASH) Caused by skin bacteria reacting with urea in the urine. The skin becomes reddened and is sore.</p>	<ol style="list-style-type: none"> 1. Keep skin dry and clean by applying protective ointments containing zinc oxide to areas at risk (e.g., buttocks and perineum). 2. Boil an infant's diapers or wash them with an antibacterial detergent to prevent infection. Rinse diapers well because detergent is irritating to an infant's skin.
<p>ACNE Inflammatory condition with papules and pustules.</p>	<ol style="list-style-type: none"> 1. Keep the skin clean to prevent secondary infection. 2. Treatment varies widely.
<p>ERYTHEMA Redness associated with a variety of conditions, such as rashes, exposure to sun, elevated body temperature.</p>	<ol style="list-style-type: none"> 1. Wash area carefully to remove excess microorganisms. 2. Apply antiseptic spray or lotion to prevent itching, promote healing, and prevent skin breakdown.
<p>HIRSUTISM Excessive hair on a person's body and face, particularly in women.</p>	<ol style="list-style-type: none"> 1. Remove unwanted hair by using depilatories, shaving, electrolysis, or tweezing. 2. Enhance client's self-concept.

ASSESSMENT INTERVIEW Skin Hygiene

SKIN CARE PRACTICES

- What are your usual showering or bathing times?
- What hygienic products do you routinely use (e.g., bath oils, powder, facial cleansing creams, body lotions or creams, deodorants, antiperspirants)?
- What facial cosmetic products do you use?
- How and when do you clean makeup applicators and puffs? (Applicators should be kept clean, and products used around the eyes in particular should be discarded after 4 months to prevent bacterial and fungal infections.)
- What hygienic or cosmetic products do you not use because of the skin problems they create (e.g., skin dryness or allergic reactions)?

SELF-CARE ABILITIES

- Do you have any problems managing your hygienic practices (e.g., baths and facial care)? If so, what are these?
- How can the nurses best help you?

SKIN PROBLEMS

- Do you have any tendency toward skin dryness, itchiness, rashes, bruising, excessive perspiration, or lack of perspiration? Have you had skin or scalp lesions in the past?
- Do you have any allergic tendencies? If so, what?

Positive responses to any of these require further exploration in terms of duration (When did it start?); frequency (How often have you had this?); description of lesion or rash; any associated signs, such as fever or nausea; aggravating factors (e.g., season of the year, stress, occupation, medication, recent travel, housing, personal contact); alleviating factors (e.g., medications, lotions, home remedies); and any family history of the problem.

data about the client's skin care practices, self-care abilities, and skin problems are shown in the accompanying Assessment Interview.

Physical Assessment

Physical assessment of the skin, which involves inspection and palpation, is described in Chapter 30. When assisting with bathing and other hygienic care, the nurse often has the opportunity to collect data about skin color, uniformity of color, texture, turgor, temperature, intactness, and lesions.

Diagnosing

The NANDA International Activity/Rest Domain includes five classes, one of which is *Self-Care* which incorporates seven nursing diagnoses (Herdman & Kamitsuru, 2014, p. 61). *Self-Care Deficit* diagnoses are used for clients who have problems performing hygiene care. Three of NANDA's four self-care deficit diagnoses, specified as *Bathing Self-Care Deficit*, *Dressing Self-Care Deficit*, and *Toileting Self-Care Deficit*, are discussed in this chapter. The fourth diagnosis, *Feeding Self-Care Deficit*, is discussed in Chapter 47.

Difficulties encountered by the client in performing bathing activities include the inability to wash the body or body parts, to obtain or get to a water source, and to regulate water temperature or flow. Difficulties in dressing and grooming include inability to obtain, put on, take off, fasten, or replace articles of clothing and to maintain appearance at a satisfactory level. Toileting problems may involve difficulties getting to the toilet or commode or sitting on and rising from it. In addition, the client may experience problems manipulating clothing for toileting, carrying out proper toilet hygiene, or flushing the toilet or emptying the commode. The reasons (etiologies or related factors) for these problems are varied (Box 33–1).

Examples of associated diagnoses include:

- *Deficient Knowledge* related to:
 - a. Lack of experience with skin condition (acne) and need to prevent secondary infection
 - b. New therapeutic regimen to manage skin problems
 - c. Lack of experience in providing hygiene care to dependent person

BOX 33–1 Etiologies of Self-Care Deficits

- Decreased or lack of motivation
- Weakness or tiredness
- Pain or discomfort
- Perceptual or cognitive impairment
- Inability to perceive body part or spatial relationship
- Neuromuscular or musculoskeletal impairment
- Medically imposed restriction
- Therapeutic procedure restraining mobility (e.g., intravenous infusion, cast)
- Severe anxiety
- Environmental barriers

- d. Unfamiliarity with devices available to facilitate sitting on or rising from toilet.
- *Situational Low Self-Esteem* related to:
 - a. Visible skin problem (e.g., acne or alopecia)
 - b. Body odor.

The diagnoses *Risk for Impaired Skin Integrity* and *Impaired Skin Integrity* are discussed in Chapter 36.

Planning

In planning care, the nurse and, if appropriate, the client and/or family set outcomes for each nursing diagnosis. The nurse then performs nursing interventions and activities to achieve the client outcomes.

The specific, detailed nursing activities provided by the nurse may include assisting dependent clients with bathing, skin care, and perineal care; providing back massages to promote circulation; instructing clients/families about appropriate hygienic practices and alternative methods for dressing; and demonstrating use of assistive equipment and adaptive activities. Although the nursing interventions discussed in this chapter focus on hygienic measures, the etiology of the nursing diagnoses established may point to other interventions that promote circulation, promote self-esteem, restore nutritional status, correct fluid deficits or excesses, or prevent problems associated with immobility.

CLIENT AND ENVIRONMENT

- *Self-care abilities for hygiene:* Assess the client's ability to bathe, to regulate water faucets, to dress and undress, to groom, and to use the toilet.
- *Self-care aids required:* Determine if there is a need for a tub/shower seat (Figure 33-1 ■), a hand shower, a nonskid surface or mat in the tub or shower, hand bars on the sides of the tub (Figure 33-2 ■), or a raised toilet seat.
- *Facilities:* Check for the presence of laundry facilities and running water.
- *Mechanical barriers:* Note furniture obstructing access to the bathroom and toilet, or a doorway too narrow for a wheelchair.

FAMILY

- *Caregiver availability, skills, and responses:* Determine whether individuals are available and able to assist with bathing, dressing, toileting, nail care, hair shampooing, or shopping for hygienic or grooming aids.

Figure 33-1 ■ Tub/shower seat in the home.
Steven Barnes/Medical/Alamy.

- *Education needs:* Assess whether the caregiver needs instruction in how to assist the client in and out of the tub, on and off the toilet, and so on.
- *Family role changes and coping:* Assess effects of client's illness on financial status, parenting, spousal roles, sexuality, and social roles.

COMMUNITY

- Explore resources that will provide assistance with bathing, laundry, and foot care (e.g., home health aide, podiatrist).
- Consult a social worker as needed to coordinate placement of a client unable to remain in the home or to identify community resources that will help the client stay in the home.
- Consider a consult with (a) a physical therapist to assess, develop, and improve the client's motor function; (b) a home health nurse to provide follow-up for care, teaching, and support; and (c) an occupational therapist to assess and develop abilities to perform activities of daily living.

Figure 33-2 ■ Raised toilet seat and hand bar on the side of the bathtub.
Scimat/Photo Researchers, Inc.

Nursing strategies to deal with these etiologies are provided in other chapters

Planning to assist a client with personal hygiene includes consideration of the client's personal preferences, health, and limitations; the best time to give the care; and the equipment, facilities, and personnel available. A client's personal preferences—about when and how to bathe, for example—should be followed as long as they are compatible with the client's health and the equipment available. Another consideration for the nurse is to assess the client's comfort level with the gender of the caregiver. Hygienic care, particularly bathing, can be embarrassing and stressful to modest individuals. Women in some cultures (e.g., Hindu, Iranian, Arab, and Navajo Indian) are generally modest. Nurses must respect a person's modesty, whether male or female, and provide adequate privacy and sensitivity. If possible, try to provide a caregiver of the

same gender (Purnell, 2013). Nurses need to provide whatever assistance the client requires, either directly or by delegating this task to other nursing personnel.

Planning for Home Care

To provide for continuity of care, the nurse should assess the client's and family's abilities to provide self-care/care and the need for referrals and home health services (see Home Care Assessment). In addition, the nurse needs to determine the client's learning needs.

Implementing

The nurse applies the general guidelines for skin care while providing one of the various types of baths available to clients. Skill 33-1 on page 676 describes how to bathe an adult client.

General Guidelines for Skin Care

- Intact, healthy skin is the body's first line of defense.** Nurses need to ensure that all skin care measures prevent injury and irritation. Scratching the skin with jewelry or long, sharp fingernails must be avoided. Harsh rubbing or use of rough towels and washcloths can cause tissue damage, particularly when the skin is irritated or when circulation or sensation is diminished. Bottom bed sheets are kept taut and free from wrinkles to reduce friction and abrasion to the skin. Top bed linens are arranged to prevent undue pressure on the toes. When necessary, footboards are used to keep bedclothes off the feet.
- The degree to which the skin protects the underlying tissues from injury depends on the general health of the cells, the amount of subcutaneous tissue, and the dryness of the skin.** Skin that is poorly nourished and dry is less easily protected and more vulnerable to injury. When the skin is dry, lotions or creams with lanolin can be applied, and bathing is limited to once or twice a week because frequent bathing removes the natural oils of the skin and causes dryness.
- Moisture in contact with the skin for more than a short time can result in increased bacterial growth and irritation.** After a bath, the client's skin is dried carefully. Particular attention is paid to areas such as the axillae, the groin, beneath the breasts, and between the toes, where the potential for irritation and fungal infection is greatest. A nonirritating dusting powder tends to reduce moisture and can be applied to these areas after they are dried. Clients who are incontinent of urine or feces or who perspire excessively are provided with immediate skin care to prevent skin irritation.
- Body odors are caused by resident skin bacteria acting on body secretions.** Cleanliness is the best deodorant. Commercial deodorants and antiperspirants can be applied only after the skin is cleaned. Deodorants diminish odors, whereas antiperspirants reduce the amount of perspiration. Neither is applied immediately after shaving because of the possibility of skin irritation, nor are they used on skin that is already irritated.
- Skin sensitivity to irritation and injury varies among individuals and in accordance with their health.** Generally speaking, skin sensitivity is greater in infants, very young children, and older people. A person's nutritional status also affects sensitivity. Emaciated and obese people tend to experience more skin irritation

and injury. The same tendency is seen in individuals with poor dietary habits and insufficient fluid intake. Even in healthy people, skin sensitivity is highly variable. Some people's skin is sensitive to the chemicals used in skin care agents and cosmetics. Hypoallergenic cosmetics and soaps or soap substitutes are now available for these people. The nurse needs to ascertain whether the client has any sensitivities and what agents are appropriate to use.

- Agents used for skin care have selective actions and purposes.** Commonly used agents are described in Table 33–4.

Bathing

Bathing removes accumulated oil, perspiration, dead skin cells, and some bacteria. The nurse can appreciate the quantity of oil and dead skin cells produced when observing a person after the removal of a cast that has been on for 6 weeks. The skin is crusty, flaky, and dry underneath the cast. Applications of oil over several days are usually necessary to remove the debris.

Excessive bathing, however, can interfere with the intended lubricating effect of the sebum, causing dryness of the skin. This is an important consideration, especially for older adults, who produce less sebum.

In addition to cleaning the skin, bathing also stimulates circulation. A warm or hot bath dilates superficial arterioles, bringing more blood and nourishment to the skin. Vigorous rubbing has the same effect. Rubbing with long smooth strokes from the distal to proximal parts of extremities (from the point farthest from the body to the point closest) is particularly effective in facilitating venous blood flow return unless there is some underlying condition (e.g., thrombosis) that would preclude this.

Bathing also produces a sense of well-being. It is refreshing and relaxing and frequently improves morale, appearance, and self-respect. Some people take a morning shower for its refreshing, stimulating effect. Others prefer an evening bath because it is relaxing. These effects are more evident when a person is ill. For example, it is not uncommon for clients who have had a restless or sleepless night to feel relaxed, comfortable, and sleepy after a morning bath.

Bathing offers an excellent opportunity for the nurse to assess clients and opens the door for establishing trust. The nurse can observe the client's skin for conditions such as sacral edema or rashes. While assisting a client with a bath, the nurse can also

TABLE 33–4 Agents Commonly Used on the Skin

Soap	Lowers surface tension and thus helps in cleaning. Some soaps contain antibacterial agents, which can change the natural flora of the skin.
Chlorhexidine gluconate (CHG)	A disposable cloth saturated with 2% CHG and skin-moisturizing substances. An advantage is continued antimicrobial activity after application. These cloths are often used in critical-care settings.
Bath oil	Used in bathwater; provides an oily film on the skin that softens and prevents chapping. Oils can make the tub surface slippery, and clients should be instructed about safety measures (e.g., using nonskid tub surface or mat).
Skin cream, lotion	Provides a film on the skin that prevents evaporation and therefore chapping.
Powder	Can be used to absorb water and prevent friction. For example, powder under the breasts can prevent skin irritation. Some powders are antibacterial.
Deodorant	Masks or diminishes body odors.
Antiperspirant	Reduces the amount of perspiration.

assess the client's psychosocial needs, such as orientation to time and ability to cope with the illness. Learning needs, such as the need for a client who has diabetes to learn foot care, can also be assessed.

Categories

Two categories of baths are given to clients: cleaning and therapeutic. **Cleansing baths** are given chiefly for hygiene purposes and include these types:

- **Complete bed bath.** The nurse washes the entire body of a dependent client in bed.
- **Self-help bed bath.** Clients confined to bed are able to bathe themselves with help from the nurse for washing the back and perhaps the feet.
- **Partial bath (abbreviated bath).** Only the parts of the client's body that might cause discomfort or odor, if neglected, are washed: the face, hands, axillae, perineal area, and back. Omitted are the arms, chest, abdomen, legs, and feet. The nurse provides this care for dependent clients and assists self-sufficient clients confined to bed by washing their backs. Some ambulatory clients prefer to take a partial bath at the sink. The nurse can assist them by washing their backs.
- **Bag bath.** This bath is a commercially prepared product that contains 10 to 12 presoaked disposable washcloths that contain no-rinse cleanser solution. The package is warmed in a microwave. The warming time is about 1 minute, but the nurse needs to determine how long it takes to attain a desirable temperature. Each area of the body is cleaned with a different cloth and then air dried. Because the body is not rubbed dry, the emollient in the solution remains on the skin.
- **Towel bath.** This bath is similar to a bag bath but uses regular towels. It is useful for clients who are bedridden and clients with dementia. The client is covered and kept warm throughout the bathing process by a bath blanket. The nurse gradually replaces the bath blanket with a large towel that has been soaked with warm water and no-rinse soap. The client is then gently massaged with the warm, wet, soapy towel. The wet towel is replaced with a large dry towel for drying the client's skin.
- **Tub bath.** Tub baths are often preferred to bed baths because it is easier to wash and rinse in a tub. Tubs are also used for therapeutic baths. The amount of assistance the nurse offers depends on the abilities of the client. There are specially designed tubs for dependent clients. These tubs greatly reduce the work of the nurse in lifting clients in and out of the tub and offer greater benefits than a sponge bath in bed.

Sponge baths are suggested for the newborn because daily tub baths are not considered necessary. After the bath, the infant should be immediately dried and wrapped to prevent heat loss. Parents need to be advised that the infant's ability to regulate body temperature has not yet fully developed. Infants perspire minimally, and shivering starts at a lower temperature than it does in adults; therefore, infants lose more heat before shivering begins. In addition, because the infant's body surface area is very large in relation to body mass, the body loses heat readily.

- **Shower.** Many ambulatory clients are able to use shower facilities and require only minimal assistance from the nurse. Clients in

Figure 33-3 ■ A shower chair.

long-term care settings are often given showers with the aid of a shower chair. The wheels on the shower chair allow clients to be transported from their room to the shower. The shower chair also has a commode seat to facilitate cleansing of the client's perineal area during the shower process (Figure 33-3 ■).

The water for a bath should feel comfortably warm to the client. People vary in their sensitivity to heat; generally, the temperature should be 43°C to 46°C (110°F to 115°F). Most clients will verify a suitable temperature. Clients with decreased circulation or cognitive problems, however, will not be able to verify the temperature. Therefore, the nurse must check the water temperature to avoid burning the client with water that is too hot. The water for a bed bath should be changed when it becomes dirty or cold.

Therapeutic baths are given for physical effects, such as to soothe irritated skin or to treat an area (e.g., the perineum). Medications may be placed in the water. A therapeutic bath is generally taken in a tub one third or one half full. The client remains in the bath for a designated time, often 20 to 30 minutes. If the client's back, chest, and arms are to be treated, these areas need to be immersed in the solution. The bath temperature is generally included in the order; 37.7°C to 46°C (100°F to 115°F) may be ordered for adults and 40.5°C (105°F) is usually ordered for infants. Skill 33-1 provides guidelines for bathing clients.

Evidence-Based Practice Is There a Difference in Development of Health Care–Associated Infections When Bathing Daily with Chlorhexidine Gluconate Compared with Soap and Water?

EVIDENCE-BASED PRACTICE

Previous research has shown that daily bathing with 2% chlorhexidine gluconate (CHG) resulted in decreased environmental and skin contamination with vancomycin-resistant enterococci (VRE), decreased bacteremia with VRE, decreased central venous catheter–associated bloodstream infections, and decreased blood culture contamination in intensive care unit (ICU) settings. Evidence has also shown that plastic bath basins are reservoirs for pathogenic microbes. Using CHG for bathing eliminates the need for the bath basins.

Researchers Kassakian, Mermel, Jefferson, Parenteau, and Machan (2011) realized that minimal research had been done on the effectiveness of CHG bathing on health care–associated infections (HAIs) *outside* of the ICU setting. Using a quasi-experimental design, they examined the effect of daily bathing with 2% CHG-impregnated cloths compared with soap and water bathing among clients in general medical units. The primary outcome was to determine the incidence of methicillin-resistant *Staphylococcus aureus* (MRSA) and VRE HAIs at any body site. They studied four adult general medical

units with a total of 94 beds in a 719-bed academic tertiary-care hospital. The control group included all clients admitted from January 1 through December 31, 2008, who were bathed with soap and water. The intervention group consisted of all clients admitted to the units from February 1, 2009, through March 31, 2010, who were bathed with CHG-impregnated cloths once daily. After adjusting for various factors, there was a 64% reduced risk of developing MRSA and VRE HAIs with the CHG bathing group compared with the soap-and-water bathing group. These findings are in agreement with similar studies in ICU settings.

IMPLICATIONS

The researchers state that their results require further confirmation before CHG bathing of non-ICU clients becomes a standard of care. A strength of their study, however, was the large sample size (over 70,000 client days). Their findings, while preliminary, suggest that daily CHG bathing may be a beneficial infection control intervention for clients outside of the ICU setting.

Bathing an Adult Client

PURPOSES

- To remove transient microorganisms, body secretions and excretions, and dead skin cells
- To stimulate circulation to the skin
- To promote a sense of well-being
- To produce relaxation and comfort
- To prevent and eliminate unpleasant body odors

ASSESSMENT

Assess

- Physical or emotional factors (e.g., fatigue, sensitivity to cold, need for control, anxiety or fear)
- Condition of the skin (color, texture and turgor, presence of pigmented spots, temperature, lesions, excoriations, abrasions, and bruises). Areas of erythema (redness) on the sacrum, bony prominences, and heels should be assessed for possible pressure sores
- Presence of pain and need for adjunctive measures (e.g., an analgesic) before the bath
- Range of motion of the joints
- Any other aspect of health that may affect the client's bathing process (e.g., mobility, strength, cognition)
- Need for use of clean gloves during the bath

PLANNING

DELEGATION

The nurse often delegates the skill of bathing to UAP. However, the nurse remains responsible for assessment and client care. The nurse needs to do the following:

- Inform the UAP of the type of bath appropriate for the client and precautions, if any, specific to the needs of the client.
- Remind the UAP to notify the nurse of any concerns or changes (e.g., redness, skin breakdown, rash) so the nurse can assess, intervene if needed, and document.
- Instruct the UAP to encourage the client to perform as much self-care as appropriate in order to promote independence and self-esteem.
- Obtain a complete report about the bathing experience from the UAP.

Equipment

- Basin or sink with warm water (between 43°C and 46°C [110°F and 115°F])
- Soap and soap dish
- Linens: bath blanket, two bath towels, washcloth, clean gown or pajamas or clothes as needed, additional bed linen and towels, if required
- Clean gloves, if appropriate (e.g., presence of body fluids or open lesions)
- Personal hygiene articles (e.g., deodorant, lotions)
- Shaving equipment
- Table for bathing equipment
- Laundry bag

Bathing an Adult Client—continued

IMPLEMENTATION

Preparation

Before bathing a client, determine (a) the purpose and type of bath the client needs; (b) self-care ability of the client; (c) any movement or positioning precautions specific to the client; (d) other care the client may be receiving, such as physical therapy or x-rays, in order to coordinate all aspects of health care and prevent unnecessary fatigue; (e) client's comfort level with being bathed by someone else; and (f) necessary bath equipment and linens.

Caution is needed when bathing clients who are receiving IV therapy. Easy-to-remove gowns that have Velcro or snap fasteners along the sleeves may be used. If a special gown is not available, the nurse needs to pay special attention when changing the client's gown after the bath (or whenever the gown becomes soiled). In addition, special attention is needed to reassess the IV site for security of IV connections and appropriate taping around the IV site.

The nurse should use universal precautions when bathing a client, particularly when performing perineal care. It is not necessary, however, to wear gloves while providing a bath and the nurse should use clinical judgment when deciding to wear gloves and offer an explanation to the client.

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss with the client their preferences for bathing and explain any unfamiliar procedures.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*
- Prepare the client and the environment.
 - Invite a family member or significant other to participate if desired or requested by the client.
 - Close windows and doors to ensure the room is a comfortable temperature. **Rationale:** *Air currents increase loss of heat from the body by convection.*
 - Offer the client a bedpan or urinal or ask whether the client wishes to use the toilet or commode. **Rationale:** *Warm water and activity can stimulate the need to void. The client will be more comfortable after voiding, and voiding before cleaning the perineum is advisable.*

- Remove the top sheet from under the bath blanket.

- Encourage the client to perform as much personal self-care as possible. **Rationale:** *This promotes independence, exercise, and self-esteem.*
- During the bath, assess each area of the skin carefully.

For a Bed Bath

- Prepare the bed and position the client appropriately.
 - Position the bed at a comfortable working height. Lower the side rail on the side close to you. Keep the other side rail up. Assist the client to move near you. **Rationale:** *This avoids undue reaching and straining and promotes good body mechanics. It also ensures client safety.*
 - Place bath blanket over top sheet. Remove the top sheet from under the bath blanket by starting at client's shoulders and moving linen down toward client's feet. 1 Ask the client to grasp and hold the top of the bath blanket while pulling linen to the foot of the bed. **Rationale:** *The bath blanket provides comfort, warmth, and privacy.*
- Note:** If the bed linen is to be reused, place it over the bedside chair. If it is to be changed, place it in the linen hamper, not on the floor.
 - Remove client's gown while keeping the client covered with the bath blanket. Place gown in linen hamper.
- Make a bath mitt with the washcloth. **Rationale:** *A bath mitt retains water and heat better than a cloth loosely held and prevents ends of washcloth from dragging across the skin. See 2*

- Making a bath mitt, triangular method. A, Lay your hand on the washcloth; B, fold the top corner over your hand; C, fold the side corners over your hand; D, tuck the second corner under the cloth on the palm side to secure the mitt.

Bathing an Adult Client—continued

3 Making a bath mitt, rectangular method. A, Lay your hand on the washcloth and fold one side over your hand; B, fold the second side over your hand; C, fold the top of the cloth down and tuck it under the folded side against your palm to secure the mitt.

for the triangular method and 3 for the rectangular method of making a bath mitt.

7. Wash the face. **Rationale:** *Begin the bath at the cleanest area and work downward toward the feet.*

- Place towel under client's head.
- Wash the client's eyes with water only and dry them well. Use a separate corner of the washcloth for each eye.

Rationale: *Using separate corners prevents transmitting microorganisms from one eye to the other. Wipe from the inner to the outer canthus.* 4 **Rationale:** *This prevents secretions from entering the nasolacrimal ducts.*

- Ask whether the client wants soap used on the face. **Rationale:** *Soap has a drying effect, and the face, which is exposed to the air more than other body parts, tends to be drier.*
- Wash, rinse, and dry the client's face, ears, and neck.
- Remove the towel from under the client's head.

8. Wash the arms and hands. (Omit the arms for a partial bath.)

- Place a towel lengthwise under the arm away from you. **Rationale:** *It protects the bed from becoming wet.*
- Wash, rinse, and dry the arm by elevating the client's arm and supporting the client's wrist and elbow. 5 Use long, firm strokes from wrist to shoulder, including the axillary area. **Rationale:** *Firm strokes from distal to proximal areas promote circulation by increasing venous blood return.*
- Apply deodorant or powder if desired. Special caution is needed for clients with respiratory alterations. **Rationale:** *Powder is not recommended for these clients due to the potential respiratory adverse effects.*
- *Optional:* Place a towel on the bed and put a washbasin on it. Place the client's hands in the basin. **Rationale:** *Many clients enjoy immersing their hands in the basin and washing themselves. Soaking loosens dirt under the nails.* Assist the client as needed to wash, rinse, and dry the hands, paying particular attention to the spaces between the fingers.
- Repeat for hand and arm nearest you. Exercise caution if an IV infusion is present, and check its flow after moving the arm. Avoid submersing the IV site if the dressing site is not a clear, transparent dressing. **Rationale:** *A clear transparent dressing will keep water from an IV site; however, a gauze dressing becomes contaminated when it becomes wet with the water.*

9. Wash the chest and abdomen. (Omit the chest and abdomen for a partial bath. However, the areas under a woman's breasts

4 Using a separate corner of the washcloth for each eye, wipe from the inner to the outer canthus.

5 Washing the arm using long, firm strokes from wrist to shoulder area.

may require bathing if this area is irritated or if the client has significant perspiration under the breast.)

- Place bath towel lengthwise over chest. Fold bath blanket down to the client's pubic area. **Rationale:** *Keeps the client warm while preventing unnecessary exposure of the chest.*

Bathing an Adult Client—continued

- Lift the bath towel off the chest, and bathe the chest and abdomen with your mitted hand using long, firm strokes. **6**
 - Give special attention to the skin under the breasts and any other skinfolds, particularly if the client is overweight. Rinse and dry well.
 - Replace the bath blanket when the areas have been dried.
- 10.** Wash the legs and feet. (Omit legs and feet for a partial bath.)
- Expose the leg farthest from you by folding the bath blanket toward the other leg, being careful to keep the perineum covered. **Rationale:** *Covering the perineum promotes privacy and maintains the client's dignity.*
 - Lift leg and place the bath towel lengthwise under the leg. Wash, rinse, and dry the leg using long, smooth, firm strokes from the ankle to the knee to the thigh. **7 Rationale:** *Washing from the distal to proximal areas promotes circulation by stimulating venous blood flow.*
 - Reverse the coverings and repeat for the other leg.
 - Wash the feet by placing them in the basin of water.
 - Dry each foot. Pay particular attention to the spaces between the toes. If preferred, wash one foot after that leg before washing the other leg.
 - Obtain fresh, warm bathwater now or when necessary. **Rationale:** *Water may become dirty or cold.* Because surface skin cells are removed with washing, the bathwater from dark-skinned clients may be dark, however, this does not mean the client is dirty. Lower the bed and raise the side rails when refilling the basin. **Rationale:** *This ensures the safety of the client.*
- 11.** Wash the back and then the perineum.
- Assist the client into a prone or side-lying position facing away from you. Place the bath towel lengthwise alongside the back and buttocks while keeping the client covered with the bath blanket as much as possible. **Rationale:** *This provides warmth and prevents undue exposure.*
 - Wash and dry the client's back, moving from the shoulders to the buttocks, and upper thighs, paying attention to the gluteal folds. **8**
 - Remove and discard gloves if used.
 - Perform a back massage now or after completion of bath. (See Skill 46-1.)
 - Assist the client to the supine position and determine whether the client can wash the perineal area independently. If the client cannot do so, drape the client as shown in Skill 33-2 and wash the area.
- 12.** Assist the client with grooming aids such as powder, lotion, or deodorant.
- Use powder sparingly. Release as little as possible into the atmosphere. **Rationale:** *This will avoid irritation of the respiratory tract by powder inhalation. Excessive powder can cause caking, which leads to skin irritation.*
 - Help the client put on a clean gown or pajamas.
 - Assist the client to care for hair, mouth, and nails. Some people prefer or need mouth care prior to their bath.

For a Tub Bath or Shower

- 13.** Prepare the client and the tub.
- Fill the tub about one third to one half full of water at 43°C to 46°C (110°F to 115°F). **Rationale:** *Sufficient water is needed to cover the perineal area.*
 - Cover all intravenous catheters or wound dressings with plastic coverings, and instruct the client to prevent wetting these areas if possible.
 - Put a rubber bath mat or towel on the floor of the tub if safety strips are not on the tub floor. **Rationale:** *These prevent slippage of the client during the bath or shower.*
- 14.** Assist the client into the shower or tub.
- Assist the client taking a standing shower with the initial adjustment of the water temperature and water flow pressure, as needed. Some clients need a chair to sit on in the shower because of weakness. Hot water can cause older people to feel faint due to vasodilation and decreased blood pressure from positional changes.
 - If the client requires considerable assistance with a tub bath, a hydraulic bathtub chair may be required (see *Variation*).
 - Explain how the client can signal for help, leave the client for 2 to 5 minutes, and place an "occupied" sign on the door. For safety reasons, do not leave a client with decreased cognition or clients who may be at risk (e.g., history of seizures, syncope).

6 Washing the chest and abdomen.

7 Washing the far leg.

8 Washing the back.

Bathing an Adult Client—continued

15. Assist the client with washing and getting out of the tub.
 - Wash the client's back, lower legs, and feet, if necessary.
 - Assist the client out of the tub. If the client is unsteady, place a bath towel over the client's shoulders and drain the tub of water before the client attempts to get out of it. **Rationale:** *Draining the water first lessens the likelihood of a fall. The towel prevents chilling.*
16. Dry the client, and assist with follow-up care.
 - Follow step 12.
 - Assist the client back to his or her bed.
 - Clean the tub or shower in accordance with agency practice, discard the used linen in the laundry hamper, and place the "unoccupied" sign on the door.
17. Document the following:
 - Type of bath given (i.e., complete, partial, or self-help). This is usually recorded on a flow sheet.
 - Skin assessment, such as excoriation, erythema, exudates, rashes, drainage, or skin breakdown.
 - Nursing interventions related to skin integrity.
 - Ability of the client to assist or participate with bathing.
 - Client response to bathing. Also, document the need for reassessment of vital signs if appropriate.

- Educational needs regarding hygiene.
- Information or teaching shared with the client or their family.

Variation: Bathing Using a Hydraulic Bathtub Chair

A hydraulic lift, often used in long-term care or rehabilitation settings, can facilitate the transfer of a client who is unable to ambulate to a tub. The lift also helps eliminate strain on the nurse's back.

- Bring the client to the tub room in a wheelchair or shower chair.
- Fill the tub and check the water temperature with a bath thermometer. **Rationale:** *This avoids thermal injury to the client.*
- Lower the hydraulic chair lift to its lowest point, outside the tub.
- Transfer the client to the chair lift and secure the seat belt.
- Raise the chair lift above the tub.
- Support the client's legs as the chair is moved over the tub. **Rationale:** *This avoids injury to the legs.*
- Position the client's legs down into the water and slowly lower the chair lift into the tub.
- Assist in bathing the client, if appropriate.
- Reverse the procedure when taking the client out of the tub.
- Dry the client and transport him or her to the room.

EVALUATION

- Note the client's tolerance of the procedure (e.g., respiratory rate and effort, pulse rate, behaviors of acceptance or resistance, statements regarding comfort).
- Conduct appropriate follow-up, such as determining:
 - Condition and integrity of skin (dryness, turgor, redness, lesions, and so on).
 - Client strength. Note range of motion and circulation, movement, and sensation for all extremities.
 - Percentage of bath done without assistance.
- Relate to prior assessment data, if available.

LIFESPAN CONSIDERATIONS Bathing

INFANTS

- Sponge baths are suggested for the newborn because daily tub baths are not considered necessary. After the bath, the infant should be immediately dried and wrapped. Parents need to be advised that the infant's ability to regulate body temperature has not yet fully developed and newborns' bodies lose heat readily.

CHILDREN

- Encourage a child's participation as appropriate for developmental level.
- Closely supervise children in the bathtub. Do not leave them unattended.

ADOLESCENTS

- Assist adolescents as needed to choose deodorants and antiperspirants. Secretions from newly active sweat glands react with bacteria on the skin, causing a pungent odor.

OLDER ADULTS

- Changes of aging can decrease the protective function of the skin in older adults. These changes include fragile skin, less oil and moisture, and a decrease in elasticity.
- To minimize skin dryness in older adults, avoid excessive use of soap. The ideal time to moisturize the skin is immediately after bathing.
- Avoid excessive powder because it causes moisture loss and is a hazardous inhalant. Cornstarch should also be avoided because in the presence of moisture it breaks down into glucose and can facilitate the growth of organisms.
- Protect older adults and children from injury related to hot water burns.

Home Care Considerations Hygiene

SAFETY

Suggest that the client or family do the following:

- Consider purchasing a bath seat that fits in the tub or shower.
- Install a hand shower for use with a bath seat and shampooing.
- Use a nonskid surface on the tub or shower.
- Install hand bars on both sides of the tub or shower to facilitate transfers in and out of the tub or shower.

- Carefully monitor the temperature of the bathwater.
- Apply lotion and oil *after* a bath, not during, because these solutions can make a tub surface slippery.

Long-Term Care Setting

From a historical perspective, the bath has always been a part of the art of nursing care and considered a component of nursing. In today's nursing world, however, the bath is seen as a necessary, routine task and is often delegated to nonprofessionals.

In spite of the previously listed beneficial values associated with bathing, the choice of bathing procedure often depends on the amount of time available to the nurses or unlicensed assistive personnel (UAP) and the client's self-care ability. The bath routine (e.g., day, time, and number per week) for clients in health care settings is often determined by agency policy, which often results in the bath becoming routine and depersonalized versus therapeutic, satisfying, and person centered. New models and a culture change process are occurring in long-term care and residential care settings. That is, these settings are trying to become less about tasks and more about people and the relationships between people. This person-centered approach to bathing is especially important for the older client in a long-term care setting. Bathing needs to focus on the experience for the client rather than the outcome (i.e., getting a bath or shower).

A nurse who provides person-centered care asks questions such as these: What is the client's usual method of maintaining cleanliness? Are there any past negative experiences related to bathing? Are factors such as pain or fatigue increasing the client's difficulty with the demands and stimuli associated with bathing or showering? A client's resistance to the bathing experience can be a cue to the nurse to consider other methods of maintaining cleanliness. For example, if the shower causes distress, is there another form of bathing (such as the bag or towel bath) that may be more therapeutic and comforting?

An individualized approach focusing on therapeutic and comforting outcomes of bathing is especially important for clients with dementia. Alzheimer's disease is the most common cause of dementia among people ages 65 and older. As the incidence of dementia increases, so does the need to preserve the dignity of people with dementia. Preserving dignity is especially a priority in the residential

care environment where more than two thirds of residents have some form of dementia (Gaspard & Cox, 2012, p. 43). This statistic has implications for nursing care. For example, people with dementia may become agitated as soon as they are told it is time to bathe and many are afraid of the noise of running water and of water on their face (Hoban, 2012). See Box 33–2 for possible strategies that can reduce the stress of the bathing experience for both the person with dementia and the caregiver.

Providing personal hygiene to a client with dementia is often an ongoing challenge. Being sensitive to the rhythm of their behavior and looking for cues can often offset problems related to this. Clients with dementia, whether they are at home or in a health care facility, often have certain times of the day when they are more agitated—these are times to avoid doing things that will increase their fear and agitation. When increased agitation occurs, the nurse should stop and change the approach. It is also sometimes helpful to wait (e.g., half an hour or so) and then try giving the bath because they may forget that they were protesting and be willing to participate.

In addition, collaboration between the nurse and UAP is a critical element to implementing the individualized person-focused approach for clients with cognitive impairments who exhibit aggressive behavior during bathing. The nurse, after observing a difficult bathing situation, should discuss with the UAP possible alternative strategies or methods they might implement for the client. More than one intervention may be required (e.g., reassurance, simple explanations, moving slowly). It is important for the nurse to subsequently evaluate the person's response to the new intervention(s). The nurse has a role in educating UAP about dementia and collaboratively problem solving bathing challenges (Gaspard & Cox, 2012).

Perineal-Genital Care

Perineal-genital care is also referred to as *perineal care* or *pericare*. Perineal care as part of the bed bath is embarrassing for many clients.

BOX 33–2 General Guidelines for Bathing People with Dementia

- Focus on the person rather than the task.
 - Cover! Keep the person covered as much as possible to keep warm.
 - Time the bath to fit the person's history, preferences, and mood.
 - Move slowly and let the person know when you are going to move them. Or, ask the client to move his or her own arm or leg.
 - Evaluate to determine if the person needs pain control before the bath.
 - Use a gentle touch. Use soft cloths. Pat dry rather than rubbing.
- Be flexible. Adapt your approach to meet the needs of the person.
 - Consider adapting your methods (e.g., distracting the person with singing while bathing), the environment (e.g., correct size of shower chair, reducing noise, playing music), or the procedure (e.g., consistently assigning the same caregiver, inviting family to help).
 - Encourage flexibility in scheduling of bath based on the individual's preference.
- Use persuasion, not coercion.
 - Give choices and respond to individual requests.
- Help the person feel in control.
 - Use a supportive, calm approach and praise the person often.
- Be prepared.
 - Gather everything that you will need for the bath (e.g., towels, washcloths, clothes) before approaching the person.
- Stop when a person becomes distressed. It is not normal to have cries, screams, or protests from the person.
 - Stop what you are doing and assess for causes of the distress.
 - Adjust your approach.
 - Shorten or stop the bath.
 - Try to end on a positive note.
 - Reapproach later to wash critical areas if necessary.
- Ask for help.
 - Talk with others, including the family, about different ways to help make the bath more comfortable for the person.

From "Dementia-Friendly Bathing," by S. Hoban, 2012, *Long-Term Living*, 61(10), pp. 41–42; "Practical Care: Creative Strategies for Bathing," by R. H. Johnson, 2011, *Nursing & Residential Care*, 13(8), pp. 392–394; and "Nursing Home Bathing Transformed," by E. F. Barbera, 2011, *Long-Term Living*, 60(10), pp. 41–43.

Nurses also may find it embarrassing initially, particularly with clients of the opposite sex. Most clients who require a bed bath from the nurse are able to clean their own genital areas with minimal assistance. The nurse may need to hand a moistened washcloth and soap to the client, rinse the washcloth, and provide a towel.

Because some clients are unfamiliar with terminology for the genitals and perineum, it may be difficult for nurses to explain what is expected. Most clients, however, understand what is meant if the nurse simply says, “I’ll give you a washcloth to finish your bath in privacy.” Some older clients may be familiar with the term *private parts*. Whatever expression the nurse uses, it needs to be one that the client understands and one that is comfortable for the nurse to use.

The nurse needs to provide perineal care efficiently and matter of factly. Nurses should wear gloves while providing this care for the comfort of the client and to protect themselves from infection. Skill 33–2 explains how to provide perineal-genital care.

CLINICAL ALERT!

Always wash or wipe from “clean to dirty.” For a female, cleanse perineal area from front to back. For a male, cleanse the urinary meatus by moving in a circular motion from the center of the urethral opening around the glans.

Client Teaching

Clients often need information about dry skin, skin rashes, and acne.

Providing Perineal-Genital Care

PURPOSES

- To remove normal perineal secretions and odors
- To promote client comfort

ASSESSMENT

Assess for the presence of

- Irritation, excoriation, inflammation, swelling
- Excessive discharge
- Odor; pain or discomfort
- Urinary or fecal incontinence

- Recent rectal or perineal surgery
- Indwelling catheter

Determine

- Perineal-genital hygiene practices
- Self-care abilities

PLANNING

DELEGATION

Perineal-genital care can be delegated to UAP; however, if the client has recently had perineal, rectal, or genital surgery, the nurse needs to assess if it is appropriate for the UAP to perform perineal-genital care.

Equipment

Perineal-genital care provided in conjunction with the bed bath:

- Bath towel
- Bath blanket

- Clean gloves
- Bath basin with warm water at 43°C to 46°C (110°F to 115°F)
- Soap
- Washcloth

Special perineal-genital care:

- Bath towel
- Bath blanket
- Clean gloves
- Solution bottle, pitcher, or container filled with warm water or a prescribed solution
- Bedpan to receive rinse water
- Perineal pad

IMPLEMENTATION

Preparation

- Determine whether the client is experiencing any discomfort in the perineal-genital area.
- Obtain and prepare the necessary equipment and supplies.

Performance

1. Prior to performing the procedure, introduce self and verify the client’s identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate, being particularly sensitive to any embarrassment displayed by the client.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide

signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*

4. Prepare the client:

- Fold the top bed linen to the foot of the bed and fold the gown up to expose the genital area.
- Place a bath towel under the client’s hips. **Rationale:** *The bath towel prevents the bed from becoming soiled.*

5. Position and drape the client and clean the upper inner thighs.

For Female Clients

- Position the female in a back-lying position with the knees flexed and spread well apart.
- Cover her body and legs with the bath blanket positioned so a corner is at her head, the opposite corner at her feet, and the other two on the sides. Drape the legs by tucking the bottom

Providing Perineal-Genital Care—continued

corners of the bath blanket under the inner sides of the legs.

1 Rationale: *Minimum exposure lessens embarrassment and helps to provide warmth.* Bring the middle portion of the base of the blanket up and then over the pubic area.

- Apply gloves. Wash and dry the upper inner thighs.

For Male Clients

- Position the male client in a supine position with knees slightly flexed and hips slightly externally rotated.
- Apply gloves and wash and dry the upper inner thighs.
- 6. Inspect the perineal area.
 - Note particular areas of inflammation, excoriation, or swelling, especially between the labia in females and the scrotal folds in males.
 - Also note excessive discharge or secretions from the orifices and the presence of odors.
- 7. Wash and dry the perineal-genital area.

FOR FEMALE CLIENTS

- Clean the labia majora. Then spread the labia to wash the folds between the labia majora and the labia minora. **2 Rationale:** *Secretions that tend to collect around the labia minora facilitate bacterial growth.*
- Use separate quarters of the washcloth for each stroke, and wipe from the pubis to the rectum. For menstruating women and clients with indwelling catheters, use clean wipes. Use a clean wipe for each stroke. **Rationale:** *Using separate quarters of the washcloth or new wipes prevents the transmission of microorganisms from one area to the other. Wipe from the area of least contamination (the pubis) to that of greatest (the rectum).*
- Rinse the area well. You may place the client on a bedpan and use a Peri-Wash or solution bottle to pour warm water over the area. Dry the perineum thoroughly, paying particular attention to the folds between the labia. **Rationale:** *Moisture supports the growth of many microorganisms.*

FOR MALE CLIENTS

- Wash and dry the penis, using firm strokes.
- If the client is uncircumcised, retract the prepuce (foreskin) to expose the glans penis (the tip of the penis) for cleaning. Replace the foreskin after cleaning the glans penis. **3 Rationale:** *Retracting the foreskin is necessary to remove the smegma (thick, cheesy secretion) that collects under the foreskin and facilitates bacterial growth. Replacing the foreskin prevents constriction of the penis, which may cause edema.*
- Wash and dry the scrotum. The posterior folds of the scrotum may need to be cleaned when the buttocks are cleaned (see step 9). **Rationale:** *The scrotum tends to be more soiled than the penis because of its proximity to the rectum; thus it is usually cleaned after the penis.*
- 8. Inspect perineal orifices for intactness.
 - Inspect particularly around the urethra in clients with indwelling catheters. **Rationale:** *A catheter may cause excoriation around the urethra.*
- 9. Clean between the buttocks.
 - Assist the client to turn onto the side facing away from you.
 - Pay particular attention to the anal area and posterior folds of the scrotum in males. Clean the anus with toilet tissue before washing it, if necessary.
 - Dry the area well.

1 Draping the client for perineal-genital care.

2 Cleaning the labia.

3 Male genitals.

- For postdelivery or menstruating females, apply a perineal pad as needed from front to back. **Rationale:** *This prevents contamination of the vagina and urethra from the anal area.*
- 10. Remove and discard gloves.
- 11. Perform hand hygiene.
- 12. Document any unusual findings such as redness, excoriation, skin breakdown, discharge or drainage, and any localized areas of tenderness.

EVALUATION

- Relate current assessments to previous assessments.
- Conduct appropriate follow-up such as prescribed ointment for excoriation.
- Report any deviation from normal to the primary care provider.

Evaluating

Using data collected during care, the nurse judges whether desired outcomes have been achieved. If the outcomes have not been achieved, the nurse explores reasons why. For example:

- Did the nurse overestimate the client's functional abilities (physical, mental, emotional) for self-care?
- Were provided instructions not clear?
- Were appropriate assistive devices or supplies not available to the client?
- Did the client's condition change?
- Were required analgesics provided before hygienic care?
- What currently prescribed medications and therapies could affect the client's abilities or tissue integrity?
- Is the client's fluid and food intake adequate or appropriate to maintain skin and mucous membrane moisture and integrity?

FEET

The feet are essential for ambulation and merit attention even when people are confined to bed. Each foot contains 26 bones, 107 ligaments, and 19 muscles. These structures function together for both standing and walking.

Developmental Variations

At birth, a baby's foot is relatively unformed. The arches are supported by fatty pads and do not take their full shape until 5 to 6 years of age. During childhood, the bones and small muscles of the feet are easily damaged by tight, binding stockings and ill-fitting shoes. For normal development, it is important that the arches be supported and that the bony structure and the feet grow with no external restrictions. Feet are not fully grown until about age 20. The average person takes 10,000 steps per day. Each step places two to three times the force of the body weight on the feet. This repetitive use leads to normal changes associated with aging. Changes include wider and longer feet, mild settling of the arches, and loss of natural padding on the bottom of the heels. The cartilage around the joints also deteriorates, producing loss of normal range of motion of the foot and ankle. All older clients should know about foot care. However, some older clients require special attention for their feet. For example, reduced blood supply and accompanying arteriosclerosis can make a foot prone to ulcers and infection following trauma. Decreased flexibility or poor eyesight can make self-care of the feet impossible for the older client.

SAFETY ALERT!

SAFETY

Clients with diabetes are at high risk for lower extremity amputations (LEAs). Routine foot assessment and client education in proper foot care can significantly reduce the risk for LEAs.

CLIENT TEACHING

Skin Problems and Care

DRY SKIN

- Use cleansing creams to clean the skin rather than soap or detergent, which cause drying and, in some cases, allergic reactions.
- Use bath oils, but take precautions to prevent falls caused by slippery tub surfaces.
- Thoroughly rinse soap or detergent, if used, from the skin.
- Bathe less frequently when environmental temperature and humidity are low.
- Increase fluid intake.
- Humidify the air with a humidifier or by keeping a tub or sink full of water.
- Use moisturizing or emollient creams that contain lanolin, petroleum jelly, or cocoa butter to retain skin moisture.

SKIN RASHES

- Keep the area clean by washing it with a mild soap. Rinse the skin well, and pat it dry.
- To relieve itching, try a tepid bath or soak. Some over-the-counter preparations, such as Caladryl lotion, may help but should be used with full knowledge of the product.
- Avoid scratching the rash to prevent inflammation, infection, and further skin lesions.
- Choose clothing carefully. Too much can cause perspiration and aggravate a rash.

ACNE

- Wash the face frequently with soap or detergent and hot water to remove oil and dirt.
- Avoid using oily creams, which aggravate the condition.
- Avoid using cosmetics that block the ducts of the sebaceous glands and the hair follicles.
- Never squeeze or pick at the lesions. This increases the potential for infection and scarring.

●○● NURSING MANAGEMENT

Assessing

Assessment of the client's feet includes a nursing health history, physical assessment of the feet, and identifying clients at risk for foot problems.

Nursing History

The nurse determines the client's history of (a) normal nail and foot care practices, (b) type of footwear worn, (c) self-care abilities, (d) presence of risk factors for foot problems, (e) any foot discomfort, and (f) any perceived problems with foot mobility. To obtain such data, the nurse asks the client the questions provided in the accompanying Assessment Interview.

Physical Assessment

Inspect each foot and toe for shape, size, and presence of lesions and palpate to assess areas of tenderness, edema, and circulatory status. Normally, the toes are straight and flat. Table 33-5 lists physical assessment methods for the feet. Common foot problems include

ASSESSMENT INTERVIEW Foot Hygiene

FOOT CARE PRACTICES

- How often do you wash your feet and cut your toenails?
- What hygiene products do you usually use on your feet (e.g., soap, foot powder or deodorant, lotion, or cream)?
- What type of shoes and socks do you wear?
- How often do you change your socks or put on clean socks?
- Do you ever go barefoot? If so, when, where, and how often?

SELF-CARE ABILITIES

- Do you have any problems managing your foot care? If so, what are these?
- How can the nurses best help you?

FOOT PROBLEMS AND RISK FACTORS

- Do you have any problems with foot odor?
- Do you have any foot discomfort? If so, where? When does this occur? What do you do to relieve the discomfort? Does this discomfort affect how you walk?
- Have you noticed any problems with foot mobility (e.g., joint stiffness)?
- Do you have diabetes, any circulatory problems with feet (e.g., swelling, changes in skin color, arthritis), or any instances of prolonged exposure to chemicals or water?

calluses, corns, unpleasant odors, plantar warts, fissures between the toes, fungal infections such as athlete's foot, and ingrown toenails.

A **callus** is a thickened portion of epidermis, a mass of keratotic material. Most calluses are painless and flat and are found on the bottom or side of the foot over a bony prominence. Calluses are usually caused by pressure from shoes. They can be softened by soaking the foot in warm water with Epsom salts, and abraded with pumice stones or similar abrasives. Creams with lanolin help to keep the skin soft and prevent the formation of calluses.

A **corn** is a keratosis caused by friction and pressure from a shoe. It commonly occurs on the fourth or fifth toe, usually on a bony prominence such as a joint. Corns are usually conical (circular and raised). The base is the surface of the corn and the apex is in deeper tissues, sometimes even attached to bone. Corns are generally removed surgically. They are prevented from re-forming by relieving the pressure on the area (i.e., wearing comfortable shoes) and by massaging the tissue to promote circulation. The use of oval corn pads should be avoided because they increase pressure and decrease circulation.

Unpleasant odors occur as a result of perspiration and its interaction with microorganisms. Regular and frequent washing of the feet and wearing clean hosiery help to minimize odor. Foot powders and deodorants also help to prevent this problem.

Plantar warts appear on the sole of the foot. These warts are caused by the papovavirus hominis virus. They are moderately contagious. The warts are frequently painful and often make walking difficult. The primary care provider may curettage the warts, freeze them with solid carbon dioxide several times, or apply salicylic acid.

Fissures, or deep grooves, frequently occur between the toes as a result of dryness and cracking of the skin. The treatment of choice is good foot hygiene and application of an antiseptic to prevent infection. Often a small piece of gauze is inserted between the toes in applying the antiseptic and left in place to assist healing by allowing air to reach the area.

CLINICAL ALERT!

Clients with diabetes often have extremely dry skin. Tell them to use a nonperfumed lotion and to avoid putting lotion between the toes. Advise to not soak their feet in water because it is drying to the skin.

Athlete's foot, or **tinea pedis** (ringworm of the foot), is caused by a fungus. The symptoms are scaling and cracking of the skin, particularly between the toes. Sometimes small blisters form, containing a thin fluid. In severe cases, the lesions may also appear on other parts

TABLE 33-5 Assessment of the Feet

Method	Normal Findings	Deviations From Normal
Inspect all skin surfaces, particularly between the toes, for cleanliness, odor, dryness, inflammation, swelling, abrasions, or other lesions.	Intact skin Absence of swelling or inflammation	Excessive dryness Areas of inflammation or swelling (e.g., corns, calluses) Fissures Scaling and cracking of skin (e.g., athlete's foot) Plantar warts
Palpate anterior and posterior surfaces of ankles and feet for edema.	No swelling	Swelling or pitting edema
Palpate dorsalis pedis pulse on dorsal surface of foot.	Strong, regular pulses in both feet	Weak or absent pulses
Compare skin temperature of both feet.	Warm skin temperature	Cool skin temperature in one or both feet

CLIENT TEACHING

Foot Care

- Wash the feet daily, and dry them well, especially between the toes.
- When washing, inspect the skin of the feet for breaks or red or swollen areas. Use a mirror if needed to visualize all areas.
- To prevent burns, check the water temperature before immersing the feet.
- Cover the feet, except between the toes, with creams or lotions to moisten the skin. Lotion will also soften calluses. A lotion that reduces dryness effectively is a mixture of lanolin and mineral oil.
- To prevent or control an unpleasant odor due to excessive foot perspiration, wash the feet frequently and change socks and shoes at least daily. Special deodorant sprays or absorbent foot powders are also helpful.
- File the toenails rather than cutting them to avoid skin injury. File the nails straight across the ends of the toes. If the nails are too thick or misshapen to file, consult a podiatrist.
- Wear clean stockings or socks daily. Avoid socks with holes or darns that can cause pressure areas.
- Wear comfortable, well-fitting shoes that neither restrict the foot nor rub on any area; rubbing can cause corns and calluses. Check worn shoes for rough spots in the lining. Break in new

shoes gradually by increasing the wearing time 30 to 60 minutes each day.

- Avoid walking barefoot, because injury and infection may result. Wear slippers in public showers and in change areas to avoid contracting athlete's foot or other infections.
- Several times each day exercise the feet to promote circulation. Point the feet upward, point them downward, and move them in circles.
- Avoid wearing constricting garments such as knee-high elastic stockings and avoid sitting with the legs crossed at the knees, which may decrease circulation.
- When the feet are cold, use extra blankets and wear warm socks rather than using heating pads or hot water bottles, which may cause burns. Test bathwater before stepping into it.
- Wash any cut on the foot thoroughly, apply a mild antiseptic, and notify the primary care provider.
- Avoid self-treatment for corns or calluses. Pumice stones and some callus and corn applications are injurious to the skin. Do not cut calluses or corns. Consult a podiatrist or the primary care provider first.
- Notify the primary care provider if you notice abnormal sores or drainage, pain, or changes in temperature, color, and sensation of the foot.

of the body, particularly the hands. Treatments usually involve the application of commercial antifungal ointments or powders. Prevention is important. Common preventive measures are keeping the feet well ventilated, drying the feet well after bathing, wearing clean socks or stockings, and not going barefoot in public showers.

An **ingrown toenail**, the growing inward of the nail into the soft tissues around it, most often results from improper nail trimming. Pressure applied to the area causes localized pain. Treatment involves frequent, hot antiseptic soaks and surgical removal of the portion of nail embedded in the skin. Preventing recurrence involves appropriate instruction and adherence to proper nail-trimming techniques.

Identifying Clients at Risk

Because of reduced peripheral circulation to the feet, clients with diabetes or peripheral vascular disease or on long-term steroid therapy are particularly prone to infection if skin breakage occurs. Many foot problems can be prevented by teaching the client simple foot care guidelines (see Client Teaching).

Diagnosing

A number of nursing diagnoses may apply to clients with foot or foot care problems. The most common diagnostic labels, along with possible related or contributing factors, are as follows:

- *Bathing Self-Care Deficit* (foot care) related to:
 - a. Visual impairment
 - b. Impaired hand coordination
 - c. Other related or contributing factors (see Box 33–1).
- *Risk for Impaired Skin Integrity* related to:
 - a. Altered tissue perfusion: peripheral (associated with edema, inadequate arterial circulation)
 - b. Poorly fitting shoes.

- *Risk for Infection* related to:
 - a. Impaired skin integrity (ingrown toenail, corn, trauma)
 - b. Deficient nail or foot care.
- *Deficient Knowledge* (diabetic foot care) related to:
 - a. Lack of teaching/learning activities about diabetic foot care
 - b. Newly established medical diagnosis (diabetes) and necessary foot hygiene practices.

Planning

Planning involves (a) identifying nursing interventions that will help the client maintain or restore healthy foot care practices and (b) establishing desired outcomes for each client. Interventions may include teaching the client about correct nail and foot care, proper footwear, wearing the correct size, and ways to prevent potential foot problems (e.g., infection, injury, and decreased circulation). For clients with self-care difficulties, the nurse plans a schedule for soaking the client's feet and assisting with regular cleaning and trimming of nails (if not contraindicated). Foot and nail care are often provided during the client's bath but may be provided at any time of the day to accommodate the client's preference or schedule. The frequency of foot care is determined by the nurse and client and is based on objective assessment data and the client's specific problems. For some clients, the feet need to be bathed daily; for those whose feet perspire excessively, bathing more than once a day may be necessary.

Implementing

Skill 33–3 describes how to provide foot care. See also the next section's discussion of nails. During these procedures, the nurse has the opportunity to teach the client appropriate methods for foot care, including those designed to prevent tissue injury and infection (see Client Teaching feature).

Providing Foot Care

PURPOSES

- To maintain the skin integrity of the feet
- To prevent foot infections
- To prevent foot odors
- To assess or monitor foot problems

ASSESSMENT

Determine

- History of any problems with foot discomfort, foot odor, foot mobility, circulatory problems (e.g., swelling, changes in skin color and/or temperature, and pain), structural problems (e.g., bunion, hammer toe, or overlapping digits)
- Usual foot care practices (e.g., frequency of washing feet and cutting nails, foot hygiene products used, how often socks are changed, whether the client ever goes barefoot, whether the client sees a podiatrist)

Assess

- Skin surfaces for cleanliness, odor, dryness, and intactness
- Each foot and toe for shape, size, presence of lesions (e.g., corn, callus, wart, or rash), and areas of tenderness, ankle edema
- Heels for erythema, blisters, or breaks in skin integrity
- Skin temperatures of both feet to assess circulatory status:
 - Pedal pulses: dorsalis pedis and posterior tibialis
 - Feet of bedbound clients for foot drop
- Self-care abilities (e.g., any problems managing foot care)

PLANNING

DELEGATION

Foot care for the *nondiabetic* client can be delegated to UAP. Remind the UAP to notify the nurse of anything that looks out of the ordinary. Review with the UAP the agency policy about cutting or trimming nails.

Equipment

- Washbasin containing warm water
- Pillow
- Moisture-resistant disposable pad
- Towels
- Soap
- Washcloth
- Toenail cleaning and trimming equipment, if agency policy permits
- Lotion or foot powder

IMPLEMENTATION

Preparation

Assemble all the necessary equipment and supplies if nails need trimming and agency policy permits.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*
4. Prepare the equipment and the client.
 - Fill the washbasin with warm water at about 40°C to 43°C (105°F to 110°F). **Rationale:** *Warm water promotes circulation, comforts, and refreshes.*
 - Assist the ambulatory client to a sitting position in a chair, or the bed client to a supine or semi-Fowler's position.
 - Place a pillow under the bed client's knees. **Rationale:** *This provides support and prevents muscle fatigue.*
 - Place the washbasin on the moisture-resistant pad at the foot of the bed for a bed client or on the floor in front of the chair for an ambulatory client.
 - For a bed client, pad the rim of the washbasin with a towel. **Rationale:** *The towel prevents undue pressure on the skin.*
5. Wash the foot and soak it.
 - Place one of the client's feet in the basin and wash it with soap, paying particular attention to the interdigital areas. Prolonged soaking is generally not recommended for clients with diabetes or individuals with peripheral vascular disease. **Rationale:** *Prolonged soaking may remove natural skin oils, thus drying the skin and making it more susceptible to cracking and injury.*
 - Rinse the foot well to remove soap. **Rationale:** *Soap irritates the skin if not completely removed.*
 - Rub callused areas of the foot with the washcloth. **Rationale:** *This helps remove dead skin layers.*
 - If the nails are brittle or thick and require trimming, replace the water and allow the foot to soak for 10 to 20 minutes. **Rationale:** *Soaking softens the nails and loosens debris under them.*
 - Clean the nails as required with an orange stick. **Rationale:** *This removes excess debris that harbors microorganisms. Use gently, especially with clients who are at risk for injury (e.g., clients with diabetes and/or peripheral vascular disease).*
 - Remove the foot from the basin and place it on the towel.
6. Dry the foot thoroughly and apply lotion or foot powder.
 - Blot the foot gently with the towel to dry it thoroughly, particularly between the toes. **Rationale:** *Harsh rubbing can damage the skin. Thorough drying reduces the risk of infection.*
 - Apply lotion or lanolin cream to the foot but not between the toes. **Rationale:** *This lubricates dry skin and keeps the area between the toes dry.*

or

 - Apply a foot powder containing a nonirritating deodorant if the feet tend to perspire excessively. **Rationale:** *Foot powders have greater absorbent properties than regular bath powders; some also contain menthol, which makes the feet feel cool.*
7. If agency policy permits, trim the nails of the first foot while the second foot is soaking.
 - See the discussion on nails for the appropriate method to trim nails. Note that in many agencies toenail trimming requires a primary care provider's order or is contraindicated for clients with diabetes mellitus, toe infections, and peripheral vascular disease, unless performed by a podiatrist, general practice physician, or advanced practice provider such as a nurse practitioner.

Providing Foot Care—continued

8. Document any foot problems observed.
 - Foot care is not generally recorded unless problems are noted.
 - Record any signs of inflammation, infection, breaks in the skin, corns, troublesome calluses, bunions, and pressure areas. This is of particular importance for clients with peripheral vascular disease and diabetes.

EVALUATION

- Inspect nails and skin after the soak.
- Compare to prior assessment data.
- Report any abnormalities to the primary care provider.

Evaluating

Examples of desired outcomes for foot hygiene include the client being able to:

- Participate in self-care (foot hygiene) to optimal level of capacity (specify).
- Describe hygienic and other interventions (e.g., proper footwear) to maintain skin integrity, prevent infection, and maintain peripheral tissue perfusion.
- Demonstrate optimal foot hygiene, as evidenced by:
 - a. Intact, pink, smooth, soft, hydrated, and warm skin
 - b. Intact cuticles and skin surrounding nails
 - c. Correct foot care and nail care practices.

NAILS

Nails are normally present at birth. They continue to grow throughout life and change very little until people are older. At that time, the nails tend to be tougher, more brittle, and in some cases thicker. The nails of an older person normally grow less quickly than those of a younger person and may be ridged and grooved.

●○○ NURSING MANAGEMENT

Assessing

During the nursing health history, the nurse explores the client's usual nail care practices, self-care abilities, and any problems associated with them (see accompanying Assessment Interview). Physical assessment involves inspection of the nails (e.g., nail shape and texture, nail bed color, and tissues surrounding the nails). See Chapter 30 ∞.

Diagnosing

Nursing diagnoses related to nail care and nail problems include *Self-Care Deficit* and *Risk for Infection*. Examples of these nursing diagnoses and contributing factors follow:

- *Bathing Self-Care Deficit* related to:
 - a. Impaired vision
 - b. Cognitive impairment.

- *Risk for Infection* around the nail bed related to:
 - a. Impaired skin integrity of cuticles
 - b. Altered peripheral circulation.

Planning

The nurse identifies measures that will assist the client to develop or maintain healthy nail care practices. A schedule of nail care needs to be established.

Implementing

To provide nail care, the nurse needs a nail cutter or sharp scissors, a nail file, an orange stick to push back the cuticle, hand lotion or mineral oil to lubricate any dry tissue around the nails, and a basin of water to soak the nails if they are particularly thick or hard. Check the agency's policy regarding nail care. Often, podiatrists must be consulted for clients with diabetes, peripheral vascular disease, long-term steroid therapy, and anticoagulant therapy.

One hand or foot is soaked, if needed, and dried; then the nail is cut or filed straight across beyond the end of the finger or toe (Figure 33-4 ■). Avoid trimming or digging into nails at the lateral corners. This predisposes the client to ingrown toenails. Clients who have diabetes or circulatory problems should have their nails filed rather than cut; inadvertent injury to tissues can occur if scissors are used. After the initial cut or filing, the nail is filed to round the corners, and the nurse cleans under the nail. The nurse then gently

Figure 33-4 ■ Fingernails are trimmed straight across.

ASSESSMENT INTERVIEW Nail Hygiene

- What are your usual nail care practices?
- Do you have any problems managing your nail care? If so, what are they?
- Have you had any problems associated with your nails (e.g., inflammation of the tissue surrounding the nail, injury, prolonged exposure to water or chemicals, circulatory problems)?

pushes back the cuticle, taking care not to injure it. The next finger or toe is cared for in the same manner. Any abnormalities, such as an infected cuticle or inflammation of the tissue around the nail, are recorded and reported.

Evaluating

Examples of desired outcomes for nail hygiene include the client being able to:

- Demonstrate healthy nail care practices, as shown by:
 - a. Clean, short nails with smooth edges
 - b. Intact cuticles and hydrated surrounding skin.
- Describe factors contributing to the nail problem.
- Describe preventive interventions for the specific nail problem.
- Demonstrate nail care as instructed.

In addition, the client should have pink nail beds and quick return of nail bed color after the blanch test.

MOUTH

Each tooth has three parts: the crown, the root, and the pulp cavity (Figure 33–5 ■). The crown is the exposed part of the tooth, which is outside the gum. It is covered with a hard substance called enamel. The ivory-colored internal part of the crown below the enamel is the dentin. The root of a tooth is embedded in the jaw and covered by a bony tissue called cementum. The pulp cavity in the center of the tooth contains the blood vessels and nerves.

Developmental Variations

Teeth usually appear 5 to 8 months after birth. Baby-bottle syndrome may result in dental caries (Edelman & Mandle, 2010). This syndrome occurs when an infant is put to bed with a bottle of formula, milk, or fruit juice. The carbohydrates in the solution cause demineralization of the tooth enamel, which leads to tooth decay. If the child wants a bottle at bedtime, it should contain only water.

By the time children are 2 years old, they usually have all 20 of their temporary teeth. At about age 6 or 7, children start losing their deciduous teeth, and these are gradually replaced by the 32 permanent teeth. By age 25, most people have all of their permanent teeth.

The incidence of periodontal disease increases during pregnancy because the rise in female hormones affects gingival tissue and increases its reaction to bacterial plaque. Many pregnant women experience more bleeding from the gingival sulcus during brushing and increased redness and swelling of the **gingiva** (the gum).

Teeth turn yellowish in color as a part of the aging process. Teeth are normally off-white and with age, the enamel thins and the yellow-gray color of the inner portion of the teeth begins to show. In addition, coffee drinking and cigarette smoking can stain the teeth. Commercial teeth-whitening products and treatments offered at

Figure 33–5 ■ The anatomic parts of a tooth.

dental offices are available to consumers who desire whiter teeth for cosmetic reasons.

Lack of fluoridated water and preventive dentistry during their developmental years have caused tooth and gum problems in older adults (Edelman & Mandle, 2010, p. 631). As a result, some older adults may have few permanent teeth left, and some have dentures. Loss of teeth occurs mainly because of **periodontal disease** (gum disease) rather than **dental caries** (cavities); however, caries are also common in middle-aged adults.

Some receding of the gums and a brownish pigmentation of the gums occur with age. Because saliva production decreases with age, dryness of the oral mucosa is a common finding in older people.

●○○ NURSING MANAGEMENT

Assessing

Assessment of the client's mouth and hygiene practices includes (a) a nursing health history, (b) physical assessment of the mouth, and (c) identification of clients at risk for developing oral problems.

Nursing History

During the nursing health history, the nurse obtains data about the client's oral hygiene practices, including dental visits, self-care abilities, and past or current mouth problems. Data about the client's oral hygiene help the nurse determine learning needs and incorporate the client's needs and preferences in the plan of care. Assessment of the client's self-care abilities determines the amount and type of nursing assistance to provide. Clients whose hand coordination is impaired, whose cognitive function is impaired, whose illness alters energy levels and motivation, or whose therapy imposes restrictions on activities will need assistance from the nurse. Information about past or current problems alerts the nurse to specific interventions required or referrals that may be necessary. Questions to elicit this information are shown in the accompanying Assessment Interview.

ASSESSMENT INTERVIEW Oral Hygiene

ORAL HYGIENE PRACTICES

- What are your usual mouth care and/or denture care practices?
- What oral hygiene products do you routinely use (e.g., mouth-wash, type of toothpaste, dental floss, denture cleaner)?
- When was your last dental examination, and how often do you see your dentist?

SELF-CARE ABILITIES

- Do you have any problems managing your mouth care?

PAST OR CURRENT MOUTH PROBLEMS

- Have you had or do you have any problems such as bleeding, swollen, or reddened gums, ulcerations, lumps, or tooth pain?

TABLE 33–6 Common Problems of the Mouth

Problem	Description	Nursing Implications
Halitosis	Bad breath	Teach or provide regular oral hygiene.
Glossitis	Inflammation of the tongue	As above
Gingivitis	Inflammation of the gums	As above
Periodontal disease	Gums appear spongy and bleeding	As above
Reddened or excoriated mucosa		Check for ill-fitting dentures.
Excessive dryness of the buccal mucosa		Increase fluid intake as health permits.
Cheilosis	Cracking of lips	Lubricate lips; use antimicrobial ointment to prevent infection.
Dental caries	Teeth have darkened areas; may be painful	Advise client to see a dentist.
Sordes	Accumulation of foul matter (food, microorganisms, and epithelial elements) in the mouth	Teach or provide regular cleaning.
Stomatitis	Inflammation of the oral mucosa	Teach or provide regular cleaning.
Parotitis	Inflammation of the parotid salivary glands	Teach or provide regular oral hygiene.

Physical Assessment

For information about mouth assessment, see Chapter 30 ∞. Dental caries (cavities) and periodontal disease are the two problems that most frequently affect the teeth. Both problems are commonly associated with plaque and tartar deposits. **Plaque** is an *invisible* soft film that adheres to the enamel surface of teeth; it consists of bacteria, molecules of saliva, and remnants of epithelial cells and leukocytes. When plaque is unchecked, tartar (dental calculus) is formed. **Tartar** is a visible, hard deposit of plaque and dead bacteria that forms at the gum lines. Tartar buildup can alter the fibers that attach the teeth to the gum and eventually disrupt bone tissue. Periodontal disease is characterized by **gingivitis** (red, swollen gingiva), bleeding, receding gum lines, and the formation of pockets between the teeth and gums. In advanced periodontal disease (**pyorrhea**), the teeth are loose and pus is evident when the gums are pressed. An oral assessment guide (OAG) is a useful tool for detecting early signs of oral problems. A number of OAG tools are available. Table 33–6 lists additional problems of the mouth.

Identifying Clients at Risk

Certain clients are prone to oral problems because of an inability to maintain oral hygiene. Among these are clients who are older, seriously ill, confused, comatose, depressed, or dehydrated. Effective oral hygiene relies on fine motor skills, adequate vision, and motivation. It can be a problem for an older adult who has cognitive, visual, or physical impairments (Bissett & Preshaw, 2011). Oral problems are common in older people in residential care homes (Burns, 2012). Critically ill clients can experience complications that may lead to ventilator-associated pneumonia, a longer hospital stay, increased cost of care, and even death if oral assessment and care are not properly performed (Roberts & Moule, 2011). A number of research studies have shown an association between pathogenic oral bacteria and the incidence of aspiration pneumonia in clients following a stroke. Furthermore, studies showed evidence that the intervention of improved oral hygiene decreased the risk of pneumonia (Dickinson, 2012). In addition, people with nasogastric tubes or who are receiving oxygen are likely to develop dry oral mucous membranes, especially if they breathe through their mouths. Clients who have had oral or

jaw surgery must have meticulous oral hygiene care to prevent the development of infections.

CLINICAL ALERT!

Clients in long-term care settings are at high risk for oral health problems. The nurse must assess the client's oral health and teach the UAP about the importance of and methods to promote oral hygiene.

Healthy-appearing individuals, too, may be at risk. High-risk variables such as lack of knowledge, inadequate nutrition, lack of money and/or insurance for dental care, excessive intake of refined sugars, and family history of periodontal disease also need to be identified. Some older people may also be at risk, for example, those who choose salty and enamel-eroding sugary foods because of a decline in their number of taste buds. The decreased saliva production in older adults, which produces a dry mouth and thinning of the oral mucosa, is another factor.

A dry mouth can be aggravated by poor fluid intake, heavy smoking, alcohol use, high salt intake, anxiety, and many medications. Medications that can cause dryness of the mouth include diuretics; laxatives, if used excessively; and tranquilizers, such as chlorpromazine (Thorazine) and diazepam (Valium). Some chemotherapeutic agents used to treat cancer also cause oral dryness and mucositis (inflammation of mucous membranes). A common side effect of the anticonvulsant drug phenytoin (Dilantin) is gingival hyperplasia. Optimal oral hygiene (e.g., brushing with a soft toothbrush and flossing) is needed.

Clients who are receiving or have received radiation treatments to the head and neck may have permanent damage to salivary glands. This results in a very dry mouth and can often be treated by providing a thick liquid called *artificial saliva*. Some clients prefer to just sip on liquids to moisten their mouth. Radiation can also cause damage to teeth and the jaw structure, with actual damage occurring years after the radiation.

Diagnosing

Two nursing diagnoses related to problems with oral hygiene and the oral cavity are *Impaired Oral Mucous Membrane* and *Deficient Knowledge*.

The nursing diagnosis *Impaired Oral Mucous Membrane* refers to injury of the lips, soft tissue, buccal cavity, and/or oropharynx (Herdman & Kamitsuru, 2014, p. 391). Manifestations can include a coated tongue; dry mouth (*xerostomia*); halitosis; gingival hyperplasia, difficulty eating, oral pain or discomfort; oral lesions or ulcers. These may be the result of inadequate oral hygiene, physical injury or drying effect (e.g., mouth breathing, oxygen therapy, decreased salivation, temperature extreme, NPO), mechanical factor (e.g., surgery, broken teeth or ill-fitting dentures), autoimmune disease, or infection. The diagnosis of *Deficient Knowledge* is discussed in Chapter 27 ∞.

Planning

In planning care, the nurse and, if appropriate, the client and/or family set outcomes for each nursing diagnosis. The nurse then performs nursing interventions and activities to achieve the client outcomes.

During the planning phase, the nurse also identifies interventions that will help the client achieve these goals. Specific, detailed nursing activities performed by the nurse may include the following:

- Monitor every shift for dryness of the oral mucosa.
- Monitor for signs and symptoms of glossitis (inflammation of the tongue) and stomatitis (inflammation of the mouth).
- Assist dependent clients with oral care.
- Provide special oral hygiene for clients who are debilitated, unconscious, or have lesions of the mucous membranes or other oral tissues.
- Teach clients about good oral hygiene practices and other measures to prevent tooth decay.
- Reinforce oral hygiene regimen as part of discharge teaching.

Implementing

Providing oral hygiene is an independent nursing function; yet, research has shown that oral hygiene is one of the most overlooked aspects of basic nursing care. Moreover, the oral care provided by nurses is often inadequate. Barriers to providing effective oral care include the low priority placed on oral care, dislike of working inside another person's mouth, and insufficient time (Bissett & Preshaw, 2011). Studies have shown that when oral care is part of a written protocol nurses document oral care consistently. Student nurse researchers found that “requiring nurses to document when they perform oral care on their clients shows responsibility and personal accountability for ensuring that oral care is done routinely, timely, and consistently” (Gardiner, Mistretta, Rader, & Walker, 2013, p. 34).

Good oral hygiene includes daily stimulation of the gums, mechanical brushing and flossing of the teeth, and flushing of the mouth. The nurse is often in a position to help people maintain oral hygiene by helping or teaching them to clean the teeth and oral cavity, by inspecting whether clients (especially children) have done so, or by actually providing mouth care to clients who are ill or incapacitated. The nurse can also be instrumental in identifying problems that require the intervention of a dentist or oral surgeon and arranging a referral.

Promoting Oral Health Throughout the Life Span

A major role of the nurse in promoting oral health is to teach clients about specific oral hygienic measures.

Infants and Toddlers

Most dentists recommend that dental hygiene should begin when the first tooth erupts and be practiced after each feeding. Cleaning can be accomplished by using a wet washcloth or small gauze moistened with water.

Dental caries occur frequently during the toddler period, often as a result of the excessive intake of sweets or a prolonged use of the bottle during naps and at bedtime. The nurse should give parents the following instructions to promote and maintain dental health:

- Beginning at about 18 months of age, brush the child's teeth with a soft toothbrush. Use only a toothbrush moistened with water at first and introduce toothpaste later. Use one that contains fluoride.
- Give a fluoride supplement daily or as recommended by the primary care provider or dentist, unless the drinking water is fluoridated.
- Schedule an initial dental visit for the child at about 2 or 3 years of age, as soon as all 20 primary teeth have erupted.
- Some dentists recommend an inspection type of visit when the child is about 18 months old to provide an early pleasant introduction to the dental examination.
- Seek professional dental attention for any problems such as discoloring of the teeth, chipping, or signs of infection such as redness and swelling.

Preschoolers and School-Age Children

Because deciduous teeth guide the entrance of permanent teeth, dental care is essential to keep these teeth in good repair. Abnormally placed or lost deciduous teeth can cause misalignment of permanent teeth. Fluoride remains important at this stage to prevent dental caries. Preschoolers need to be taught to brush their teeth after eating and to limit their intake of refined sugars. Parental supervision may be needed to ensure the completion of these self-care activities. Regular dental checkups are required during these years when permanent teeth appear.

Adolescents and Adults

Proper diet and tooth and mouth care should be evaluated and reinforced to adolescents and adults. Specific measures to prevent tooth decay and periodontal disease are listed in Client Teaching.

CLIENT TEACHING

Measures to Prevent Tooth Decay

- Brush the teeth thoroughly after meals and at bedtime. Assist children or inspect their mouths to be sure the teeth are clean. If the teeth cannot be brushed after meals, vigorous rinsing of the mouth with water is recommended.
- Floss the teeth daily.
- Ensure an adequate intake of nutrients, particularly calcium, phosphorus, vitamins A, C, and D, and fluoride.
- Avoid sweet foods and drinks between meals. Take them in moderation at meals.
- Eat coarse, fibrous foods (cleansing foods), such as fresh fruits and raw vegetables.
- Have topical fluoride applications as prescribed by the dentist.
- Have a checkup by a dentist every 6 months.

Older Adults

The rate of edentulism (lack of teeth) among older adults continues to decline (Burns, 2012). As a result, older clients are at risk for dental cavities and periodontal disease. Older adults who have self-care deficits are at an increased risk because they cannot maintain their oral hygiene practices and/or may not be able to visit the dentist on a routine basis. Furthermore, those who suffer the worst oral health and hygiene include older adults residing in nursing homes and older adults with dementia. Poor oral hygiene among frail and dependent nursing home residents can place them at risk for serious illness such as pneumonia.

Furthermore, along with the increasing evidence that poor oral health is a serious problem among older clients is the lack of effective oral care by health caregivers. Examples of interventions that can improve the oral health of residents in long-term care settings include consistent oral assessment by the nurses, instruction of UAP on how to deliver effective oral care, providing sufficient oral hygiene supplies, and expectations of the administration that oral care should receive the same priority as other kinds of care.

Nurses have an important role in promoting optimal geriatric oral health care.

Brushing and Flossing the Teeth

Thorough brushing of the teeth is important in preventing tooth decay. The mechanical action of brushing removes food particles that can harbor and incubate bacteria. It also stimulates circulation in the gums, thus maintaining their healthy firmness. One of the techniques recommended for brushing teeth is called the sulcular technique, which removes plaque and cleans under the gingival margins. Many toothpastes are marketed. Fluoride toothpaste is often recommended because of its antibacterial protection.

Caring for Artificial Dentures

Some people have artificial teeth in the form of a plate—a complete set of teeth for one jaw. A person may have a lower plate or an upper plate or both. When only a few artificial teeth are needed, the individual may have a bridge rather than a plate. A bridge may be fixed or removable. Artificial teeth are fitted to the individual and usually will not fit another person.

People who wear dentures or other types of oral prostheses should be encouraged to use them. Ill-fitting dentures or other oral prostheses can cause discomfort, chewing difficulties, and contribute to oral problems as well as poor nutrition and enjoyment of food.

Figure 33-6 ■ Example of foam swab used to clean the mouth of a dependent client.

Those who do not wear their prostheses are prone to shrinkage of the gums, which results in further tooth loss.

Like natural teeth, artificial dentures collect microorganisms and food. They need to be cleaned regularly, at least once a day. They can be removed from the mouth, scrubbed with a toothbrush, rinsed, and reinserted. Some people use a dentifrice (toothpaste) for cleaning teeth, and others use commercial cleaning compounds for plates.

Assisting Clients with Oral Care

When providing mouth care for partially or totally dependent clients, the nurse should wear gloves to guard against infections. Other required equipment includes a curved basin that fits snugly under the client's chin (e.g., a kidney basin) to receive the rinse water and a towel to protect the client and the bedclothes. See Skill 33-4.

Foam swabs are often used in health care agencies to clean the mouths of dependent clients (Figure 33-6 ■). These swabs are convenient and effective in removing excess debris from the teeth and mouth, but are not effective for plaque removal. If using foam swabs, soak the foam swab in alcohol-free 0.12% CHG and swab all surfaces of the oral cavity (Chan, Lee, Poh, Ng, & Prabhakaran, 2011).

Most people prefer privacy when they take their artificial teeth out to clean them. Many do not like to be seen without their teeth; one of the first requests of many postoperative clients is "May I have my teeth in, please?" The *Variation* section in Skill 33-4 describes how to clean artificial dentures. Special care should be taken so as not to lose the client's dentures.

Brushing and Flossing the Teeth

PURPOSES

- To remove food particles from around and between the teeth
- To remove dental plaque
- To promote the client's feelings of well-being
- To prevent sores and infection of the oral tissues

ASSESSMENT

- Determine the extent of the client's self-care abilities.
- Assess the client's usual mouth care practices.
- Inspect lips, gums, oral mucosa, and tongue for deviations from normal.
- Identify presence of oral problems such as tooth caries, halitosis, gingivitis, and loose or broken teeth.
- Check if the client has bridgework or wears dentures. If the client has dentures, ask if any tenderness or soreness is present and, if so, the location of the area(s) for ongoing assessment.

Brushing and Flossing the Teeth—continued

PLANNING

DELEGATION

Oral care, brushing and flossing of teeth, and denture care can be delegated to the UAP. After performing the above assessment, the nurse should instruct the UAP as to the type of oral care and amount of assistance needed by the client. Remind the UAP to report changes in the client's oral mucosa.

Equipment

Brushing and Flossing

- Towel
- Clean gloves
- Curved basin (emesis basin)
- Toothbrush (soft bristle)

- Cup of tepid water
- Dentifrice (toothpaste)
- Mouthwash
- Dental floss, at least two pieces 20 cm (8 in.) in length
- Floss holder (optional)

For Cleaning Artificial Dentures

- Clean gloves
- Tissue or piece of gauze
- Denture container
- Clean washcloth
- Toothbrush or stiff-bristled brush
- Dentifrice or denture cleaner
- Tepid water
- Container of mouthwash
- Curved basin (emesis basin)
- Towel

IMPLEMENTATION

Preparation

Assemble all the necessary equipment.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures. **Rationale:** *Wearing gloves while providing mouth care prevents the nurse from acquiring infections. Gloves also prevent transmission of microorganisms to the client.*
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*
4. Prepare the client.
 - Assist the client to a sitting position in bed, if health permits. If not, assist the client to a side-lying position with the head turned. **Rationale:** *This position prevents liquid from draining down the client's throat.*
5. Prepare the equipment.
 - Place the towel under the client's chin.
 - Apply clean gloves.
 - Moisten the bristles of the toothbrush with tepid water and apply the dentifrice to the toothbrush.
 - Use a soft toothbrush (a small one for a child) and the client's choice of dentifrice.
 - For the client who must remain in bed, place or hold the curved basin under the client's chin, fitting the small curve around the chin or neck.
 - Inspect the mouth and teeth.
6. Brush the teeth.
 - Hand the toothbrush to the client, or brush the client's teeth as follows:
 - a. Hold the brush against the teeth with the bristles at a 45-degree angle. The tips of the outer bristles should rest against and penetrate under the gingival sulcus.
 - 1 The brush will clean under the sulcus of two or three teeth at one time. **Rationale:** *This sulcular technique removes plaque and cleans under the gingival margins.*

1 The sulcular technique: Place the bristles at a 45-degree angle with the tips of the outer bristles under the gingival margins.

2 Brushing from the sulcus to the crowns of the teeth.

- b. Move the bristles up and down gently in short strokes from the sulcus to the crowns of the teeth. 2
- c. Repeat until all outer and inner surfaces of the teeth and sulci of the gums have been cleaned.

Continued on page 694

Brushing and Flossing the Teeth—continued

- d. Clean the biting surfaces by moving the brush back and forth over them in short strokes. **3**
- e. Brush the tongue gently with the toothbrush.

Rationale: *Brushing removes bacteria and freshens breath. A coated tongue may be caused by poor oral hygiene and low fluid intake. Brushing gently and carefully helps prevent gagging or vomiting.*

- Hand the client the water cup or mouthwash to rinse the mouth vigorously. Then ask the client to spit the water and excess dentifrice into the basin. Some agencies supply a standard mouthwash. Alternatively, a mouth rinse of normal saline can be an effective cleaner and moisturizer. **Rationale:** *Vigorous rinsing loosens food particles and washes out already loosened particles.*
 - Repeat the preceding steps until the mouth is free of dentifrice and food particles.
 - Remove the curved basin and help the client wipe the mouth.
7. Floss the teeth.
 - Assist the client to floss independently, or floss the teeth of an alert and cooperative client as follows. Waxed floss is less likely to fray than unwaxed floss; however, particles between the teeth attach more readily to unwaxed floss than to waxed floss.
 - a. Wrap one end of the floss around the third finger of each hand. **4**
 - b. To floss the upper teeth, use your thumb and index finger to stretch the floss. Move the floss up and down between the teeth. When the floss reaches the gum line, gently slide the floss into the space between the gum and the tooth. Gently move the floss away from the gum with up and down motions (American Dental Association, 2014). Start at the back on the right side and work around to the back of the left side, or work from the center teeth to the back of the jaw on either side.
 - c. To floss the lower teeth, use your index fingers to stretch the floss. **5**
 - Give the client tepid water or mouthwash to rinse the mouth and a curved basin in which to spit the water.
 - Assist the client in wiping the mouth.
 8. Remove and dispose of equipment appropriately.
 - Remove and clean the curved basin.
 - Remove and discard the gloves.
 - Perform hand hygiene.
 9. Document assessment of the teeth, tongue, gums, and oral mucosa. Include any problems such as sores or inflammation, bleeding and swelling of the gums. Brushing and flossing teeth are not usually recorded.

3 Brushing the biting surfaces.

4 Stretching the floss between the third finger of each hand.

5 Flossing the lower teeth by using the index fingers to stretch the floss.

Variation: Artificial Dentures

1. Remove the dentures.
 - Apply gloves. **Rationale:** *Wearing gloves decreases the likelihood of spreading infection.*
 - If the client cannot remove the dentures, take a tissue or gauze, grasp the upper plate at the front teeth with your thumb and second finger, and move the denture up and

Brushing and Flossing the Teeth—continued

down slightly. **6 Rationale:** *The slight movement breaks the suction that holds the plate on the roof of the mouth.*

- Lower the upper plate, move it out of the mouth, and place it in the denture container.
 - Lift the lower plate, turning it so that the left side, for example, is slightly lower than the right, to remove the plate from the mouth without stretching the lips. Place the lower plate in the denture container.
 - Remove a partial denture by exerting equal pressure on the border of each side of the denture, not on the clasps, which can bend or break.
2. Clean the dentures.
 - Take the denture container to a sink. Take care not to drop the dentures. Place a washcloth in the bowl of the sink. **Rationale:** *This prevents damage if the dentures are dropped.*
 - Using a toothbrush or special stiff-bristled brush, scrub the dentures with the cleaning agent and tepid water.
 - Rinse the dentures with tepid running water. **Rationale:** *Rinsing removes the cleaning agent and food particles.* If the dentures are stained, soak them in a commercial cleaner. Be sure to follow the manufacturer's directions. To prevent corrosion, dentures with metal parts should not be soaked overnight.
 3. Inspect the dentures and the mouth.
 - Observe the dentures for any rough, sharp, or worn areas that could irritate the tongue or mucous membranes of the mouth, lips, and gums.
 - Inspect the mouth for any redness, irritated areas, or indications of infection.
 - Assess the fit of the dentures. People who have them should see a dentist at least once a year to check the fit and the presence of any irritation to the soft tissues of the mouth. Clients who need repairs to their dentures or new dentures may need a referral for financial assistance.
 4. Return the dentures to the mouth.
 - Offer some mouthwash and a curved basin to rinse the mouth. If the client cannot insert the dentures independently, insert the plates one at a time. Hold each plate at a slight angle while inserting it, to avoid injuring the lips. **7**
 - **Note:** If clients perform self-cleaning of dentures ensure that dentures are placed in the appropriate container. **Rationale:** *Many older adult clients leave dentures on food trays and risk losing them when food trays are removed. Replacement dentures may not be covered by Medicare.*

6 Removing the top dentures by first breaking the suction.

7 Inserting the dentures at a slight angle.

5. Assist the client as needed.
 - Wipe the client's hands and mouth with the towel.
 - If the client does not want to or cannot wear the dentures, store them in a denture container with water. Label the container with the client's name and identification number. (Do not place the container on the food tray.)
6. Remove and discard gloves.
7. Perform hand hygiene.
8. Document all assessments and include any problems such as an irritated area on the mucous membrane.

Clients with Special Oral Hygiene Needs

For the client who is debilitated or unconscious or who has excessive dryness, sores, or irritations of the mouth, it may be necessary to clean the oral mucosa and tongue in addition to the teeth. Agency practices differ in regard to special mouth care and the frequency with which it is provided. Depending on the health of the client's mouth, special care may be needed every 2 to 8 hours.

Mouth care for clients who are unconscious or debilitated is important because their mouths tend to become dry and consequently predisposed to tooth decay and infections. Saliva has antiviral, antibacterial, and antifungal effects. Dry mouth—called **xerostomia**—occurs when the supply of saliva is reduced. This condition can be caused by side effects of certain medications (e.g., antihistamines,

antidepressants, antihypertensives). The drying irritates the soft tissues in the mouth, which can cause inflammation and susceptibility to infection (American Dental Association, 2013). Other reasons for a client to experience xerostomia include oxygen therapy, tachypnea, and NPO status in which the client cannot take fluids by mouth.

For clients with special oral hygiene needs, the nurse focuses on removal of plaque and microorganisms as well as client comfort. If possible, a soft-bristled toothbrush should be used because it provides the best means of plaque removal. A sodium bicarbonate toothpaste or diluted sodium bicarbonate (i.e., one part sodium bicarbonate to three parts water) will help dissolve and remove viscous oral debris (Chan et al., 2011, p. 177). If the client cannot tolerate the use of a toothbrush, the nurse can use an oral swab or a gauze

wrapped around a gloved finger and soaked with saline to swab the teeth, tongue, and oral mucosa. A foam swab (see Figure 33–6) can be used to provide oral hygiene to dependent clients. Use of lemon-glycerin swabs is not recommended because they irritate and dry the oral mucosa and can decalcify teeth. Mouthwashes containing alcohol can irritate the oral mucosa and cause dryness. Mineral oil is contraindicated as a moisturizer for the lips or inside the mouth

because aspiration of it can initiate an infection (lipid pneumonia). A water-soluble moisturizer, absorbed by the skin and tissue, provides important hydration. Saliva substitutes can also help moisturize the oral cavity.

Skill 33–5 focuses on oral care for a client who is unconscious but may be adapted for conscious clients who are seriously ill or have mouth problems.

Providing Special Oral Care for the Unconscious Client

PURPOSES

- To maintain the intactness and health of the lips, tongue, and mucous membranes of the mouth
- To prevent oral infections
- To clean and moisten the membranes of the mouth and lips

ASSESSMENT

- Inspect lips, gums, oral mucosa, and tongue for deviations from normal.
- Identify presence of oral problems such as tooth caries, halitosis, gingivitis, and loose or broken teeth.
- Assess for gag reflex, when appropriate.

PLANNING

DELEGATION

Special oral care may be delegated to UAP; however, the nurse needs to assess for the gag reflex. Dependent on this assessment, the nurse needs to inform the UAP of the correct positioning of the client and how to use the oral suction catheter, if needed. Remind the UAP to report changes in the client's oral mucosa.

Equipment

- Towel
- Curved basin (emesis basin)
- Clean gloves
- Bite-block to hold the mouth open and teeth apart (optional)
- Toothbrush
- Cup of tepid water
- Dentifrice or denture cleaner
- Tissue or piece of gauze to remove dentures (optional)
- Denture container as needed
- Mouthwash
- Rubber-tipped bulb syringe
- Suction catheter with suction apparatus when aspiration is a concern
- Foam swabs and cleaning solution for cleaning the mucous membranes
- Water-soluble lip moisturizer

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client and the family what you are going to do and why it is necessary.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*
4. Prepare the client.
 - Position the unconscious client in a side-lying position, with the head of the bed lowered. **Rationale:** *In this position, the saliva automatically runs out by gravity rather than being aspirated into the lungs.* This position is chosen for the unconscious client receiving mouth care. If the client's head cannot be lowered, turn it to one side. **Rationale:** *The fluid will readily run out of the mouth or pool in the side of the mouth, where it can be suctioned.*
 - Place the towel under the client's chin.
 - Place the curved basin against the client's chin and lower cheek to receive the fluid from the mouth. ①
 - Apply gloves.
5. Clean the teeth and rinse the mouth.
 - If the person has natural teeth, brush the teeth as described in the first part of Skill 33–4. Brush gently and carefully to avoid injuring the gums. If the client has artificial teeth, clean them as described in the *Variation* section of Skill 33–4.

① Position of the client and placement of the curved basin when providing special mouth care.

- Rinse the client's mouth by drawing about 10 mL of water or alcohol-free mouthwash into the syringe and injecting it gently into each side of the mouth. **Rationale:** *If the solution is injected with force, some of it may flow down the client's throat and be aspirated into the lungs.*
- Watch carefully to make sure that all the rinsing solution has run out of the mouth into the basin. If not, suction the fluid from the mouth. **Rationale:** *Fluid remaining in the mouth may be aspirated into the lungs.*
- Repeat rinsing until the mouth is free of dentifrice, if used.

Providing Special Oral Care for the Unconscious Client—continued

6. Inspect and clean the oral tissues.
 - If the tissues appear dry or unclean, clean them with the foam swabs or gauze and cleaning solution following agency policy.
 - Use a moistened foam swab to wipe the mucous membrane of one cheek. Discard the swab in a waste container; use a fresh one to clean the next area. **Rationale:** *Using separate applicators for each area of the mouth prevents the transfer of microorganisms from one area to another.*
 - Clean all mouth tissues in an orderly progression, using separate applicators: the cheeks, roof of the mouth, base of the mouth, and tongue.
 - Observe the tissues closely for inflammation and dryness.
7. Ensure client comfort.
 - Rinse the client's mouth as described in step 5.
 - Remove the basin, and dry around the client's mouth with the towel. Replace artificial dentures, if indicated.
 - Lubricate the client's lips with water-soluble moisturizer. **Rationale:** *Lubrication prevents cracking and subsequent infection.*
 - Remove and discard gloves.
 - Perform hand hygiene.
8. Document assessment of the teeth, tongue, gums, and oral mucosa. Include any problems such as sores or inflammation and swelling of the gums.

EVALUATION

- Consider the client's medical diagnosis and treatment (e.g., chemotherapy, oxygen) and the necessary nursing interventions related to oral hygiene.
- Conduct an ongoing assessment, if appropriate, of the oral mucosa, gums, tongue, and lips.
- Report deviations from normal to the primary care provider.
- Conduct appropriate follow-up such as a referral to a dentist for dental caries.

LIFESPAN CONSIDERATIONS Oral Hygiene

INFANTS

- Most dentists recommend that dental hygiene should begin when the first tooth erupts and be practiced after each feeding. Cleaning can be accomplished by using a wet washcloth or small gauze moistened with water.

CHILDREN

- Beginning at about 18 months of age, brush the child's teeth with a soft toothbrush. Use only a toothbrush moistened with water. Introduce toothpaste later and use one that contains fluoride.
- Frequent snacking on products containing sugar increases the child's risk for developing cavities.

OLDER ADULTS

- Oral care is often difficult for certain older adults to perform due to problems with dexterity or cognitive problems with dementia.
- Most long-term health care facilities have dentists that come on a regular basis to see clients with special needs.
- Dryness of the oral mucosa is a common finding in older adults. Because this can lead to tooth decay, advise clients to discuss it with their dentist or primary care provider.
- Decay of the tooth root is common among older adults. When the gums recede, the tooth root is more vulnerable to decay.

Home Care Considerations Oral Hygiene

PATIENT-CENTERED CARE

- Assess the oral hygiene practices and attitude toward oral hygiene of family members and the client.
- Remind adults to replace their toothbrush every 3 to 4 months and a child's toothbrush more frequently.
- Clients with nasogastric tubes or who are receiving oxygen are likely to develop dry oral mucous membranes, especially if they breathe through their mouths. More frequent oral hygiene will be needed.

Evaluating

Using data collected during care—status of oral mucosa, lips, tongue, teeth, and so on—the nurse judges whether desired outcomes have been achieved.

If outcomes have not been achieved, the nurse and client need to explore the reasons before modifying the care plan. Examples of questions to consider are as follows:

- Did the nurse overestimate the client's functional abilities?
- Is the client's hand coordination or cognitive function impaired?
- Did the client's condition change?
- Has there been a change in the client's energy level and/or motivation?

HAIR

The appearance of the hair often reflects a person's feelings of self-concept and sociocultural well-being. Becoming familiar with hair care needs and practices that may be different than our own is an important aspect of providing competent nursing care to all clients. People who feel ill may not groom their hair as before. A dirty scalp and hair are itchy, uncomfortable, and can have an odor. The hair may also reflect state of health (e.g., excessive coarseness and dryness may be associated with endocrine disorders such as hypothyroidism).

Each person has particular ways of caring for hair. Many dark-skinned people need to oil their hair daily because it tends to be dry. Oil prevents the hair from breaking and the scalp from drying.

A wide-toothed comb is usually used because finer combs pull and break the hair. Some people brush their hair vigorously before retiring; others comb their hair frequently.

Developmental Variations

Newborns may have **lanugo** (the fine hair on the body of the fetus, also referred to as *down* or *woolly hair*) over their shoulders, back, and sacrum. This generally disappears, and the hair distribution on the eyebrows, head, and eyelashes of young children subsequently becomes noticeable. Some newborns have hair on their scalps; others are free of hair at birth but grow hair over the scalp during the first year of life.

Pubic hair usually appears in early puberty followed in about 6 months by the growth of axillary hair. Boys develop facial hair in later puberty.

In adolescence, the sebaceous glands increase in activity as a result of increased hormone levels. As a result, hair follicle openings enlarge to accommodate the increased amount of sebum, which can make the adolescent's hair more oily.

In older adults, the hair is generally thinner, grows more slowly, and loses its color as a result of aging tissues and diminishing circulation. Men often lose their scalp hair and may become completely bald. This phenomenon may occur even when a man is relatively young. The older person's hair also tends to be drier than normal. With age, axillary and pubic hair becomes finer and sparser, in contrast to the eyebrows, which become bristly and coarse. Many women develop hair on their faces, which may be a concern to them.

●○● NURSING MANAGEMENT

Assessing

Assessment of the client's hair, hair care practices, and potential problems includes a nursing health history and physical assessment.

Nursing History

During the nursing history the nurse elicits data about usual hair care, self-care abilities, history of hair or scalp problems, and conditions known to affect the hair. Chemotherapeutic agents and radiation of the head may cause **alopecia** (hair loss). Hypothyroidism may cause the hair to be thin, dry, and/or brittle. Use of some hair dyes and curling or straightening preparations can cause the hair to become dry and brittle. Questions to elicit these data are shown in the accompanying Assessment Interview.

Physical Assessment

Physical assessment of the hair is discussed in Chapter 30 ∞. Problems include dandruff, hair loss, ticks, pediculosis, scabies, and hirsutism.

Dandruff

Often accompanied by itching, **dandruff** appears as a diffuse scaling of the scalp. In severe cases it involves the auditory canals and the eyebrows. Dandruff can usually be treated effectively with a commercial shampoo. In severe or persistent cases, the client may need the advice of the primary care provider.

Hair Loss

Hair loss and growth are continual processes. Some permanent thinning of hair normally occurs with aging. Baldness, common in men, is thought to be a hereditary problem for which there is no known remedy other than the wearing of a hairpiece or a costly surgical hair transplant, in which hair is taken from the back or the sides of the scalp and surgically moved to the hairless area. Although some medications are being developed, their long-term outcomes are unknown.

Ticks

Small gray-brown parasites that bite into tissue and suck blood, **ticks** transmit several diseases to people, in particular Rocky Mountain spotted fever, Lyme disease, and tularemia. To remove a tick, use a blunt tweezers or gloved fingers and grasp the tick as close to the skin as possible. Gently pull the tick away using perpendicular traction to remove the tick. Be careful to not twist or squeeze the tick's body. If the head breaks off and remains in the skin, use tweezers to remove in a manner similar to that used for removing a splinter. Wash the area with antibacterial soap. Save the tick in a bottle of rubbing alcohol in case the primary care provider wants to identify the type of tick. The following practices to remove a tick are ineffective or dangerous: applying heat with a match and applying substances such as petroleum jelly or gasoline.

Pediculosis (Lice)

Lice are parasitic insects that infest mammals. Infestation with lice is called **pediculosis**. Hundreds of varieties of lice infest humans. Three common kinds are *Pediculus capitis* (the head louse), *Pediculus corporis* (the body louse), and *Pediculus pubis* (the crab louse).

Pediculus capitis is found on the scalp and tends to stay hidden in the hairs; similarly, *Pediculus pubis* stays in pubic hair. *Pediculus corporis* tends to cling to clothing, so that when a client undresses, the lice may not be in evidence on the body; these lice suck blood from the person and lay their eggs on the clothing. The nurse can suspect their presence in the clothing if (a) the person habitually scratches, (b) there are scratches on the skin, and (c) there are hemorrhagic spots on the skin where the lice have sucked blood.

Head and pubic lice lay their eggs on the hairs; the eggs look like oval particles, similar to dandruff, clinging to the hair. Bites and pustular eruptions may also be noticed at the hair lines and behind the ears.

ASSESSMENT INTERVIEW Hair Care

HAIR CARE PRACTICES

- What are your usual hair care practices?
- What hair care products do you routinely use (e.g., hair spray, lubricant, shampoo, conditioners, hair dye, curling or straightening preparations)?

SELF-CARE ABILITIES

- Do you have any problems managing your hair?

PAST OR CURRENT HAIR PROBLEMS

- Have you had any of the following conditions or therapies: recent chemotherapy, hypothyroidism, radiation of the head, unexplained loss of hair, growth of excessive body hair?

Lice are very small, grayish white, and difficult to see. The crab louse in the pubic area has red legs. Lice may be contracted from infested clothes and direct contact with an infested person.

The treatment often includes topical pediculicides. Lice have become more of a nuisance because the resistance to previous agents has increased, resulting in the development of newer products. As of 2010, the Centers for Disease Control and Prevention and the American Academy of Pediatrics recommend over-the-counter permethrin (i.e., Nix) and synergized pyrethrins (i.e., Rid) as first-line treatments. Other older pediculicides are available (i.e., Malathion [Ovide] and Lindane [Kwell]); however, the risks of treatment are greater than the benefits (Eisenhower & Farrington, 2012, p. 452). The newer products hope to decrease the issue of resistance and increase the safety of use; however, they are costly. They include benzyl alcohol (Ulesfia), spinosad (Natroba), and ivermectin (Sklice) (Eisenhower & Farrington, 2012). Natural products offered by health food stores are also available (e.g., Lice B Gone). However, the literature does not show evidence supporting the use of herbal treatments when used in the curative treatment of head lice. Clients need to be reminded that natural products are not required to meet U.S. Food and Drug Administration (FDA) standards. Some home remedies suggest applying an oily substance, such as olive oil, mayonnaise, or petroleum jelly to smother the lice. There is no clear scientific evidence to support this form of treatment. Another home remedy that is not recommended is tea tree oil because application often leads to local irritation and inflammation (Eisenhower & Farrington, 2012).

Removal of nits (eggs) after applying the treatment is necessary. Fine-toothed “nit” combs are available. Transmission is from head-to-head (hair-to-hair) contact. The hair care items and bedding of a person who has a lice infestation should be washed with hot water.

Scabies

Scabies is a contagious skin infestation by the itch mite. The characteristic lesion is the burrow produced by the female mite as it penetrates into the upper layers of the skin. Burrows are short, wavy, brown or black, threadlike lesions most commonly observed between the fingers, creases of the wrists and elbows, beneath breast tissue, and in the groin area (Gunning, Pippitt, Kiraly, & Sayler, 2012). The mites cause intense itching that is more pronounced at night because the increased warmth of the skin has a stimulating effect on the parasites. Secondary lesions caused by scratching include vesicles, papules, pustules, excoriations, and crusts. Treatment involves thorough cleansing of the body with soap and water to remove scales and debris from crusts, and then an application of a scabicide lotion. All bed linens and clothing should be washed in very hot or boiling water.

Hirsutism

The growth of excessive body hair is called **hirsutism**. The acceptance of body hair in the axillae and on the legs is largely dictated by culture. In North America, the well-groomed woman, as depicted in magazines, has no hair on her legs or under her axillae. In many European cultures, it is not customary for well-groomed women to remove this hair.

Excessive facial hair on a woman is thought unattractive in most Western and Asian cultures. For example, some Japanese brides follow the custom of shaving their faces the day before the wedding.

The cause of excessive body hair is not always known. Older women may have some on their faces, and women in menopause

may also experience the growth of facial hair. Excessive body hair may be due to the action of the endocrine system. Heredity is also thought to influence the pattern of hair distribution.

Diagnosing

Nursing diagnoses related to hair hygiene and hair and scalp problems include *Dressing Self-Care Deficit*, *Impaired Skin Integrity*, *Risk for Infection*, and *Disturbed Body Image*. Examples of these nursing diagnoses with contributing factors follow:

- *Dressing Self-Care Deficit* related to:
 - a. Activity intolerance
 - b. Imposed immobility (bed rest)
 - c. Pain in upper extremities
 - d. Altered level of consciousness
 - e. Lack of motivation associated with depression.
- *Impaired Skin Integrity* related to:
 - a. Pruritus secondary to scabies
 - b. Pruritus secondary to head lice
 - c. Insect bite.
- *Risk for Infection* related to:
 - a. Scalp laceration
 - b. Insect bite.
- *Disturbed Body Image* related to alopecia.

Planning

In planning care, the nurse and, if appropriate, the client and/or family set outcomes for each nursing diagnosis. The nurse then performs nursing interventions and activities to achieve the client outcomes.

The specific, detailed nursing activities provided by the nurse to assist the client should take into account the client's personal preferences, health, and energy resources as well as the time, equipment, and personnel available. Often, clients like to receive hair care after a bath, before receiving visitors, and before retiring. Nursing interventions may include instructing the client/family in alternative methods for hair care including facilitating the assistance of a barber or beautician, as necessary. At some agencies, shampoos can be given to clients only after a primary care provider's order.

Implementing

Hair needs to be brushed or combed daily and washed, as needed, to keep it clean. Nurses may need to provide hair care for clients who cannot meet their own self-care needs.

Brushing and Combing Hair

To be healthy, hair needs to be brushed daily. Brushing has three major functions: It stimulates the circulation of blood in the scalp, it distributes the oil along the hair shaft, and it helps to arrange the hair.

Long hair may present a problem for clients confined to bed because it may become matted. It should be combed and brushed at least once a day to prevent this. One method is to comb the back of the head while clients are positioned on their side during back care. A brush with stiff bristles provides the best stimulation to blood circulation in the scalp. The bristles should not be so sharp that they injure the client's scalp, however. A comb with dull, even teeth is advisable. A comb with sharp teeth might injure the scalp; combs that are too fine can pull and break the hair. Some clients are pleased to have their hair

tied neatly in the back or braided until other assistance is available or until they feel better and can look after it themselves. Braiding also prevents tangling and matting for clients confined to bed.

CLINICAL ALERT!

Excessively matted or tangled hair may be infested with lice.

Dark-skinned people often have thicker, drier, curlier hair than light-skinned people. Very curly hair may stand out from the scalp. Although the shafts of curly or kinky hair look strong and wiry, they have less strength than straight hair shafts and can break easily. Many African American people have hair that is naturally curly, and it can easily become matted and tangled in a short period of time. African Americans generally wash their hair less often than other ethnic groups because the hair is drier. Frequent shampooing could damage their hair.

Some African Americans have their hair straightened. Even if straightened, the hair tends to tangle and mat easily, especially at the back and the sides if the client is confined to bed. Other African Americans style their hair in small braids (Figure 33–7 ■). These braids do not have to be unbraided for shampooing and washing. If, however, unbraiding becomes necessary, the nurse should obtain the client's permission to do so. Some African American clients may use

Figure 33–7 ■ An African American's hair styled with braids.
Cavan Images/Getty Images.

oil by applying it between the braids and massaging it into the scalp. The oil prevents the hair strands from breaking and the scalp from becoming too dry. Not all African American individuals have curly or kinky hair. Some have naturally straight hair. Keeping the scalp and hair clean and oiled remains important and necessary. Skill 33–6 describes how to provide hair care for clients.

Providing Hair Care

PURPOSES

- To stimulate the blood circulation to the scalp
- To distribute hair oils and provide a healthy sheen
- To increase the client's comfort
- To assess or monitor hair or scalp problems (e.g., matted hair or dandruff)

ASSESSMENT

Determine

- History of the following conditions or therapies: recent chemotherapy, hypothyroidism, radiation of the head, unexplained hair loss, and growth of excessive body hair
- Usual hair care practices and routinely used hair care products (e.g., hair spray, shampoo, conditioners, hair oil preparation, hair dye, curling or straightening preparations)
- Whether wetting the hair will make it difficult to comb. Kinky hair is easier to comb when wet and is very difficult to comb when it dries.
- Condition of the hair and scalp. Is the hair straight, curly, kinky? Is the hair matted or tangled? Is the scalp dry?
- Evenness of hair growth over the scalp, in particular, any patchy loss of hair; hair texture, oiliness, thickness, or thinness; presence of lesions, infections, or infestations on the scalp; presence of hirsutism
- Self-care abilities (e.g., any problems managing hair care)

PLANNING

DELEGATION

Brushing and combing hair, shampooing hair, and shaving facial hair can be delegated to UAP unless the client has a condition in which the procedure would be contraindicated (e.g., cervical spinal injury or trauma). The nurse needs to assess the UAP's knowledge and experience of hair care for clients of other cultures, if appropriate.

Equipment

- Clean brush and comb (A wide-toothed comb is usually used for many dark-skinned people because finer combs pull the hair into knots and may also break the hair.)
- Towel
- Hair oil preparation, if appropriate

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide

Providing Hair Care—continued

signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*

4. Position and prepare the client appropriately.
 - Assist the client who can sit to move to a chair. **Rationale:** *Hair is more easily brushed and combed when the client is in a sitting position.*
 - If health permits, assist a client confined to a bed to a sitting position by raising the head of the bed. Otherwise, assist the client to alternate side-lying positions, and do one side of the head at a time.
 - If the client remains in bed, place a clean towel over the pillow and the client's shoulders. Place it over the sitting client's shoulders. **Rationale:** *The towel collects any removed hair, dirt, and scaly material.*
 - Remove any pins or ribbons in the hair.
5. Remove any mats or tangles gradually.
 - Mats can usually be pulled apart with fingers or worked out with repeated brushings.
 - If the hair is very tangled, rub alcohol or an oil, such as mineral oil, on the strands to help loosen the tangles.
 - Comb out tangles in a small section of hair toward the ends. Stabilize the hair with one hand and comb toward the ends of the hair with the other hand. **Rationale:** *This avoids scalp trauma.*
6. Brush and comb the hair.
 - For short hair, brush and comb one side at a time. Divide long hair into two sections by parting it down the middle

from the front to the back. If the hair is very thick, divide each section into front and back subsections or into several layers.

7. Arrange the hair as neatly and attractively as possible, according to the individual's desires.
 - Braiding long hair helps prevent tangles.
8. Document assessments and special nursing interventions. Daily combing and brushing of the hair are not normally recorded.

VARIATION: HAIR CARE FOR AFRICAN AMERICAN CLIENTS

- Position and prepare the client.
 - Separate the hair into four sections, proceeding from one section to the next.
- Untangle the hair first, if appropriate.
 - Use fingers to reduce hair breakage and discomfort. Move fingers in a circular motion starting at the roots and gently moving up to the tip of the hair.
- Comb the hair.
 - Dampen the hair with water or a leave-in conditioner. **Rationale:** *This will help loosen any tangles.*
- Apply hair oil preparation as the client indicates.
 - Using a large and open-toothed comb, grasp a small section of hair and, holding the hair at the tip, start untangling at the tip and work down toward the scalp.
- Ask the client if he or she would like the hair braided. **Rationale:** *Braiding will decrease tangling; however, the choice is the client's.*

EVALUATION

- Conduct ongoing assessments for problems such as dandruff, alopecia, pediculosis, scalp lesions, or excessive dryness or matting.
- Evaluate effectiveness of medication (e.g., for treating pediculosis), if appropriate.

Shampooing the Hair

Hair should be washed as often as needed to keep it clean. There are several ways to shampoo clients' hair, depending on their health, strength, and age. The client who is well enough to take a shower can shampoo while in the shower. The client who is unable to shower may be given a shampoo while sitting on a chair in front of a sink. The back-lying client who can move to a stretcher can be given a shampoo on a stretcher wheeled to a sink. The client who must remain in bed can be given a shampoo with water brought to the bedside. A commercial product, similar to the bag bath, called a "head bath" is another approach (Figure 33-8 ■). It consists

of a specially designed cap (looks like a shower cap) placed over the hair. The cap contains shampoo and conditioner and gently massaging the cap cleans the hair and scalp. In some agencies, volunteer beauticians with portable shampoo chairs may be available to assist with hair care.

Water used for the shampoo should be 40.5°C (105°F) for an adult or child to be comfortable and not injure the scalp. Usually the client will supply a liquid or cream shampoo. If the shampoo is being given to destroy lice, a medicated shampoo should be used. Dry shampoos are also available. They will remove some of the dirt, odor, and oil. Their main disadvantage is that they dry the hair and scalp.

How often a person needs a shampoo is highly individual, depending largely on the person's activities and the amount of sebum secreted by the scalp. Oily hair tends to look stringy and dirty, and it feels unclean to the person.

Figure 33-8 ■ Using a rinse-free shampoo cap.

LIFESPAN CONSIDERATIONS Hair Care

INFANTS

- Shampoo an infant's hair daily to prevent seborrhea.

CHILDREN

- Monitor school-age children for nits (pediculosis).

OLDER ADULTS

- Ensure adequate warmth for older adults when shampooing their hair, because they are susceptible to chilling.

BOX 33-3 Using a Safety Razor to Shave Facial**Hair**

- Wear gloves in case facial nicks occur and you come in contact with blood.
- Apply shaving cream or soap and water to soften the bristles and make the skin more pliable.
- Hold the skin taut, particularly around creases, to prevent cutting the skin.
- Hold the razor so that the blade is at a 45-degree angle to the skin, and shave in short, firm strokes in the direction of hair growth.
- After shaving the entire area, wipe the client's face with a wet washcloth to remove any remaining shaving cream and hair.
- Dry the face well, then apply aftershave lotion or powder as the client prefers.
- To prevent irritating the skin, pat on the lotion with the fingers and avoid rubbing the face.

Note: Check agency policy as some do not allow safety razors because of the risk of impaired skin integrity from cutting the skin.

Beard and Mustache Care

Beards and mustaches also require daily care. The most important aspect of the care is to keep them clean. Food particles tend to collect in beards and mustaches, and they need washing and combing periodically. Clients may also wish a beard or mustache trim to maintain a well-groomed appearance.

CLINICAL ALERT!

A beard or mustache should not be shaved off without the client's consent.

Male clients often shave or are shaved after a bath. Frequently clients supply their own electric or safety razors. See Box 33-3 for the steps involved in shaving facial hair with a safety razor. If a client is taking an anticoagulant (e.g., Coumadin, heparin), an electric shaver should be used. Check agency policy because some facilities do not provide safety razors.

Evaluating

Using data collected during care, the nurse judges whether desired outcomes have been achieved. Examples of client outcomes that are measurable or observable include the client being able to:

- Perform hair grooming with assistance (specify).
- Exhibit clean, well-groomed, resilient hair with a healthy sheen.
- Reduce or get rid of scalp lesions or infestations.
- Describe factors, interventions, and preventive measures for specific hair problem (e.g., dandruff).

EYES

Normally eyes require no special hygiene, because lacrimal fluid continually washes the eyes, and the eyelids and lashes prevent the entrance of foreign particles. Special interventions are needed, however, for unconscious clients and for clients recovering from eye surgery or having eye injuries, irritations, or infections. In unconscious clients, the blink reflex may be absent, and excessive drainage may accumulate along eyelid margins. In clients with eye trauma or eye infections, excessive discharge or drainage is common. Excessive secretions on the lashes need to be removed before they dry on the lashes as crusts. Clients who wear eyeglasses or contact lenses also may require instruction from and care by the nurse.

●○○ NURSING MANAGEMENT**Assessing**

Assessment of the client's eyes includes a nursing health history and physical assessment.

Nursing History

During the nursing history, the nurse obtains data about the client's eyeglasses or contact lenses, recent examination by an ophthalmologist, and any history of eye problems and related treatments. Questions to elicit these data are shown in the accompanying Assessment Interview.

Physical Assessment

In physical assessment, all external eye structures are inspected for signs of inflammation, excessive drainage, encrustations, or other

ASSESSMENT INTERVIEW Eyes**FOR CLIENTS WHO WEAR EYEGLASSES**

- When do you use your glasses?
- What is your vision like with and without the glasses?

FOR CLIENTS WHO WEAR CONTACT LENSES

- How often do you wear lenses? Daily? On special occasions?
- How long do you wear your lenses in a given day, including sleep time?
- Do you have any problems with the lenses (e.g., cleaning, insertion, removal, damage)?
- Do you carry an emergency identification label to alert others to remove the lenses and ensure appropriate care in an emergency? (If not, advise the client to acquire one.)
- What are your insertion and removal procedures?
- What are your cleaning and storage procedures?

- Have you had any problems with either or both eyes or eyelids, such as excessive tearing, burning, redness, sensitivity to light, swelling, or feelings of dryness? Describe them.
- Are you using any eyedrops or ointments? (These medications can combine chemically with soft lenses and cause lens damage and eye irritation.)

FOR ALL CLIENTS

- When did you last have your eyesight tested?
- Are you currently taking any eye medication? If so, provide name, dosage, and frequency.
- Do you have any of the following eye problems: difficulty reading or seeing objects, blurring of vision, tearing, spots or floaters, photophobia (sensitivity to light), burning, itching, pain, double vision, flashing lights, or halos around lights?

obvious abnormalities. Inspection of the external eye structures is discussed in Chapter 30 ∞.

Diagnosing

Nursing diagnoses related to eye problems may include *Risk for Infection* and *Risk for Injury*. Examples of these diagnoses and possible contributing factors follow:

- *Risk for Infection* related to:
 - a. Improper contact lens hygiene
 - b. Accumulation of secretions on eyelids.
- *Risk for Injury* related to:
 - a. Prolonged wearing of contact lenses
 - b. Absence of blink reflex associated with unconsciousness.

Planning

In planning care, the nurse identifies nursing activities that will assist the client to maintain the integrity of the eye structures and to prevent eye injury and infection.

Implementing

Nursing activities may include teaching clients about how to insert, clean, and remove contact lenses and ways to protect the eyes from injury and strain.

Eye Care

Dried secretions that have accumulated on the lashes need to be softened and wiped away. Soften dried secretions by placing a sterile cotton ball moistened with sterile water or normal saline over the lid margins. Wipe the loosened secretions from the inner canthus of the eye to the outer canthus to prevent the particles and fluid from draining into the lacrimal sac and nasolacrimal duct.

If the client is unconscious and lacks a blink reflex or cannot close the eyelids completely, drying and irritation of the cornea must be prevented. Lubricating eyedrops may be ordered. Box 33–4 gives suggestions for providing eye care for the comatose client.

BOX 33–4 Eye Care for the Comatose Client

When a comatose client's corneal reflex is impaired, eye care is essential to keep moist the areas of the cornea that are exposed to air.

- Administer moist compresses to cover the eyes every 2 to 4 hours.
- Clean the eyes with saline solution and cotton balls. Wipe from the inner to outer canthus. This prevents debris from being washed into the nasolacrimal duct.
- Use a new cotton ball for each wipe. This prevents extending infection in one eye to the other eye.
- Instill ophthalmic ointment or artificial tears into the lower lids as ordered. This keeps the eyes moist.
- If the client's corneal reflex is absent, keep the eyes moist with artificial tears and protect the eye with a protective shield. These should be ordered by a primary care provider.
- Monitor the eyes for redness, exudate, or ulceration.

Eyeglass Care

It is essential that the nurse exercise caution when cleaning eyeglasses to prevent breaking or scratching the lenses. Glass lenses can be cleaned with warm water and dried with a soft tissue that will not scratch the lenses. Plastic lenses are easily scratched and may require special cleaning solutions and drying tissues. When not being worn, all glasses should be placed in an appropriately labeled case and stored in the client's bedside table drawer.

Contact Lens Care

Contact lenses, thin curved disks of hard or soft plastic, fit on the cornea of the eye directly over the pupil. They float on the tear layer of the eye. For some people, contact lenses offer several advantages over eyeglasses: (a) They cannot be seen and thus have cosmetic value; (b) they are highly effective in correcting some astigmatisms; (c) they are safer than glasses for some physical activities; (d) they do not fog, as eyeglasses do; and (e) they provide better vision in many cases.

Contact lenses may be either hard or soft or a compromise between the two types—gas-permeable lenses. *Hard contact lenses* are made of a rigid, unwettable, airtight plastic that does not absorb water or saline solutions. They usually cannot be worn for more than 12 to 14 hours and are rarely recommended for first-time wearers.

Soft contact lenses cover the entire cornea. Being more pliable and soft than hard lenses, they mold to the eye for a firmer fit. The duration of extended wear varies by brand from 1 to 30 days or more. Eye specialists recommend that long-wear brands be removed and cleaned at least once a week. These lenses require scrupulous care and handling.

Gas-permeable lenses are rigid enough to provide clear vision but are more flexible than the traditional hard lens. They permit oxygen to reach the cornea, thus providing greater comfort, and will not cause serious damage to the eye if left in place for several days.

Most clients normally care for their own contact lenses. In general, each lens manufacturer provides detailed cleaning instructions. Depending on the type of lens and cleaning method used, warm tap water, normal saline, or special rinsing or soaking solutions may be used.

All users should have a special container for their lenses. Some contain a solution so that the lenses are stored wet; in others, the lenses are dry. Each lens container has a slot or cup with a label indicating whether it is for the right or left lens. It is essential the correct lens be stored in the appropriate slot so that it will be placed in the correct eye.

General Eye Care

Many clients may need to learn specific information about care of the eyes. Some examples follow:

- Avoid home remedies for eye problems. Eye irritations or injuries at any age should be treated medically and immediately.
- If dirt or dust gets into the eyes, clean them copiously with clean, tepid water as an emergency treatment.
- Take measures to guard against eyestrain and to protect vision, such as maintaining adequate lighting for reading and obtaining shatterproof lenses for glasses.
- Schedule regular eye examinations, particularly after age 40, to detect problems such as cataracts and glaucoma.

Evaluating

Using data collected during care, the nurse judges whether desired outcomes have been achieved. Examples of desired outcomes to evaluate the effectiveness of nursing interventions follow:

- Conjunctiva and sclera free of inflammation
- Eyelids free of secretions
- No tearing
- No eye discomfort
- Demonstrates appropriate methods of caring for contact lenses
- Describes interventions to prevent eye injury and infection.

EARS

Normal ears require minimal hygiene. Clients who have excessive **cerumen** (earwax) and dependent clients who have hearing aids may require assistance from the nurse. Hearing aids are usually removed before surgery.

Cleaning the Ears

The auricles of the ear are cleaned during the bed bath. The nurse or client must remove excessive cerumen that is visible or that causes discomfort or hearing difficulty. Visible cerumen may be loosened and removed by retracting the auricle up and back. If this measure is ineffective, the use of a ceruminolytic (wax-softening agents used to soften the cerumen) or irrigation may be necessary. Irrigation, however, may cause complications, including pain, tinnitus, and external otitis media (Holcomb, 2009; Stevenson, 2010). Because ear irrigations have the potential to cause discomfort or even injury, the nurse must have competence in aural irrigation prior to performing the procedure.

Clients with hearing aids are at greater risk for cerumen impaction for two reasons. The hearing aid (a foreign body) causes excessive cerumen production and the presence of the hearing aid prevents the body's normal mechanism for removal of cerumen from functioning.

It is important for nurses to advise clients to never use bobby pins, toothpicks, or cotton-tipped applicators to remove cerumen. Bobby pins and toothpicks can injure the ear canal and rupture the tympanic membrane. Cotton-tipped applicators can cause wax to become impacted within the canal and have also been shown to enhance cerumen production (Holcomb, 2009).

Care of Hearing Aids

A hearing aid is a battery-powered, sound-amplifying device used by people with hearing impairments. It consists of a microphone that picks up sound and converts it to electric energy, an amplifier that magnifies the electric energy electronically, a receiver that converts the amplified energy back to sound energy, and an earmold that directs the sound into the ear. There are several types of hearing aids:

- **Behind-the-ear (BTE) open fit.** BTEs are the newest in hearing aid technology. A BTE has no earmold and it is barely visible with a clear tube that runs down into the ear canal. It does not occlude the ear canal (Figure 33-9 ■).
- **Behind-the-ear (BTE) with earmold.** This is a widely used type because it fits snugly behind the ear. The hearing aid case, which holds the microphone, amplifier, and receiver, is attached to the earmold by a plastic tube (Figure 33-10 ■).

A

B

Jane Schemilt/Science Photo Library,
Photo Researchers, Inc.

Figure 33-13 ■ A completely-in-the-canal (CIC) hearing aid in place.

- **In-the-ear (ITE) aid.** This one-piece aid has all its components housed in the earmold. It is more visible than other types but has more room for features such as volume control (Figure 33-11 ■).
- **In-the-canal (ITC) aid.** Compact and barely visible, an ITC aid fits completely inside the ear canal. In addition to having cosmetic appeal, the ITC does not interfere with telephone use or the wearing of eyeglasses. However, it is not suitable for clients with progressive hearing loss, it requires adequate ear canal diameter and length for a good fit, and it tends to plug with cerumen more than other aids (Figure 33-12 ■).
- **Completely-in-the-canal (CIC) aid.** Almost invisible to an observer, the CIC aid has to be custom designed to fit the individual's ear (Figure 33-13 ■).
- **Eyeglasses aid.** This is similar to the behind-the-ear aid, but the components are housed in the temple of the eyeglasses. A hearing aid can be in one or both temples of the glasses.
- **Body hearing aid.** This pocket-sized aid, used for more severe hearing losses, clips onto an undergarment, shirt pocket, or harness carrier supplied by the manufacturer. The case, containing the microphone and amplifier, is connected by a cord to the receiver, which snaps into the earpiece.

For correct functioning, hearing aids require appropriate handling during insertion and removal, regular cleaning of the earmold, and replacement of dead batteries. With proper care, hearing aids generally last 5 to 10 years. Earmolds generally need readjustment every 2 to 3 years. Skill 33-7 describes how to remove, clean, and insert a hearing aid.

Removing, Cleaning, and Inserting a Hearing Aid

PURPOSE

- To maintain proper hearing aid function

ASSESSMENT

Determine if the client has experienced any problems with the hearing aid and hearing aid practices. Assess for the presence of inflammation, excessive wax, drainage, or discomfort in the external ear.

PLANNING

DELEGATION

A nurse can delegate the task of caring for a hearing aid to the UAP. It is important, however, for the nurse to first determine that the UAP knows the correct way to care for a hearing aid. Inform the UAP to report the presence of ear inflammation, discomfort, excess wax, or drainage to the nurse.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy by drawing the curtains around the bed or closing the door to the room. Some agencies provide signs indicating the need for privacy. **Rationale:** *Hygiene is a personal matter.*
4. Remove the ITE hearing aid.
 - Turn the hearing aid off and lower the volume. The on/off switch may be labeled "O" (off), "M" (microphone), "T"

Equipment

- Client's hearing aid
- Soap, water, and towels or a damp cloth
- Pipe cleaner or toothpick (optional)
- New battery (if needed)

Removing, Cleaning, and Inserting a Hearing Aid—continued

(telephone), or “TM” (telephone/microphone). **Rationale:** *The batteries continue to run if the hearing aid is not turned off.*

- Remove the earmold by rotating it slightly forward and pulling it outward.
 - If the hearing aid is not to be used for several days, remove the battery. **Rationale:** *Removal prevents corrosion of the hearing aid from battery leakage.*
 - Store the hearing aid in a safe place and label with client's name. Avoid exposure to heat and moisture. **Rationale:** *Proper storage prevents loss or damage.*
5. Clean the earmold.
- Detach the earmold if possible. Disconnect the earmold from the receiver of a body hearing aid or from the hearing aid case of behind-the-ear and eyeglass hearing aids where the tubing meets the hook of the case. **Rationale:** *Removal facilitates cleaning and prevents inadvertent damage to the other parts.* Do not remove the earmold if it is glued or secured by a small metal ring.
 - If the earmold is detachable, soak it in a mild soapy solution. Rinse and dry it well. Do not use isopropyl alcohol. **Rationale:** *Alcohol can damage the hearing aid.*
 - If the earmold is not detachable or is for an in-the-ear aid, wipe the earmold with a damp cloth.
 - Check that the earmold opening is patent. Blow any excess moisture through the opening or remove debris (e.g., ear-wax) with a pipe cleaner or toothpick.
 - Reattach the earmold if it was detached from the rest of the hearing aid.
6. Insert the hearing aid.
- Determine from the client if the earmold is for the left or the right ear.
 - Check that the battery is inserted in the hearing aid. Turn off the hearing aid, and make sure the volume is turned all the way down. **Rationale:** *A volume that is too loud is distressing.*
 - Inspect the earmold to identify the ear canal portion. Some earmolds are fitted for only the ear canal and concha; others are fitted for all contours of the ear. The canal portion, common to all, can be used as a guide for correct insertion.
- Line up the parts of the earmold with the corresponding parts of the client's ear.
 - Rotate the earmold slightly forward, and insert the ear canal portion.
 - Gently press the earmold into the ear while rotating it backward.
 - Check that the earmold fits snugly by asking the client if it feels secure and comfortable.
 - Adjust the other components of a behind-the-ear or body hearing aid.
 - Turn the hearing aid on, and adjust the volume according to the client's needs.
7. Correct problems associated with improper functioning.
- If the sound is weak or there is no sound:
 - a. Ensure that the volume is turned high enough.
 - b. Ensure that the earmold opening is not clogged.
 - c. Check the battery by turning the hearing aid on, turning up the volume, cupping your hand over the earmold, and listening. A constant whistling sound indicates the battery is functioning. If necessary, replace the battery. Be sure that the negative (–) and positive (+) signs on the battery match those where indicated on the hearing aid.
 - d. Ensure that the ear canal is not blocked with wax, which can obstruct sound waves.
 - If the client reports a whistling sound or squeal after insertion:
 - a. Turn the volume down.
 - b. Ensure that the earmold is properly attached to the receiver.
 - c. Reinsert the earmold.
8. Document pertinent data.
- The removal and the insertion of a hearing aid are not normally recorded.
 - Report and record any problems the client has with the hearing aid.

EVALUATION

- Speak to the client in a normal conversational tone and observe client behaviors.
- Compare the client's hearing ability to previous assessments.
- Report to the primary care provider any deviations from normal for the client.

Home Care Considerations Hearing Aids

PATIENT-CENTERED CARE

- People who need a hearing aid may not wear one because they view the hearing aid as a stigma of old age.
- It is important for the client who just purchased a hearing aid to know that it often takes weeks or even months to adjust to the hearing aid. At first, the sounds will seem shrill as they start hearing high-frequency sounds that had been forgotten. Remind them that it is a hearing aid, not a hearing cure. Encourage them to not give up.
- The client needs to adjust to the hearing aid gradually by increasing the amount of time each day until the aid can be worn for a full day.
- Encourage clients to purchase their hearing aids from a company that has a minimum warranty of a 30-day return policy.
- Emphasize the importance of maintaining the hearing aid, that is, having it cleaned and checked regularly.

NOSE

Nurses usually need not provide special care for the nose, because clients can ordinarily clear nasal secretions by blowing gently into a soft tissue. When the external nares are encrusted with dried secretions, they should be cleaned with a cotton-tipped applicator or moistened with saline or water. The applicator should not be inserted beyond the length of the cotton tip; inserting it further may cause injury to the mucosa.

SUPPORTING A HYGIENIC ENVIRONMENT

Because people are usually confined to bed when ill, often for long periods, the bed becomes an important element in the client's life. A place that is clean, safe, and comfortable contributes to the client's ability to rest and sleep and to a sense of well-being. From a holistic perspective, bed-making can be viewed as the preparation of a healing space. When performed with caring intention for benefit of the

clients occupying the space during their healing journey, the environment will be affected in positive ways.

Basic furniture in a health care facility includes the bed, bedside table, overbed table, one or more chairs, and a storage space for clothing. Most bed units also have a call light, light fixtures, electric outlets, and hygienic equipment in the bedside table. Three types of equipment often installed in an acute care facility are a suction outlet for several kinds of suction, an oxygen outlet for most oxygen equipment, and a sphygmomanometer to measure the client's blood pressure. Some long-term care agencies also permit clients to have personal furniture, such as a television, a chair, and lamps, at the bedside. In the home, a client often has personal and medical equipment.

Environment

In Florence Nightingale's book, *Notes on Nursing*, she discussed many concepts including ventilation and warming, light, cleanliness of rooms, noise, and beds and bedding. These concepts are just as important today and the nurse is often an influencing factor (e.g., dimming lights, controlling noise, providing a clean bed). When providing a comfortable environment, it is important to consider the client's age, severity of illness, and level of activity.

ROOM TEMPERATURE

People who are very young, very old, or acutely ill frequently need a room temperature higher than normal. A room temperature between 20°C and 23°C (68°F and 74°F) is comfortable for most clients.

VENTILATION

Good ventilation is important to remove unpleasant odors and stale air. Odors caused by urine, draining wounds, or vomitus, for example, can be offensive to people. Room deodorizers can help eliminate odors. However, good hygienic practices are the best way to prevent offensive body and breath odors. Hospitals prohibit smoking in client rooms, and many prohibit smoking throughout the entire hospital.

NOISE

Hospital environments can be quite noisy, and special care needs to be taken to reduce noise in the hallways and nursing care units. Environmental distractions such as environmental noises and staff communication noise are particularly troublesome for hospitalized clients. For example, increased noise has been linked to stress reaction, sleep disturbance, and increased perception of pain, and also has been demonstrated to delay wound healing (Mazer, 2012). Environmental noises include the sound of paging systems, telephones, and call lights; doors closing; elevator chimes; industrial floor cleaners; and carts being wheeled through corridors.

Acute care settings have a multitude of medical device alarms that create a noisy environment for both client and nurse. It has produced the term "alarm fatigue." Device alarms are intended to alert nurses to a potential problem; however, medical devices create many false alarms. For example, one study revealed that only 3.6% of cardiac alarm conditions indicated critical events (Mazer, 2012, p. 351). As a result, apathy and desensitization occur, and the alarms are less likely to be acted on or are even disabled (Cvach, 2012). Alarm hazards are receiving national attention. The ECRI Institute, a federal patient safety organization, raised alarm hazards to number one on its 2012 list of "Top 10 Health Technology Hazards" (Ferenc, 2012). In addition, the FDA and The Joint Commission are investigating alarm fatigue because "of high noise levels that can hinder the performance of the health care staff"

(U.S. Food and Drug Administration, 2012). Cvach (2012) reports that organizations committed to finding solutions have formed interdisciplinary alarm management committees to conduct an alarm risk assessment and explore strategies for alarm reduction (p. 273).

Staff communication is a major source of noise, particularly at staff change of shift in the morning when staff conversations and many of the environmental noises occur simultaneously. It is important for nurses to raise their awareness of noise on their units and intervene to find solutions. Some hospitals have instituted "quiet times" in the afternoon on nursing units where "quiet" signs are placed around the unit, the lights lowered, and activity and noise purposefully decreased so clients can rest or nap. The "quiet times" are in the afternoon because many of the required activities for client care take place in the morning.

Hospital Beds

The frame of a hospital bed is divided into three sections. This permits the head and the foot to be elevated separately. Most hospital beds have electric motors to operate the movable joints. The motor is activated by pressing a button or moving a small lever, located either at the side of the bed or on a small panel separate from the bed but attached to it by a cable, which the client can readily use. Common bed positions are shown in Table 33–7.

Hospital beds are usually 66 cm (26 in.) high and 0.9 m (3 ft) wide, narrower than the usual bed, so that the nurse can reach the client from either side of the bed without undue stretching. The length is usually 1.9 m (6.5 ft). Some beds can be extended in length to accommodate very tall clients. Long-term care facilities for ambulatory clients usually have low beds to facilitate movement in and out of bed. Most hospital beds have "high" and "low" positions that can be adjusted either mechanically or electrically by a button or lever. The high position permits the nurse to reach the client without undue stretching or stooping. The low position allows the client to step easily to the floor.

Mattresses

Mattresses are usually covered with a water-repellent material that resists soiling and can be cleaned easily. Most mattresses have handles on the sides called lugs by which the mattress can be moved.

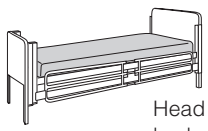

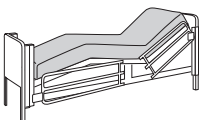

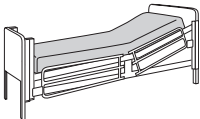

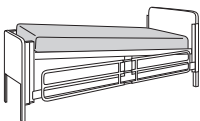

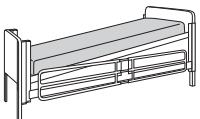

Many special mattresses are also used in hospitals to relieve pressure on the body's bony prominences, such as the heels. They are particularly helpful for clients confined to bed for a long time. For additional information about mattresses, see Chapter 36 .

Side Rails

Side rails, also referred to as bed rails, are used on both hospital beds and stretchers. They are of various shapes and sizes and are usually made of metal. A bed can have two full-length side rails or four half- or quarter-length side rails (also called split rails). Some side rails have two positions: up and down. Others have three: high, intermediate, and low. Devices to raise and lower side rails differ. Often one or two knobs are pulled to release the side and permit it to be moved. When side rails are being used, it is important that the nurse never leave the bedside while the rail is lowered.

For decades, the use of side rails has been routine practice with the rationale that the side rails serve as a safe and effective means of preventing clients from falling out of bed. Research, however, has not validated this assumption. In fact, studies have shown that raised side rails do not deter clients from getting out of bed unassisted and have led to more serious falls, injuries, and even death (Minnick, Mion, Johnson, Catrambone, & Leipzig, 2008). If all the bed's side rails are up and restrict

TABLE 33-7 Commonly Used Bed Positions

<p>Flat</p>  <p>Head of bed</p> <p>Foot of bed</p>	<p>Mattress is completely horizontal.</p>	<p>Client sleeping in a variety of bed positions, such as back-lying, side-lying, and prone (face down)</p> <p>To maintain spinal alignment for clients with spinal injuries</p> <p>To assist clients to move and turn in bed</p> <p>Bed-making by nurse</p>
<p>Fowler's position</p> 	<p>Semi-sitting position in which head of bed is raised to an angle between 45° and 60°, typically at 45°. Knees may be flexed or horizontal.</p>	<p>Convenient for eating, reading, visiting, watching TV</p> <p>Relief from lying positions</p> <p>To promote lung expansion for client with respiratory problem</p> <p>To assist a client to a sitting position on the edge of the bed</p>
<p>Semi-Fowler's position</p> 	<p>Head of bed is raised between 15° and 45°, typically at 30°.</p>	<p>Relief from lying position</p> <p>To promote lung expansion</p>
<p>Trendelenburg's position</p> 	<p>Head of bed is lowered and the foot raised in a straight incline.</p>	<p>To promote venous circulation in certain clients</p> <p>To provide postural drainage of basal lung lobes</p>
<p>Reverse Trendelenburg's position</p> 	<p>Head of bed raised and the foot lowered. Straight tilt in direction opposite to Trendelenburg's position.</p>	<p>To promote stomach emptying and prevent esophageal reflux in client with hiatal hernia</p>

the client's freedom to leave the bed, and the client did not voluntarily request all rails to be up, they are considered a restraint by the Centers for Medicare and Medicaid Services (CMS). If, however, one side rail is up to assist the client to get in and out of the bed, it is not a restraint.

In addition to falls because of raised side rails, side rail entrapment can occur. The FDA has received reports of more than 400 deaths as a direct result of side rail entrapment from a variety of health care settings, including hospitals (Minnick et al., 2008, p. 36). Client entrapment occurs when a client gets caught or entangled in the openings or gaps around the hospital bed—this usually involves a side rail. Clients at highest risk for entrapment include older or frail adults and clients who are agitated, delirious, confused, and hypoxic.

The CMS mandates that nurses in both acute care and long-term care facilities decrease the routine use of side rails. Alternatives to side rails do exist and can include low-height bed, mats placed at the side of the bed, motion sensors, and bed alarms (see Chapter 32 ∞).

Footboard or Footboot

These are used to support the immobilized client's foot in a normal right angle to the legs to prevent plantar flexion contractures (see Chapter 44 ∞).

SAFETY ALERT!

SAFETY

Side rail entrapment, injuries, and death do occur. When side rails are used, the nurse must assess the client's physical and mental status and closely monitor high-risk (frail, older, or confused) clients.

Intravenous Rods

Intravenous rods (poles, stands, standards), usually made of metal, support IV infusion containers while fluid is being administered to a client. These rods were traditionally freestanding on the floor beside the bed. Now, IV rods are often attached to the hospital beds. Some hospital units have overhead hanging rods on a track for IVs.

MAKING BEDS

Nurses need to be able to prepare hospital beds in different ways for specific purposes. In most instances, beds are made after the client receives hygienic care and when beds are unoccupied. At times, however, nurses need to make an occupied bed or prepare a bed for a client who is having surgery (an anesthetic, postoperative, or surgical bed). Regardless of what type of bed equipment is available, whether the bed is occupied or unoccupied, or the purpose for which the bed is being prepared, certain practice guidelines pertain to all bed-making.

Unoccupied Bed

An unoccupied bed can be either closed or open. Generally the top covers of an open bed are folded back (thus the term *open bed*) to make it easier for a client to get in. Open and closed beds are made the same way, except that the top sheet, blanket, and bedspread of a *closed bed* are drawn up to the top of the bed and under the pillows.

Beds are often changed after bed baths. The replacement clean linen can be collected before the bath. The linen is not usually changed unless it is soiled. Check the policy at each clinical agency. Unfitted sheets, blankets, and bedspreads are mitered at the corners

PRACTICE GUIDELINES

Bed-Making

- Wear gloves while handling a client's used bed linen. Linens and equipment that have been soiled with secretions and excretions harbor microorganisms that can be transmitted to others directly or by the nurse's hands or uniform. Wash hands after removing gloves.
- Hold soiled linen away from uniform.
- Linen for one client is never (even momentarily) placed on another client's bed.
- Place soiled linen directly in a portable linen hamper or tucked into a pillow case at the end of the bed before it is gathered up for disposal.
- Do not shake soiled linen in the air because shaking can disseminate secretions and excretions and the microorganisms they contain.
- When stripping and making a bed, conserve time and energy by stripping and making up one side as much as possible before working on the other side.
- To avoid unnecessary trips to the linen supply area, gather all linen before starting to strip a bed.

of the bed. The purpose of mitering is to secure the bedclothes while the bed is occupied. Figure 33–14 ■ shows how to miter the corner of a bed. Skill 33–8 explains how to change an unoccupied bed.

A

B

Figure 33–14 ■ Mitering the corner of a bed. *A*, Tuck in the bedcover (sheet, blanket, and/or spread) firmly under the mattress at the bottom of the bed. *B*, Lift the bedcover so that it forms a triangle with the side edge of the bed and the edge of the bedcover is parallel to the end of the bed. *C*, Tuck the part of the cover that hangs below the mattress under the mattress while holding the triangle up or against the bed. *D*, Bring the tip of the triangle down toward the floor while holding the fold of the cover against the side of the mattress. *E*, Remove the hand and tuck the remainder of the cover under the mattress, if appropriate. The sides of the top sheet, blanket, and bedspread may be left hanging freely rather than tucked in, if desired.

C

D

E

Changing an Unoccupied Bed

PURPOSES

- To promote the client's comfort
- To provide a clean, neat environment for the client
- To provide a smooth, wrinkle-free bed foundation, thus minimizing sources of skin irritation

ASSESSMENT

Assess

- Client's health status to determine that the person can safely get out of bed. In some hospitals it is necessary to have a written order to get out of bed if the client has been in bed continuously.
- Client's BP, pulse and respirations if indicated. **Rationale:** *Client may experience postural hypotension when moved from a lying position to standing to sitting, particularly if it is the first time out of bed for awhile.*
- Client's mobility status. **Rationale:** *This may influence the need for additional assistance with transferring the client from the bed to a chair.*
- Tubes and equipment connected to the client. **Rationale:** *This may influence the need for additional linens or waterproof pads.*

PLANNING

DELEGATION

Bed-making is usually delegated to UAP. If appropriate, inform the UAP of the proper disposal method of linens that contain drainage. Ask the UAP to inform you immediately if any tubes or dressings become dislodged or removed. Stress the importance of the call light being readily available while the client is out of bed.

Equipment

- Clean gloves, if needed
- Two flat sheets or one fitted and one flat sheet
- Cloth drawsheet (optional)
- One blanket
- One bedspread
- Incontinent pads (optional)
- Pillowcase(s) for the head pillow(s)
- Plastic laundry bag or portable linen hamper, if available

IMPLEMENTATION

Preparation

Determine what linens the client may already have in the room. **Rationale:** *This avoids stockpiling of unnecessary extra linens.*

Performance

1. If the client is in bed, prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection control procedures.
3. Provide for client privacy.
4. Place the fresh linen on the client's chair or overbed table; do not use another client's bed. **Rationale:** *This prevents cross contamination (the movement of microorganisms from one client to another) via soiled linen.*
5. Assess and assist the client out of bed using assistive devices (e.g., cane, walker, safety belt) as appropriate. **Rationale:** *This ensures client safety.*
 - Make sure that this is an appropriate and convenient time for the client to be out of bed.
 - Assist the client to a comfortable chair.
6. Raise the bed to a comfortable working height.
7. Apply clean gloves if linens and equipment have been soiled with secretions and/or excretions.
8. Strip the bed.
 - Check bed linens for any items belonging to the client, and detach the call bell or any drainage tubes from the bed linen.
 - Loosen all bedding systematically, starting at the head of the bed on the far side and moving around the bed up to the head of the bed on the near side. **Rationale:** *Moving around the bed systematically prevents stretching and reaching and possible muscle strain.*
 - Remove the pillowcases, if soiled, and place the pillows on the bedside chair near the foot of the bed.
 - Fold reusable linens, such as the bedspread and top sheet on the bed, into fourths. First, fold the linen in half by bringing the top edge even with the bottom edge, and then grasp it at the center of the middle fold and bottom edges.
 - 1 **Rationale:** *Folding linens saves time and energy when reapplying the linens on the bed and keeps them clean.*

1 Fold reusable linens into fourths when removing them from the bed.

2 Roll soiled linen inside the bottom sheet and hold away from the body.

- Remove the incontinent pad and discard it if soiled.
- Roll all soiled linen inside the bottom sheet, hold it away from your uniform, and place it directly in the linen hamper, not on the floor. 2 **Rationale:** *These actions are essential to*

Changing an Unoccupied Bed—continued

prevent the transmission of microorganisms to the nurse and others.

- Grasp the mattress securely, using the lugs if present, and move the mattress up to the head of the bed.
 - Remove and discard gloves if used. Perform hand hygiene.
9. Apply the bottom sheet and drawsheet (optional).
- If using a flat sheet, place the folded bottom sheet with its center fold on the center of the bed. Make sure the sheet is hem side down for a smooth foundation. Spread the sheet out over the mattress, and allow a sufficient amount of sheet at the top to tuck under the mattress **Rationale:** *The top of the sheet needs to be well tucked under to remain securely in place, especially when the head of the bed is elevated.*
 - If using a fitted sheet, pull sheet over ends of mattress. ③
- Place the flat sheet along the edge of the mattress at the foot of the bed and do not tuck it in (unless it is a contour or fitted sheet).
- Miter the sheet at the top corner on the near side (see Figure 33-14) and tuck the sheet under the mattress, working from the head of the bed to the foot.
 - If a drawsheet is used, place it over the bottom sheet so that the center fold is at the centerline of the bed and the top and bottom edges extend from the middle of where the client's back would be on the bed to the area where the midthigh or knee would be. Fanfold the uppermost half of the folded drawsheet at the center or far edge of the bed and tuck in the near edge.
 - Optional:** Before moving to the other side of the bed, place the top linens on the bed hem side up, unfold them, tuck them in, and miter the bottom corners. **Rationale:** *Completing one entire side of the bed at a time saves time and energy.*
10. Move to the other side and secure the bottom linens.
- Tuck in the bottom sheet under the head of the mattress, pull the sheet firmly, and miter the corner of the sheet.
 - Pull the remainder of the sheet firmly so that there are no wrinkles. **Rationale:** *Wrinkles can cause discomfort for the client and breakdown of skin. Tuck the sheet in at the side.*
 - Tuck in the drawsheet, if appropriate.
11. Apply or complete the top sheet, blanket, and spread.
- Place the top sheet, hem side up, on the bed so that its center fold is at the center of the bed and the top edge is even with the top edge of the mattress.
 - Unfold the sheet over the bed.
 - Optional:** Make a vertical or a horizontal toe pleat in the sheet to provide additional room for the client's feet.
 - Vertical toe pleat:** Make a fold in the sheet 5 to 10 cm (2 to 4 in.) perpendicular to the foot of the bed. ④
 - Horizontal toe pleat:** Make a fold in the sheet 5 to 10 cm (2 to 4 in.) across the bed near the foot. ⑤

Loosening the top covers around the feet after the client is in bed is another way to provide additional space.
 - Follow the same procedure for the blanket and the spread, but place the top edges about 15 cm (6 in.) from the head of the bed to allow a cuff of sheet to be folded over them.
 - Tuck in the sheet, blanket, and spread at the foot of the bed, and miter the corner, using all three layers of linen. Leave the sides of the top sheet, blanket, and spread hanging freely unless toe pleats were provided.
 - Fold the top of the top sheet down over the spread, providing a cuff. ⑥ **Rationale:** *A cuff on the sheet makes it easier for the client to pull the covers up.*
 - Move to the other side of the bed and secure the top bedding in the same manner.

③ Placing the bottom sheet on the bed.

④ A vertical toe pleat.

⑤ A horizontal toe pleat.

⑥ Making a cuff of the top linens.

Changing an Unoccupied Bed—continued

12. Put clean pillowcases on the pillows as required.
 - Grasp the closed end of the pillowcase at the center with one hand.
 - Gather up the sides of the pillowcase and place them over the hand grasping the case. Then grasp the center of one short side of the pillow through the pillowcase. **7**
 - With the free hand, pull the pillowcase over the pillow.
 - Adjust the pillowcase so that the pillow fits into the corners of the case and the seams are straight. **Rationale:** *A smoothly fitting pillowcase is more comfortable than a wrinkled one.*
 - Place the pillows appropriately at the head of the bed.
13. Provide for client comfort and safety.
 - Attach the signal cord so that the client can conveniently reach it. Some cords have clamps that attach to the sheet or pillowcase. Others are attached by a safety pin. Most beds now have a call light button on the side rail.
 - If the bed is currently being used by a client, either fold back the top covers at one side or fanfold them down to the center of the bed. **Rationale:** *This makes it easier for the client to get into the bed.*
 - Place the bedside table and the overbed table so that they are available to the client.
 - Leave the bed in the high position if the client is returning by stretcher, or place it in the low position if the client is returning to bed after being up.
14. Document and report pertinent data.
 - Bed-making is not normally recorded.
 - Record any nursing assessments, such as the client's physical status and pulse and respiratory rates before and after being out of bed, as indicated.

Variation: Surgical Bed

A surgical bed is used for the client who is having surgery and will return to bed for the postoperative phase. When making a surgical bed, the linens are horizontally fanfolded to facilitate transfer of the client into the bed. In some agencies, the client is brought back to the unit on a stretcher and transferred to the bed in the room. In other agencies, the client's bed is brought to the surgery suite and the client is transferred there. In the latter situation, the bed needs to be made with clean linens as soon as the client goes to surgery so that it can be taken to the operating room when needed.

1. Strip the bed.
2. Place and leave the pillows on the bedside chair. **Rationale:** *Pillows are left on a chair to facilitate transferring the client into the bed.*
3. Apply the bottom linens as for an unoccupied bed. Place a bath blanket on the foundation of the bed if this is agency practice. **Rationale:** *A flannel bath blanket provides additional warmth.*
4. Place the top covers (sheet, blanket, and bedspread) on the bed as you would for an unoccupied bed. Do not tuck them in, miter the corners, or make a toe pleat.
5. Make a cuff at the top of the bed as you would for an unoccupied bed. Fold the top linens up from the bottom.
6. On the side of the bed where the client will be transferred, fold up the two outer corners of the top linens so they meet in the middle of the bed forming a triangle. **8**
7. Pick up the apex of the triangle and fanfold the top linens lengthwise to the other side of the bed. **9** **Rationale:** *This facilitates the client's transfer into the bed.*
8. Leave the bed in high position with the side rails down. **Rationale:** *The high position facilitates the transfer of the client.*

EVALUATION

- Make sure the call light is accessible to the client.
- Relate client parameters of activity (e.g., pulse and respirations) to previous assessment data particularly if the client has been

7 Method for putting a clean pillowcase on a pillow.

8 Fold up the two outer corners of the top linens, forming a triangle.

9 Surgical bed. The linens are horizontally fanfolded to the other side of the bed to facilitate transfer of the client into the bed.

9. Lock the wheels of the bed if the bed is not to be moved. **Rationale:** *Locking the wheels keeps the bed from rolling when the client is transferred from the stretcher to the bed.*

on bed rest for an extended period of time or if it is the first time that the client is getting out of bed after surgery.

Changing an Occupied Bed

Some clients may be too weak to get out of bed. Either the nature of their illness may contraindicate their sitting out of bed, or they may be restricted in bed by the presence of traction or other therapies. When changing an occupied bed, the nurse works quickly and disturbs the client as little as possible to conserve the client's energy, using the following guidelines:

- Maintain the client in good body alignment. Never move or position a client in a manner that is contraindicated by the client's health. Obtain help if necessary to ensure safety.

- Move the client gently and smoothly. Rough handling can cause the client discomfort and abrade the skin.
- Explain what you plan to do throughout the procedure before you do it. Use terms that the client can understand. Encourage client participation when appropriate.
- Use the bed-making time, like the bed bath time, to assess and meet the client's needs.

See Skill 33–9 for instructions on changing an occupied bed.

Changing an Occupied Bed

PURPOSES

- To conserve the client's energy
- To promote client comfort

- To provide a clean, neat environment for the client
- To provide a smooth, wrinkle-free bed foundation, thus minimizing sources of skin irritation

ASSESSMENT

- Assess skin condition and need for a special mattress (e.g., an egg-crate mattress), footboard, or heel protectors.
- Assess client's ability to reposition self. **Rationale:** *This will determine if additional assistance is needed.*

- Determine presence of incontinence or excessive drainage from other sources indicating the need for protective waterproof pads.
- Note specific orders or precautions for moving and positioning the client.

PLANNING

DELEGATION

Bed-making is usually delegated to UAP. Inform the UAP to what extent the client can assist or if another person will be needed to assist the UAP. Instruct the UAP about the handling of any dressings and/or tubes of the client and also the need for special equipment (e.g., footboard, heel protectors), if appropriate.

Equipment

- Two flat sheets or one fitted and one flat sheet
- Cloth drawsheet (optional)
- One blanket
- One bedspread
- Incontinent pads (optional)
- Pillowcase(s) for the head pillow(s)
- Plastic laundry bag or portable linen hamper, if available

IMPLEMENTATION

Preparation

- Determine what linens the client may already have in the room. **Rationale:** *This avoids stockpiling of unnecessary extra linens.*

Performance

1. Prior to performing the procedure introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection control procedures. Apply clean gloves if linen is soiled with body fluids.
3. Provide for client privacy.
4. Remove the top bedding.
 - Remove any equipment attached to the bed linen, such as a signal light.
 - Loosen all top linen at the foot of the bed, and remove the spread and the blanket.
 - Leave the top sheet over the client (the top sheet can remain over the client if it is being changed and if it will provide sufficient warmth), or replace it with a bath blanket as follows:
 - a. Spread the bath blanket over the top sheet.
 - b. Ask the client to hold the top edge of the blanket.
 - c. Reaching under the blanket from the side, grasp the top edge of the sheet and draw it down to the foot of the bed, leaving the blanket in place. ❶
 - d. Remove the sheet from the bed and place it in the soiled linen hamper.

❶ Removing top linens under a bath blanket.

5. Change the bottom sheet and drawsheet.
 - Raise the side rail that the client will turn toward. **Rationale:** *This protects clients from falling and allows them to support themselves in the side-lying position.* If there is no side rail, have another nurse support the client at the edge of the bed.
 - Assist the client to turn on the side away from the nurse and toward the raised side rail.
 - Loosen the bottom linens on the side of the bed near the nurse.

Changing an Occupied Bed—continued

2 Moving soiled linen as close to the client as possible.

3 Placing a new bottom sheet on half of the bed.

- Fanfold the dirty linen (i.e., drawsheet and the bottom sheet) toward the center of the bed 2 as close to and under the client as possible. **Rationale:** *Doing this leaves the near half of the bed free to be changed.*
 - Place the new bottom sheet on the bed, and vertically fanfold the half to be used on the far side of the bed as close to the client as possible. 3 Tuck the sheet under the near half of the bed and miter the corner if a contour sheet is not being used.
 - Place the clean drawsheet on the bed with the center fold at the center of the bed. Fanfold the uppermost half vertically at the center of the bed and tuck the near side edge under the side of the mattress. 4
 - Assist the client to roll over toward you, over the fanfolded bed linens at the center of the bed, onto the clean side of the bed.
 - Move the pillows to the clean side for the client's use. Raise the side rail before leaving the side of the bed.
 - Move to the other side of the bed and lower the side rail.
 - Remove the used linen and place it in the portable hamper.
 - Unfold the fanfolded bottom sheet from the center of the bed.
 - Facing the side of the bed, use both hands to pull the bottom sheet so that it is smooth and tuck the excess under the side of the mattress.
 - Unfold the drawsheet fanfolded at the center of the bed and pull it tightly with both hands. Pull the sheet in three divisions: (a) Face the side of the bed to pull the middle division, (b) face the far top corner to pull the bottom division, and (c) face the far bottom corner to pull the top division.
 - Tuck the excess drawsheet under the side of the mattress.
6. Reposition the client in the center of the bed.
- Reposition the pillows at the center of the bed.
 - Assist the client to the center of the bed. Determine what position the client requires or prefers and assist the client to that position.
7. Apply or complete the top bedding.
- Spread the top sheet over the client and either ask the client to hold the top edge of the sheet or tuck it under the shoulders. The sheet should remain over the client when the bath blanket or used sheet is removed. 5
 - Complete the top of the bed.

4 Placing a clean drawsheet on the bed.

5 Client holds the top edge of sheet while the nurse removes the bath blanket.

8. Ensure continued safety of the client.
- Raise the side rails. Place the bed in the low position before leaving the bedside.
 - Attach the call light to the bed linen within the client's reach.
 - Put items used by the client within easy reach.
9. Bed-making is not normally recorded.

EVALUATION

- Conduct appropriate follow-up, such as determining client's comfort and safety, patency of all drainage tubes, and client's access to call light to summon help when needed.
- Reassess all tubing, oxygen apparatus, IV pumps, and so forth. **Rationale:** *This prevents errors in supportive devices resulting from procedure.*

Critical Thinking Checkpoint

It is the fourth day following a female client's abdominal surgery. She is progressing well, is ambulating several times each day, has been providing for her own hygienic needs, and is planning on going home tomorrow. During your early morning assessment, you note that the client's hair is oily and matted and she has an unpleasant body odor. Her dentures in a container at the bedside are in need of cleaning. You check her abdominal incision and verify that there is no drainage, redness, or signs of infection. You inquire about her ability to take care of her own bath and personal needs, and offer to assist her with her bath. She replies that she had a bath yesterday, doesn't feel that she needs another one today, and requests to omit her personal care for the day.

1. You are considering *Self-Care Deficit: Bathing* as an appropriate nursing diagnosis for the client. You review the defining characteristics and related factors and discover what?

2. What else should you ask the client?
3. Why is it important that you obtain the assessments you have already completed along with the above questions you asked?
4. What approaches might you use if you feel that the client does need her hair shampooed and needs to have her personal care attended to?
5. What advantages does performing baths and personal hygiene for clients offer to the nurse?

See Critical Thinking Possibilities on student resource website.

Chapter 33 Review

CHAPTER HIGHLIGHTS

- Clients' hygienic practices are influenced by numerous factors including culture, religion, environment, developmental level, health and energy, and personal preferences.
- The major functions of the skin are to protect underlying tissues, regulate body temperature, secrete sebum, transmit sensations through nerve receptors for sensory perception, and produce and absorb vitamin D in conjunction with ultraviolet rays from the sun.
- When planning hygiene care, the nurse must take the client's preferences into consideration.
- Nurses provide perineal-genital care for clients who are unable to do so for themselves.
- Nurses can often teach clients how to prevent foot problems.
- Oral hygiene should include daily dental flossing and mechanical brushing of the teeth.
- Regular dental checkups and fluoride supplements are recommended to maintain healthy teeth.
- Nurses provide special oral care to clients who are unconscious or debilitated.
- Hair care includes daily combing and brushing and regular shampooing.
- African American clients' hair may require special care.
- Clients with a hearing aid may require nursing assistance with the device.
- Nurses need to provide a positive and safe environment for clients.
- Nurses need to be able to prepare hospital beds in different ways for specific purposes.

TEST YOUR KNOWLEDGE

1. A client can bathe most of her body except for the back, hands, and feet. She also can walk to and from the bathroom and dress herself when given clothing. Which functional level describes this client?
 1. Totally dependent (+4)
 2. Moderately dependent (+3)
 3. Semidependent (+2)
 4. Independent (0)
2. The client is unresponsive and requires total care by nursing staff. Which assessment does the nurse check first before providing special oral care to the client?
 1. Presence of pain
 2. Condition of the skin
 3. Gag reflex
 4. Range of motion
3. A client with diabetes has very dry skin on her feet and lower extremities. The nurse plans to inform the client to do which of the following to maintain intact skin?
 1. Soak her feet frequently.
 2. Use a nonperfumed lotion.
 3. Apply foot powder.
 4. Avoid knee-high elastic stockings.
4. The client wears an in-the-ear (ITE) hearing aid and because of arthritis needs someone to insert the hearing aid. Which action does the nurse teach the unlicensed assistive personnel (UAP) to do before inserting the client's hearing aid?
 1. Turn the hearing aid off.
 2. Soak the hearing aid in soapy solution to clean it.
 3. Turn the volume all the way up.
 4. Remove the batteries.

5. The client is in surgery and will be returning to his bed via a stretcher. Which bed option reflects that the nurse appropriately planned ahead for this client?
 1. Open bed in low position
 2. Occupied bed in low position
 3. Closed bed in high position
 4. Surgical bed in high position
6. The nurse is discussing strategies with the unlicensed assistive personnel (UAP) for bathing a client with dementia. Which strategies would be appropriate for the client? Select all that apply.
 1. Cover the client as much as possible.
 2. Sing or talk to the client.
 3. Complete the bath as quickly as possible.
 4. Be organized.
 5. Expect the client to protest—finish quickly.
7. The nurse is observing the unlicensed assistive personnel (UAP) perform perineal care for a client. Which action indicates that the nurse needs to discuss additional teaching with the UAP?
 1. Uses a clean portion of the washcloth for each stroke
 2. Wipes from the pubis to the rectum
 3. Uses clean gloves
 4. Does not retract the foreskin
8. The nurse is planning a presentation on oral health at an intergenerational community center. Which statements will be important to include? Select all that apply.
 1. Using a bottle during naps and bedtime can cause dental caries in a toddler.
 2. Schedule a visit to the dentist when your child is ready to go to school.
 3. It is important for parents to supervise a child's brushing of their teeth.
 4. Most older adults have dentures and don't need to worry about oral care.
 5. Older adults are at risk for periodontal disease.
9. The nurse is discussing foot care with a client who was recently diagnosed with diabetes. Which statement by the client indicates a need for further teaching?
 1. "I am going to use a mirror to check my feet."
 2. "I enjoy walking barefoot around the house."
 3. "I will file my nails."
 4. "I will increase the time that I wear new shoes each day."
10. The client is complaining of shortness of breath. His respirations are 28 and labored. The bed is currently in the flat position. The nurse puts the bed in which position?
 1. Fowler's
 2. Semi-Fowler's
 3. Trendelenburg
 4. Reverse Trendelenburg

34 Diagnostic Testing

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Describe the nurse's role for each of the phases involved in diagnostic testing.
2. List common blood tests.
3. Discuss the nursing responsibilities for specimen collection.
4. Explain the rationale for the collection of each type of specimen.
5. Describe how to collect and test stool specimens.
6. Compare and contrast the different types of urine specimens.
7. Describe how to collect sputum and throat specimens.
8. Describe visualization procedures that may be used for the client with gastrointestinal, urinary, and cardiopulmonary alterations.
9. Compare and contrast CT, MRI, and nuclear imaging studies.
10. Describe the nurse's role in caring for clients undergoing aspiration/biopsy procedures.
11. Verbalize the steps used in:
 - a. Obtaining a capillary blood specimen to measure blood glucose.
 - b. Collecting a urine specimen for culture and sensitivity by clean catch.
12. Recognize when it is appropriate to delegate diagnostic testing skills to unlicensed assistive personnel.
13. Demonstrate appropriate documentation and reporting of diagnostic testing information.

INTRODUCTION

Diagnostic and laboratory tests (commonly called laboratory tests) are tools that provide information about clients. Tests may be used for basic screening as part of a wellness check. Frequently tests are used to help confirm a diagnosis, monitor an illness, and provide valuable information about the client's response to treatment. Nurses require knowledge of the most common laboratory and diagnostic tests because one primary role of the nurse is to teach the client and family or significant other how to prepare for the test and the care that may be required following the test. Nurses must also know the implications of the test results in order to provide the most appropriate nursing care for the client.

DIAGNOSTIC TESTING PHASES

Diagnostic testing occurs in many environments. The traditional sites include hospitals, clinics, and the primary care provider's office. Many test sites, however, are moving to the community. Examples

718

include the home, workplace, shopping malls, and mobile units. The more complex diagnostic tests are performed at diagnostic centers specifically built to provide those tests.

Diagnostic testing involves three phases: pretest, intratest, and post-test.

Pretest

The major focus of the pretest phase is client preparation. A thorough assessment and data collection (e.g., biologic, psychological, sociologic, cultural, and spiritual) assist the nurse in determining communication and teaching strategies. Prior to radiologic studies it is important to ask female clients if pregnancy is possible. If pregnancy is suspected, special precautions may be necessary or the test may need to be postponed.

The nurse also needs to know what equipment and supplies are needed for the specific test. Common questions include the

following: What type of sample will be needed and how will it be collected? Does the client need to stop oral intake for a certain number of hours prior to the test? Does the test include administration of dye (contrast media) and, if so, is it injected or swallowed? Are fluids restricted or forced? Are medications given or withheld? How long is the test? Is a consent form required? Answers to these types of questions can help avoid costly mistakes and reduce inconvenience to all involved. Most facilities have information about the tests available to the health care team. The laboratory at the facility can also act as a resource for information.

Intratest

This phase focuses on specimen collection and performing or assisting with certain diagnostic testing. The nurse uses standard precautions and sterile technique as appropriate. During the procedure the nurse provides emotional and physical support while monitoring the client as needed (e.g., vital signs, pulse oximetry, ECG). The nurse ensures correct labeling, storage, and transportation of the specimen to avoid invalid test results.

Post-Test

The focus of this phase is on nursing care of the client and follow-up activities and observations. As appropriate, the nurse compares the

Culturally Responsive Care

PATIENT-CENTERED CARE

Drawing Blood Samples

An Asian client practicing traditional medicine views blood as a source of life and believes that the body cannot replace lost blood (Spector, 2013). As a result, Asian clients may be upset by venipuncture or the drawing of blood for testing, especially if there are numerous tests. They may view this as upsetting the body's normal balance and weakening the body. Also, blood represents a person's essence and they may fear that their essence is being given away. Therefore, Asian clients may need to be informed that their blood will not be given to anyone else.

CLIENT TEACHING

Preparing for Diagnostic Testing

- Instruct the client and family about the procedure for the diagnostic test ordered (e.g., whether food is allowed prior to or after testing, and the length of time of the test).
- Explain the purpose of the test.
- Instruct the client and family about activity restrictions related to testing (e.g., remain supine for 1 hour after testing is completed).
- Instruct the client and family on the reaction the diagnostic test may produce (e.g., flushing if a dye is injected).
- Provide the client with detailed information about the diagnostic testing equipment.
- Inform the client and family of the time frame for when the results will be available.
- Instruct the client and family to ask any questions so that the health care provider can clarify information and allay any fears.

Kee, 2013, Upper Saddle River, NJ: Pearson; and *Brunner & Suddarth's Handbook of Laboratory and Diagnostic Tests* (pp. 2–3), by M. August-Brady, 2010, Philadelphia, PA: Lippincott Williams & Wilkins.

SAFETY ALERT!

SAFETY

2014 THE JOINT COMMISSION NATIONAL PATIENT SAFETY GOALS (2013)

Goal 2: Improve the Effectiveness of Communication Among Caregivers.

- Report critical results of tests and diagnostic procedures on a timely basis. **Rationale:** *Critical results of tests and diagnostic procedures fall significantly outside the normal range and may indicate a life-threatening situation.* The objective is to provide the responsible licensed caregiver these results within an established time frame so that the client can be promptly treated.

previous and current test results and modifies nursing interventions as needed. The nurse also reports the results to appropriate health team members. The National Patient Safety Goals identify the importance of reporting critical results of tests and diagnostic procedures.

Nursing Diagnoses

Nursing diagnoses are based on client data and need. Examples of nursing diagnoses include (Herdman & Kamitsuru, 2014):

- *Anxiety or Fear* related to possible diagnosis of acute or chronic illness pending conclusion of diagnostic testing
- *Impaired Physical Mobility* related to prescribed bed rest and restricted movement of involved extremity after testing
- *Deficient Knowledge* (state diagnostic test) related to misperceptions received from others regarding process for test.

BLOOD TESTS

Blood tests are commonly used diagnostic tests that can provide valuable information about the hematologic system and many other body systems. A **venipuncture** (puncture of a vein for collection of a blood specimen) can be performed by various members of the health care team. A **phlebotomist**, a person from a laboratory who performs venipuncture, usually collects the blood specimen for the tests ordered by the primary care provider. In some institutions, nurses may draw blood samples. The nurse needs to know the guidelines for drawing blood samples for the facility and also the state's nurse practice act.

Complete Blood Count

Specimens of venous blood are taken for a **complete blood count (CBC)**, which includes hemoglobin and hematocrit measurements, erythrocyte (red blood cells) count, red blood cell indices, leukocyte (white blood cell) count, and a differential white cell count. The CBC is a basic screening test and one of the most frequently ordered blood tests (Table 34–1).

Hemoglobin (Hgb) is the main intracellular protein of erythrocytes. It is the iron-containing protein in the red blood cells that transports oxygen through the body (Osborn, Wraa, & Watson, 2010). The hemoglobin test is a measure of the total amount of hemoglobin in the blood. The **hematocrit (Hct)** measures the percentage of RBCs in the total blood volume. Normal values for both hemoglobin and hematocrit vary, with males having higher levels than females. Hemoglobin and hematocrit are often ordered together and commonly referred to as “H&H” when ordering laboratory tests.

TABLE 34-1 Complete Blood Count with Clinical Implications

Component	Normal Findings (Adult)	Possible Causes of Abnormal Findings	
		Increased	Decreased
RED BLOOD CELL (RBC) COUNT The number of RBCs per cubic millimeter (mm^3).	<i>Men:</i> 4.6–6.0 million/ mm^3 <i>Women:</i> 4.0–5.0 million/ mm^3	Dehydration Polycythemia vera High altitude Cardiovascular disease	Blood loss Anemias Overhydration Leukemias Chronic renal failure Pregnancy
HEMOGLOBIN (HGB) Composed of a pigment (heme), which contains iron, and a protein (globin).	<i>Men:</i> 13.5–18 g/dL <i>Women:</i> 12–15 g/dL	Polycythemia Dehydration Chronic obstructive pulmonary disease Heart failure	Blood loss Anemias Kidney diseases Cancers
HEMATOCRIT (HCT) The hematocrit or packed cell volume (Hct, PCV, or crit) is a fast way to determine the percentage of RBCs in the plasma. The Hct is reported as a percentage because it is the concentration of RBCs in the blood.	<i>Men:</i> 40–54% <i>Women:</i> 36–46%	Dehydration Burns Hypovolemia	Acute blood loss Pregnancy Dietary deficiencies Anemias
RBC INDICES <i>Mean corpuscular volume (MCV)</i> The mean or average size of the individual RBC.	<i>Men:</i> 80–98 μm^3 <i>Women:</i> 78–102 μm^3	Chronic liver disease Pernicious anemia	Microcytic iron deficiency anemia Lead poisoning
<i>Mean corpuscular hemoglobin (MCH)</i> Amount of Hgb present in one cell.	25–35 pg	Macrocytic anemias	Radiation
<i>Mean corpuscular hemoglobin concentration (MCHC)</i> The proportion of each cell occupied by Hgb.	31–37%	Rarely seen	Microcytic, hypochromic anemia
WHITE BLOOD CELL (WBC) COUNT Count of the total number of WBCs in a cubic millimeter of blood.	4,500–11,000/ mm^3	Acute infections Tissue necrosis (e.g., myocardial infarction) Collagen diseases	Viral infections Hematopoietic diseases Rheumatoid arthritis
DIFFERENTIAL COUNT The proportion of each of the five types of WBCs in a sample of 100 WBCs.			
<i>Neutrophils</i>	50–70%	Acute infections	Viral diseases Leukemias Aplastic and iron deficiency anemia
<i>Lymphocytes</i>	25–35%	Viral infection Chronic infections Lymphocytic leukemia	Cancers Leukemia Multiple sclerosis Renal failure
<i>Monocytes</i>	4–6%	Viral diseases Parasitic diseases Collagen diseases Cancer	Lymphocytic leukemia Aplastic anemia

TABLE 34–1 Complete Blood Count with Clinical Implications—*continued*

Component	Normal Findings (Adult)	Possible Causes of Abnormal Findings	
		Increased	Decreased
<i>Eosinophils</i>	1–3%	Allergic reactions Phlebitis Thrombophlebitis Parasitic infestations	Stress (burns, shock) Adrenocortical hyperfunction
<i>Basophils</i>	0.4–1.0%	Leukemia Inflammatory process	Hypersensitivity reaction Stress Pregnancy
PLATELET COUNT Platelets are basic elements in the blood that promote coagulation.	150,000–400,000/mm ³	Infections Polycythemia vera Acute blood loss Splenectomy	Idiopathic (unknown cause) thrombocytopenic purpura Cancer Systemic lupus erythematosus (SLE) Some types of anemias

From Pearson Handbook of Laboratory and Diagnostic Tests with Nursing Implications, 7th ed. (pp. 208; 210; 312–313; 337–338; 392–393; 395–396), by J. Kee, 2013. Reprinted and electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

Hemoglobin and hematocrit increase with dehydration as the blood becomes more concentrated, and decrease with hypervolemia and resulting hemodilution. Both the hemoglobin and hematocrit are related to the **red blood cell (RBC) count**, which is the number of RBCs per cubic millimeter of whole blood. Low RBC counts are indicative of anemia. Clients with chronic hypoxia may develop higher than normal counts, a condition known as **polycythemia**. **Red blood cell (RBC) indices** may be performed as part of the CBC to evaluate the size, weight, and hemoglobin concentration of RBCs.

The **leukocyte or white blood cell (WBC) count** determines the number of circulating WBCs per cubic millimeter of whole blood. High WBC counts are often seen in the presence of a bacterial infection; by contrast, WBC counts may be low if a viral infection is present. In the WBC differential, leukocytes are identified by type, and the percentage of each type is determined. This information is useful in diagnosing certain disorders that have characteristic patterns of distribution (Figure 34–1 ■).

Serum Electrolytes

Serum electrolytes are often routinely ordered for any client admitted to a hospital as a screening test for electrolyte and

acid–base imbalances. Serum electrolytes also are routinely assessed for clients at risk in the community, for example, clients who are being treated with a diuretic for hypertension or heart failure. The most commonly ordered serum tests are for sodium, potassium, chloride, and bicarbonate ions. Serum electrolytes may be ordered as a Chem 7 or BMP (basic metabolic panel). The laboratory terminology varies depending on the laboratory. Normal values of commonly measured electrolytes are shown in Box 34–1.

Blood levels of two metabolically produced substances, urea and creatinine, are routinely used to evaluate renal function. The kidneys, through filtration and tubular secretion, normally eliminate both. Urea, the end product of protein metabolism, is measured as **blood urea nitrogen (BUN)**. **Creatinine** is produced in relatively constant quantities by the muscles and is excreted by the kidneys. Thus the amount of creatinine in the blood relates to renal excretory function.

Serum Osmolality

Serum osmolality is a measure of the solute concentration of the blood. The particles included are sodium ions, glucose, and urea (BUN). Serum osmolality can be estimated by doubling the serum sodium, because sodium and its associated chloride ions are the major determinants of serum osmolality. Serum osmolality values are used primarily to evaluate fluid balance. Normal values are 280 to 300 mOsm/kg. An increase in serum osmolality indicates a fluid volume deficit; a decrease reflects a fluid volume excess.

Drug Monitoring

Therapeutic drug monitoring is often conducted when a client is taking a medication with a narrow therapeutic range (e.g., digoxin, theophylline, aminoglycosides). This monitoring includes drawing

Culturally Responsive Care

PATIENT-CENTERED CARE

Biocultural Considerations

Studies have documented differences in clinical laboratory reference ranges between African and Western populations. For example, one study found that participants from western Kenya had lower hemoglobin, hematocrit, and RBC levels than North American and European populations. Thus some researchers recommend the development of region-specific hematologic reference values (Zeh et al., 2011).

Figure 34-1 ■ Composition of blood.

BOX 34-1 Normal Electrolyte Values for Adults*

Venous Blood	
Sodium	135–145 mEq/L
Potassium	3.5–5.3 mEq/L
Chloride	95–105 mEq/L
Calcium (total) (ionized)	4.5–5.5 mEq/L or 8.5–10.5 mg/dL
	56% of total calcium (2.5 mEq/L or 4.0–5.0 mg/dL)
Magnesium	1.5–2.5 mEq/L or 1.6–2.5 mg/dL
Phosphate	1.8–2.6 mEq/L (phosphorus)
Serum osmolality	280–300 mOsm/kg water

*Normal laboratory values vary from agency to agency.

blood samples for peak and trough levels to determine if the blood serum levels of a specific drug are at a therapeutic level and not a subtherapeutic or toxic level. The **peak level** indicates the highest concentration of the drug in the blood serum, and the **trough level** represents the lowest concentration. Ideally, a client's peak and trough levels fall within the therapeutic range.

Arterial Blood Gases

Measurement of **arterial blood gases** is another important diagnostic procedure (see Chapter 50 ∞). Specialty nurses, medical technicians, and respiratory therapists normally take specimens of arterial blood from the radial, brachial, or femoral arteries. Because of the relatively great pressure of the blood in

these arteries, it is important to prevent hemorrhaging by applying pressure to the puncture side for about 5 to 10 minutes after removing the needle.

Blood Chemistry

A number of other tests may be performed on blood serum (the liquid portion of the blood). These are often referred to as a **blood chemistry**. In addition to serum electrolytes, common chemistry examinations include determining certain enzymes that may be present (including lactic dehydrogenase [LDH], creatine kinase [CK], aspartate aminotransferase [AST], and alanine aminotransferase [ALT]), serum glucose, hormones such as thyroid hormone, and other substances such as cholesterol and triglycerides. These tests provide valuable diagnostic cues. For example, cardiac markers (e.g., CPK-MB, myoglobin, troponin T, and troponin I) are released into the blood during a myocardial infarction (MI, or heart attack). Elevated levels of these markers in the venous blood can help differentiate between an MI and chest pain that is caused by angina or pleuritic pain.

A common laboratory test is the glycosylated hemoglobin or **hemoglobin A_{1c} (HbA_{1c})** test, which is a measurement of blood glucose that is bound to hemoglobin. Hemoglobin A_{1c} is a reflection of how well blood glucose levels have been controlled during the prior 3 to 4 months. The normal range is 4.0% to 5.5%. An elevated HbA_{1c} reflects hyperglycemia in people with diabetes.

The first specific blood test used to detect and guide treatment for heart failure is the brain natriuretic peptide or B-type natriuretic peptide (BNP) test. B-type natriuretic peptide is secreted primarily by the left ventricle in response to increased ventricular volume and pressure. BNP levels increase as heart failure becomes more severe.

See Table 34–2 for normal values of common blood chemistry tests.

Metabolic Screening

Newborns are routinely screened for congenital metabolic conditions. Tests for phenylketonuria (PKU) and congenital hypothyroidism are required in all states in the United States. Other conditions that are frequently screened for include sickle cell disease and galactosemia. Screening involves collecting peripheral venous blood (via a heel-stick) on prepared blotting paper and sending the specimen to the state laboratory for analysis. Discovered abnormalities allow the provider and parents to plan early care (e.g., special diets for children with PKU) that can prevent long-term complications.

Capillary Blood Glucose

A capillary blood specimen is taken to measure the current blood glucose level when frequent tests are required or when a venipuncture cannot be performed. This technique is less painful than a venipuncture and easily performed. Hence, clients can perform this technique on themselves.

The development of home glucose test kits and reagent strips has simplified the testing of blood glucose and greatly facilitated the management of home care by clients with diabetes. A number

Figure 34–2 ■ Blood glucose monitor, test strips, and lancet injector.

of manufacturers have developed blood glucose meters or monitors (Figure 34–2 ■).

Advances in technology have resulted in clients having greater choices for a glucose meter that meets their needs. For example, a person with a visual impairment could choose a voice-activated glucose meter or a meter with a large visual display (Wahowiak, 2013). Some meters may be used for alternative site testing (AST). This is when the client obtains a blood sample from an area of the body other than the finger such as the palm of the hand, forearm, or thigh. It is important to instruct a client who is using one of these devices that AST may not be as accurate as fingertip testing. It is recommended that AST only be used by people with fairly stable diabetes and for testing before meals (Whitmore, 2012, p. 585). For high-tech clients, mini-meters are available in different colors and meters that automatically analyze their trends in glucose control, medications, food, and exercise. This allows clients to see patterns and trends that can help them be successful in controlling their diabetes.

Glucose meters can vary in the following ways: amount of blood needed, code vs. noncode requirement, testing speed, size, ability to store results, cost of the meter, and test strips. It is important that clients who require glucose monitoring be comfortable and confident in the use of the meter. Once the client chooses a blood glucose meter, it is imperative for the nurse or client to review the manufacturer's operating guidelines. Being familiar with the proper use of the equipment helps ensure accurate readings. This will assist clients in controlling their diabetes. Clients who are comfortable taking their blood glucose readings and knowledgeable about interpreting the results will feel empowered to make changes, as needed, for optimal self-management skills.

TABLE 34-2 Common Blood Chemistry Tests with Clinical Implications

Test	Normal Findings (Adult)	Significance	Possible Causes of Increased Level	Possible Causes of Decreased Level
LIVER FUNCTION TESTS				
ALT (alanine aminotransferase), formerly known as serum pyretic transaminase (SGPT)	<i>Men:</i> 10–55 unit/L <i>Women:</i> 7–30 unit/L	Marker of hepatic injury; more specific of liver damage than AST	Hepatitis, infectious mononucleosis, acute pancreatitis, acute myocardial infarction, heart failure	Not clinically significant
AST (aspartate aminotransferase), formerly known as serum glutamic-oxaloacetic transaminase (SGOT)	<i>Men:</i> 10–40 unit/L <i>Women:</i> 9–25 unit/L	Found in heart, liver, and skeletal muscle. Can also be used to indicate liver injury	Liver diseases (e.g., hepatitis, alcoholism, drug toxicity), acute myocardial infarction, anemias, skeletal muscle diseases	Chronic renal dialysis, vitamin B ₆ deficiency
Albumin	<i>Adults:</i> 3.5–4.8 g/dL or 35–48 g/L <i>Panic value:</i> <1.5 g/dL	Is a protein produced by the liver	No pathology causes the liver to produce more albumin. An increased level reflects dehydration	Chronic liver dysfunction, AIDS, severe burns, malnutrition, renal disease, acute and chronic infections
Alkaline phosphatase	<i>Adults:</i> 25–100 unit/L	Found in the tissues of the liver, bone, intestine, kidney, and placenta. Used as an index of liver and bone disease when correlated with other clinical findings	Liver disease, bone disease, hyperparathyroidism, myocardial infarction, chronic renal failure, heart failure	Malnutrition, pernicious anemia and severe anemias, hypothyroidism, magnesium and zinc deficiency (nutritional)
Ammonia	<i>Adults:</i> 15–45 mcg/dL	The liver converts ammonia, a by-product of protein metabolism, into urea, which is excreted by the kidneys	Liver disease, cirrhosis, Reye's syndrome, GI hemorrhage	Renal failure
Bilirubin	<i>Adults:</i> <i>Total:</i> 0.3–1.0 mg/dL <i>Direct:</i> 0.0–0.2 mg/dL <i>Indirect:</i> 0.1–1.0 mg/dL <i>Panic value:</i> >10 mg/dL	Results from the breakdown of hemoglobin in the red blood cells; removed from the body by the liver, which excretes it into the bile	<i>Total:</i> hepatitis, obstruction of the common bile or hepatic ducts, pernicious anemia, sickle cell disease <i>Direct:</i> cancer of the head of the pancreas, choledocholithiasis <i>Indirect:</i> hemolytic anemias, drug toxicity, transfusion reaction	Not clinically significant
GGT (gamma-glutamyl transferase)	<i>Men:</i> 1–94 unit/L <i>Women:</i> 1–70 unit/L	Found primarily in the liver, kidney, prostate, and spleen. Is more specific for the hepatobiliary system	Liver disease, alcohol abuse	Not clinically significant
Prothrombin	<i>Adults:</i> 11–13 seconds <i>Critical value:</i> >20 seconds for non-anticoagulated individuals	A protein produced by the liver for clotting of blood	Liver disease or damage, vitamin K deficiency, obstruction of common bile duct, deficiency of factors II, V, VII, or X	Thrombophlebitis, malignant tumor
CARDIAC MARKERS				
CK (creatinine kinase)	<i>Total:</i> <i>Men:</i> 38–174 unit/L <i>Women:</i> 26–140 unit/L <i>Isoenzymes:</i> MM (CK ₃): 96–100% MB (CK ₂): 0–6% BB (CK ₁): 0%	An enzyme found in the heart and skeletal muscles. Has three isoenzymes: MM or CK ₃ , MB or CK ₂ , and BB or CK ₁	<i>Total:</i> acute MI, myocarditis, after open heart surgery, acute cerebrovascular disease, muscular dystrophy, chronic alcoholism <i>CK isoenzymes:</i> MB (CK ₂): myocardial infarct, myocardial ischemia, angina pectoris	Not clinically significant

TABLE 34-2 Common Blood Chemistry Tests with Clinical Implications—*continued*

Test	Normal Findings (Adult)	Significance	Possible Causes of Increased Level	Possible Causes of Decreased Level
Myoglobin	5–70 ng/mL	After an MI, serum levels of myoglobin rise in 2–4 h, making it an early marker for muscle damage in MI	MI, angina, other muscle injury (e.g., trauma), renal failure, rhabdomyolysis	Rheumatoid arthritis, myasthenia gravis
Troponin I Troponin T	<i>Troponin I</i> : <0.35 ng/mL <i>Critical value</i> : >1.5 ng/mL <i>Troponin T</i> : <0.2 ng/mL	Cardiac troponin is highly concentrated in the heart muscle. This test is used in the early diagnosis of MI. After an MI, troponin I begins to increase in 4–6 h and remains elevated for 5–7 days Troponin T begins to increase in 3–4 h and remains elevated for 10–14 days	<i>Troponin I</i> : small infarct, myocardial injury <i>Troponin T</i> : acute MI, unstable angina, myocarditis	Not clinically significant
BNP (BRAIN NATRIURETIC PEPTIDE, OR B-TYPE NATRIURETIC PEPTIDE)	<100 pg/mL or <100 ng/L	A hormone produced by the ventricles of the heart; is a marker of ventricular systolic and diastolic dysfunction. This test is useful in diagnosing and guiding treatment of heart failure	Heart failure, symptomatic cardiac volume overload, paroxysmal atrial tachycardia	Not clinically significant
LIPOPROTEIN PROFILE				
Cholesterol	<i>Adults (desirable)</i> : <200 mg/dL	This test is an important screening test for heart disease	Type II familial hypercholesterolemia, biliary cirrhosis, chronic renal failure, poorly controlled diabetes mellitus, alcoholism, diet high in cholesterol and fats	Severe hepatocellular disease, hyperthyroidism, malnutrition, chronic anemias, severe burns
HDL-C (high-density lipoprotein cholesterol)	<i>Men</i> : 35–65 mg/dL <i>Women</i> : 35–80 mg/dL	A class of lipoproteins produced by the liver and intestines; the “good” cholesterol	HDL excess, chronic liver disease, long-term aerobic or vigorous exercise	Familial hypolipoproteinemia, familial hypertriglyceridemia, poorly controlled diabetes mellitus, chronic renal failure
LDL (low-density lipoprotein)	<i>Adults (desirable)</i> : <130 mg/dL	Up to 70% of the total serum cholesterol is present in LDL; the “bad” cholesterol	Type II familial hyperlipidemia. Secondary causes can include diet high in cholesterol and saturated fat, nephritic syndrome, multiple myeloma, diabetes mellitus, chronic renal failure	Hypolipoproteinemia, hyperthyroidism, chronic anemias, severe hepatocellular disease
Triglycerides	<i>Desirable</i> : <150 mg/dL	This test evaluates suspected atherosclerosis and measures the body’s ability to metabolize fat	Hyperlipoproteinemia, liver disease, renal disease, hypothyroidism, pancreatitis, myocardial infarction	Malnutrition, hyperthyroidism, brain infarction, chronic obstructive lung disease

Capillary blood specimens are commonly obtained from the lateral aspect or side of the finger in adults. This site avoids the nerve endings and calloused areas at the fingertip. The earlobe may be used if the client is in shock or the fingers are edematous. Some newer

monitors allow for obtaining specimens from less sensitive areas on the arms, legs, or abdomen (i.e., AST).

Skill 34-1 describes how to obtain a capillary blood specimen and measure blood glucose using a portable meter.

Obtaining a Capillary Blood Specimen to Measure Blood Glucose

PURPOSES

- To determine or monitor blood glucose levels of clients at risk for hyperglycemia or hypoglycemia
- To promote blood glucose regulation by the client
- To evaluate the effectiveness of insulin administration

ASSESSMENT

Before obtaining a capillary blood specimen, determine:

- The policies and procedures for the facility
- The frequency and type of testing
- The client's understanding of the procedure
- The client's response to previous testing.
- Assess the client's skin at the puncture site to determine if it is intact and the circulation is not compromised. Check color, warmth, and capillary refill.
- Review the client's record for medications that may prolong bleeding such as anticoagulants, or medical problems that may increase the bleeding response.
- Assess the client's self-care abilities that may affect accuracy of test results, such as visual impairment and finger dexterity.

PLANNING

DELEGATION

Check the applicable nurse practice act and the facility policy and procedure manual to determine who can perform this skill. It is usually considered an invasive technique and one that requires problem solving and application of knowledge. It is the responsibility of the nurse to know the results of the test, and supervise unlicensed assistive personnel (UAP) responsible for assisting the nurse.

Equipment

- Blood glucose meter (glucometer)
- Blood glucose reagent strip compatible with the meter
- 2 × 2 gauze
- Warm cloth or other warming device (optional)
- Antiseptic swab
- Clean gloves
- Sterile lancet (a sharp device to puncture the skin)
- Lancet injector (a spring-loaded mechanism that holds the lancet)

IMPLEMENTATION

Preparation

Review the type of meter and the manufacturer's instructions. Assemble the equipment at the bedside.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the equipment.
 - Some meters turn on when a test strip is inserted into the meter. 1
 - Calibrate the meter and run a control sample according to the manufacturer's instructions and/or confirm the code number. The newer no-code models do not require calibration. The technology is integrated into the test strips.
5. Select and prepare the vascular puncture site.
 - Choose a vascular puncture site (e.g., the side of an adult's finger). Avoid sites beside bone. Wrap the finger first in a warm cloth or hold a finger in a dependent (below heart level) position. If the earlobe is used, rub it gently with a small piece of gauze. **Rationale:** *These actions increase the blood flow to the area, ensure an adequate specimen, and reduce the need for a repeat puncture.*

- Clean the site with the antiseptic swab or soap and water and allow it to dry completely. **Rationale:** *Alcohol can affect accuracy, and the site stings when punctured if wet with alcohol.*

- 1 Insert the test strip into the meter.

Obtaining a Capillary Blood Specimen to Measure Blood Glucose—continued

2 Place the injector against the site.

6. Obtain the blood specimen.

- Apply gloves.
- Place the injector, if used, against the site, and release the needle, thus permitting it to pierce the skin. Make sure the lancet is perpendicular to the site. **Rationale:** *The lancet is designed to pierce the skin at a specific depth when it is in a perpendicular position relative to the skin.* 2
- or
- Prick the site with a lancet or needle, using a darting motion.
- Gently squeeze (but do not touch) the puncture site until a drop of blood forms. The size of the drop of blood can vary depending on the meter. Some meters require as little as 0.3 mL of blood to accurately test blood sugar.
- Hold the reagent strip under the puncture site until adequate blood covers the indicator square. The pad will absorb the blood and a chemical reaction will occur. Do not smear the blood. **Rationale:** *Smearing will cause an inaccurate reading.*
- Some meters wick the blood by just touching the puncture site with the strip. 3
- Ask the client to apply pressure to the skin puncture site with a 2×2 gauze. **Rationale:** *Pressure will assist hemostasis.*

7. Expose the blood to the test strip for the period and the manner specified by the manufacturer. As soon as the blood is placed on the test strip:

- Follow the manufacturer's recommendations on the glucose meter and monitor for the amount of time indicated by the manufacturer. **Rationale:** *The blood must remain in contact with the test strip for a prescribed time to obtain accurate results.*

Some glucometers have the test strip placed in the machine before the specimen is obtained.

8. Measure the blood glucose.

- Place the strip into the meter according to the manufacturer's instructions. Refer to the specific manufacturer's recommendations for the specific procedure.
- After the designated time, most glucose meters will display the glucose reading automatically. Correct timing ensures accurate results. 4

3 Apply the blood to the test strip.

4 Read the results.

- Turn off the meter and discard the test strip and 2×2 gauze in a biohazard container. Discard the lancet into a sharps container.
- Remove and discard gloves.
- Perform hand hygiene.

9. Document the method of testing and results on the client's record. If appropriate, record the client's understanding and ability to demonstrate the technique. The client's record may also include a flow sheet on which capillary blood glucose results and the amount, type, route, and time of insulin administration are recorded. Always check if a diabetic flow sheet is being used for the client.

10. Check for orders for sliding scale insulin based on capillary blood glucose results. Administer insulin as prescribed.

Obtaining a Capillary Blood Specimen to Measure Blood Glucose—continued

EVALUATION

- Compare glucose meter reading with normal blood glucose level, status of puncture site, and motivation of the client to perform the test independently.
- Relate blood glucose reading to previous readings and the client's current health status.
- Report abnormal results to the primary care provider. Some agencies may have a standing policy to obtain a venipuncture blood glucose if the capillary blood glucose exceeds a certain value.
- Conduct appropriate follow-up such as asking the client to explain the meaning of the results and/or demonstrating the procedure at the next scheduled test.
- Prepare the client for home glucose monitoring and review frequency, record keeping, and insulin administration if appropriate.

LIFESPAN CONSIDERATIONS Capillary Blood Glucose

INFANTS

- The outer aspect of the heel is the most common site for neonates and infants. Placing a warm cloth on the infant's heel often increases the blood flow to the area.

CHILDREN

- Use the side of a fingertip for a young client older than age 2, unless contraindicated.
- Allow the child to choose the puncture site, when possible.
- Praise the young client for cooperating and assure the child that the procedure is not a punishment.

OLDER ADULTS

- Older adults may have arthritic joint changes, poor vision, or hand tremors and may need assistance using the glucose meter or obtaining a meter that accommodates their limitations.
- Older adults may have difficulty obtaining diabetic supplies due to financial concerns or homebound status.
- Older adults often have poor circulation. Warming the hands by wrapping with a warm washcloth for 3 to 5 minutes or placing the hand dependent for a few moments may help in obtaining a blood sample.

Home Care Considerations Capillary Blood Glucose

PATIENT-CENTERED CARE

- Assess the client or caregiver's ability and willingness to perform blood glucose monitoring at home.
- Teach the proper use of the lancet and glucose monitor, and provide written guidelines. Allow time for a return demonstration. The client may need several visits to completely learn the procedure.
- Ensure the client's ability to obtain supplies and purchase reagent strips. The strips are relatively expensive and may not be covered by the client's insurance.
- Stress the importance of record keeping. Instruct the client on when to do glucose monitoring, how to record the blood glucose levels, and when to notify the primary care provider.
- Children with diabetes who need to perform finger-sticks should be taught about safe practices for cleaning blood from surfaces (household bleach is best) and about safe storage of equipment to prevent other children from gaining access to it. Identify a place in the school where the child can store glucose-monitoring equipment and perform the procedure in private.

SPECIMEN COLLECTION AND TESTING

The nurse contributes to the assessment of a client's health status by collecting specimens of body fluids. All hospitalized clients have at least one laboratory specimen collected during their stay at a health care facility. Laboratory examination of specimens such as urine, blood, stool, sputum, and wound drainage provides important adjunct information for diagnosing health care problems and also provides a measure of the responses to therapy.

Nurses often assume the responsibility for specimen collection. Depending on the type of specimen and skill required, the nurse may be able to delegate this task to UAP under the supervision of the nurse.

Nursing responsibilities associated with specimen collection include the following:

- Provide client comfort, privacy, and safety. Clients may experience embarrassment or discomfort when providing a specimen. The nurse should provide the client with as much privacy as possible and handle the specimen discreetly. The nurse needs to be nonjudgmental and sensitive to possible sociocultural beliefs that may affect the client's willingness to participate in the specimen collection procedure.
- Explain the purpose of the specimen collection and the procedure for obtaining the specimen. Clients may experience anxiety about the procedure, especially if it is perceived as being intrusive or if they fear an unknown test result. A clear explanation will facilitate the client's cooperation in the collection of the specimen. With proper instruction, many clients are able to collect their own specimen, which promotes independence and reduces or avoids embarrassment.
- Use the correct procedure for obtaining a specimen or ensure that the client or staff follows the correct procedure. Aseptic technique is used in specimen collection to prevent contamination that can cause inaccurate test results. A nursing procedure or laboratory manual is often available if the nurse is unfamiliar with the procedure. If there is any question about the procedure, the nurse calls the laboratory for directions before collecting the specimen.
- Note relevant information on the laboratory requisition slip, for example, medications the client is taking that may affect the results.

- Transport the specimen to the laboratory promptly. Fresh specimens provide more accurate results.
- Report abnormal laboratory findings to the health care provider in a timely manner consistent with the severity of the abnormal results.

Stool Specimens

Analysis of stool specimens can provide information about a client's health condition. Some of the reasons for testing feces include the following:

- To determine the presence of **occult** (hidden) **blood**. Bleeding can occur as a result of gastrointestinal ulcers, inflammatory disease, or tumors. The test for occult blood, often referred to as the **guaiac test**, can be readily performed by the nurse in the clinical area or by the client at home. Guaiac paper used in the test is sensitive to fecal blood content.
- To analyze for dietary products and digestive secretions. For example, an excessive amount of fat in the stool (**steatorrhea**) can indicate faulty absorption of fat from the small intestine. A decreased amount of bile can indicate obstruction of bile flow from the liver and gallbladder into the intestine. For these kinds of tests, the nurse needs to collect and send the total quantity of stool expelled at one time instead of a small sample.
- To detect the presence of ova and parasites. When collecting specimens for parasites, it is important that the sample be transported immediately to the laboratory while it is still warm. Usually three stool specimens, over a period of days, are evaluated to confirm the presence of and to identify the organism so that appropriate treatment can be ordered.
- To detect the presence of bacteria or viruses. Only a small amount of feces is required because the specimen will be cultured. Collection containers or tubes must be sterile and aseptic technique used during collection. Stools need to be sent immediately to the laboratory. The nurse needs to note on the laboratory requisition if the client is receiving any antibiotics.

COLLECTING STOOL SPECIMENS

The nurse is responsible for collecting stool specimens ordered for laboratory analysis. Before obtaining a specimen, the nurse needs to determine the reason for collecting the stool specimen and the correct method of obtaining and handling it (i.e., how much stool to obtain, whether a preservative needs to be added to the stool, and whether it needs to be sent immediately to the laboratory). It may be necessary to confirm this information by checking with the agency laboratory. In many situations only a single specimen is required; in others, timed specimens are necessary, and every stool passed is collected within a designated time period.

UAP may obtain and collect stool specimen(s) in certain situations, so the nurse needs to consider the collection process before delegating this task. For example, a random stool specimen collected in a specimen container may be delegated, but the nurse should do a stool culture requiring a sterile swab in a test tube. An incorrect collection technique can cause inaccurate test results.

The task of obtaining and testing a stool specimen for occult blood may be performed by UAP. It is important for the nurse to instruct the UAP to inform the nurse if blood is detected and/or whether the test is positive. In addition, the stool specimen should be saved to allow the nurse to repeat the test.

Nurses need to give clients the following instructions:

- Defecate in a clean bedpan or bedside commode.
- If possible, do not contaminate the specimen with urine or menstrual discharge. Void before the specimen collection.
- Do not place toilet tissue in the bedpan after defecation. Contents of the paper can affect the laboratory analysis.
- Notify the nurse as soon as possible after defecation, particularly for specimens that need to be sent to the laboratory immediately.

When obtaining stool samples—that is, when handling the client's bedpan, when transferring the stool sample to a specimen container, and when disposing of the bedpan contents—the nurse follows medical aseptic technique meticulously. Wear clean gloves to prevent hand contamination and take care not to contaminate the outside of the specimen container. Use one or two clean tongue blades to transfer the specimen to the container and then wrap them in a paper towel before disposing of them in the waste container. This practice reduces the chance of contact with other articles and the spread of microorganisms. The amount of stool to be sent depends on the purpose for which the specimen is collected. Usually about 2.5 cm (1 in.) of formed stool or 15 to 30 mL of liquid stool is adequate. For some timed specimens, however, the entire stool passed may need to be sent. Visible pus, mucus, or blood should be included in sample specimens. For a stool culture, the nurse dips a sterile swab into the specimen, preferably where purulent fecal matter is present and, using sterile technique, places the swab in a sterile test tube.

Ensure that the specimen label and the laboratory requisition have the correct information on them and are securely attached to the specimen container. Inappropriate identification of the specimen risks errors of diagnosis or therapy for the client.

Because fresh specimens provide the most accurate results, the nurse sends the specimen to the laboratory immediately. If this is not possible, the nurse follows the directions on the specimen container. In some instances, refrigeration is indicated because bacteriologic changes take place in stool specimens left at room temperature. To prevent contamination, never place a stool specimen in a refrigerator that contains food or medication.

Document all relevant information. Record the collection of the specimen on the client's chart and on the nursing care plan. Include in the recording the date and time of the collection and all nursing assessments (e.g., color, odor, consistency, and amount of feces); presence of abnormal constituents, such as blood or mucus; results of test for occult blood if obtained; discomfort during or after defecation; status of perianal skin; and any bleeding from the anus after defecation.

FECAL OCCULT BLOOD TESTING

Fecal occult blood testing (FOBT) is the most frequently performed fecal analysis. There are two types of FOBT: the traditional guaiac smear (Hemoccult) and the fecal immunochemical test (FIT).

A commonly used test product to measure occult blood is the Hemoccult test, which uses a chemical **reagent** (substance used in a chemical reaction to detect a specific substance). This reagent detects the presence of the enzyme peroxidase in the hemoglobin molecule. To perform the test, the nurse or client uses a tongue blade to place a small amount of stool on a slide or card and then closes the card. The card is turned over and two drops of a reagent are placed onto each smear on the back of the card. The nurse then observes for a color change (Figure 34-3 ■). A blue color indicates a guaiac-positive

A

B

Figure 34-3 ■ A, Opening the front cover of a Hemoccult slide and applying a thin smear of feces on the slide. B, Opening the flap on the back of the slide and applying two drops of developing fluid over each smear.

result, that is, the presence of occult blood. No color change or any color other than blue is a negative finding, indicating the absence of blood in the stool. Because the results are color based, a nurse who is color blind should not be responsible for reading the results.

Certain foods, medications, and vitamin C produce inaccurate test results. False-positive results can occur if the client has recently ingested (a) red meat (beef, lamb, liver, and processed meats); (b) raw vegetables or fruits, particularly radishes, turnips, horseradish, and melons; or (c) certain medications that irritate the gastric mucosa and cause bleeding, such as aspirin or other nonsteroidal anti-inflammatory drugs, steroids, iron preparations, and anticoagulants. False-negative results can occur if the client has taken more than 250 mg/day of vitamin C from all sources (dietary and supplemental) up to 3 days before the test—even if bleeding is present.

The newer method used for FOBT is the FIT, which has a higher sensitivity and specificity for the detection of cancer (Daly, 2012, p. 67). When comparing the two types of FOBT, the FIT has the following advantages: No dietary or medication restrictions, fewer false positives, and requires only two samples as opposed to the three required for the guaiac test. There are two different types of FITs: a liquid-based method that stores the stool sample in a liquid buffer and a dry-slide method, which stores the sample on a collection card. A new noninvasive test for colon cancer, called Cologuard, was recommended for approval to the Food and Drug Administration in March, 2014. It is a noninvasive stool DNA test for colorectal cancer screening. The DNA test measures human hemoglobin and certain cancer-specific mutations (NewsCAP, 2014).

Guidelines for instructing clients to collect their stool for occult blood are listed in Client Teaching.

CLIENT TEACHING

Collecting Stool for Occult Blood

USING THE HEMOCCULT TEST

- Avoid restricted foods, medications, and vitamin C for the period recommended by the manufacturer and during the test. Usually specified foods and vitamin C are restricted for 3 days before the test and specified medications for 7 days before the test.
- Use a ballpoint pen to label the specimens with your name, address, age, and date of specimen. Usually three specimens are collected from consecutive and different bowel movements. Each specimen must be dated accurately.
- Avoid collecting specimens during your menstrual period and for 3 days afterward, and while you have bleeding hemorrhoids or blood in your urine.
- Remove toilet bowl cleaners from the toilet bowl. Flush the toilet twice before proceeding with the test.
- Avoid contaminating the specimen with urine or toilet tissue. Empty your bladder before the test. To facilitate specimen collection, transfer the stool to a clean, dry container. Wear clean gloves.
- Use the tongue blade provided to transfer the specimen to the test folder or tape. Only a small amount of stool is required. Take the sample from the center of a formed stool to ensure a uniform sample.
- Wrap the tongue blade in a paper towel and dispose of it in the waste receptacle. Do not flush the stick.

- Follow the manufacturer's directions explicitly for the test product being used. Test products vary. For example, for the Hemoccult test, a thin layer of feces is smeared over the boxes inside the envelope, and a drop of developing solution is applied on the opposite side of the specimen paper. For the Hematest, a thin layer of feces is smeared onto guaiac filter paper, a tablet is placed in the middle of the specimen, and two or three drops of water are added to the tablet. If there is space for two specimens in the test folder, take the sample from two different areas of the stool specimen.
- Consult your health care provider if there is any problem understanding the instructions.
- Return completed specimens to your primary care provider or laboratory as instructed.

USING FITS

- The sampling procedure varies depending on the specific test. For the liquid FIT, a test strip inside the sampling tube is exposed to the stool sample and the resulting change in color indicates a positive or negative result (Daly, 2012, p. 68). For the dry-slide method, the sample is collected using a long-handled brush to stroke the surface of the stool while in the toilet bowl. The brush bristles are then dabbed on the test card. After the card is dried, the sample is sent to the laboratory for testing (Kessenich & Cronin, 2013, p. 7).

LIFESPAN CONSIDERATIONS Stool Specimen**INFANTS**

- To collect a stool specimen for an infant, the stool is scraped from the diaper, being careful not to contaminate the stool with urine.

CHILDREN

- A child who is toilet trained should be able to provide a fecal specimen, but may prefer being assisted by a parent.
- When explaining the procedure to the child, use words appropriate for the child's age rather than medical terms. Ask the parent what words the family normally uses to describe a bowel movement.

- A specimen for pinworms is collected by the parent early in the morning, after sleep and before the child has a bowel movement. Scotch tape is attached to a tongue blade and the sticky side is laid flat against the perineum and anus to pick up any eggs or small worms. The tongue blade is then examined under a microscope.

OLDER ADULTS

- Older adults may need assistance if serial stool specimens are required.

Home Care Considerations Stool Specimen**PATIENT-CENTERED CARE**

- Ask the client or caregiver to call when the stool specimen is obtained. If a laboratory test is needed, the home health nurse can pick up the specimen or a family member may take it to the laboratory.
- Place the stool specimen inside a plastic biohazard bag. Carry the bag in a sealed container marked "Biohazard" and take it to the laboratory promptly. Do not expose the specimen to extreme temperatures in the car.

Evidence-Based Practice Is There an Effective Strategy to Improve the Use of Colorectal Cancer Screening Among Medically Underserved Populations?**EVIDENCE-BASED PRACTICE**

Colorectal cancer is the second leading cause of cancer death in the United States, and screening can greatly reduce its morbidity and mortality rates. Jean-Jacques et al. (2012) state that "despite improvements in the rate of colorectal cancer screening, marked disparities persist, with lower rates of colorectal cancer screening among racial and ethnic minorities, individuals with lower income or lower educational attainment, the uninsured, and individuals who were not born in the United States" (pp. 412–413). Earlier studies have shown that the direct mailing of FOBT kits to clients who are due for colorectal cancer screening has been both clinically effective and cost effective. Most of those studies, however, did not include clients with lower socioeconomic status or from racial or ethnic minority groups. Thus this group of researchers sought to examine the effects of direct mailing of FOBT kits to clients who were overdue for colorectal cancer screening and were receiving care at a community health center that served a low-income population with a high percentage of immigrants and refugees.

This randomized controlled trial consisted of 202 eligible participants; that is, they were between 50 and 80 years old, had at least two visits to the study site, and were due for colorectal cancer screening. The participants were randomly assigned to one of two groups: 98 to the usual care group and 104 to the outreach intervention. The participants in the usual care group were referred for colorectal cancer screening per the usual health center protocol. The outreach intervention participants were sent a mailing that

included a letter notifying them that it was time for the colorectal cancer screening and encouraging them to use the enclosed FOBT, instructions for using the FOBT, and a colorectal cancer fact sheet. All were instructed to return the completed FOBT kit to the health center laboratory in person or to use the postage-paid envelope. The study included additional telephone outreach every 2 weeks to participants who had not responded.

The outcome measure was the percentage of participants who completed the FOBT within 4 months after the start of the outreach protocol. Thirty percent of the participants (31 of 104) of the outreach intervention and 5% of the participants (5 of 98) of the usual care group completed colorectal cancer screening. This study demonstrated that the outreach strategy improves colorectal cancer screening rates among economically disadvantaged clients from a wide range of racial, ethnic, and cultural backgrounds.

IMPLICATIONS

The results show that the outreach strategy of direct mailing of FOBT kits to clients is a positive approach to improving colorectal cancer screening for clients in underserved communities. The authors made the important point that this strategy overcomes barriers to colorectal screening because the clients did not have to miss work in order to complete the screening at a clinic, did not have to worry about obtaining transportation to a clinic, and did not need to take time away from family obligations.

Urine Specimens

The nurse is responsible for collecting urine specimens for a number of tests: **clean voided urine specimens** for routine urinalysis, **clean-catch** or **midstream urine specimens** for urine culture, and timed urine specimens for a variety of tests that depend on the client's specific health problem. Urine specimen collection may require collection via straight catheter insertion. If this is necessary, refer to Chapter 48 ∞, Skill 48–2.

CLEAN VOIDED URINE SPECIMEN

A clean voided specimen is usually adequate for routine examination. Many clients are able to collect a clean voided specimen and provide the specimen independently with minimal instructions. Male clients generally are able to void directly into the specimen container, and female clients usually sit or squat over the toilet, holding the container between their legs during voiding. Routine urine examination is usually done on the first voided specimen in the morning because

it tends to have a higher, more uniform concentration and a more acidic pH than specimens later in the day.

At least 10 mL of urine is generally sufficient for a routine urinalysis. Clients who are seriously ill, physically incapacitated, or disoriented may need to use a bedpan or urinal in bed; others may require supervision or assistance in the bathroom. Whatever the situation, clear and specific directions are required:

- The specimen must be free of fecal contamination, so urine must be kept separate from feces.
- Female clients should discard the toilet tissue in the toilet or in a waste bag rather than in the bedpan because tissue in the specimen makes laboratory analysis more difficult.
- Put the lid tightly on the container to prevent spillage of the urine and contamination of other objects.
- If the outside of the container has been contaminated by urine, clean it with a disinfectant.

The nurse must (a) make sure that the specimen label and the laboratory requisition carry the correct information and (b) attach them securely to the specimen. Inappropriate identification of the specimen can lead to errors of diagnosis or therapy for the client.

UAP may be assigned to collect a routine urine specimen. Provide the UAP with clear directions on how to instruct the client to collect his or her own urine specimen or how to correctly collect the specimen for the client who may need to use a bedpan or urinal.

CLINICAL ALERT!

Kidney function directly relates to cardiac output. Therefore, any health problem that changes cardiac output may affect urine output.

CLEAN-CATCH OR MIDSTREAM URINE SPECIMEN

Clean-catch or midstream voided specimens are collected when a urine culture is ordered to identify microorganisms causing a urinary

Figure 34-4 ■ Disposable clean-catch specimen equipment.

tract infection. Although some contamination by skin bacteria may occur with a clean-catch specimen, the risk of introducing microorganisms into the urinary tract through catheterization is more significant. Care is taken to ensure that the specimen is as free as possible from contamination by microorganisms around the urinary meatus. Clean-catch specimens are collected in a sterile specimen container with a lid (Figure 34-4 ■). Disposable clean-catch kits are available. Skill 34-2 explains how to collect a clean-catch urine specimen for culture.

Collecting a Urine Specimen for Culture and Sensitivity by Clean Catch

PURPOSE

- To determine the presence of microorganisms, the type of organism(s), and the antibiotics to which the organisms are sensitive

ASSESSMENT

- Determine the ability of the client to provide the specimen.
- Assess the color, odor, and consistency of the urine and the presence of clinical signs of urinary tract infection (e.g., frequency, urgency, dysuria, hematuria, flank pain, cloudy urine with foul odor).

PLANNING

DELEGATION

UAP may perform the collection of a clean-catch or midstream urine specimen. It is important, however, for the nurse to inform the UAP about how to instruct the client in the correct process for obtaining the specimen. Proper cleansing of the urethra should be emphasized to avoid contaminating the urine specimen.

Equipment

Equipment used varies from agency to agency. Some agencies use commercially prepared disposable clean-catch kits. Others use

agency-prepared sterile trays. Both prepared trays and kits generally contain the following items:

- Clean gloves
 - Antiseptic towelettes
 - Sterile specimen container
 - Specimen identification label.
- In addition the nurse needs to obtain the following:
- Completed laboratory requisition form
 - Urine receptacle, if the client is not ambulatory
 - Basin of warm water, soap, washcloth, and towel for the nonambulatory client.

Collecting a Urine Specimen for Culture and Sensitivity by Clean Catch—continued

IMPLEMENTATION

Preparation

Gather the necessary equipment needed for the collection of the specimen. Use visual aids, if available, to assist the client to understand the midstream collection technique.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client that a urine specimen is required, give the reason, and explain the method to be used to collect it. Discuss how the results will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. For an ambulatory client who is able to follow directions, instruct the client on how to collect the specimen.
 - Direct or assist the client to the bathroom.
 - Ask the client to wash and dry the genitals and perineal area with soap and water. **Rationale:** *Washing the perineal area reduces the number of skin and transient bacteria, decreasing the risk of contaminating the urine specimen.*
 - Ask the client if he or she is sensitive to any antiseptic or cleansing agent. **Rationale:** *This will avoid unnecessary irritation of the genitals or perineum.*
 - Instruct the client on how to clean the urinary meatus with antiseptic towelettes. **Rationale:** *The antiseptic further reduces bacterial contamination of the urinary meatus and the risk of contaminating the specimen.*

For Female Clients

- Use each towelette only once. Clean the perineal area from front to back and discard the towelette. ① Use all towelettes provided (usually two or three). **Rationale:** *Cleaning from front to back cleans the area of least contamination to the area of greatest contamination.*

For Male Clients

- If uncircumcised, retract the foreskin slightly to expose the urinary meatus.
- Using a circular motion, clean the urinary meatus and the distal portion of the penis. ② Use each towelette only once, then discard. Clean several inches down the shaft of the penis. **Rationale:** *This cleans from the area of least contamination to the area of greatest contamination.*

- ① Cleansing the female urinary meatus. Spread the labia minora with one hand and with the other hand, cleanse the perineal area from front to back.

- ② Cleansing the male urinary meatus. Retract the foreskin if needed. Using a towelette, cleanse the urinary meatus by moving in a circular motion from the center of the urethral opening around the glans and down the distal portion of the shaft of the penis.
5. For a client who requires assistance, prepare the client and equipment.
 - Apply clean gloves.
 - Wash the perineal area with soap and water, rinse, and dry.
 - Assist the client onto a clean commode or bedpan. If using a bedpan or urinal, position the client as upright as allowed or tolerated. **Rationale:** *Assuming a normal anatomic position for voiding facilitates urination.*
 - Remove and discard gloves.
 - Perform hand hygiene.
 - Open the clean-catch kit, taking care not to contaminate the inside of the specimen container or lid. **Rationale:** *It is important to maintain sterility of the specimen container to prevent contamination of the specimen.*
 - Apply clean gloves.
 - Clean the urinary meatus and perineal area as described in step 4.
6. Collect the specimen from a nonambulatory client or instruct an ambulatory client on how to collect it.
 - Instruct the client to start voiding. **Rationale:** *Bacteria in the distal urethra and at the urinary meatus are cleared by the first few milliliters of urine expelled.*
 - Place the specimen container into the midstream of urine and collect the specimen, taking care not to touch the container to the perineum or penis. **Rationale:** *It is important to avoid contaminating the interior of the specimen container and the specimen itself.*
 - Collect urine in the container.
 - Cap the container tightly, touching only the outside of the container and the cap. **Rationale:** *This prevents contamination or spilling of the specimen.*
 - If necessary, clean the outside of the specimen container with disinfectant. **Rationale:** *This prevents transfer of microorganisms to others.*
 - Remove and discard gloves.
 - Perform hand hygiene.
7. Label the specimen and transport it to the laboratory.
 - Ensure that the specimen label is attached to the specimen cup, not the lid, and that the laboratory requisition provides the correct information. Place the specimen in a plastic bag that has a biohazard label on it. Attach the requisition securely to the bag. **Rationale:** *Inaccurate identification or information on the specimen container risks errors in diagnosis or therapy.*
 - Arrange for the specimen to be sent to the laboratory immediately. **Rationale:** *Bacterial cultures must be started immediately before any contaminating organisms can grow, multiply, and produce false results.*

Collecting a Urine Specimen for Culture and Sensitivity by Clean Catch—continued

8. Document pertinent data.

- Record collection of the specimen, any pertinent observations of the urine such as color, odor, or consistency, and any difficulty in voiding that the client experienced.
- Indicate on the laboratory slip if the client is taking any current antibiotic therapy or if the client is menstruating.

SAMPLE DOCUMENTATION

6/15/15 0800 Informed of MD order for clean-catch urine for C&S. Instructed how to perform. Stated she understood. Urine specimen cloudy. States she continues to have burning on urination. Urine specimen sent to laboratory. Antibiotic started per MD orders.
—T. Sanchez, RN

EVALUATION

- Report laboratory results to the primary care provider.
- Discuss findings of the laboratory test with primary care provider.
- Conduct appropriate follow-up nursing interventions as needed, such as administering ordered medications and client teaching.

LIFESPAN CONSIDERATIONS Urine Specimen

INFANTS

- Clean the perineal area and the urethral opening as you would with an adult client. Apply a specimen bag that has an adhesive backing that attaches to the skin. After the infant has voided the desired amount, gently remove the bag from the skin.

CHILDREN

- When collecting a routine urine specimen, explain the procedure in simple nonmedical terms appropriate to the child and ask the child to void using a clean collecting receptacle (e.g., specimen cup, potty chair, bedpan, toilet collection device).
- Give the child a clean specimen container to play with.

- Allow a parent to assist the child, if possible. The child may feel more comfortable with a parent present.
- For sterile urine specimens, straight catheterization may be necessary, in which a urinary catheter is inserted using sterile technique, the specimen is obtained, and the catheter is removed.

OLDER ADULTS

- For a clean-catch urine specimen, older adults may have difficulty controlling the stream of urine.
- Older women with arthritis may have difficulty holding the labia apart during the collection of clean-catch urine.

Home Care Considerations Urine Specimen

PATIENT-CENTERED CARE

- Assess the client's ability and willingness to collect a timed urine specimen. If poor eyesight or hand tremors are a problem, suggest using a clean funnel to pour the urine into the container.
- Always wash hands well with warm, soapy water before and after collecting urine samples.
- Always wear gloves if handling another person's urine.
- The home should have a refrigerator or other method for cooling the urine samples. Tell the client to keep the specimen container in plastic in the refrigerator, separate from other refrigerator contents. The client may also use a cooler with ice.

TIMED URINE SPECIMEN

Some urine examinations require collection of all urine produced and voided over a specific period of time, ranging from 1 to 2 hours to 24 hours. Timed specimens generally either are refrigerated or contain a preservative to prevent bacterial growth or decomposition of urine components. Each voiding of urine is collected in a small, clean container and then emptied immediately into the large refrigerated bottle or carton.

Timed urine specimens tests are performed for the following purposes:

- To assess the ability of the kidney to concentrate and dilute urine.
- To determine disorders of glucose metabolism, for example, diabetes mellitus.
- To determine levels of specific constituents, for example, albumin, amylase, creatinine, urobilinogen, or certain hormones (e.g., estriol or corticosteroids), in the urine.

To collect a timed urine specimen, follow these steps:

- Obtain a specimen container with preservative (if indicated) from the laboratory. Label the container with identifying information

for the client, the test to be performed, time started, and time of completion.

- Provide a clean receptacle to collect urine (bedpan, commode, or toilet collection device).
- Post signs in the client's chart or electronic medical record, Kardex, room, and bathroom alerting personnel to save all urine during the specified time.
- At the start of the collection period, have the client void and discard this urine.
- Save all urine produced during the timed collection period in the container, refrigerating or placing the container on ice as indicated. Avoid contaminating the urine with toilet paper or feces.
- At the end of the collection period, instruct the client to completely empty the bladder and save this voiding as part of the specimen. Take the entire amount of urine collected to the laboratory with the completed requisition.
- Record collection of the specimen, time started and completed, and any pertinent observations of the urine on appropriate records.

CLINICAL ALERT!

If the client or staff forgets and discards the client's urine during a timed collection, the procedure must be restarted from the beginning.

INDWELLING CATHETER SPECIMEN

Sterile urine specimens can be obtained from closed drainage systems by inserting a sterile needle attached to a syringe through a drainage port in the tubing. Aspiration of urine from catheters can be done only with self-sealing rubber catheters—not plastic, silicone, or Silastic catheters. When self-sealing rubber catheters are used, the needle is inserted just above the location where the catheter is attached to the drainage tubing. The area from which to obtain urine may be marked by a patch on the catheter.

Closed drainage urinary systems now have needleless ports, which means that needles are not needed to obtain a sample. This protects the nurse from a needlestick injury and maintains the integrity and sterility of the catheter system by eliminating the need to puncture the tubing. The needleless port accepts a Luer-Lok syringe (Figure 34–5 ■). Position the syringe perpendicular to the center of the port and insert, twist, and lock into the port. When the specimen is obtained and the syringe removed, the port seals itself.

To collect a specimen from a Foley (retention) catheter or a drainage tube, follow these steps:

- Apply clean gloves.
- If there is no urine in the catheter, clamp the drainage tubing at least 8 cm (3 in.) below the sampling port for about 30 minutes. This allows fresh urine to collect in the catheter.
- Wipe the area where the needle or Luer-Lok syringe will be inserted with a disinfectant swab. The site should be distal to the tube leading to the balloon to avoid puncturing this tube. Disinfecting the needle insertion site removes any microorganisms on the surface of the catheter, thereby avoiding contamination of the needle and the entrance of microorganisms into the catheter.
- Insert the needle at a 30- to 45-degree angle. This angle of entrance facilitates self-sealing of the rubber. Insert the Luer-Lok syringe at a 90-degree angle for the needleless port.
- Unclamp the catheter.
- Withdraw the required amount of urine, for example, 3 mL for a urine culture or 30 mL for a routine urinalysis.

Figure 34–5 ■ Obtaining a urine specimen from a retention catheter using a needleless port.

- Transfer the urine to the specimen container. If a sterile culture tube is used, make sure the needle or syringe (depending on the system) does not touch the outside of the container.
- Discard the syringe and needle or syringe (depending on the system) in an appropriate sharps container.
- Cap the container.
- Remove gloves and discard.
- Perform hand hygiene.
- Label the container, and send the urine to the laboratory immediately for analysis or refrigeration.
- Record collection of the specimen and any pertinent observations of the urine on the appropriate records.

URINE TESTING

Several simple urine tests are often done by nurses on the nursing units. These include tests for specific gravity, pH, and the presence of abnormal constituents such as glucose, ketones, protein, and occult blood.

Nurses in a health care facility or clients in the home setting can use commercially prepared kits to test for abnormal constituents in the urine. These kits contain the required equipment and an appropriate reagent, which may be in the form of a tablet, fluid, or paper test strip or dipstick. When the urine contacts the reagent, a chemical reaction occurs, causing a color change that is then compared with a chart to interpret the significance of the color (Figure 34–6 ■). Specific directions for the amount of urine needed, the time required for the chemical reaction, and the meaning of the colors produced vary among manufacturers. Thus it is essential that nurses and clients read and follow directions supplied by each manufacturer. In addition, testing materials need to be checked to ascertain that they are not outdated.

Urine testing may be performed by UAP. It is important for the UAP to understand the specific specimen collection procedure and report the results of the test to the nurse. Inform the UAP to save the urine sample to allow the nurse to repeat the test if necessary.

SPECIFIC GRAVITY Specific gravity is an indicator of urine concentration, or the amount of solutes (metabolic wastes and electrolytes) present in the urine. The specific gravity of distilled water is 1.00; the specific gravity of urine normally ranges from 1.010 to 1.025. As urine becomes more concentrated, its specific

Figure 34–6 ■ After dipping the reagent strip (dipstick) into fresh urine, wait the stated time period and compare the results to the color chart.

gravity increases. Excess fluid intake or diseases affecting the ability of the kidneys to concentrate urine can result in low specific gravity readings. A high specific gravity may indicate fluid deficit or dehydration, or excess solutes such as glucose in the urine. Specific gravity can be measured with the use of a multiple-test dipstick that has a separate reagent area for specific gravity.

URINARY pH Urinary pH is measured to determine the relative acidity or alkalinity of urine and assess the client's acid–base status. Quantitative measurements of urine pH can be performed in the laboratory, but dipsticks or litmus paper often are used on nursing units or in clinics to obtain less precise pH measurements. Urine normally is slightly acidic, with an average pH of 6 (7 is neutral, less than 7 is acidic, greater than 7 is alkaline). Because the kidneys play a critical role in regulating acid–base balance, assessment of urine pH can be useful in determining whether the kidneys are responding appropriately to acid–base imbalances. In metabolic acidosis, urine pH should decrease as the kidneys excrete hydrogen ions; in metabolic alkalosis, the pH should increase (see Chapter 52 ∞).

GLUCOSE Urine is tested for glucose to screen clients for diabetes mellitus and to assess clients during pregnancy for abnormal glucose tolerance. Normally, the amount of glucose in the urine is negligible, although individuals who have ingested large amounts of sugar may show small amounts of glucose in their urine.

Testing urine for glucose is *not* a measure of current blood glucose level and is considered an inadequate measurement. The American Diabetes Association (ADA) (n.d.) states that testing urine for glucose is *only* for people who *cannot or will not* test their blood glucose levels. It is important for clients to understand that urine testing is considered an inadequate measurement of blood glucose.

KETONES Ketone bodies, a product of the breakdown of fatty acids, normally are not present in the urine. They may, however, be found in the urine of clients with poorly controlled diabetes. Urine testing for ketone level is advised for type 1 diabetics who are at home and not feeling well, who are running a fever, or who have blood glucose consistently over 300 mg/dL (ADA, n.d.). Urine ketone testing with reagent tablets or a dipstick is also used to evaluate ketoacidosis in clients with alcoholism or those who are fasting, starving, or consuming high-protein diets.

PROTEIN Protein molecules normally are too large to escape from glomerular capillaries into the filtrate. If the glomerular membrane has been damaged, however (e.g., because of an inflammatory process such as glomerulonephritis), it can become “leaky,” allowing proteins to escape. Urine testing for the presence of protein generally is done with a reagent strip (commonly referred to as a *dipstick*).

OCCULT BLOOD Normal urine is free from blood. When blood is present, it may be clearly visible or not visible (occult). Commercial reagent strips are used to test for occult blood in the urine.

CLINICAL ALERT!

Blood in urine is indicative of damage to the kidney or urinary tract.

OSMOLALITY Urine **osmolality** is a measure of the solute concentration of urine that is a more exact measurement of urine concentration than specific gravity. It is also used to monitor fluid

and electrolyte balance. The particles included are nitrogenous wastes, such as creatinine, urea, and uric acid. Normal values are 50 to 1,200 mOsm/kg. The average urine osmolality is 200 to 800 mOsm/kg. An increased urine osmolality indicates a fluid volume deficit; a decreased urine osmolality reflects fluid volume excess. This test is sent to the laboratory rather than being tested at the bedside like the previous tests.

Sputum Specimens

Sputum is the mucous secretion from the lungs, bronchi, and trachea. It is important to differentiate it from **saliva**, the clear liquid secreted by the salivary glands in the mouth, sometimes referred to as “spit.” Healthy individuals do not produce sputum. Clients need to cough to bring sputum up from the lungs, bronchi, and trachea into the mouth in order to expectorate it into a collecting container.

A UAP can obtain a sputum specimen that is expectorated by a client. It is important to instruct the UAP on when to collect the specimen, how to position the client, and how to correctly collect the specimen. Obtaining a sputum specimen by use of pharyngeal suctioning, however, should be performed by the nurse because it is an invasive process requiring aseptic technique and knowledge application and problem solving. A “sputum trap” is used when the specimen is obtained by suctioning. (See Chapter 50 ∞, Skill 50–2.)

Sputum specimens are usually collected for one or more of the following reasons:

- For culture and sensitivity to identify a specific microorganism and its drug sensitivities.
- For cytology to identify the origin, structure, function, and pathology of cells. Specimens for cytology often require serial collection of three early-morning specimens and are tested to identify cancer in the lung and its specific cell type.
- For acid-fast bacillus (AFB), which also requires serial collection, often for 3 consecutive days, to identify the presence of tuberculosis (TB). Some agencies use a special glass container when the presence of AFB is suspected.
- To assess the effectiveness of therapy.

Sputum specimens are often collected in the morning. Upon awakening, the client can cough up the secretions that have accumulated during the night. Sometimes specimens are collected during postural drainage, when the client can usually produce sputum. When a client cannot cough, the nurse must sometimes use pharyngeal suctioning to obtain a specimen.

To collect a sputum specimen, the nurse follows these steps:

- Offer mouth care so that the specimen will not be contaminated with microorganisms from the mouth.
- Ask the client to breathe deeply and then cough up 1 to 2 teaspoons (4 to 10 mL) of sputum.
- Wear gloves and personal protective equipment to avoid direct contact with the sputum. Follow special precautions if tuberculosis is suspected. Obtain the specimen in a room equipped with a special airflow system or ultraviolet light, or outdoors. If these options are not available, wear a mask capable of filtering droplet nuclei.
- Ask the client to **expectorate** (cough up) the sputum into the specimen container. Make sure the sputum does not contact the outside of the container (Figure 34–7 ■). If the outside of the container does become contaminated, wash it with a disinfectant.

Figure 34-7 ■ Sputum specimen container.

- Following sputum collection, offer mouthwash to remove any unpleasant taste.
- Label and transport the specimen to the laboratory. Ensure that the specimen label and the laboratory requisition contain the correct information. Arrange for the specimen to be sent to the laboratory immediately or refrigerated. Bacterial cultures must be started immediately before any contaminating organisms can grow, multiply, and produce false results.
- Document the collection of the sputum specimen on the client's chart. Include the amount, color, consistency (thick, tenacious, watery), presence of **hemoptysis** (blood in the sputum), odor of the sputum, any measures needed to obtain the specimen (e.g., postural drainage), and any discomfort experienced by the client.

Throat Culture

A throat culture sample is collected from the mucosa of the oropharynx and tonsillar regions using a culture swab. The sample is then cultured and examined for the presence of disease-producing microorganisms. Obtaining a throat culture is an invasive procedure that requires the application of scientific knowledge and potential problem solving to ensure client safety. Thus it is best for the nurse to perform this procedure.

Figure 34-8 ■ Depressing the tongue to view the pharynx.

To obtain a throat culture specimen, the nurse applies clean gloves, then inserts the swab into the oropharynx and runs the swab along the tonsils and areas on the pharynx that are reddened or contain exudate. The gag reflex, active in some clients, may be decreased by having the client sit upright if health permits, open the mouth, extend the tongue, and say “ah,” and by taking the specimen quickly. The sitting position and extension of the tongue help expose the pharynx; saying “ah” relaxes the throat muscles and helps minimize contraction of the constrictor muscle of the pharynx (the gag reflex). If the posterior pharynx cannot be seen, use a light and depress the tongue with a tongue blade (Figure 34-8 ■).

VISUALIZATION PROCEDURES

Visualization procedures include *indirect visualization* (noninvasive) and *direct visualization* (invasive) techniques for visualizing body organ and system functions.

Clients with Gastrointestinal Alterations

Direct visualization techniques include **anoscopy**, the viewing of the anal canal; **proctoscopy**, the viewing of the rectum; **proctosigmoidoscopy**, the viewing of the rectum and sigmoid

LIFESPAN CONSIDERATIONS Sputum and Throat Specimens

INFANTS

- When taking a throat swab, avoid occluding an infant's nose because infants normally breathe only through the nose.

CHILDREN

- Have a parent stand the young child between the parent's legs with the child's back to the parent and the parent's arms gently but firmly around the child. As the parent tips the child's head back, ask the child to open wide and stick the tongue out.

Assure the child that the procedure will be over quickly and may “tickle” but should not hurt.

OLDER ADULTS

- Older adults may need encouragement to cough because a decreased cough reflex occurs with aging.
- Allow time for older adults to rest and recover between coughs when obtaining a sputum specimen.

Home Care Considerations Specimen Collection

PATIENT-CENTERED CARE

- If specimen collection is done on an outpatient basis or in the home, the nurse teaches the client how to obtain the specimens. Provide written instructions and specimen containers to ensure correct and safe performance of the procedure.
- Ensure that the laboratory knows where to send the test results.

Figure 34–9 ■ Enhanced color x-ray of the colon during a barium enema exam.

CNRI/Science Photo Library; Photo Researchers, Inc.

colon; and **colonoscopy**, the viewing of the large intestine. Indirect visualization of the gastrointestinal tract is achieved by roentgenography. X-rays of the gastrointestinal tract can detect strictures, obstructions, tumors, ulcers, inflammatory disease, or other structural changes such as hiatal hernias. Visualization of the tract is enhanced by the introduction of a radiopaque substance such as barium. For examination of the upper gastrointestinal tract or small bowel, the client drinks the barium sulfate. This examination is often referred to as a *barium swallow*. For examination of the lower gastrointestinal tract, the client is given an enema containing the barium. This examination is commonly referred to as a *barium enema*. These x-rays usually include fluoroscopic examination; that is, projection of the x-ray films onto a screen, which permits continuous observation of the flow of barium (Figure 34–9 ■). Nurses are responsible for preparing clients before these studies and for follow-up care.

Clients with Urinary Alterations

Visualization procedures also may be used to evaluate urinary function. An x-ray of the **kidneys/ureters/bladder** is commonly referred to as a **KUB**. **Intravenous pyelography (IVP)** and **retrograde pyelography** are also radiographic studies used to evaluate the urinary tract. In an IVP, contrast medium is injected intravenously; during retrograde pyelography, the contrast medium is instilled directly into the kidney pelvis via the urethra, bladder, and ureters. Following injection or instillation of the contrast medium, x-rays are taken to evaluate urinary tract structures. Renal **ultrasonography** is a noninvasive test that uses reflected sound waves to visualize the kidneys. During a **cystoscopy**, the bladder, ureteral orifices, and urethra can be directly visualized using a **cystoscope**, a lighted instrument inserted through the urethra. Nurses are responsible for preparing clients before these studies and for follow-up care.

Clients with Cardiopulmonary Alterations

A number of visualization procedures can be done to examine the cardiovascular system and respiratory tract.

Electrocardiography provides a graphic recording of the heart's electrical activity. Electrodes placed on the skin transmit the

electrical impulses to an oscilloscope or graphic recorder. With the wave forms recorded, the **electrocardiogram (ECG)** can then be examined to detect dysrhythmias and alterations in conduction indicative of myocardial damage, enlargement of the heart, or drug effects.

Stress electrocardiography uses ECGs to assess the client's response to an increased cardiac workload during exercise. As the body's demand for oxygen increases with exercising, the cardiac workload increases, as does the oxygen demand of the heart muscle itself. Clients with coronary artery disease may develop chest pain and characteristic ECG changes during exercise.

Angiography is an invasive procedure requiring informed consent of the client. A radiopaque dye is injected into the vessels to be examined. Using fluoroscopy and x-rays, the flow through the vessels is assessed and areas of narrowing or blockage can be observed. Coronary angiography is performed to evaluate the extent of coronary artery disease; pulmonary angiography may be performed to assess the pulmonary vascular system, particularly if pulmonary emboli are suspected. Other vessels that may be studied include the carotid and cerebral arteries, the renal arteries, and the vessels of the lower extremities.

An **echocardiogram** is a noninvasive test that uses ultrasound to visualize structures of the heart and evaluate left ventricular function. Images are produced as ultrasound waves are reflected back to a transducer after striking cardiac structures. The nurse should tell the client that this test causes no discomfort, although the conductive gel used may be cold.

X-ray examination of the chest is done both to diagnose disease and to assess the progress of a disease. For an x-ray examination, the nurse needs to inform the client that jewelry and clothing from the waist up must be removed.

A **lung scan**, also known as a V/Q (ventilation/perfusion) scan, records the emissions from radioisotopes that indicate how well gas and blood are traveling through the lungs. The *perfusion scan* (Q scan—P usually stands for “pulmonary,” so apparently the next letter in the alphabet was used for “perfusion”) is used to assess blood flow through the pulmonary vascular system. For this, the radioisotope is injected intravenously and measured as it circulates through the lung. The *ventilation scan* (V scan) detects ventilation abnormalities, particularly in clients with emphysema. For this scan, the client inhales a radioactive gas through a mask and then exhales it into room air. The client needs to be informed that no radiation precautions are necessary because the amount of radioactivity is very small. The scan may take 20 to 40 minutes. Laryngoscopy and bronchoscopy are sterile procedures that are conducted with a laryngoscope and bronchoscope, respectively. Tissue samples may also be taken for biopsy. A local anesthetic is usually given before the examination. A local anesthetic is sprayed on the client's pharynx to prevent gagging; alternatively, the client gargles with an anesthetic to anesthetize the throat. The bronchoscope is then inserted to visualize the larynx or bronchi (Figure 34–10 ■). Informed consent is required for these procedures.

Computed Tomography

Computed tomography (CT), also called *CT scanning*, *computerized tomography*, or *computerized axial tomography (CAT)*, is a painless, noninvasive x-ray procedure that has the unique capability of distinguishing minor differences in the density of tissues. The CT produces a three-dimensional image of the organ or structure, making it more sensitive than the x-ray machine.

Figure 34-10 ■ Bronchoscopy.

From *Medical Terminology: A Living Language*, 5th ed. (p. 239), by B. Fremgen and S. Frucht, 2013. Reprinted and electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) is a noninvasive diagnostic scanning technique in which the client is placed in a magnetic field. Clients with implanted metal devices (e.g., pacemaker, metal hip prosthesis) cannot undergo an MRI because of the strong magnetic field. There is no exposure to radiation. If a contrast media is injected during the procedure, it is not an iodine contrast. Another advantage to the MRI is that it provides a better contrast between normal and abnormal tissue than the CT scan. It is, however, more costly.

All removable metallic objects (e.g., rings, watches, cell phones, body jewelry) should be removed before entering the area of the magnet. Body jewelry made of titanium, niobium, or surgical stainless steel, however, will not be attracted to the magnet. Assess for body tattoos, especially red in color, because they may get warm during an MRI (Kee, 2013, p. 507). Recent reports have shown that in a very few instances, people with tattoos or permanent cosmetics have experienced edema or burning in the tattoo during an MRI.

Transdermal patches containing a foil backing may cause burning or injury. It is important to ask clients if they are using a transdermal patch so it can be removed before undergoing an MRI. Because the patch may lose its adhesiveness, advise the client to apply a new patch after the MRI.

SAFETY ALERT!

SAFETY

Advise clients to inform the MRI operator if they have a tattoo or permanent makeup and to let the operator know of any unusual sensations felt at the site of the tattoo during the MRI.

The MRI is commonly used for visualization of the brain, spine, limbs and joints, heart, blood vessels, abdomen, and pelvis. The procedure involves the client lying on a platform that moves into either a narrow, closed, high-magnet scanner, or into an open, low-magnet scanner. The client must lie very still. A two-way communication system is used to monitor the client's response and to help relieve feelings of claustrophobia. Earplugs are offered to the client to reduce the discomfort from the loud noises that occur during the test. The procedure lasts between 60 and 90 minutes (Figure 34-11 ■).

Nuclear Imaging Studies

Nuclear imaging studies involve the therapeutic use of radioactive isotopes for diagnostic purposes. A **radiopharmaceutical**,

Figure 34-11 ■ MRI laboratory.
Will and Deni McIntyre/Photo Researchers, Inc.

Figure 34-12 ■ PET scan comparing the metabolic activity levels of the brain of an individual with Alzheimer’s disease and a normal brain. Red and yellow colors indicate high activity levels; blue colors represent low activity levels.
Dr. Robert Friedland/Science Source/Photo Researchers.

a pharmaceutical (targeted to a specific organ) with an embedded radioisotope, is administered through various routes for the test. The distribution of the isotope is different in normal tissue than it is in diseased tissue. For example, the distribution of the isotope in normal tissue is equal, uniform, and gray. Hyperfunction of an organ shows darker images that are referred to as “hot” spots. In contrast, hypofunctioning of an organ appears as lighter images that are called “cold” spots.

Positron emission tomography (PET) is a noninvasive radiologic study that involves the injection or inhalation of a radioisotope. Images are created as the radioisotope is distributed in the body. This allows study of various aspects of organ function and may include evaluation of blood flow and tumor growth, for example (Figure 34-12 ■).

ASPIRATION/BIOPSY

Aspiration is the withdrawal of fluid that has abnormally collected (e.g., pleural cavity, abdominal cavity) or the obtaining of a specimen (e.g., cerebrospinal fluid). A **biopsy** is the removal and examination of tissue. Biopsies are usually performed to determine a diagnosis or to detect malignancy. Both aspiration and biopsy are invasive procedures and require strict sterile technique.

CLINICAL ALERT!

Determine if the facility requires a signed consent form for an aspiration/biopsy procedure.

Lumbar Puncture

In a **lumbar puncture (LP, or spinal tap)**, cerebrospinal fluid (CSF) is withdrawn through a needle (Figure 34-13 ■) inserted into the subarachnoid space of the spinal canal between the third and fourth lumbar vertebrae or between the fourth and fifth lumbar vertebrae. At this level the needle avoids damaging the spinal cord and major nerve roots (Figure 34-14 ■). The client is positioned laterally with the head bent toward the chest, the knees flexed onto the abdomen, and the back at the edge of the bed or examining table (Figure 34-15 ■).

Figure 34-13 ■ A spinal needle with the stylet protruding from the hub.

Figure 34-14 ■ A diagram of the vertebral column, indicating a site for insertion of the lumbar puncture needle into the subarachnoid space of the spinal canal.

Figure 34-15 ■ Supporting the client for a lumbar puncture.

Figure 34-17 ■ A common site for an abdominal paracentesis.

Figure 34-16 ■ A preassembled lumbar puncture set. Note the manometer at the top of the set.

Figure 34-18 ■ A trocar and cannula may be used for an abdominal paracentesis.

LIFESPAN CONSIDERATIONS Lumbar Puncture

CHILDREN

- Briefly demonstrate the procedure on a doll or stuffed animal. Allow time to answer questions.
- One member of the health care team should stay in close physical contact with the child, maintain eye contact, and talk to and reassure the child during the procedure.

OLDER ADULTS

- Some clients need help maintaining the flexed position due to arthritis, weakness, or tremors.
- Provide an extra blanket to keep the client warm during the procedure. Older adults have a decreased metabolism and less subcutaneous fat.
- If the client has a hearing loss, speak slowly, distinctly, and loud enough, especially when unable to make eye contact.

In this position the back is arched, increasing the spaces between the vertebrae so that the spinal needle can be inserted readily. During a lumbar puncture, the primary care provider frequently takes CSF pressure readings using a **manometer**, a glass or plastic tube calibrated in millimeters (Figure 34-16 ■).

Abdominal Paracentesis

Normally the body creates just enough peritoneal fluid for lubrication. The fluid is continuously formed and absorbed into the lymphatic system. However, in some disease processes, a large amount of fluid accumulates in the abdominal cavity; this condition is called **ascites**. Normal ascitic fluid is serous, clear, and light yellow in color. An **abdominal paracentesis** is carried out to obtain a fluid specimen for laboratory study and to relieve pressure on the abdominal organs due to the presence of excess fluid.

A primary care provider performs the procedure with the assistance of a nurse. Strict sterile technique is followed. A common site for abdominal paracentesis is midway between the umbilicus and the symphysis pubis on the midline (Figure 34-17 ■). The primary care provider makes a small incision with a scalpel, inserts the **trocar** (a sharp, pointed instrument) and **cannula** (tube), and then withdraws the trocar, which is inside the cannula (Figure 34-18 ■). Tubing is attached to the cannula and the fluid flows through the tubing into a receptacle. If the purpose of the paracentesis is to obtain a specimen, the primary care provider may use a long aspirating needle attached to a syringe rather than making an incision and using a trocar and cannula. Normally about 1,500 mL is the maximum amount of fluid drained at one time to avoid hypovolemic shock.

LIFESPAN CONSIDERATIONS Abdominal Paracentesis**OLDER ADULTS**

- Provide pillows and blankets to help older adults remain comfortable during the procedure.
- Ask the client to empty the bladder just before the procedure. Older adults may need to void more frequently and in smaller amounts.

- Remove ascitic fluid slowly and monitor the client for signs of hypovolemia. Older adults have less tolerance for fluid loss and may develop hypovolemia if a large volume of fluid is drained rapidly.

The fluid is drained very slowly for the same reason. Some fluid is placed in the specimen container before the cannula is withdrawn. The small incision may or may not be sutured; in either case, it is covered with a small sterile bandage.

Thoracentesis

Normally, only sufficient fluid to lubricate the pleura is present in the pleural cavity. However, excessive fluid can accumulate as a result of injury, infection, or other pathology. In such a case or in the case of pneumothorax, a primary care provider may perform a **thoracentesis** to remove the excess fluid or air to ease breathing. Thoracentesis is also performed to introduce chemotherapeutic drugs intrapleurally.

The nurse assists the client to assume a position that allows easy access to the intercostal spaces. This is usually a sitting position with the arms above the head, which spreads the ribs and enlarges the intercostal space. Two positions commonly used are one in which the arm is elevated and stretched forward (Figure 34–19A ■) and one in which the client leans forward over a pillow (Figure 34–19B). To make sure that the needle is inserted below the fluid level when fluid is to be removed (or above any fluid if air is to be removed), the primary care provider will palpate and percuss the chest and select the exact site for insertion of the needle. A site on the lower posterior chest is often used to remove fluid, and a site on the upper anterior chest is used to remove air (Figure 34–20 ■). A chest x-ray prior to the procedure will help pinpoint the best insertion site.

The primary care provider and the assisting nurse follow strict sterile technique. The primary care provider attaches a syringe and/or stopcock to the aspirating needle. The stopcock must be in the closed position so that no air can enter the pleural space. The primary care provider inserts the needle through the intercostal space to the

Figure 34–20 ■ Needle is inserted into the pleural space on the lower posterior chest to withdraw fluid.

From *Medical Terminology: A Living Language*, 5th ed. (p. 241), by B. Fremgen and S. Frucht, 2013. Reprinted and electronically reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

pleural cavity. In some instances, the primary care provider threads a small plastic tube through the needle and then withdraws the needle. (The tubing is less likely to puncture the pleura.)

If a syringe is used to collect the fluid, the plunger is pulled out to withdraw the pleural fluid as the stopcock is opened. If a large container is used to receive the fluid, the tubing is attached from the stopcock to the adapter on the receiving bottle. When the adapter and stopcock are opened, gravity allows fluid to drain from the pleural

Figure 34–19 ■ Two positions commonly used for a thoracentesis: A, sitting on one side with arm held to the front and up; B, sitting and leaning forward over a pillow.

LIFESPAN CONSIDERATIONS Thoracentesis**OLDER ADULTS**

- Some older clients will need help maintaining the proper position due to arthritis, tremors, or weakness.
- Provide support with pillows during the procedure.
- Absence of body fat in older adults can help the primary care provider locate the intercostal spaces.
- Provide an extra blanket to keep your client warm during the procedure. Older adults have a decreased metabolism and less subcutaneous fat.

cavity into the container, which should be kept below the level of the client's lungs. After the fluid has been withdrawn, the primary care provider removes the needle or plastic tubing.

Bone Marrow Biopsy

Another type of diagnostic study is the *biopsy*. A biopsy is a procedure whereby tissue is obtained for examination. Biopsies are performed on many different types of tissues, for example, bone marrow, liver, breast, lymph nodes, and lung.

A bone marrow biopsy is the removal of a specimen of bone marrow for laboratory study. The biopsy is used to detect specific diseases of the blood, such as pernicious anemia and leukemia. The bones of the body commonly used for a bone marrow biopsy are the sternum, iliac crests, anterior or posterior iliac spines, and proximal tibia in children. The *posterior superior iliac crest* is the preferred site with the client placed prone or on the side (Figure 34–21 ■).

Figure 34–21 ■ The sternum and the iliac crests are common sites for a bone marrow biopsy.

Figure 34–22 ■ A cross section of a bone.

After injecting a local anesthetic, a small incision may be made with a scalpel to avoid tearing the skin or pushing skin into the bone marrow with a needle. The primary care provider then introduces a bone marrow needle with stylet into the red marrow of the spongy bone (Figure 34–22 ■).

Once the needle is in the marrow space, the stylet is removed and a 10-mL syringe is attached to the needle. The plunger is withdrawn until 1 to 2 mL of marrow has been obtained. The primary care provider replaces the stylet in the needle, withdraws the needle, and places the specimen in test tubes and/or on glass slides.

Liver Biopsy

A liver biopsy is a short procedure, generally performed at the client's bedside, in which a sample of liver tissue is aspirated. A primary care provider inserts a needle in the intercostal space between two of the right lower ribs and into the liver (Figure 34–23 ■) or through the abdomen below the right rib cage (subcostally).

The client exhales and is instructed to hold his or her breath while the primary care provider inserts the biopsy needle, injects a small amount of sterile normal saline to clear the needle of blood

LIFESPAN CONSIDERATIONS Bone Marrow Biopsy**CHILDREN**

- Young clients need emotional support due to the pain and pressure associated with this procedure.
- Young clients may require gentle restraint to prevent movement during the procedure.

OLDER ADULTS

- Older adults with osteoporosis will experience less needle pressure.
- Ask the client to empty the bladder for comfort before the procedure.
- Provide pillows and blankets to help older adults remain comfortable during the procedure.

Figure 34-23 ■ A common site for a liver biopsy.

or particles of tissue picked up during insertion, and aspirates liver tissue by drawing back on the plunger of the syringe. After the needle is withdrawn, the nurse applies pressure to the site to

Figure 34-24 ■ The position to provide pressure on a liver biopsy site.

prevent bleeding, often by positioning the client on the biopsy site (Figure 34-24 ■).

Because many clients with liver disease have blood clotting defects and are prone to bleeding, prothrombin time and platelet count are normally taken well in advance of the test. If the test results are abnormal, the biopsy may be contraindicated.

Table 34-3 describes how the nurse assists with the above aspiration/biopsy procedures.

TABLE 34-3 Assisting with Aspiration and Biopsy Procedures

Procedure	Preprocedure	During the Procedure	Postprocedure
Lumbar puncture	<p>Prepare the client:</p> <ul style="list-style-type: none"> • Explain the procedure to the client and support people. The primary care provider will be taking a small sample of spinal fluid from the lower spine. A local anesthetic will be given to minimize discomfort. Explain when and where the procedure will occur (e.g., the bedside or in a treatment room) and who will be present (e.g., the primary care provider and the nurse). Explain that it will be necessary to lie in a certain position without moving for about 15 min. A slight pinprick will be felt when the local anesthetic is injected and a sensation of pressure as the spinal needle is inserted. • Have the client empty the bladder and bowels prior to the procedure to prevent unnecessary discomfort. • Position and drape the client. • Open the lumbar puncture set. 	<p>Support and monitor the client throughout:</p> <ul style="list-style-type: none"> • Stand in front of the client and support the back of the neck and knees if the client needs help remaining still. • Reassure the client throughout the procedure by explaining what is happening. Encourage normal breathing and relaxation. • Observe the client's color, respirations, and pulse during the procedure. Ask the client to report headache or persistent pain at the insertion site. <p>Handle specimen tubes appropriately:</p> <ul style="list-style-type: none"> • Wear gloves when handling test tubes. • Label the specimen tubes in sequence. • Send the CSF specimens to the laboratory immediately. <p>Place a small sterile dressing over the puncture site.</p>	<p>Ensure the client's comfort and safety:</p> <ul style="list-style-type: none"> • Assist the client to a dorsal recumbent position with only one head pillow. The client remains in this position for 1–12 h, depending on the primary care provider orders. • Determine whether analgesics are ordered and can be given for headaches. • Offer oral fluids frequently, unless contraindicated, to help restore the volume of CSF. <p>Monitor the client:</p> <ul style="list-style-type: none"> • Observe for swelling or bleeding at the puncture site. • Monitor changes in neurologic status. • Determine whether the client is experiencing any numbness, tingling, or pain radiating down the legs. <p>Document the procedure on the client's chart:</p> <ul style="list-style-type: none"> • Include date and time performed; the primary care provider's name; the color, character, and amount of CSF; and the number of specimens obtained. Also document CSF pressure and the nurse's assessments and interventions.

TABLE 34–3 Assisting with Aspiration and Biopsy Procedures—*continued*

Procedure	Preprocedure	During the Procedure	Postprocedure
Abdominal paracentesis	<p>Prepare the client:</p> <ul style="list-style-type: none"> • Explain the procedure: obtaining the specimen usually takes about 15 min. Emphasize the importance of remaining still during the procedure. Tell the client when and where the procedure will occur and who will be present. • Have the client void just before the paracentesis to reduce the possibility of puncturing the urinary bladder. • Help the client assume a sitting position in bed, in a chair, or on the edge of the bed supported by pillows. • Maintain the client's privacy and provide blankets for warmth. 	<p>Assist and monitor the client:</p> <ul style="list-style-type: none"> • Support the client verbally and describe the steps of the procedure as needed. • Observe the client closely for signs of distress (e.g., abnormal pulse rate, skin color, and blood pressure). • Observe for signs of hypovolemic shock induced by the loss of fluid: pallor, dyspnea, diaphoresis, drop in BP, and restlessness or increased anxiety. <p>Place a small sterile dressing over the site of the incision after the cannula or aspirating needle is withdrawn.</p>	<p>Monitor the client closely:</p> <ul style="list-style-type: none"> • Observe for hypovolemic shock. • Observe for scrotal edema with male clients. • Monitor VS, urine output, and drainage from the puncture site every 15 min for at least 2 h and every hour for 4 h or as the client's condition indicates. • Measure the abdominal girth at the level of the umbilicus. <p>Document all relevant information:</p> <ul style="list-style-type: none"> • Include date and time performed; the primary care provider's name; abdominal girth before and after; the color, clarity, and amount of drained fluid; and the nurse's assessments and interventions. <p>Transport the correctly labeled specimens to the laboratory.</p>
Thoracentesis	<p>Prepare the client:</p> <ul style="list-style-type: none"> • Explain the procedure to the client. Normally, the client may experience some discomfort and a feeling of pressure when the needle is inserted. The procedure may bring considerable relief if breathing has been difficult. The procedure takes only a few minutes, depending primarily on the time it takes for the fluid to drain from the pleural cavity. To avoid puncturing the lungs, it is important for the client not to cough while the needle is inserted. Explain when and where the procedure will occur and who will be present. • Help position the client and cover the client as needed with a bath blanket. 	<p>Support and monitor the client throughout:</p> <ul style="list-style-type: none"> • Support the client verbally and describe the steps of the procedure as needed. • Observe the client for signs of distress, such as dyspnea, pallor, and coughing. <p>Collect drainage and laboratory specimens. Place a small sterile dressing over the site of the puncture.</p>	<p>Monitor the client:</p> <ul style="list-style-type: none"> • Assess pulse rate, respiratory rate, and skin color. • Do not remove more than 1,000 mL of fluid from the pleural cavity within the first 30 min. • Observe changes in the client's cough, sputum, respiratory depth, and breath sounds, and note complaints of chest pain. <p>Position the client appropriately:</p> <ul style="list-style-type: none"> • Some agency protocols recommend that the client lie on the unaffected side with the head of the bed elevated 30° for at least 30 min because this position facilitates expansion of the affected lung and eases respirations. <p>Document all relevant information:</p> <ul style="list-style-type: none"> • Include date and time performed; the primary care provider's name; the amount, color, and clarity of fluid drained; and nursing assessments and interventions provided. <p>Transport the correctly labeled specimens to the laboratory.</p>
Bone marrow biopsy	<p>Prepare the client:</p> <ul style="list-style-type: none"> • Explain the procedure. The client may experience pain when the marrow is aspirated and hear a crunching sound as the needle is pushed through the cortex of the bone. The procedure usually takes 15–30 min. Explain when and where the procedure will occur, who will be present, and which site will be used. 	<p>Monitor and support the client throughout:</p> <ul style="list-style-type: none"> • Describe the steps of the procedure as needed and provide verbal support. • Observe the client for pallor, diaphoresis, and faintness due to bleeding or pain. <p>Place a small dressing over the site of the puncture after the needle is withdrawn:</p>	<p>Monitor the client:</p> <ul style="list-style-type: none"> • Assess for discomfort and bleeding from the site. The client may experience some tenderness in the area. Bleeding and hematoma formation need to be assessed for several days. Report bleeding or pain to the nurse in charge. • Provide an analgesic as needed and ordered.

Continued on page 746

TABLE 34–3 Assisting with Aspiration and Biopsy Procedures—*continued*

Procedure	Preprocedure	During the Procedure	Postprocedure
Liver biopsy	<ul style="list-style-type: none"> Administer a sedative as ordered. Help the client assume a supine position (with one pillow if desired) for a biopsy of the sternum (sternal puncture) or a prone position for a biopsy of either iliac crest. Fold the bedclothes back or drape the client to expose the area. <p>Prepare the client:</p> <ul style="list-style-type: none"> Give preprocedural medications as ordered. Vitamin K may be given for several days before the biopsy to reduce the risk of hemorrhage. Explain the procedure and tell the client that the primary care provider will take a small sample of liver tissue by putting a needle into the client’s side or abdomen. Explain that a sedative and local anesthetic will be given, so the client will feel no pain. Explain when and where the procedure will occur, who will be present, the time required, and what to expect as the procedure is being performed (e.g., the client may experience mild discomfort when the local anesthetic is injected and slight pressure when the biopsy needle is inserted). Ensure that the client fasts for at least 2 h before the procedure. Administer the appropriate sedative about 30 min beforehand or at the specified time. Help the client assume a supine position with the upper right quadrant of the abdomen exposed. Cover the client with the bedclothes so that only the abdominal area is exposed. 	<ul style="list-style-type: none"> Some agency protocols recommend direct pressure over the site for 5–10 min to prevent bleeding. <p>Assist with preparing specimens as needed.</p> <p>Monitor and support the client throughout:</p> <ul style="list-style-type: none"> Support the client in a supine position. Instruct the client to take a few deep inhalations and exhalations and to hold the breath after the final exhalation for up to 10 sec as the needle is inserted, the biopsy obtained, and the needle withdrawn. Holding the breath after exhalation immobilizes the chest wall and liver and keeps the diaphragm in its highest position, avoiding injury to the lung and laceration of the liver. Instruct the client to resume breathing when the needle is withdrawn. Apply pressure to the site of the puncture to help stop any bleeding. <p>Apply a small dressing to the site of the puncture.</p>	<p>Document all relevant information:</p> <ul style="list-style-type: none"> Include date and time of the procedure; the primary care provider’s name; and any nursing assessments and interventions. Document any specimens obtained. <p>Transport the correctly labeled specimens to the laboratory.</p> <p>Position the client appropriately:</p> <ul style="list-style-type: none"> Assist the client to a right side-lying position with a small pillow or folded towel under the biopsy site. Instruct the client to remain in this position for several hours. <p>Monitor the client:</p> <ul style="list-style-type: none"> Assess the client’s VS every 15 min for the first hour following the test or until the signs are stable. Then monitor vital signs every hour for 24 h or as needed. Determine whether the client is experiencing abdominal pain. Severe abdominal pain may indicate bile peritonitis. Check the biopsy site for localized bleeding. Pressure dressings may be required if bleeding does occur. <p>Document all relevant information:</p> <ul style="list-style-type: none"> Include date and time performed; the primary care provider’s name; and all nursing assessments and interventions. <p>Transport the correctly labeled specimens to the laboratory.</p>

LIFESPAN CONSIDERATIONS Liver Biopsy

OLDER ADULTS

- Observe for skin irritation from tape applied to the sterile dressing. Older adults often have fragile skin.

- Ask the client to empty the bladder before the procedure. Older adults may need to void more often and in smaller amounts.

LIFESPAN CONSIDERATIONS General Considerations**CHILDREN**

- Children may be frightened of even noninvasive procedures to collect specimens if they are not sure what is going to happen. Cooperation can be maximized by:
 - Demonstrating on dolls or teddy bears.
 - Allowing the child to examine and explore the collection materials being used.
 - Explaining in age-appropriate language what will be done.
 - Having parents actively involved in gently holding and comforting the child during and after the procedure.
 - Being well prepared to conduct the procedure.
 - Performing the procedure quickly, competently, and as gently as possible.

OLDER ADULTS

- In older adults, homeostatic mechanisms are not as efficient as in the younger person. When undergoing diagnostic tests that

challenge these functions, care must be taken to accurately monitor functions and note any changes. Examples:

- Dehydration and electrolyte imbalance can occur from laxative preps given before bowel diagnostic tests, such as a colonoscopy.
- Fluid restrictions and NPO status for a length of time can lead to hypovolemia and electrolyte imbalances.
- Many dye contrasts used for x-rays and scans can cause renal damage (especially in clients with diabetes).
- Sedation used for certain procedures may require a longer recovery time for older clients.
- Having several tests at a time or for several days compounds these potential problems and increases fatigue.

**Critical Thinking Checkpoint**

A 68-year-old woman is admitted with fever, nausea, vomiting, and abdominal pain. She informs you that she is a “borderline diabetic” and “only has to watch what she eats.” She tells you that she has not eaten for 3 days and has had difficulty “keeping liquids down.” While doing the nursing history, she describes her urine as dark and foul smelling. Upon further questions, she states she does have some burning upon urination. She describes her abdominal pain as constant, generalized, and rates it as a 5 or 6 on a scale of 0 to 10. The primary care provider called in the following orders:

CBC and electrolytes STAT
 Capillary blood glucose STAT and q4h
 VS and TPR q4h
 Urine specimen for C&S
 CXR
 Flat plate abdominal x-ray.

1. When measuring the client’s capillary blood glucose, you do not obtain enough blood to cover the indicator square on the reagent strip. What could be possible reasons and what should you do?

2. The laboratory work returns with the following results: WBC = $17 \times 10^3/\text{mL}^3$ with neutrophils = 80%; Hct = 43.2. Based on these results, what are your nursing interventions?
3. The primary care provider orders IV fluids and an antibiotic with the first dose to be given STAT. You have not obtained the urine specimen yet. Which has priority (e.g., starting the IV, administering the antibiotic, or obtaining the urine specimen) and why?
4. Three days later, the client has the following laboratory results: Hct = 39.2 and WBC = $10.8 \times 10^3/\text{mL}^3$. What do those results indicate to you?
5. The abdominal x-ray shows a possible mass. An MRI of the abdomen is ordered. The client is quite anxious because she has heard from her friend that the procedure is difficult for people who are claustrophobic. How will you respond?

See Critical Thinking Possibilities on student resource website.

Chapter 34 Review

CHAPTER HIGHLIGHTS

- Diagnostic testing involves three phases. Client preparation is the focus during the pretest phase. During the intratest phase, the nurse performs or assists with the diagnostic test and collects the specimen. Providing nursing care of the client and follow-up activities and observations are the role of the nurse during the post-test phase.
- Blood tests are commonly used diagnostic tests. Routinely ordered blood tests can include complete blood count (CBC) and serum electrolytes.
- A capillary blood glucose is a frequent test performed by nurses and clients. This test is used to monitor glucose levels of clients at risk for hyper- and hypoglycemia. It also evaluates the effectiveness of insulin administration.
- Nursing responsibilities associated with specimen collection include (a) providing client comfort, privacy, and safety; (b) explaining the purpose of and procedure for the specimen collection; (c) using correct procedure for obtaining the specimen; (d) noting relevant information on the laboratory requisition slip; (e) transporting the specimen promptly; and (f) reporting abnormal findings.

- The nurse is responsible for obtaining stool specimens ordered for laboratory analysis.
- Nurses collect urine specimens for a number of tests. A clean voided specimen is used for routine examination. A clean-catch or midstream voided specimen is collected when a urine culture is ordered to identify microorganisms. Timed urine specimens are collected for a variety of tests, depending on the client's health problem. Nurses can complete some simple urine tests (e.g., specific gravity, pH, glucose, ketones, protein, and occult blood) by using a reagent strip.
- Sputum and throat culture specimens help determine the presence of disease-producing organisms.
- Visualization procedures include indirect visualization or noninvasive procedures such as lung scan, echocardiogram, electrocardiography, x-ray, CT, and MRI. In contrast, direct visualization or invasive techniques visualize body organs and system functions. Examples of invasive procedures include colonoscopy, barium enema, intravenous pyelography, and angiography.
- Examples of aspiration/biopsy tests include lumbar puncture, abdominal paracentesis, thoracentesis, bone marrow biopsy, and liver biopsy. These tests are invasive procedures and require strict sterile technique. After the procedure, the nurse assesses the client for possible complications and provides appropriate nursing interventions as needed.

TEST YOUR KNOWLEDGE

- The nurse would call the primary care provider immediately for which laboratory result?
 - Hgb = 16 g/dL for a male client
 - Hct = 22% for a female client
 - WBC = $9 \times 10^9/\text{mL}^3$
 - Platelets = $300 \times 10^3/\text{mL}^3$
- A 78-year-old male client needs to complete a 24-hour urine specimen. In planning his care, the nurse realizes that which measure is most important?
 - Instruct the client to empty his bladder and save this voiding to start the collection.
 - Instruct the client to use sterile individual containers to collect the urine.
 - Post a sign stating "Save All Urine" in the bathroom.
 - Keep the urine specimen in the refrigerator.
- The client has a urinary health problem. Which procedure is performed using indirect visualization?
 - Intravenous pyelography (IVP)
 - Kidneys, ureter, bladder (KUB)
 - Retrograde pyelography
 - Cystoscopy
- Which noninvasive procedure provides information about the physiology or function of an organ?
 - Angiography
 - Computerized tomography (CT)
 - Magnetic resonance imaging (MRI)
 - Positron emission tomography (PET)
- When assisting with a bone marrow biopsy, the nurse should take which action?
 - Assist the client to a right side-lying position after the procedure.
 - Observe for signs of dyspnea, pallor, and coughing.
 - Assess for bleeding and hematoma formation for several days after the procedure.
 - Stand in front of the client and support the back of the neck and knees.
- During an assessment, the nurse learns that the client has a history of liver disease. Which diagnostic tests might be indicated for this client? Select all that apply.
 - Alanine aminotransferase (ALT)
 - Myoglobin
 - Cholesterol
 - Ammonia
 - Brain natriuretic peptide or B-type natriuretic peptide (BNP)
- The nurse practitioner requests a laboratory blood test to determine how well a client has controlled her diabetes during the past 3 months. Which blood test will provide this information?
 - Fasting blood glucose
 - Capillary blood specimen
 - Glycosylated hemoglobin
 - GGT (gamma-glutamyl transferase)
- The client is supposed to have a fecal occult blood test done on a stool sample. The nurse is going to use the Hemoccult test. Which of the following indicates that the nurse is using the correct procedure? Select all that apply.
 - Mixes the reagent with the stool sample before applying to the card.
 - Collects a sample from two different areas of the stool specimen.
 - Assesses for a blue color change.
 - Asks a colleague to verify the pink color results.
 - Asks the client if he has taken vitamin C in the past few days.
- A primary care provider is going to perform a thoracentesis. The nurse's role will include which action?
 - Place the client supine in the Trendelenburg position.
 - Position the client in a seated position with elbows on the overbed table.
 - Instruct the UAP to measure vital signs.
 - Administer an opioid analgesic.
- The nurse needs to collect a sputum specimen to identify the presence of tuberculosis (TB). Which nursing action(s) is/are indicated for this type of specimen? Select all that apply.
 - Collect the specimen in the evening.
 - Send the specimen immediately to the laboratory.
 - Ask the client to spit into the sputum container.
 - Offer mouth care before and after collection of the sputum specimen.
 - Collect a specimen for 3 consecutive days.

35 Medications

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Define selected terms related to the administration of medications.
2. Describe legal aspects of administering medications.
3. Describe actions of drugs on the body.
4. Identify factors affecting medication action.
5. Describe various routes of medication administration.
6. Identify essential parts of a medication order.
7. List examples of various types of medication orders.
8. State systems of measurement that are used in the administration of medications.
9. Describe four formulas for calculating drug dosages.
10. List six essential steps to follow when administering medication.
11. State the “rights” to accurate medication administration.
12. Describe the physiological changes in older adults that alter medication administration and effectiveness.
13. Verbalize the steps used in administering oral medications safely.
14. Outline the steps required for nasogastric and gastrostomy tube medication administration.
15. Identify equipment required for parenteral medications.
16. Verbalize the steps used in:
 - a. Preparing medications from ampules.
 - b. Preparing medications from vials.
 - c. Mixing medications in one syringe.
17. Identify the sites used for:
 - a. Intradermal injection.
 - b. Subcutaneous injection.
 - c. Intramuscular injection.
18. Verbalize the steps used in administering parenteral medications by the following routes:
 - a. Intradermal
 - b. Subcutaneous
 - c. Intramuscular.
19. Verbalize the steps used in:
 - a. Adding medications to intravenous fluid containers.
 - b. Administering intravenous medications using IV push.
20. Verbalize the steps used in administering the following topical medications:

a. Dermatologic	e. Vaginal
b. Ophthalmic	f. Rectal
c. Otic	g. Respiratory inhalation.
d. Nasal	
21. Recognize when it is appropriate to delegate medication administration to unlicensed assistive personnel.
22. Demonstrate appropriate documentation and reporting of medication administration skills.

INTRODUCTION

A **medication** is a substance administered for the diagnosis, cure, treatment, or relief of a symptom or for prevention of disease. In the health care context, the words *medication* and *drug* are generally used interchangeably. The term **drug** also has the connotation of an illicitly obtained substance such as heroin, cocaine, or amphetamines. Medications have been known and used since antiquity. Crude drugs, such as opium, castor oil, and vinegar, were used in ancient times. Over the centuries the number of drugs available has increased greatly, and knowledge about these drugs has become correspondingly more accurate and detailed.

In the United States, medications are usually dispensed on the order of primary care providers and dentists. In some U.S. states, specially qualified nurse practitioners or other advanced practice nurses and physician assistants may prescribe drugs. The written direction for the preparation and administration of a drug is called a **prescription**. One drug can have as many as four kinds of names: its generic name, trade name (or brand name), official name, and chemical name. The **generic name** is assigned by the United States Adopted Names (USAN) Council and is used throughout the drug's lifetime. A drug's **trade name** (sometimes called the **brand name**) is the name given by the drug manufacturer and identifies it as property of that company. The name selected is usually short and easy to remember. When the drug is under patent protection, the company markets the drug under its trade name. When the drug is no longer protected by patent, the company may market its product under either the generic or

trade name. Other companies that wish to market the off-patent drug must use the same generic name but will create their own trade name. Thus, one drug may be manufactured by several companies and have several trade names. For example, the drug hydrochlorothiazide (generic name) is known by the trade names Esidrix and HydroDIURIL. The **official name** is the name under which a drug is listed in one of the official publications (e.g., the *United States Pharmacopeia*). The **chemical name** is the name by which a chemist knows it; this name describes the constituents of the drug precisely.

Medications are often available in a variety of forms (Table 35–1).

Pharmacology is the study of the effect of drugs on living organisms. **Pharmacy** is the art of preparing, compounding, and dispensing drugs. The word also refers to the place where drugs are prepared and dispensed. The licensed **pharmacist** prepares, makes, and dispenses drugs as ordered by a physician, dentist, nurse practitioner, or physician assistant. A clinical pharmacist is a specialist who often guides the primary care provider in prescribing drugs. A pharmacy technician is a member of the health team who in some states administers drugs to clients.

DRUG STANDARDS

Drugs may have natural (e.g., plant, mineral, and animal) sources, or they may be synthesized in the laboratory. For example, digitalis and opium are plant derived, iron and sodium chloride are minerals, insulin and vaccines have animal or human sources, and the

TABLE 35–1 Types of Drug Preparations

Type	Description
Aerosol spray or foam	A liquid, powder, or foam deposited in a thin layer on the skin by air pressure
Aqueous solution	One or more drugs dissolved in water
Aqueous suspension	One or more drugs finely divided in a liquid such as water
Caplet	A solid form, shaped like a capsule, coated and easily swallowed
Capsule	A gelatinous container to hold a drug in powder, liquid, or oil form
Cream	A nongreasy, semisolid preparation used on the skin
Elixir	A sweetened and aromatic solution of alcohol used as a vehicle for medicinal agents
Extract	A concentrated form of a drug made from vegetables or animals
Gel or jelly	A clear or translucent semisolid that liquefies when applied to the skin
Liniment	A medication mixed with alcohol, oil, or soapy emollient and applied to the skin
Lotion	A medication in a liquid suspension applied to the skin
Lozenge (troche)	A flat, round, or oval preparation that dissolves and releases a drug when held in the mouth
Ointment (salve, unction)	A semisolid preparation of one or more drugs used for application to the skin and mucous membrane
Paste	A preparation like an ointment, but thicker and stiff, that penetrates the skin less than an ointment
Pill	One or more drugs mixed with a cohesive material, in oval, round, or flattened shapes
Powder	A finely ground drug or drugs; some are used internally, others externally
Suppository	One or several drugs mixed with a firm base such as gelatin and shaped for insertion into the body (e.g., the rectum); the base dissolves gradually at body temperature, releasing the drug
Syrup	An aqueous solution of sugar often used to disguise unpleasant-tasting drugs
Tablet	A powdered drug compressed into a hard small disk; some are readily broken along a scored line; others are enteric coated to prevent them from dissolving in the stomach
Tincture	An alcoholic or water-and-alcohol solution prepared from drugs derived from plants
Transdermal patch	A semipermeable membrane shaped in the form of a disk or patch that contains a drug to be absorbed through the skin over a long period of time

sulfonamides and propoxyphene hydrochloride (the analgesic Darvon) are the products of laboratory synthesis. Early drugs were derived from the three natural sources only. More and more drugs, however, are being produced synthetically.

Drugs vary in strength and activity. Drugs derived from plants, for example, vary in strength according to the age of the plant, the variety, the place in which it is grown, and the method by which it is preserved. Drugs must be pure and of uniform strength if drug dosages are to be predictable in their effect. Drug standards have therefore been developed to ensure uniform quality. In the United States, official drugs are those so designated by the federal Food, Drug, and Cosmetic Act. These drugs are officially listed in the *United States Pharmacopeia (USP)* and described according to their source, physical and chemical properties, tests for purity and identity, method of storage, assay, category, and normal dosages. There is a trend for people to purchase “natural” vitamins and supplements from health food stores or over the counter (OTC) at pharmacies. An example of this is a thyroid supplement. The natural form varies in strength and is difficult to regulate, while the synthetic thyroid is much more predictable in strength and management of symptoms for clients who need to take a thyroid supplement.

A **pharmacopoeia** (also spelled *pharmacopeia*) is a book containing a list of products used in medicine, with descriptions of the product, chemical tests for determining identity and purity, and formulas and prescriptions. The United States’ *National Formulary* lists drugs and their therapeutic value and can include drugs that may still be used but not listed in the *USP*.

Pharmacopoeias and formularies are invaluable reference sources for nurses and nursing students. Nurses not only administer thousands of medications but also are responsible for assessing their effectiveness and recognizing unfavorable reactions to drugs. Medication or drug handbooks and agency formularies are valuable resources for nurses. Because it is impossible to commit to memory all pertinent information about a very large number of drugs, nurses must have a reliable reference readily available.

LEGAL ASPECTS OF DRUG ADMINISTRATION

Within the United States, laws have been enacted to control the development and administration of drugs. Table 35–2 provides a summary of U.S. drug legislation.

Nurses need to (a) know how nursing practice acts in their areas define and limit their functions and (b) be able to recognize the limits of their own knowledge and skill. To function beyond the limits of

nursing practice acts or one’s ability is to endanger clients’ lives and leave oneself open to professional negligence lawsuits. Under the law, nurses are responsible for their own actions regardless of whether there is a written order. If a primary care provider writes an incorrect order (e.g., morphine 100 mg instead of morphine 10 mg), *a nurse who administers the written incorrect dosage is responsible for the error as well as the primary care provider*. Therefore, nurses should question any order that appears unreasonable and refuse to give the medication until the order is clarified.

Another aspect of nursing practice governed by law is the use of controlled substances. In hospitals, controlled substances are kept in a locked drawer, cupboard, medication cart, or computer-controlled dispensing system. Agencies may have special inventory forms for recording the use of controlled substances. The information required usually includes the name of the client, the date and time of administration, the name of the drug, the dosage, and the signature of the person who prepared and gave the drug. The name of the primary care provider who ordered the drug may also be part of the record. Some agencies may require a verifying signature of another registered nurse for administration of a controlled substance. Most health care agencies maintain a list of high-alert medications, including controlled substances, which require the verification of two registered nurses. Before removing a controlled substance, the nurse verifies the number actually available with the number indicated on the narcotic or controlled substance inventory record (Figure 35–1 ■). If the number is not the same, the nurse must investigate and correct the discrepancy before proceeding.

Included on the record are the controlled substances wasted during preparation. When a portion or all of a controlled substance dose is discarded, the nurse must ask a second nurse to witness the discarding. Both nurses must sign the control inventory form.

In most agencies, counts of controlled substances are taken at the end of each shift. The count total should tally with the total at the end of the last shift minus the number used. If the totals do not tally and the discrepancy cannot be resolved, it must be reported immediately to the nurse manager, nursing supervisor, and pharmacy according to agency policy. In facilities that use a computerized dispensing system, manual counts are not required, because the dispensing system runs a continuous count; however, discrepancies must be reported and accounted for.

EFFECTS OF DRUGS

The **therapeutic effect** of a drug, also referred to as the **desired effect**, is the primary effect intended, that is, the reason the drug is prescribed. For example, the therapeutic effect of morphine sulfate is

TABLE 35–2 U.S. Drug Legislation

Legislation	Content
Food, Drug, and Cosmetic Act (1938)	Implemented by Food and Drug Administration (FDA); requires that labels be accurate and that all drugs be tested for harmful effects.
Durkham-Humphrey Amendment (1952)	Clearly differentiates drugs that can be sold only with a prescription, those that can be sold without a prescription, and those that should not be refilled without a new prescription.
Kefauver-Harris Amendment (1962)	Requires proof of safety and efficacy of a drug for approval.
Comprehensive Drug Abuse Prevention and Control Act (1970) (Controlled Substances Act)	Categorizes controlled substances and limits how often a prescription can be filled; established government-funded programs to prevent and treat drug dependence.

Figure 35-1 ■ Some narcotics are kept in specially designed packages or plastic containers that are sectioned and numbered.

analgesia, and the therapeutic effect of diazepam is relief of anxiety. See Table 35-3 for kinds of therapeutic actions.

A **side effect**, or secondary effect, of a drug is one that is unintended. Side effects are usually predictable and may be either harmless or potentially harmful. For example, digitalis increases the strength of myocardial contractions (desired effect), but it can have the side effect of inducing nausea and vomiting. Some side effects are tolerated for the drug's therapeutic effect; more severe side effects, also called **adverse effects** or reactions, may justify the discontinuation of a drug. The nurse should monitor for dose-related side or adverse effects and report these to the health care provider who may discontinue the medication or change the dosage.

Drug toxicity (harmful effects of a drug on an organism or tissue) results from overdosage, ingestion of a drug intended for external use, or buildup of the drug in the blood because of impaired metabolism or excretion (cumulative effect). Some toxic effects are apparent immediately; some are not apparent for weeks or months. Fortunately, most drug toxicity is avoidable if careful attention is paid to dosage and monitoring for toxicity. An example of a toxic effect is respiratory depression due to the cumulative effect of morphine sulfate in the body.

A **drug allergy** is an immunologic reaction to a drug. When a client is first exposed to a foreign substance (antigen), the body may react by producing antibodies. A client can react to a drug in the same manner as an antigen and thus develop symptoms of an allergic reaction.

Allergic reactions can be either mild or severe. A mild reaction has a variety of symptoms, from skin rashes to diarrhea (Table 35-4).

TABLE 35-3 Therapeutic Actions of Drugs

Drug Type	Description	Examples
Palliative	Relieves the symptoms of a disease but does not affect the disease itself.	Morphine sulfate, aspirin for pain
Curative	Cures a disease or condition.	Penicillin for infection
Supportive	Supports body function until other treatments or the body's response can take over.	Norepinephrine bitartrate for low blood pressure; aspirin for high body temperature
Substitutive	Replaces body fluids or substances.	Thyroxine for hypothyroidism, insulin for diabetes mellitus
Chemotherapeutic	Destroys malignant cells.	Busulfan for leukemia
Restorative	Returns the body to health.	Vitamin, mineral supplements

TABLE 35-4 Common Mild Allergic Responses

Symptom	Description/Rationale
Skin rash	Either an intraepidermal vesicle rash or a rash typified by an urticarial wheal or macular eruption; rash is usually generalized over the body
Pruritus	Itching of the skin with or without a rash
Angioedema	Edema due to increased permeability of the blood capillaries
Rhinitis	Excessive watery discharge from the nose
Lacrimal tearing	Excessive tearing
Nausea, vomiting	Stimulation of these centers in the brain
Wheezing and dyspnea	Shortness of breath and wheezing on inhalation and exhalation due to accumulated fluids and swelling of the respiratory tissues
Diarrhea	Irritation of the mucosa of the large intestine

An allergic reaction can occur anytime from a few minutes to 2 weeks after the administration of the drug. A severe allergic reaction usually occurs immediately after the administration of the drug and is called an **anaphylactic reaction**. This response can be fatal if the symptoms are not noticed immediately and treatment is not obtained promptly. The earliest symptoms are a subjective feeling of swelling in the mouth and tongue, acute shortness of breath, acute hypotension, and tachycardia.

Drug tolerance exists in a person who exhibits an unusually low physiological response to a drug and who requires increases in the dosage to maintain a given therapeutic effect. Drugs that commonly produce tolerance are opiates, barbiturates, and ethyl alcohol. A **cumulative effect** is the increasing response to repeated doses of a drug that occurs when the rate of administration exceeds the rate of metabolism or excretion. As a result, the amount of the drug builds up in the client's body unless the dosage is adjusted. Toxic symptoms may occur. An **idiosyncratic effect** is one that is unexpected and may be individual to a client. Underresponse and overresponse to a drug may be idiosyncratic. Also, the drug may have a completely different effect from the normal one or cause unpredictable and unexplainable symptoms in a particular client.

A **drug interaction** occurs when the administration of one drug before, at the same time as, or after another drug alters the effect of one or both drugs. Drug interactions may be beneficial or harmful. The effect of one or both drugs may be either increased (**potentiating effect**) or decreased (**inhibiting effect**). Potentiating effects may be additive or synergistic. When two of the same types of drug increase the action of each other, the effect is known as additive. A **synergistic effect** occurs when two different drugs increase the action of one or another drug. For example, probenecid, which blocks the excretion of penicillin, can be given with penicillin to increase blood levels of the penicillin for longer periods (synergistic effect). Two analgesics, such as aspirin and codeine, are often given together because together they provide greater pain relief (additive effect). In this example of aspirin and codeine, using a combination of drugs often decreases the total dose of narcotics needed. In addition, certain foods may interact adversely with a medication (see Table 47-1 in Chapter 47 ∞).

Iatrogenic disease (disease caused unintentionally by medical therapy) can be a result of drug therapy. Hepatic toxicity resulting in biliary obstruction, renal damage, and malformations of the fetus as a result of specific drugs taken during pregnancy are examples.

DRUG MISUSE

Drug misuse is the improper use of common medications in ways that lead to acute and chronic toxicity. Both OTC drugs and prescription drugs may be misused. Laxatives, antacids, vitamins, headache remedies, and cough and cold medications are often self-prescribed and overused. Most people suffer no harmful effects from these drugs, but some do. For example, a client might use an OTC cough medicine to treat a cough that might be caused by a serious underlying problem such as throat cancer.

Drug abuse is the inappropriate intake of a substance, either continually or periodically. By definition, drug use is abusive when society considers it abusive. For example, the intake of alcohol at work may be considered alcohol abuse, but intake at a social gathering may not. Drug abuse has two main facets, drug dependence and habituation. **Drug dependence** is a person's reliance on or need to take a drug or substance. The two types of dependence, physiological and

psychological, may occur separately or together. **Physiological dependence** is due to biochemical changes in body tissues, especially the nervous system. These tissues come to require the substance for normal functioning. A dependent person who stops using the drug experiences withdrawal symptoms. **Psychological dependence** is emotional reliance on a drug to maintain a sense of well-being, accompanied by feelings of need or cravings for that drug. There are varying degrees of psychological dependence, ranging from mild desire to craving and compulsive use of the drug.

Drug habituation denotes a mild form of psychological dependence. The individual develops the habit of taking the substance and feels better after taking it. The habituated individual tends to continue the habit even though it may be injurious to health.

Illicit drugs, also called *street drugs*, are those sold illegally. Illicit drugs are of two types: (a) drugs unavailable for purchase under any circumstances, such as heroin (in the United States), and (b) drugs normally available with a prescription that are being obtained through illegal channels. Illicit drugs often are taken because of their mood-altering effect; that is, they make the person feel happy or relaxed.

ACTIONS OF DRUGS ON THE BODY

The action of a drug in the body can be described in terms of its half-life, the time interval required for the body's elimination processes to reduce the concentration of the drug in the body by one-half. For example, if a drug's half-life is 8 hours, then the amount of drug in the body is as follows:

Initially: 100%
 After 8 hours: 50%
 After 16 hours: 25%
 After 24 hours: 12.5%
 After 32 hours: 6.25%

Because the purpose of most drug therapy is to maintain a constant drug level in the body, repeated doses are required to maintain that level. When an orally administered drug is absorbed from the gastrointestinal (GI) tract into the blood plasma, its concentration in the plasma increases until the elimination rate equals the rate of absorption. This point is known as the *peak plasma level* (Figure 35-2 ■). When a drug is given intravenously (IV), its level is high immediately

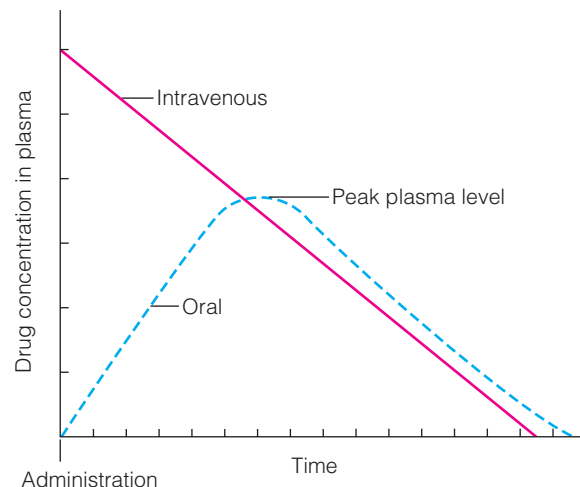

Figure 35-2 ■ A graphic plot of drug concentration in the blood plasma following a single dose.

after administration and decreases through time. Another dose is given in order to maintain therapeutic levels. If the client does not receive another dose of the drug (either orally or IV), the concentration steadily decreases. Key terms related to drug actions are as follows:

- **Onset of action:** the time after administration when the body initially responds to the drug
- **Peak plasma level:** the highest plasma level achieved by a single dose when the elimination rate of the drug equals the absorption rate
- **Drug half-life (elimination half-life):** the time required for the elimination process to reduce the concentration of the drug to one-half what it was at initial administration
- **Plateau:** a maintained concentration of a drug in the plasma during a series of scheduled doses.

Pharmacodynamics

Pharmacodynamics is the mechanism of drug action and the relationships between drug concentration and responses in the body (Adams & Urban, 2013, p. 56). A **receptor** is the drug's specific target, usually a protein located on the surface of a cell membrane or within the cell. As the drug binds to the receptor, it enhances or inhibits the normal cellular function. The binding is usually reversible and the action of the drug terminated once the drug leaves the receptor (Adams & Urban, 2013, p. 60).

Most drugs exert their effects by chemically binding with receptors at the cellular level. When a drug binds to its receptor, the pharmacologic effects are either agonism or antagonism. When a drug produces the same type of response as the physiological or endogenous substance, it is referred to as an **agonist**. For example, epinephrine-like drugs act on the heart to increase the heart rate. Conversely, a drug that inhibits cell function by occupying receptor sites is called an **antagonist**. The antagonist prevents natural body substances or other drugs from activating the functions of the cell by occupying the receptor sites. For example, naloxone (Narcan) is an opioid antagonist used as an antidote for respiratory depression caused by an opioid drug (e.g., morphine). This drug competes with opioid receptor sites in the brain and thereby prevents the opioid from binding to its receptors. By blocking the effect of the opioid, respiratory depression is reversed.

Pharmacokinetics

Pharmacokinetics is the study of the absorption, distribution, biotransformation, and excretion of drugs.

ABSORPTION

Absorption is the process by which a drug passes into the bloodstream. Unless the drug is administered directly into the bloodstream, absorption is the first step in the movement of the drug through the body. For absorption of a drug to occur, the correct form of the drug must be administered through the correct route.

The rate of absorption of a drug in the stomach is variable. Food, for example, can delay the dissolution and absorption of some drugs as well as their passage into the small intestine, where most drug absorption occurs. Food can also combine with molecules of certain drugs, thereby changing their molecular structure and subsequently inhibiting or preventing their absorption. Another factor that affects the absorption of some drugs is the acid medium in the stomach. Acidity can vary according to the time of day, foods ingested, use of antacid medications, and the age of the client. Some drugs do not

dissolve or have limited ability to dissolve in the GI fluids, decreasing their absorption into the bloodstream. Absorption of some drugs can occur in the tissues of the mouth prior to reaching the stomach. For example, nitroglycerin is administered under the tongue, where it is absorbed into the blood vessels that carry it directly to the heart, the intended site of action. If swallowed, this drug will be absorbed into the bloodstream and carried to the liver, where it will be destroyed. The first-pass effect occurs when oral drugs first pass through the liver and are partially metabolized prior to reaching the target organ. This requires higher oral doses in order to achieve the appropriate effect.

A drug administered directly into the bloodstream, that is, intravenously, is immediately in the vascular system without having to be absorbed. This, then, is the route of choice for rapid action. The intramuscular route is the next most rapid route due to the highly vascular nature of muscle tissue. Because subcutaneous tissue has a poorer blood supply than muscle tissue, absorption from subcutaneous tissue is slower. The rate of absorption of a drug can be accelerated by the application of heat, which increases blood flow to the area; conversely, absorption can be slowed by the application of cold. In addition, the injection of a vasoconstrictor drug such as epinephrine into the tissue can slow absorption of other drugs. Some drugs intended to be absorbed slowly are suspended in a low-solubility medium, such as oil. The absorption of drugs from the rectum into the bloodstream tends to be unpredictable. Therefore, this route is normally used when other routes are unavailable or when the intended action is localized to the rectum or sigmoid colon.

DISTRIBUTION

Distribution is the transportation of a drug from its site of absorption to its site of action. When a drug enters the bloodstream, it is carried to the most vascular organs—that is, liver, kidneys, and brain. Body areas with lower blood supply—that is, skin and muscles—receive the drug later. The chemical and physical properties of a drug largely determine the area of the body to which the drug will be attracted. For example, fat-soluble drugs will accumulate in fatty tissue, whereas other drugs may bind with plasma proteins.

BIOTRANSFORMATION

Biotransformation, also called **detoxification** or **metabolism**, is a process by which a drug is converted to a less active form. Most biotransformation takes place in the liver, where many drug-metabolizing enzymes in the cells detoxify the drugs. The products of this process are called **metabolites**. There are two types of metabolites: active and inactive. An *active metabolite* has a pharmacologic action itself, whereas an *inactive metabolite* does not.

Biotransformation may be altered if a person is very young, is older, or has an unhealthy liver. Nurses must be alert to the accumulation of the active drug in these clients and to subsequent toxicity.

EXCRETION

Excretion is the process by which metabolites and drugs are eliminated from the body. Most drug metabolites are eliminated by the kidneys in the urine; however, some are excreted in the feces, the breath, perspiration, saliva, and breast milk. Certain drugs, such as general anesthetic agents, are excreted in an unchanged form via the respiratory tract. The efficiency with which the kidneys excrete drugs and metabolites diminishes with age. Older people may require smaller doses of a drug because the drug and its metabolites may accumulate in the body.

ANATOMY & PHYSIOLOGY REVIEW

Pharmacokinetics of an Oral Medication

GI SYSTEM: STOMACH, SMALL INTESTINE

The oral medication reaches the systemic circulation through the GI system. As a result, numerous factors can affect the absorption of the pill.

QUESTIONS

1. Which would be absorbed the fastest: pill, capsule, or liquid?
2. A client is experiencing diarrhea. How could this affect absorption of an oral drug?
3. How does the presence of food in the stomach affect the rate of absorption?

CARDIOVASCULAR SYSTEM

Once the pill is absorbed into the bloodstream, it is carried or delivered to the sites of pharmacologic action where the drug produces its effects.

QUESTION

1. How is distribution of the oral medication affected if a client has less than normal cardiac output (e.g., low BP, prolonged capillary refill)?

LIVER

Most biotransformation takes place in the liver. Any decrease in the ability of the liver to metabolize medication could lead to an accumulation of the active drug in the bloodstream. This could put the client at risk for toxic effects and adverse reactions.

QUESTIONS

1. What are risk factors that can affect liver function?
2. A client is suspected of having decreased liver function. What information would be essential for the nurse to know about the oral medication that is to be given?

KIDNEYS

Drug excretion occurs mainly through the kidneys into the urine. If there is any impairment in kidney function, medications may not be excreted at the anticipated speed. Subsequent medication administration may lead to accumulation and potential toxicity.

QUESTIONS

1. Why would very young and very old clients need to be closely monitored by the nurse for signs and symptoms of drug toxicity?
2. How can the nurse assess kidney function?

See student resource website for answers.

FACTORS AFFECTING MEDICATION ACTION

A number of factors other than the drug itself can affect its action. A person may not respond in the same manner to successive doses of a drug. In addition, the identical drug and dosage may affect different clients differently.

Developmental Factors

During pregnancy women must be very careful about taking medications. Drugs taken during pregnancy pose a risk throughout the pregnancy, but pose the highest risk during the first trimester, due to the formation of vital organs and functions of the fetus during this time.

Most drugs are contraindicated because of their possible adverse effects on the fetus.

Infants usually require small dosages because of their body size and the immaturity of their organs, especially the liver and kidneys. Differences in gastric acidity and liver enzymes required for drug metabolism may require different medication choices and dosages than adults. In adolescence or adulthood, allergic reactions may occur to drugs formerly tolerated.

Older adults have different responses to medications due to physiological changes that accompany aging. These changes include decreased liver and kidney function, which can result in the accumulation of the drug in the body. In addition, the older person may be on multiple drugs and incompatibilities may occur.

Older adults often experience decreased gastric motility and decreased gastric acid production and blood flow, which can impair drug absorption. Increased adipose tissue and decreased total body fluid proportionate to the body mass can increase the possibility of drug toxicity. Older adults may also experience a decreased number of protein-binding sites and changes in the blood–brain barrier. The latter permits fat-soluble drugs to move readily to the brain, often resulting in dizziness and confusion. This is particularly evident with beta-blockers.

Gender

Differences in the way men and women respond to drugs are chiefly related to the distribution of body fat and fluid and hormonal differences. Because most drug research is done on men, more research on women is required to reflect the effects of hormonal changes on drug actions in women.

Cultural, Ethnic, and Genetic Factors

A client's response to a drug is influenced by genetic variations such as gender, size, and body composition. This variation in response is called **pharmacogenetics**, a branch of pharmacology that examines the role of genetics in drug response.

Pharmacogenetics has identified genetic differences in the production of enzymes that affect drug metabolism. For example, the genes that control liver metabolism vary. The liver eliminates drugs in a variety of ways, but the metabolic cytochromes in the liver are the primary route of metabolism. Researchers continue to learn about cytochromes, especially the cultural and genetic variations that seem to account for differences in a client's response to drug therapy, including adverse drug reactions (Cheek, 2013). For example, some clients may have slow liver metabolism and not achieve an adequate response to a medication, whereas others are rapid metabolizers and may require lower doses of a medication to avoid adverse reactions. A genetic blood test can analyze genes in a client's blood to determine if they could cause variations in the metabolism of certain drugs. This information can help health care providers to individualize medication treatment and avoid adverse reactions.

Ethnopharmacology is the study of the effect of racial and ethnic differences/responses to prescribed medication. For example, certain medications may work well at usual therapeutic dosages for certain ethnic groups but be toxic for others. Ethnopharmacology also incorporates pharmacogenetics, which can also vary by race or ethnic group. While not cost effective at this time, it is anticipated that pharmacogenetics may change the way drug therapy is practiced in the future.

Cultural factors and practices (e.g., values and beliefs) can also affect a drug's action. For example, an herbal remedy (e.g., the Chinese herb ginseng) may speed up or slow down the metabolism of prescribed medications. Culturally Responsive Care provides guidelines for nurses who care for clients from other cultures.

Diet

Nutrients can affect the action of a medication. For example, vitamin K, found in green leafy vegetables, can counteract the effect of an anticoagulant such as warfarin (Coumadin). See Table 47–1 in Chapter 47 ∞.

Culturally Responsive Care

PATIENT-CENTERED CARE

Ethnopharmacology

Drug response can be affected by ancestry. Until recently, clinical drug research was conducted on Caucasian males even when the health condition being studied was prevalent in other ethnic groups. Research has shown that one size does *not* fit all.

IMPLICATIONS FOR NURSING INTERVENTIONS

- Remember that there may be differences in medication responses among different ethnic groups and differences *within* ethnic groups.
- Avoid profiling and stereotyping.
- Ask about health beliefs, values, and customs/practices.
- Be accepting of differences in cultural beliefs and practices.
- Conduct a cultural assessment with each client.
- Learn about drug responses (including adverse effects) that are related to ancestry.
- Ask the client direct, specific questions to reveal the presence or absence of potential adverse effects of medications.
- Monitor the client and document findings carefully because it may be possible to maintain a therapeutic benefit at a lower dosage of a given drug.
- Implement a treatment plan with the client and family that is consistent with their cultural and traditional beliefs while incorporating the necessary modern treatments.
- Keep cultural context in mind when planning education for clients and families.

Environment

The client's environment can affect the action of drugs, particularly those used to alter behavior and mood. Therefore, nurses assessing the effects of a drug need to consider the drug in the context of the client's personality and milieu.

Environmental temperature may also affect drug activity. When environmental temperature is high, the peripheral blood vessels dilate, thus intensifying the action of vasodilators. In contrast, a cold environment and the consequent vasoconstriction inhibit the action of vasodilators but enhance the action of vasoconstrictors. A client who takes a sedative or analgesic in a busy, noisy environment may not benefit as fully as if the environment were quiet and peaceful.

Psychological Factors

A client's expectations about what a drug can do can affect the response to the medication. For example, a client who believes that codeine is ineffective as an analgesic may experience no relief from pain after it is given.

Illness and Disease

Illness and disease can also affect the action of drugs. For example, aspirin can reduce the body temperature of a feverish client but has no effect on the body temperature of a client without fever. Drug action is altered in clients with circulatory, liver, or kidney dysfunction.

Time of Administration

The time of administration of oral medications affects the relative speed with which they act. Some orally administered medications are absorbed more quickly if the stomach is empty, whereas other medications have a more rapid absorption when administered with food. For example, the anti-infective agent ampicillin absorbs more rapidly on an empty stomach, but the antidepressant trazodone

hydrochloride is absorbed more rapidly with food. Iron supplements are known to cause GI irritation. Administering the iron supplement after a meal can reduce GI irritation.

ROUTES OF ADMINISTRATION

Pharmaceutical preparations are generally designed for one or two specific routes of administration (Table 35–5). The route of administration should be indicated when the drug is ordered. When administering a drug, the nurse should ensure that the pharmaceutical preparation is appropriate for the route specified.

Oral

Oral administration is the most common, least expensive, and most convenient route for most clients. In oral administration, the drug is

swallowed. Because the skin is not broken as it is for an injection, oral administration is also a safe method.

The major disadvantages can include an unpleasant taste of the drugs, irritation of the gastric mucosa, irregular absorption from the GI tract, slow absorption, and, in some cases, harm to the client's teeth. For example, the liquid preparation of ferrous sulfate (iron) can stain the teeth.

Sublingual

In **sublingual** administration a drug is placed under the tongue, where it dissolves (Figure 35–3 ■). In a relatively short time, the drug is largely absorbed into the blood vessels on the underside of the tongue. The medication should not be swallowed. Nitroglycerin is one example of a drug commonly given in this manner.

TABLE 35–5 Routes of Administration

Route	Advantages	Disadvantages
Oral	Most convenient Usually least expensive Safe, does not break skin barrier Administration usually does not cause stress Some new oral medications are designed to rapidly dissolve on the tongue, allowing for faster absorption and action	Inappropriate for clients with nausea or vomiting Drug may have unpleasant taste or odor Inappropriate when GI tract has reduced motility Inappropriate if client cannot swallow or is unconscious Cannot be used before certain diagnostic tests or surgical procedures Drug may discolor teeth, harm tooth enamel Drug may irritate gastric mucosa Drug can be aspirated by seriously ill clients
Sublingual	Same as for oral, <i>plus</i> : Drug can be administered for local effect More potent than oral route because drug directly enters the blood and bypasses the liver	If swallowed, drug may be inactivated by gastric juice Drug must remain under tongue until dissolved and absorbed. May cause stinging or irritation of the mucous membranes Drug is rapidly absorbed into the bloodstream
Buccal	Same as for sublingual	Same as for sublingual
Rectal	Can be used when drug has objectionable taste or odor Drug released at slow, steady rate Provides a local therapeutic effect	Dose absorbed is unpredictable May be perceived as unpleasant by the client Limited use
Vaginal	Provides a local effect	May be messy and may soil clothes
Topical	Few side effects	Drug can enter body through abrasions and cause systemic effects Leaves residue on the skin that may soil clothes
Transdermal	Prolonged systemic effect Few side effects Avoids GI absorption problems Onset of drug action faster than oral	Rate of delivery may be variable Verify that the previous patch has been removed and disposed of appropriately to avoid overdose
Subcutaneous	Absorption is slower (an advantage for insulin and heparin administration)	Must involve sterile technique because breaks skin barrier More expensive than oral Can administer only small volume Some drugs can irritate tissues and cause pain Can produce anxiety Breaks skin barrier
Intramuscular	Can administer larger volume than subcutaneous Drug is rapidly absorbed	Can produce anxiety Breaks skin barrier
Intradermal	Absorption is slow (this is an advantage in testing for allergies)	Amount of drug administered must be small Breaks skin barrier
Intravenous	Rapid effect	Limited to highly soluble drugs Drug distribution inhibited by poor circulation
Inhalation	Introduces drug throughout respiratory tract Rapid localized relief Drug can be administered to unconscious client	Drug intended for localized effect can have systemic effect Of use only for the respiratory system

Figure 35-3 ■ Sublingual administration of a tablet.

Figure 35-4 ■ Buccal administration of a tablet.

Buccal

Buccal means “pertaining to the cheek.” In buccal administration, a medication (e.g., a tablet) is held in the mouth against the mucous membranes of the cheek until the drug dissolves (Figure 35-4 ■). The drug may act locally on the mucous membranes of the mouth or systemically when it is swallowed in the saliva.

Parenteral

The **parenteral** route is defined as other than through the alimentary or respiratory tract; that is, by needle. The following are some of the more common routes for parenteral administration:

- **Subcutaneous (hypodermic)**—into the subcutaneous tissue, just below the skin
- **Intramuscular (IM)**—into a muscle
- **Intradermal (ID)**—under the epidermis (into the dermis)
- **Intravenous (IV)**—into a vein.

Some of the less commonly used routes for parenteral administration are intra-arterial (into an artery), intracardiac (into the heart muscle), intraosseous (into a bone), **intrathecal** or **intraspinial** (into the spinal canal), intrapleural (into the pleural space), **epidural** (into the epidural space), and intra-articular (into a joint). Sterile equipment and sterile drug solution are essential for all parenteral therapy. The main advantage is fast absorption.

Topical

Topical applications are those applied to a circumscribed surface area of the body. They affect only the area to which they are applied. Topical applications include the following:

- Dermatologic preparations—applied to the skin
- Instillations and irrigations—applied into body cavities or orifices, such as the urinary bladder, eyes, ears, nose, rectum, or vagina

- Inhalations—administered into the respiratory tract by a nebulizer or positive pressure breathing apparatus. Air, oxygen, and vapor are generally used to carry the drug into the lungs.

MEDICATION ORDERS

A physician usually determines the client's medication needs and orders medications, although in some settings nurse practitioners and physician assistants now order some drugs. State law dictates whether the nurse practitioner and physician assistant have prescriptive ability and the class of drug for which they may prescribe. Also, each health agency will have its own policies. Usually the order is written, although telephone and verbal orders are acceptable in a number of agencies. Nursing students need to know the agency policies about medication orders. In some hospitals, for example, only licensed nurses are permitted to accept telephone and verbal orders. Patient Safety Solutions (2012), a health care consulting service that focuses on client safety, strongly recommends that health organizations have solid guidelines in place to reduce or eliminate errors stemming from verbal orders. For example, for all verbal or telephone orders the nurse must first write down the order and then read it back, verbatim, to the prescribing care provider.

SAFETY ALERT!

SAFETY

Encourage the prescribing care provider to provide correct spelling of a drug, using aids such as “B as in boy.” It is also important for the provider to pronounce numbers separately. For example, the number 16 should be stated as “one six” to avoid confusion with the number 60.

Policies about primary care providers' orders vary considerably from agency to agency. For example, a client's orders may be automatically canceled after surgery or an examination involving an anesthetic agent. The primary care provider must then write new orders.

Most agencies also have lists of abbreviations officially accepted for use in the agency. To prevent medication errors, The Joint Commission (2012) mandated that agencies must standardize abbreviations, acronyms, and symbols used throughout the organization and *must* list abbreviations that are never to be used. The Institute for Safe Medication Practices (ISMP) has published a comprehensive list of error-prone abbreviations, symbols, and dose designations that should not be used when communicating medical information. See Table 35–6 for the list of unacceptable abbreviations.

Types of Medication Orders

Four types of medication orders are commonly used:

1. A **stat order** indicates that the medication is to be given immediately and only once (e.g., morphine sulfate 10 milligrams IV stat).
2. The **single order** or *one-time order* is for medication to be given once at a specified time (e.g., Seconal 100 milligrams at bedtime before surgery).

3. The **standing order** may or may not have a termination date. A standing order may be carried out indefinitely (e.g., multiple vitamins daily) until an order is written to cancel it, or it may be carried out for a specified number of days (e.g., KCl twice daily × 2 days). In some agencies, standing orders are automatically canceled after a specified number of days and must be reordered.
4. A **prn order**, or *as-needed order*, permits the nurse to give a medication when, in the nurse’s judgment, the client requires it (e.g., Amphojel 15 mL prn). The nurse must use good judgment about when the medication is needed and when it can be safely administered.

Essential Parts of a Medication Order

The drug order has seven essential parts, as listed in Box 35–1. In addition, unless it is a standing order it should state the number of doses or the number of days the drug is to be administered.

The *client’s full name*, that is, the first and last names and middle initials or names, should always be used to avoid confusion between

TABLE 35–6 Unacceptable Abbreviations—“Do Not Use” List from The Joint Commission and Institute for Safe Medication Practices (ISMP)

Abbreviation	Potential Problem	Use Instead
**U, u (unit)	Mistaken for “0” (zero), the number “4” (four), or “cc”	Write “unit”
**IU (international unit)	Mistaken for IV (intravenous) or the number 10 (ten)	Write “International Unit”
**Q.D., QD, q.d., qd (daily)	Mistaken for each other	Write “daily”
**Q.O.D., QOD, q.o.d., qod (every other day)	Period after the Q mistaken for “I” and the “O” mistaken for “I”	Write “every other day”
**Trailing zero (X.0 mg)	Decimal point is missed	Write X mg
**Lack of leading zero (.X mg)	Decimal point is missed	Write 0.X mg
**MS	Can mean morphine sulfate or magnesium sulfate Confused for one another	Write “morphine sulfate”
**MSO ₄ and MgSO ₄	Can mean morphine sulfate or magnesium sulfate Confused for one another	Write “magnesium sulfate”
> (greater than) < (less than)	Opposite of intended; mistakenly use incorrect symbol	Write “greater than” Write “less than”
@	Mistaken for the number “2” (two)	Write “at”
cc	Mistaken for U (units) when poorly written	Write “mL” or “milliliters”
µg	Mistaken for mg (milligrams) resulting in one thousand-fold overdose	Write “mcg” or “micrograms”
TIW (three times a week)	Has been misinterpreted as “two times a week” or “three times a day” resulting in misdosing	Write “three times weekly”
AS (left ear) AD (right ear) AU (both ears) OD (right eye) OS (left eye) OU (each eye)	Mistaken for OS (left eye), OD (either “overdose” or “optic density”), and OU (“each eye” or “both eyes”) Mistaken as AD, AS, AU (right ear, left ear, each ear)	Write “left ear,” “right ear,” or “both ears,” as appropriate Use “right eye,” “left eye,” or “each eye”
HS	Has been used to indicate “half strength” and “bedtime” or “hour of sleep”	Write out “half strength” or “at bedtime,” as appropriate
SC and SQ (subcutaneous) Apothecary units	Have been read as “SL” (sublingual) and as “5 every hour” Unfamiliar to many practitioners Confused with metric units	Write “subq” or “subcutaneous” Use metric units
Abbreviations for drug names	Misinterpreted due to similar abbreviations for multiple drugs	Write drug names in full

**These abbreviations are from The Joint Commission’s *Official “Do Not Use” List* and the others are from ISMP’s *Error-Prone Abbreviations, Symbols, and Dose Designations* list. From *Facts About the Official “Do Not Use” List of Abbreviations*, by The Joint Commission, 2012; and *ISMP’s List of Error-Prone Abbreviations, Symbols, and Dose Designations* by the Institute for Safe Medication Practices, 2013a.

BOX 35-1 Essential Parts of a Drug Order

- Full name of the client
- Date and time the order is written
- Name of the drug to be administered
- Dosage of the drug
- Frequency of administration
- Route of administration
- Signature of the person writing the order

two clients who have the same last name. In some agencies, the client's identification number and primary care provider's name are placed on the order as further identification. Some hospitals imprint the client's name, identification number, and room number on all forms; some agencies use stickers with similar information.

In addition to the *day*, the *month*, and the *year* the order was written, some agencies also require that the time of day be written. Writing the *time of day* on the order can eliminate errors when the nursing shifts change and makes clear when certain orders automatically terminate. For example, in some settings narcotics can be ordered only for 48 hours after surgery. Therefore, a drug that is ordered at 1600 hours November 1, 2015, is automatically canceled at 1600 hours November 3, 2015. Many health agencies use the 24-hour clock, which eliminates confusion between morning and afternoon times. Time with the 24-hour clock starts at midnight, which is 0000 hours (see Chapter 15 ∞).

The *name of the drug to be administered* must be clearly written. In some settings only generic names are permitted; however, trade names are widely used in hospitals and health agencies.

The *dosage of the drug* includes the amount, the times or *frequency of administration*, and in many instances the strength; for example, tetracycline 250 mg (amount) four times a day (frequency); potassium chloride 10% (strength) 5 mL (amount) three times a day with meals (time and frequency). Dosages can be written in apothecary or metric systems. The metric system, however, is strongly suggested for safety reasons because many practitioners are unfamiliar with apothecary units.

Also included in the order is the *route of administration* of the drug. This part of the order, like other parts, is frequently abbreviated. It is not unusual for a drug to have several possible routes of administration; therefore, it is important that the route be included in the order.

The *signature* of the ordering primary care provider or nurse makes the drug order a legal request. *An unsigned order has no validity*, and the ordering physician or nurse practitioner needs to be notified if the order is unsigned.

When a primary care provider writes a prescription for a client, the prescription also includes information for the pharmacist. Therefore, a prescription's content differs from that of a medication order in a hospital. Compare the parts of a prescription listed in Box 35-2 with those shown in Figure 35-5 ■.

Communicating a Medication Order

A drug order is written on the client's chart by a primary care provider or by a nurse receiving a telephone or verbal order from a primary care provider. Most acute care agencies have a specified time frame (e.g., 24 or 48 hours) in which the primary care provider issuing the telephone or verbal order must cosign the order written by the nurse. The nurse or clerk then copies the medication order to a Kardex or

BOX 35-2 Parts of a Prescription

- Descriptive information about the client: name, address, and sometimes age
- Date on which the prescription was written
- The Rx symbol, meaning "take thou"
- Medication name, dosage, and strength
- Route of administration
- Dispensing instructions for the pharmacist, for example, "Dispense 30 capsules"
- Directions for administration to be given to the client, for example, "take on an empty stomach"
- Refill and/or special labeling, for example, "Refill × 1"
- Prescriber's signature

Name	<u>Jane Cleary</u>	Age	<u>36</u>	
Address	<u>3376 W. 141st St., Scottsdale</u>		Date	<u>Nov 1, 2015</u>
This prescription will be filled generically unless physician signs on line stating "Dispense as written."

Figure 35-5 ■ A prescription filled out by a primary care provider.

medication administration record (MAR). Increasingly, nurses receive computer printouts of a client's medications instead of a copy of the primary care provider's order. This method avoids errors and saves nursing time.

CLINICAL ALERT!

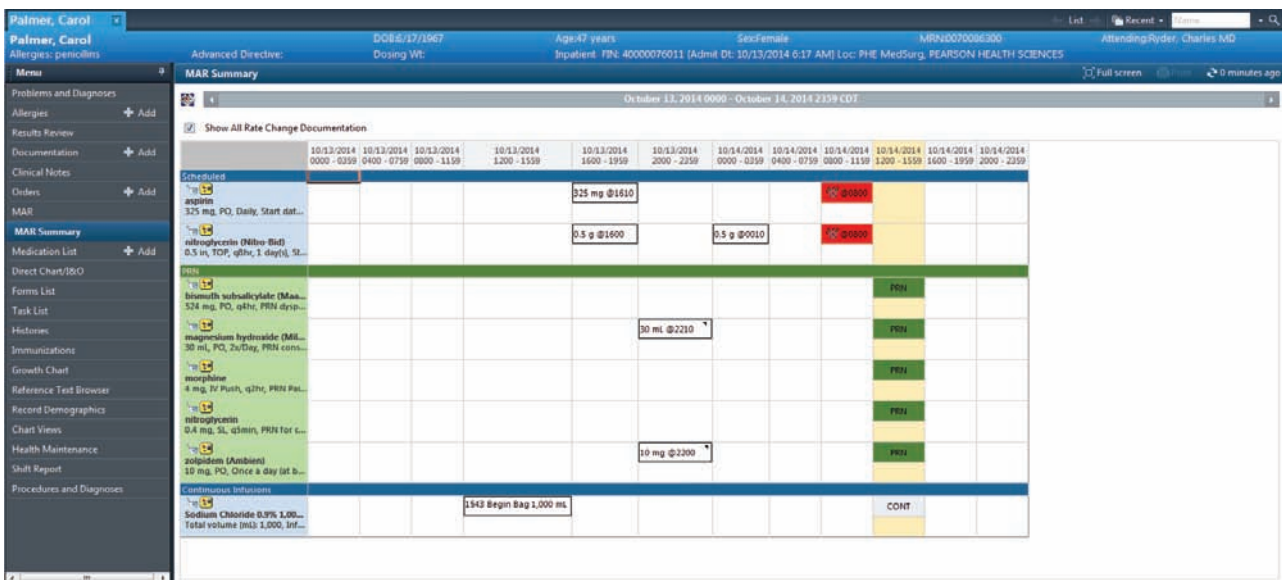

If your assigned client receives new medication orders, double-check the transcribed information with the primary care provider's order. This ensures client safety.

MARs vary in form, but all include the client's name, drug name and dose; and times and method of administration (Figure 35-6 ■). In some agencies, the date the order was prescribed and the date the order expires are also included.

The nurse should always question the primary care provider about any order that is ambiguous, unusual (e.g., an abnormally high dosage of a medication), or contraindicated by the client's condition.

When the nurse judges a primary care provider–ordered medication inappropriate, the following actions are required:

- Contact the primary care provider and discuss the rationale for believing the medication or dosage to be inappropriate.
- Document in notes the following: when the primary care provider was notified, what was conveyed to the primary care provider, and how the primary care provider responded.
- If the primary care provider cannot be reached, document all attempts to contact the primary care provider and the reason for withholding the medication.
- If someone else gives the medication, document data about the client’s condition before and after the medication.
- If an incident report (see Chapter 4 ∞) is indicated, clearly document factual information.

SYSTEMS OF MEASUREMENT

Three systems of measurement are used in North America: the metric system, the apothecaries’ system, and the household system, which is similar to the apothecaries’ system.

Metric System

The metric system, devised by the French in the latter part of the 18th century, is the system prescribed by law in most European countries and in Canada. The metric system is logically organized into units of 10; it is a decimal system. Basic units can be multiplied or divided by 10 to form secondary units. Multiples are calculated by moving the decimal point to the right, and division is accomplished by moving the decimal point to the left.

Volume		Weight
	Thousands	Kilogram
	Hundreds	Hectogram
	Tens	Dekagram
Liter	1 Unit	Gram
Deciliter	Tenths	Decigram
	Hundredths	Centigram
Milliliter	Thousandths	Milligram

Figure 35–7 ■ Basic metric measurements of volume and weight.

Basic units of measurement are the *meter*, the *liter*, and the *gram*. Prefixes derived from Latin designate subdivisions of the basic unit: *deci* (1/10 or 0.1), *centi* (1/100 or 0.01), and *milli* (1/1,000 or 0.001). Multiples of the basic unit are designated by prefixes derived from Greek: *deka* (10), *hecto* (100), and *kilo* (1,000). Only the measurements of volume (the liter) and of weight (the gram) are discussed in this chapter. These are the measures used in medication administration (Figure 35–7 ■). The *kilogram* (kg) is the only multiple of the gram used, and the *milligram* (mg) and *microgram* (mcg) are subdivisions. Fractional parts of the liter are usually expressed in *milliliters* (mL), for example, 600 mL; multiples of the liter are usually expressed as *liters* or *milliliters*, for example, 2.5 liters or 2,500 mL. In nursing practice it is important to understand the difference between weight and volume. A drug dosage may be ordered by weight (i.e., grams, mg, mcg), but administered by volume (mL). For example, a health care provider prescribes 20 mg (weight) of codeine in an elixir (liquid) form. The codeine elixir bottle is labeled 10 mg per 5 mL. The nurse administers 10 mL (volume) of codeine elixir.

Apothecaries' System

The apothecaries' system, older than the metric system, was brought to the United States from England during the colonial period. Many now consider the apothecaries' system out of date and have replaced it with the metric system. The basic unit of weight in the apothecaries' system is the *grain* (gr), likened to a grain of wheat, and the basic unit of volume is the *minim*, a volume of water equal in weight to a grain of wheat. The word *minim* means "the least." In ascending order, the other units of weight are the *scruple*, the *dram*, the *ounce*, and the *pound*. Today, the scruple is seldom used. The units of volume are, in ascending order, the fluid dram, the fluid ounce, the pint, the quart, and the gallon.

Quantities in the apothecaries' system are often expressed by lowercase Roman numerals, particularly when the unit of measure is abbreviated. Unlike other measurement systems, the Roman numeral follows rather than precedes the unit of measure. For example, two grains are written as gr ii. Quantities less than 1 are expressed as a fraction, for example, gr 1/6. As stated earlier, apothecary units are unfamiliar to many practitioners and they may be confused with metric units. Therefore, nurses are advised *not* to use apothecary units. Use metric units instead to avoid medication errors.

Household System

Household measures may be used when more accurate systems of measure are not required. Included in household measures are

drops, teaspoons, tablespoons, cups, and glasses. Although pints and quarts are often found in the home, they are defined as apothecaries' measures.

Converting Units of Weight and Measure

Sometimes drugs are dispensed from the pharmacy in grams when the order specifies milligrams, or they are dispensed in milligrams though ordered in grains. For example, a primary care provider orders morphine gr 1/4. The medication is available labeled only in milligrams. The nurse knows that 1 mg = 1/60 gr or 60 mg = 1 grain. To convert the ordered dose to milligrams, the nurse calculates as follows:

$$\begin{aligned} \text{If } 60 \text{ mg} &= 1 \text{ gr} \\ \text{Then } x \text{ mg} &= 1/4 \text{ gr (0.25 gr)} \\ x &= \frac{(60 \times 0.25)}{1} \\ x &= 15 \text{ mg} \end{aligned}$$

CONVERTING WEIGHTS WITHIN THE METRIC SYSTEM

It is relatively simple to arrive at equivalent units of weight within the metric system because the system is based on units of 10. Only three metric units of weight are used for drug dosages, the gram (g), milligram (mg), and microgram (mcg): 1,000 mg or 1,000,000 mcg equals 1 gram (g). Equivalents are computed by dividing or multiplying; for example, to change milligrams to grams, the nurse divides the number of milligrams by 1,000. The simplest way to divide by 1,000 is to move the decimal point three places to the left:

$$500 \text{ mg} = ? \text{ g}$$

Move the decimal point three places to the *left*:

$$\text{Answer} = 0.5 \text{ g}$$

It is important to put a 0 in front of the decimal point; otherwise, the reader may miss the decimal point and administer a wrong dose of medication.

Conversely, to convert grams to milligrams, multiply the number of grams by 1,000, or move the decimal point three places to the right:

$$0.006 \text{ g} = ? \text{ mg}$$

Move the decimal point three places to the *right*:

$$\text{Answer} = 6 \text{ mg}$$

CONVERTING WEIGHTS AND MEASURES BETWEEN SYSTEMS

When preparing client medications, a nurse may need to convert weights or volumes from one system to another. As an example, the pharmacy may dispense milligrams or grams of chloral hydrate, yet the nurse must administer an order that reads "chloral hydrate gr v." To prepare the correct dose, the nurse must convert from the apothecaries' to the metric system. To give clients a useful, realistic measure for home use, the nurse may have to convert from the apothecaries' or metric system to the household system. All conversions are approximate, that is, not totally precise.

CONVERTING UNITS OF VOLUME

Commonly used approximate equivalents are shown in Table 35–7. By learning these equivalents, the nurse can make many conversions readily. For example, 15 minims = approximately 15 drops (gtt); therefore, 1 minim is approximately 1 drop. Similarly, 1 quart approximates 1,000 mL, and 1 gallon approximates 4,000 mL.

The following are some situations in which nurses need to apply knowledge of volume conversion:

- Fluid drams and ounces are commonly used in prescribing liquid medications, such as cough syrups, laxatives, antacids, and antibiotics for children. The fluid ounce is frequently converted to milliliters when measuring a client’s fluid intake or output.
- Liters and milliliters are the volumes commonly used in preparing solutions for enemas, irrigating solutions for bladder irrigations, and solutions for cleaning open wounds. In some situations, the nurse needs to convert the volumes of such solutions.

CONVERTING UNITS OF WEIGHT

The units of weight most commonly used in nursing practice are the gram, milligram, and kilogram and the grain and the pound. Household units of weight are generally not applicable.

Table 35–8 shows metric and apothecaries’ approximate equivalents. Learning these equivalents helps the nurse make weight conversions readily, as for example in the following situations:

- Converting milligrams to grains and vice versa, for example, when preparing medications
- Converting pounds to kilograms and vice versa, for example, when determining a person’s weight.

When converting units of weight from the metric system to the apothecaries’ system, the nurse should keep in mind that a milligram is smaller than a grain (1 mg = 1/60 grain and 1 grain = 60 mg). The result of converting a smaller unit (milligram) to a larger unit (grain) is a smaller number. Thus, the nurse must divide (by 60 if converting from milligrams to grains). Conversely, when converting from a larger unit to a smaller unit, the nurse multiplies (by 60 if converting from grains to milligrams), and the product is a larger number. In other words:

Small units (mg) to large units (grains) = a smaller number
 Large units (grains) to small units (mg) = a larger number

$$\frac{3,000 \text{ mg}}{60} = 50 \text{ grains}$$

$$50 \text{ grains} \times 60 = 3,000 \text{ mg}$$

TABLE 35–8 Approximate Weight Equivalents: Metric and Apothecaries’ Systems

Metric		Apothecaries’
1 mg	=	1/60 grain
60 mg	=	1 grain
1 g	=	15 grains
4 g	=	1 dram
30 g	=	1 ounce
500 g	=	1.1 pound (lb)
1,000 g (1 kg)	=	2.2 lb

When converting pounds to kilograms, the nurse applies the same rule. The pound is a smaller unit than the kilogram, and the nurse converts by dividing or multiplying by 2.2:

$$2.2 \text{ lb} = 1 \text{ kg}$$

$$110 \text{ lb} = x \text{ kg}$$

$$x = \frac{110 \times 1}{2.2}$$

$$= 50 \text{ kg}$$

or

$$50 \text{ kg} = x \text{ lb}$$

$$1 \text{ kg} = 2.2 \text{ lb}$$

$$x = \frac{2.2 \times 50}{1}$$

$$= 110 \text{ lb}$$

The conversion of milligrams to grams was previously discussed. The decimal point is moved three spaces to the left:

$$3,000 \text{ mg} = 3 \text{ g}$$

Methods of Calculating Dosages

Four common formulas are used to calculate drug dosages. Any of the formulas can be used. Nursing students are encouraged to review all four and to choose the method that works best for them. It is important to use one method consistently to avoid confusion in calculations and, thus, promote client safety. When calculating drug dosages, there are times when the nurse may need to round numbers. Box 35–3 reviews general guidelines for rounding.

TABLE 35–7 Approximate Volume Equivalents: Metric, Apothecaries’, and Household Systems

Metric		Apothecaries’		Household
1 mL	=	15 minims (min or m)	=	15 drops (gtt)
4–5 mL	=	1 fluid dram	=	1 teaspoon
15 mL	=	4 fluid drams	=	1 tablespoon (Tbsp)
30 mL	=	1 fluid ounce	=	same
500 mL	=	1 pint (pt)	=	same
1,000 mL	=	1 quart (qt)	=	same
4,000 mL	=	1 gallon (gal)	=	same

BOX 35-3 Guidelines for Rounding Numbers in Drug Calculations

Generally . . .

- Quantities *greater than 1* are rounded to the nearest *tenth*.
- Quantities *less than 1* are rounded to the nearest *hundredth* (Giangrasso & Shrimpton, 2013, p. 11).

To round to the nearest tenth:

- Look at the number in the hundredths place. If this number is 5 or greater, add 1 to the tenths place number. For example, 1.67 = 1.7. If the number in the hundredths place is less than 5, leave the number in the tenths place as is. For example, 1.63 = 1.6.

To round to the nearest hundredth:

- Look at the number in the thousandths place. If this number is 5 or greater, add 1 to the hundredths place number. For example, 0.825 = 0.83. If the number in the thousandths place is less than 5, leave the number in the hundredths place as is. For example, 0.823 = 0.82.

ORAL MEDICATIONS

- A capsule cannot be divided.
- Tablets that are scored (a line marked on the tablet) may be divided. A tablet must be scored by the manufacturer to be divided properly.
- For tablets that are *not* scored and capsules, it may not be realistic to administer the exact amount as calculated. For example, if the calculation for x results in 1.9 tablets or capsules, the nurse gives 2 tablets or capsules because it is unrealistic to accurately administer 1.9 tablets or capsules.
- If the oral medication is a liquid, the nurse checks to see if it is possible to administer an accurate dosage. This often depends on the syringes used to draw up the medication. For example, a tuberculin (TB) syringe is a 1-mL syringe that includes markings for hundredths of a milliliter. These syringes are often used in pediatrics because they can measure medications given in very small amounts. The nurse needs to pay attention to the markings on the syringe. Some syringes (e.g., 3-mL)

have calibrations where each line indicates one tenth of a milliliter. In contrast, the calibration lines for larger syringes (e.g., 10-mL) indicate a 0.2-mL increment. The nurse must select the proper size syringe for the calculated volume of medication.

PARENTERAL MEDICATIONS

- Rounding depends on the amount (i.e., less than or more than 1) and the syringe used. As indicated above, a TB syringe can be used for very small amounts (e.g., to the hundredth of a mL). Larger syringes would be used for rounding to a tenth of a milliliter.

IV INFUSION

- By gravity:
 - Round to the nearest whole number. For example, if the flow rate calculation equals 37.5 drops/minute, the nurse adjusts the flow rate to 38 drops/minute.
- By IV pump:
 - If the IV pump uses only whole numbers, round to the nearest whole number.
 - Some IV pumps used in critical care units can be set to a tenth of a rate (e.g., 11.1 mL/hr). Round to the nearest tenth decimal point.

ROUNDING DOWN

- Rounding down may be used in pediatrics or when administering high-alert medications to adults. This type of rounding is done to avoid the danger of an overdose (Giangrasso & Shrimpton, 2013, p. 11).
- To round down to hundredths, drop all of the numbers after the hundredth place. For tenths, drop all of the numbers after the tenth place, and for whole numbers, all of the numbers after the decimal. For example, 6.6477 rounded down to the nearest
 - Hundredth = 6.64.
 - Tenth = 6.6.
 - Whole number = 6.

BASIC FORMULA

The basic formula for calculating drug dosages is commonly used and easy to remember:

D = desired dose (i.e., dose ordered by primary care provider)

H = dose on hand (i.e., dose on label of bottle, vial, ampule)

V = vehicle (i.e., form in which the drug comes, such as tablet or liquid).

$$\text{Formula} = \frac{D \times V}{H} = \text{amount to administer}$$

Example

Order: Erythromycin 500 mg

On hand: 250 mg in 5 mL

$$D = 500 \text{ mg} \quad H = 250 \text{ mg} \quad V = 5 \text{ mL}$$

$$\frac{500 \text{ mg}}{250 \text{ mg}} \times 5 \text{ mL} = \frac{2,500}{250} = 10 \text{ mL}$$

Another Example

Order: Phenobarbital gr ii

On hand: Phenobarbital 30 mg tablets

Note: Before doing the drug calculation, the nurse needs to convert to one system and unit of measurement. In this case, the nurse converts the grains (order) to the measurement on hand (mg):

$$2 \text{ gr} = 120 \text{ mg}$$

$$D = 120 \text{ mg} \quad H = 30 \text{ mg} \quad V = \text{tablet}$$

$$\frac{120 \text{ mg}}{30 \text{ mg}} \times 1 \text{ tablet} = 4 \text{ tablets}$$

RATIO AND PROPORTION METHOD

The ratio and proportion method is considered the oldest method used for calculating dosage problems. The equation is set up with the known quantities on the left side (i.e., H and V). The right side of the equation consists of the desired dose (i.e., D) and the unknown amount to administer (i.e., x). The equation looks like this:

$$H : V :: D : x$$

Once the equation is set up, multiply the extremes (i.e., H and x) and the means (i.e., V and D). Then solve for x .

Example

Order: Keflex 750 mg

On hand: Keflex 250 mg capsules

$$H = 250 \text{ mg} : V = 1 \text{ capsule} :: D = 750 \text{ mg} : x \\ 250 : 1 :: 750 : x$$

Multiply the extremes (i.e., H and x) and the means (V and D):

$$250x = 750 \\ x = 3 \text{ tablets}$$

Another Example

Order: Aspirin gr 10

On hand: Aspirin 325 mg tablets

Note: Before doing the drug calculation, the nurse needs to convert to one system and unit of measurement. In this case, the nurse converts the grains to milligrams:

$$1 \text{ gr} = 60 \text{ mg} \\ 10 \text{ gr} = 600 \text{ mg}$$

$$H = 325 \text{ mg} : V = 1 \text{ tablet} :: D = 600 \text{ mg} : x \\ 325 : 1 :: 600 : x$$

Multiply the extremes (i.e., H and x) and the means (V and D):

$$\frac{325x}{325} = \frac{600}{325}$$

We determine that $x = 1.8 = 2$ tablets since a tablet cannot be accurately cut into 0.8.

FRACTIONAL EQUATION METHOD

The fractional equation method is similar to ratio and proportion, except it is written as a fraction:

$$\frac{H}{V} = \frac{D}{x}$$

The formula consists of cross multiplying and solving for x :

$$\frac{H}{V} = \frac{D}{x} \\ Hx = DV \\ x = \frac{DV}{H}$$

Example

Order: Lanoxin 0.25 mg

On hand: Lanoxin 0.125 mg tablets

$$\frac{0.125 \text{ mg}}{1 \text{ tablets}} = \frac{0.25 \text{ mg}}{x \text{ tablets}}$$

Cross multiply:

$$0.125x = 0.25$$

Solve for x :

$$\frac{0.125x}{0.125} = \frac{0.25}{0.125} \\ x = 2 \text{ tablets}$$

Example Requiring Conversion

Order: Atropine gr 1/100

On hand: Atropine 0.4 mg/mL

Note: Before doing the drug calculation, the nurse must convert from two systems to one system and unit of measurement. In this case,

because the dosage on hand is in milligrams, the nurse converts the grains to milligrams:

$$1 \text{ gr} = 60 \text{ mg} \\ 1/100 \text{ gr} = 0.6 \text{ mg} \\ \frac{0.4 \text{ mg}}{1 \text{ mL}} = \frac{0.6 \text{ mg}}{x \text{ mL}}$$

Cross multiply:

$$0.4x = 0.6$$

Solve for x :

$$\frac{0.4x}{0.4} = \frac{0.6}{0.4} \\ x = 1.5 \text{ mL}$$

DIMENSIONAL ANALYSIS

The dimensional analysis method is often used in the physical sciences when a quantity in one unit of measurement is converted to an equivalent quantity in a different unit of measurement by canceling matching units of measurement. In some of the previous examples, the nurse needed to convert from one or two systems to one system and unit of measurement. This involved extra steps or equations. One advantage of dimensional analysis is that only one equation is needed. The three components (D, H, and V) are still needed to solve the problem. However, when the units of measurement differ for D and H, the dimensional analysis method includes the conversion factor in the equation. In *Dosage Calculations Made Incredibly Easy!* (2010, p. 77) six steps are suggested when using dimensional analysis:

1. Identify the dose on hand.
2. Identify the desired dose.
3. Write down the conversion factor, if needed.
4. Set up the equation.
5. Cancel units that appear in the numerator and denominator.
6. Multiply the numerator. Multiply the denominator. Divide the products.

Example:

Order: Valsartan 120 mg

On hand: Valsartan 40 mg tablets

1. Identify the dose on hand: 40 mg
2. Identify the desired dose: 120 mg
3. No conversion is needed.
4. Set up the equation. Remember to put V (the form in which the drug comes) in the *numerator*:

$$\frac{1 \text{ tablet}}{40 \text{ mg}} \times \frac{120 \text{ mg}}{1}$$

5. Cancel units:

$$\frac{1 \text{ tablet}}{40 \text{ mg}} \times \frac{120 \text{ mg}}{1}$$

6. Multiply the numerator and denominator and then divide:

$$\frac{1 \text{ tablet}}{40} \times \frac{120}{1} = \frac{120}{40} = 3 \text{ tablets}$$

Example Using a Conversion Factor*Order:* dofetilide 0.5 mg*On hand:* 125 mcg capsules

1. Identify the dose on hand: 125 mcg capsule
2. Identify the desired dose: 0.5 mg
3. Write down conversion:

$$\frac{1000 \text{ mcg}}{1 \text{ mg}}$$

4. Set up the equation. Remember (a) to put the form of the drug in the numerator and (b) to set up the conversion factor so that units that need to cancel appear in both numerator and denominator:

$$\frac{1 \text{ capsule}}{125 \text{ mcg}} \times \frac{1000 \text{ mcg}}{1 \text{ mg}} \times \frac{0.5 \text{ mg}}{1}$$

5. Cancel units:

$$\frac{1 \text{ capsule}}{125 \text{ mcg}} \times \frac{1000 \text{ mcg}}{1 \text{ mg}} \times \frac{0.5 \text{ mg}}{1}$$

6. Multiply numerator and denominator and then divide:

$$\frac{1 \text{ capsule}}{125} \times \frac{1000}{1} \times \frac{0.5}{1} = \frac{500}{125} = 4 \text{ capsules}$$

Another Example Requiring Conversion*Order:* Tylenol gr xv*On hand:* Tylenol 325 mg tablets

1. Identify the dose on hand: 325 mg tablet
2. Identify the desired dose: gr xv
3. Write down the conversion:

$$\frac{60 \text{ mg}}{1 \text{ gr}}$$

4. Set up the equation. Remember (a) to put the form of the drug in the numerator and (b) to set up the conversion factor so that units that need to cancel appear in both numerator and denominator:

$$\frac{1 \text{ tablet}}{325 \text{ mcg}} \times \frac{60 \text{ mg}}{1 \text{ gr}} \times \frac{15 \text{ gr}}{1}$$

5. Cancel units:

$$\frac{1 \text{ tablet}}{325 \text{ mg}} \times \frac{60 \text{ mg}}{1 \text{ gr}} \times \frac{15 \text{ gr}}{1}$$

6. Multiply numerator and denominator and divide:

$$\frac{1 \text{ tablet}}{325} \times \frac{60}{1} \times \frac{15}{325} = 900$$

= 2.76 tablets = 3 tablets because a tablet cannot be accurately cut into 0.76

CALCULATION FOR INDIVIDUALIZED DRUG DOSAGES

Nurses often need to individualize the dosage of a medication for pediatric clients. Other clients who may require an individualized dosage include those receiving chemotherapy and clients who are critically ill. The two methods for individualizing drug dosages are body weight and body surface area.

BODY WEIGHT Unlike adult dosages, children's dosages are not always standard. Body weight significantly affects dosage; therefore, dosages are calculated. Dosages based on weight use kilograms of body weight and per kilogram medication recommendations to arrive at appropriate and safe doses.

The steps involved in calculating an individualized dose are as follows:

1. Convert pounds to kilograms.
2. Determine the drug dose per body weight by multiplying drug dose \times body weight \times frequency.
3. Choose a method of drug calculation to determine the amount of medication to administer.

Example

Order: Keflex, 20 mg/kg/day in three divided doses. The client weighs 20 pounds.

On hand: Keflex oral suspension 125 mg per 5 mL

1. Convert pounds to kilograms:
 $20 \div 2.2 = 9 \text{ kg}$
2. Multiply drug dose \times body weight \times frequency:
 $20 \text{ mg} \times 9 \text{ kg} = 180 \text{ mg/day}$
 $180 \div 3 \text{ divided doses} = 60 \text{ mg per dose}$
3. The nurse chooses his or her preferred method of calculation (e.g., basic formula, ratio and proportion, fractional, dimensional analysis) to determine how many milliliters per dose of medication. (The answer is 2.4 mL per dose.)

BODY SURFACE AREA Sometimes the body surface calculation may be used instead of body weight to individualize the medication dosage. It is considered to be the most accurate method of calculating a child's dose. Body surface area is determined by using a nomogram and the child's height and weight. Figure 35-8 ■ shows a standard nomogram that will give a child's body surface area based on the weight and height of the child. The formula is the ratio of the child's body surface area to the surface area of an average adult (1.7 square meters, or 1.7 m²), multiplied by the normal adult dose of the drug:

$$\frac{\text{Child's dose}}{1.7 \text{ m}^2} = \frac{\text{surface area of child (m}^2\text{)}}{1.7 \text{ m}^2} \times \text{normal adult dose}$$

For example, a child who weighs 10 kg and is 50 cm tall has a body surface area of 0.4 m². Therefore, the child's dose of tetracycline corresponding to an adult dose of 250 mg would be as follows:

$$\frac{0.4 \text{ (surface area of child)}}{1.7 \text{ (surface area of average adult)}} = 0.2$$

$$0.2 + 250 \text{ (normal adult dose)} = 50 \text{ mg}$$

ADMINISTERING MEDICATIONS SAFELY

The nurse should always assess a client's health status and obtain a medication history prior to giving any medication. The extent of the assessment depends on the client's illness or current condition, the intended drug, and the route of administration. For example, if a client has dyspnea, the nurse assesses respirations carefully before

Figure 35-8 ■ Nomogram with estimated body surface area. A straight line is drawn between the child's height (on the left) and the child's weight (on the right). The point at which the line intersects the surface area column is the estimated body surface area.

administering any medication that might affect breathing. It is important to determine whether the route of administration is suitable. For example, a client who is nauseated may not be able to keep down a drug taken orally. In general, the nurse assesses the client *prior* to administering any medication to obtain baseline data by which to evaluate the effectiveness of the medication.

The medication history includes information about the drugs the client is taking currently or has taken recently. This includes prescription drugs; OTC drugs such as antacids, alcohol, and tobacco; and nonsanctioned drugs such as marijuana. Sometimes an incompatibility with one or more of these drugs affects the choice of a new medication.

Older adults often take vitamins, herbs, and food supplements, and/or use folk remedies that they do not list in their medication history. Because many of these have unknown or unpredictable actions and side effects, they need to be noted, with attention paid to possible incompatibilities with other prescribed medications.

An important part of the history is clients' knowledge of their drug allergies. Some clients can tell a nurse, "I am allergic to penicillin, adhesive tape, and curry." The nurse should clarify with the client any side effects, adverse reactions, or allergic responses due to

medications. Other clients may not be sure about allergic reactions. An illness occurring after a drug was taken may not be identified as an allergy, but the client may associate the drug with an illness or unusual reaction. The client's primary care provider can often give information about allergies. During the history, the nurse tries to elicit information about drug dependencies. How often drugs are taken and the client's perceived need for them are measures of dependence.

Also included in the history are the client's normal eating habits. Sometimes the medication schedule needs to be coordinated with mealtimes or the ingestion of foods. When a medication must be taken with food on a specified schedule, clients can often adjust their mealtime or have a snack (e.g., with a bedtime medication). In addition, certain foods are incompatible with certain medications; for example, milk is incompatible with tetracycline.

It is also important for the nurse to identify any problems the client may have in self-administering a medication. A client with poor eyesight, for example, may require special labels for the medication container; older clients with unsteady hands may not be able to hold a syringe or to inject themselves or another person. Obtaining information as to how and where clients store their medications is also important. If clients have difficulty opening certain containers, they may change containers, but leave old labels on, which increases the risk of medication errors.

The nurse needs to consider socioeconomic factors for all clients, but especially for older clients. Two common problems are lack of transportation to obtain medications and inadequate finances to purchase medications. When aware of these problems, the nurse can refer the client to the proper resources.

Medication Administration Errors

The National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP) (2013) estimates that 98,000 people die annually from medical errors that occur in hospitals and that a significant number of those deaths are due to medication errors. The NCC MERP defines a medication error as "any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use" (para 2).

Medication errors can occur at all stages of the medication administration process. Tzeng, Yin, and Schneider (2013, p. 14) describe the four main types of medication errors that occur with hospitalized clients: (1) prescription errors (e.g., wrong drug or dose); (2) transcription/interpretation error (e.g., misinterpretation of abbreviations); (3) preparation errors (e.g., calculation error); and (4) administration errors (e.g., wrong dose, wrong time, omission, or additional dose). Most medication errors occur during the administration stage.

Medication administration errors result from system and individual factors. Individual factors include fatigue and stress. Many studies report medication errors occur related to the system factor of interruptions and distractions during medication administration. Research has demonstrated that interruptions create a great risk for and severity of errors in medication administration (Flanders & Clark, 2010, p. 282). Interruptions and distractions hinder the ability of the nurse to stay focused on the task. In addition, after the

PRACTICE GUIDELINES

Administering Medications

- Nurses who administer medications are responsible for their own actions. Question any order that is illegible or that you consider incorrect. Call the person who prescribed the medication for clarification.
- Be knowledgeable about the medications you administer. You need to know why the client is receiving the medication. Look up the necessary information if you are not familiar with the medication.
- Federal laws govern the use of narcotics and barbiturates. Keep these medications in a locked place.
- Use only medications that are in a clearly labeled container.
- Do not use liquid medications that are cloudy or have changed color.
- Calculate drug doses accurately. If you are uncertain, ask another nurse to double-check your calculations.
- Administer only medications personally prepared.
- Before administering a medication, identify the client correctly using the appropriate means of identification, such as checking the identification bracelet.
- Do not leave medications at the bedside, with certain exceptions (e.g., nitroglycerin, cough syrup). Check agency policy.
- If a client vomits after taking an oral medication, report this to the nurse in charge, or the primary care provider, or both.
- Take special precautions when administering certain medications; for example, have another nurse check the dosages of anticoagulants, insulin, and certain IV preparations.
- Most hospital policies require new orders from the primary care provider for a client's postsurgery care.
- When a medication is omitted for any reason, record the fact together with the reason.
- When a medication error is made, report it immediately to the nurse in charge, the primary care provider, or both.
- Always check a medication's expiration date.

interruption, the nurse needs additional time to refocus concentration and determine what has been done and remains to be done—all of which increase the risk for error (Clark & Flanders, 2012; Lewis, Smith, & Williams-Jones, 2012). Many nurses pride themselves on being able to multitask. Scientists, however, who study short-term memory, agree that the less a person tries to hold in mind at one time, the better. Clark and Flanders (2012) report that “research into the effects of interruptions and multitasking is accumulating and has a consistent theme—the brain is not capable of multitasking” (p. 242). This is especially true during medication administration.

Of interest are the studies that investigated the sources of interruption during medication administration. Sources include overhead pages, monitor alarms, telephone calls, and family inquiries, with the most common source being questions from nursing colleagues and other health care team members (Flanders & Clark, 2010; Hall et al., 2010; Lewis et al., 2012). As a result, some studies have evaluated the effectiveness of interventions to reduce interruptions and distractions during medication administration. Strategies to reduce interruptions include using a medication safety checklist, placing signs outside and within medication rooms to promote a quiet environment, having others take non-urgent telephone calls for the nurse who is administering medications, creating a “No Interruption or Quiet Zone” by placing red duct tape around the medication cart and/or medication-dispensing machines. The red-taped area indicates “do not disturb

with non-urgent matters” to others. Another approach is where the nurse wears a bright, colorful “Do Not Disturb” sash or vest during medication administration (Flanders & Clark, 2010; Klejka, 2012). All the studies have shown that one or more of these strategies has resulted in reduced medication errors.

Nurses play an important role in medication safety because they perform the last safety checks before a medication is administered to a client. Therefore, it is important that health care leaders recognize the complexity of the nurse's environment and the importance of medication administration, and examine ways to reduce system factors that impact client safety, such as interruptions during medication administration.

Medication Reconciliation

Another safety issue that affects the nurse is the need to ensure that clients receive the appropriate medications and dosages as they move or transition through a facility. The Institute for Healthcare Improvement (IHI) (2011b) defines **medication reconciliation** as “the process of creating the most accurate list possible of all medications a patient is taking—including drug name, dosage, frequency, and route—and comparing that list against the physician's admission, transfer, and/or discharge orders, with the goal of providing correct medications to the patient at all transition points within the hospital.” Preventing adverse drug events (ADEs) is the incentive behind the idea of medication reconciliation. Over half of hospital medication errors occur when clients transition in care both within and outside of the organization (IHI, 2011a; Joint Commission 2013a).

All facilities accredited by The Joint Commission must have protocols and processes in place for medication reconciliation, particularly in the following transition areas: on admission, during transfer between units, and at discharge. (See Box 35–4 for an overview of the elements of medication reconciliation.) The nurse needs to make a complete list of the client's medications (including prescriptions, vitamins, supplements, and OTC) on admission. This current list needs to be compared to any new medications ordered by the primary care provider on admission and during the client's hospital

BOX 35–4 Elements of Medication Reconciliation

The Joint Commission (2013a) requires medication reconciliation to occur:

- *At admission:* Collect a list of the medications the client is currently taking when he or she is admitted to the hospital or seen in an outpatient setting (p. 5).
- *At discharge:* Consult the client's home medication list and current medication orders, and compare them with the discharge medication orders to ensure that medications are appropriately continued, resumed, or discontinued. Provide the client (or family) with written information about the medications the client should be taking when discharged from the hospital or outpatient setting. Explain the importance of managing medication information to the client upon discharge (p. 6).

The IHI (2011a) recommends that medication reconciliation also occur when transferring the client from one level of care to another. That is, compare the medication information the client brought to the hospital with the current medications ordered for the client by the hospital and to the transfer orders to identify and resolve any discrepancies (p. 9).

SAFETY ALERT!**SAFETY****2014 THE JOINT COMMISSION NATIONAL PATIENT SAFETY GOALS (2013a)**

Goal 3: Maintain and Communicate Accurate Client Medication Information

Rationale: *There is evidence that medication discrepancies can affect client outcomes. Medication reconciliation is intended to identify and resolve discrepancies—it is a process of comparing the medications a client is taking (and should be taking) with newly ordered medications. The comparison addresses duplication, omissions, and interactions, and the need to continue current medications.*

stay. Medications that are to be administered around the time of shift report need to be discussed at the report. For example, insulin is a common medication scheduled between night and day shifts. It is important that the oncoming nurse know if the medication was given or not. If a client is transferred to another setting, within or outside of the facility, a complete list of the client's medications must be communicated to the next provider of care. This list is also provided to clients on discharge from the facility. In addition, the client should receive, at discharge, written and oral information on each medication to be taken at home. It is important for the nurse to emphasize to clients the importance of keeping the list of their medications handy and taking it with them to their follow-up visits and to future hospitalizations, if any. Maintaining their list of current medications helps improve communication and avoid potential errors in medication administration. The FDA (2011) developed a form called "My Medicine Record" to help consumers keep track of their prescription medications, OTC drugs, and dietary supplements. This form is available online and can be downloaded. Individuals can then complete it by either writing in the information or entering the information on their computers and printing it.

Medication Dispensing Systems

Medical facilities vary in their medication dispensing systems. The systems can include the following:

- **Medication cart.** The medication cart is on wheels, allowing the nurse to move the cart to outside the client's room. The cart contains small numbered drawers that correlate to the room numbers on the nursing unit. The small drawer is labeled with the name of the client currently in that room and holds the client's medications for the shift or 24 hours (Figure 35–9 ■). The medication is usually in unit-dose packaging; that is, the individual drug package states the drug name, dose, and expiration date (Figure 35–10 ■). A larger locked drawer in the cart contains the controlled substances rather than keeping them in the client's individual drawer. The cart may also include a supply drawer that contains client-labeled bulk containers, such as Metamucil, that are too large for the small individual drawer. The MAR is usually located in a binder or a computer located on top of the medication cart. The nurse either carries a key for the medication cart or enters a special code to open the cart, because it must be kept locked when not in use (Figure 35–11 ■).
- **Medication cabinet.** Some facilities have a locked cabinet in the client's room. This cabinet holds the client's unit-dose medications and MAR. Controlled substances are not kept in this cabinet but

Figure 35–9 ■ Medication cart.

Figure 35–10 ■ Unit-dose medication packages.

at another location on the nursing unit. The nurse uses either a key or a special code to open the client's medication cabinet, because it must be locked when not in use.

- **Medication room.** Depending on the facility, a medication room may be used for a variety of purposes. For example, the medication carts, when not in use, may be placed in this room. The medication room may also be the central location for stock medications, controlled medications, and/or drugs used for emergencies. The medication room may have a refrigerator for IV and other medications needing a cold environment. The room may also contain

Figure 35–11 ■ The medication cart is kept locked when not in use. The nurse is using a key to access client medications.

Figure 35–12 ■ Automated dispensing cabinet (ADC).

other medication administration supplies (syringes, needles, etc.). Nurses access the medication room by either a key or a special code as the room is often kept locked. Check agency policy.

- **Automated dispensing cabinet (ADC).** This computerized access system (Figure 35–12 ■) automates the distribution, management, and control of medications. Similar to automated teller machines, the nurse uses a password to access the system, selects the client's name from an on-screen list, and selects the medication(s). More than 80% of hospitals use ADCs (Stachowiak, 2013). The benefit of using ADCs is the reduction in the risk for medication errors. These benefits include improved drug security, inventory control, computerized alerts, and the potential to limit access to certain high-alert drugs (Mandrack et al., 2012, p. 135). To further promote safety, many facilities have instituted a pharmacy

profiling system as part of the ADC. This means that a nurse cannot remove a medication from an ADC unless a pharmacist has reviewed the order and released the medication.

The expectation of the ISMP is that the nurse obtains the medications for one client from the ADC and then goes to the client's bedside to administer the medications. This is a challenge for nurses because of the increased time it would take to administer medications to six clients. Another challenge is that there are often not enough ADCs on the unit, and the nurses wait in line to access the ADC. This leads to rushed medication selection, errors in medication removal, and unsafe workarounds such as removing more than one client's medications at a time (Mandrack et al., 2012, p. 138; Stachowiak, 2013). The nursing literature recommends that nurses, pharmacists, and hospital leaders collaborate and discuss a process that addresses these challenges and improve ADC safety.

Process of Administering Medications

When administering any drug, regardless of the route of administration, the nurse must do the following:

1. **Identify the client.** Errors can and do occur, usually because one client gets a drug intended for another. One of The Joint Commission's National Patient Safety Goals is to improve the accuracy of client identification. This goal requires a nurse to use at least two client identifiers whenever administering medications. Neither identifier can be the client's room number or physical location (The Joint Commission, 2013a). Acceptable identifiers may be the person's name, assigned identification number, telephone number, photograph, or other person-specific identifier. In hospitals, most clients wear some sort of identification, such as a wristband with name and hospital identification number. Before giving the client any drug, always check the client's identification band. Some hospitals use bar-code technology for medication administration. A nurse preparing to administer a medication using bar-code technology scans or enters the nurse's own ID, the client's wristband, and each package of medication to be administered. Bar coding often includes two or more person-specific identifiers that meet the identifier requirement (Figure 35–13 ■). In long-term care and home care settings, the requirement for two identifiers is appropriate at the first encounter. Thereafter, and in any situation of continuing one-to-one care in which the clinician knows the resident, one identifier can be facial recognition (The Joint Commission, 2013b).

SAFETY ALERT!

SAFETY

2014 The Joint Commission National Patient Safety Goals (2013a)

GOAL 1: IMPROVE THE ACCURACY OF PATIENT IDENTIFICATION

- Use at least two patient identifiers when providing care, treatment, and services.

Rationale: *Wrong-patient errors occur in virtually all stages of diagnosis and treatment. The intent for this goal is twofold: first, to reliably identify the individual as the person for whom the service or treatment is intended; second, to match the service or treatment to that individual. Acceptable identifiers may be the individual's name, an assigned identification number, telephone number, or other person-specific identifier.*

A

B

C

Figure 35-13 ■ A, A sample bar code. B, The nurse scans the bar code on the medication package and C, the bar code on the client's wristband before administering the medication.

CLINICAL ALERT!

Do not ask “Are you John Jones?” because the client may answer “yes” to the wrong name.

BOX 35-5 Check Three Times for Safe Medication Administration

FIRST CHECK

- Read the MAR and remove the medication(s) from the client's drawer. Verify that the client's name and room number match the MAR.
- Compare the label of the medication against the MAR.
- If the dosage does not match the MAR, determine if you need to do a math calculation.
- Check the expiration date of the medication.

SECOND CHECK

While preparing the medication (e.g., pouring, drawing up, or placing unopened package in a medication cup), look at the medication label and check against the MAR.

THIRD CHECK

Recheck the label on the container (e.g., vial, bottle, or unused unit-dose medications) against the MAR before returning to its storage place *OR* before giving the medication to the client.

2. **Inform the client.** If the client is unfamiliar with the medication, the nurse should explain the intended action as well as any side effects or adverse effects that might occur. Listen to the client. It is easy to get so focused on the task of timely medication administration that the nurse may miss relevant information provided by the client. For example, if the client says that he doesn't take a pill for high blood pressure, this should be an “alert” for the nurse to stop and check if this is the correct medication for that client.
3. **Administer the drug.** Read the MAR carefully and perform three checks with the labeled medications (Box 35-5). Then administer the medication in the prescribed dosage, by the route ordered, at the correct time. There has recently been a change in what is considered the correct time. Historically, a “30-minute rule” (i.e., administer medications within 30 minutes before or after the scheduled time) was used. In medication error research, one third of reported medication errors were because of wrong time (Stokowski, 2012). Moreover, the ISMP (2011) conducted an extensive survey in 2010 and the 18,000 nurses who responded clearly stated that the “30-minute rule” was unsafe, impossible to follow given the current complex nature of medication administration, and created pressure to take shortcuts that led to errors. The ISMP maintains that “timely medication administration is a multifaceted issue that cannot be managed appropriately with a single standard” (Stokowski, 2012). Subsequently, the ISMP developed new guidelines for timely administration of scheduled medications. These guidelines are to be used as a resource for hospitals as they develop their own specific guidelines for their facility through an interdisciplinary team that includes nurses. The underlying principle of the guidelines is that medication administration still has to be timely; however, hospitals can determine which medications should be on a tight time schedule and which can be administered with greater flexibility at the discretion of the nurse (ISMP, 2011; Stokowski, 2012). See Table 35-9 for the ISMP guidelines for timely medication administration.

Certain aspects of medication administration are important for the nurse to check each time a medication is administered. These are referred to as the “rights.” Traditionally, there were 5 rights to medication administration. More rights have

TABLE 35–9 Acute Care Guidelines for Timely Administration of Scheduled Medications

Type of Scheduled Medication	Goals for Timely Administration
TIME-CRITICAL SCHEDULED MEDICATIONS	
Hospital-defined time-critical medications* *Limited number of drugs where delayed or early administration of more than 30 minutes may cause harm or sub-therapeutic effect Includes but not limited to: Medications with a dosing schedule more frequent than every 4 hours	Administer at the exact time indicated when necessary (e.g., rapid-acting insulin), otherwise, within 30 minutes before or after the scheduled time
NON-TIME-CRITICAL SCHEDULED MEDICATIONS	
Daily, weekly, monthly medications	Within 2 hours before or after the scheduled time
Medications prescribed more frequently than daily, but no more frequently than every 4 hours	Within 1 hour before or after the scheduled time

From *Acute Care Guidelines for Timely Administration of Scheduled Medications*, by the Institute for Safe Medication Practices, © 2011. Used by permission of the Institute for Safe Medication Practices.

been added during the past few years with one being the 10 rights (Bryant, 2011; Elliott & Liu, 2010). See Box 35–6.

4. **Provide adjunctive interventions as indicated.** Clients may need help when receiving medications. They may require physical assistance, for instance, in assuming positions for intramuscular injections, or they may need guidance about measures to enhance drug effectiveness and prevent complications, such as drinking fluids. Some clients express fear about their medications. The nurse can relieve fears by listening carefully to clients' concerns and giving correct information.

5. **Record the drug administered.** The facts recorded in the chart, in ink or by computer printout, are name of the drug, dosage, method of administration, specific relevant data such as pulse rate (taken in most settings prior to the administration of digitalis), and any other pertinent information. The record should also include the exact time of administration and the signature of the nurse providing the medication. Many medication records are designed so that the nurse signs once on the page and initials each medication administered. Often, medications that are given regularly are recorded on a special flow record.

BOX 35–6 Ten “Rights” of Medication Administration

RIGHT MEDICATION

- The medication given was the medication ordered.

RIGHT DOSE

- The dose ordered is appropriate for the client.
- Give special attention if the calculation indicates multiple pills/tablets or a large quantity of a liquid medication. This can be an indication that the math calculation may be incorrect.
- Double-check calculations that appear questionable.
- Know the usual dosage range of the medication.
- Question a dose outside of the usual dosage range.

RIGHT TIME

- Give the medication at the right frequency and at the time ordered according to agency policy.
- Medications should be given within the agency guidelines.

RIGHT ROUTE

- Give the medication by the ordered route.
- Make certain that the route is safe and appropriate for the client.

RIGHT CLIENT

- Medication is given to the intended client.
- Check the client's identification band with each administration of a medication.
- Know the agency's name alert procedure when clients with the same or similar last names are on the nursing unit.

RIGHT CLIENT EDUCATION

- Explain information about the medication to the client (e.g., why receiving, what to expect, any precautions).

RIGHT DOCUMENTATION

- Document medication administration after giving it, not before.
- If time of administration differs from prescribed time, note the time on the MAR and explain the reason and follow-through activities (e.g., pharmacy states medication will be available in 2 hours) in nursing notes.
- If a medication is not given, follow the agency's policy for documenting the reason why.

RIGHT TO REFUSE

- Adult clients have the right to refuse any medication.
- The nurse's role is to ensure that the client is fully informed of the potential consequences of refusal and to communicate the client's refusal to the health care provider.

RIGHT ASSESSMENT

- Some medications require specific assessments prior to administration (e.g., apical pulse, blood pressure, lab results).
- Medication orders may include specific parameters for administration (e.g., do not give if pulse less than 60 or systolic blood pressure less than 100).

RIGHT EVALUATION

- Conduct appropriate follow-up (e.g., was the desired effect achieved or not? Did the client experience any side effects or adverse reactions?).

PRN (as-needed) or stat (at once) medications are recorded separately.

6. **Evaluate the client's response to the drug.** The kinds of behavior that reflect the action or lack of action of a drug and its untoward effects (both minor and major) are as variable as the purposes of the drugs themselves. The anxious client may show the desired effects of a tranquilizer by behavior that reflects a lowered stress level (e.g., slower speech or fewer random movements). How well a client slept can often measure the effectiveness of a sedative, and the effectiveness of an analgesic can be measured by how much pain the client feels. In all nursing activities, nurses need to be aware of the medications that a client is taking and record their effectiveness as assessed by the client and the nurse on the client's chart. The nurse may also report the client's response directly to the nurse manager and primary care provider.

Developmental Considerations

It is important for the nurse to be aware of how growth and development affect administration of medications for all age groups, particularly the very young and the very old.

INFANTS AND CHILDREN

Knowledge of growth and development is essential for the nurse administering medications to children. Oral medications for children are usually prepared in sweetened liquid form to make them more palatable. The parents may provide suggestions about what method is best for their child. Do not use necessary foods such as milk or orange juice to mask the taste of medications, because the child may develop unpleasant associations and refuse that food in the future.

Children tend to fear any procedure in which a needle is used because they anticipate pain or because the procedure is unfamiliar and threatening. The nurse needs to acknowledge that the child will feel some pain; denying this fact only deepens the child's distrust. After the injection, the nurse (or the parent) can cuddle and speak softly to the infant and give the child a toy to dispel the child's association of the nurse only with pain.

OLDER ADULTS

Older adults can have special problems, most of which are related to physiological changes, to past experiences, and to established attitudes toward medications. See Box 35–7 for a list of the physiological changes in older adults that may affect the administration and effectiveness of medications.

Many of these changes enhance the possibility of cumulative effects and toxicity. For example, impaired circulation delays the action of medications given intramuscularly or subcutaneously. Digitalis, which is frequently taken by older adults, can accumulate to toxic levels and be lethal. It is not uncommon for older adults to take several different medications daily. The possibility of error increases with the number of medications taken, whether self-administered at home or administered in a hospital. The greater number of medications also compounds the problem of drug interactions. A general rule to follow is that older adults should take as few medications as possible.

Older adults usually require smaller dosages of drugs, especially sedatives and other central nervous system depressants. Reactions of older adults to medications, particularly sedatives, are unpredictable and often bizarre. It is not uncommon to see irritability, confusion, disorientation, restlessness, and incontinence as a result of sedatives.

BOX 35–7 Physiological Changes Associated with Aging That Influence Medication Administration and Effectiveness

- Altered memory
- Decreased visual acuity
- Decrease in renal function, resulting in slower elimination of drugs and higher drug concentrations in the bloodstream for longer periods
- Less complete and slower absorption from the GI tract
- Increased proportion of fat to lean body mass, which facilitates retention of fat-soluble drugs and increases potential for toxicity
- Decreased liver function, which hinders biotransformation of drugs
- Decreased organ sensitivity, which means that the response to the same drug concentration in the vicinity of the target organ is less in older people than in the young
- Altered quality of organ responsiveness, resulting in adverse effects becoming pronounced before therapeutic effects are achieved
- Decrease in manual dexterity due to arthritis and/or decrease in flexibility

Nurses therefore need to observe clients carefully for untoward reactions. Prescribers often follow the unwritten rule to “start low and go slow” when prescribing medications for older adults. The initial prescribed dosage will often be low and then gradually increased with careful monitoring of the actions and side effects of the drug.

Attitudes of older adults toward medical care and medications vary. Older adults tend to believe in the wisdom of the health care provider more readily than younger people. Some older people are bewildered by the prescription of several medications and may passively accept their medications from nurses but not swallow them, spitting out tablets or capsules after the nurse leaves the room. For this reason, the nurse is advised to stay with clients until they have swallowed the medications. Others may be suspicious of medications and actively refuse them.

Older adults are mature adults capable of reasoning. Therefore, the nurse needs to explain the reasons for and the effects of medications. This education can prevent clients from continuing to take a medication long after there is a need for it or discontinuing a drug too quickly. For example, clients should know that diuretics will cause them to urinate more frequently and may reduce ankle edema. All clients need instructions about medications. These instructions should include when to take the drugs, what effects to expect, and when to consult a primary care provider.

Because some clients are required to take several medications daily and because visual acuity and memory may be impaired, the nurse needs to develop simple, realistic plans for clients to follow at home. For example, remembering to take drugs can be difficult for most people, including older adults. Scheduling medications at mealtime or at bedtime helps clients to remember to take their medications. Some clients may take their medications and then an hour later may not remember whether they took them. One solution to forgetfulness is to use a special container or glass strictly for medications. An empty glass or container indicates that the person took the pills. Special containers with individual slots and markings for each day can reduce confusion. Loss of visual acuity presents problems that can be overcome by writing out the plan in block letters large enough

to be read. In some situations, enlisting the help of a spouse, son, or daughter can be helpful.

Older adults often have decreased dexterity due to arthritis or stiffness of their hands and fingers due to aging. This causes difficulty in opening medication containers or in self-administration of other medications such as eyedrops, eardrops, insulin injections, and inhalers. Nurses can help clients make the necessary changes or enlist the assistance of another person to help them administer their medications.

ORAL MEDICATIONS

The oral route is the most common route by which medications are given. As long as a client can swallow and retain the drug in the stomach, this is the route of choice (see Skill 35–1). Oral medications are contraindicated when a client is vomiting, has gastric or intestinal suction, or is unconscious and unable to swallow. Such clients in a hospital are usually on orders for “nothing by mouth” (the Latin is *nil per os*: **NPO**).

Evidence-Based Practice What Clinical Reasoning Processes Are Used by Nurses for the Safe Practice of Medication Administration?

EVIDENCE-BASED PRACTICE

The client safety movement has evolved to the point where medication errors are currently viewed from the perspective of a failure within the safety system rather than the fault of nurse error. Nurses are in the key position of “catching” many errors before they reach the client. Researchers Dickson and Flynn (2012) explored nurses’ clinical reasoning thought processes and actions that are critical to the interception of medication errors before they reach the client. They used a grounded theory design, which consisted of transcribing the recorded interviews of 50 medical-surgical nurses from 10 mid-Atlantic hospitals in the United States. The nurses provided in-depth interviews of what they thought and did to prevent errors and to identify factors that increased the chance of a medication error. All the participants were female, primarily Caucasian (70%) with an average age of 42 years. Over half (51%) had more than 14 years of nursing experience. Seventy-one percent of the nurses held an associate degree/diploma, 27% held a baccalaureate degree, and one nurse had just completed a nursing graduate program. The hospitals where the nurses worked varied from academic health centers to smaller community hospitals with a mixture of nonmagnet and magnet accreditation status.

The two research questions were “What are the thoughts and actions used to identify medication errors and prevent them from reaching their clients?” and “What factors in the environment had an impact on the medication safety care practices identified by the hospital nurses?” When analyzing the data, the researchers realized

that the nurses used decision making based on reasoning within a clinical context, which is how Benner, Sutphen, Leonard, and Day (2010) defined clinical reasoning. The researchers found that the use of clinical reasoning resulted in the prevention of medication errors reaching the client. They identified two different clinical reasoning themes as safety care processes: (1) maintaining medication safety and (2) managing the environment. Maintaining medication safety focused on how the nurses kept clients safe from medication errors and consisted of the following six medication safety practices: educating clients, taking everything into consideration (e.g., all factors about the client), advocating for clients with the pharmacy department, coordinating care with health care providers, conducting independent medication reconciliation, and verifying drug dosages with colleagues. The second process of clinical reasoning, managing the clinical environment, consisted of the following four categories of how the nurses managed the chaotic environment to protect the clients: coping with interruptions and distractions, interpreting physician orders, documenting “near misses,” and encouraging open communication between disciplines.

IMPLICATIONS

This research clearly demonstrated how nurses used clinical reasoning to prevent potential errors and the key role that nurses play in keeping clients safe from medication errors. The research provided a beginning model of medication safety processes and practices.

Administering Oral Medications

PURPOSE

- To provide a medication that has systemic effects or local effects on the GI tract or both (see specific drug action)

ASSESSMENT

Assess

- Allergies to medication(s)
- Client’s ability to swallow the medication
- Presence of vomiting or diarrhea that would interfere with the ability to absorb the medication
- Specific drug action, side effects, interactions, and adverse reactions
- Client’s knowledge of and learning needs about the medication

Perform appropriate assessments (e.g., vital signs, laboratory results) specific to the medication.

Determine if the assessment data influence administration of the medication (i.e., is it appropriate to administer the medication or does the medication need to be held and the prescriber notified?).

PLANNING

DELEGATION

In acute care settings, administration of oral/enteral medications is performed by the nurse and is not delegated to unlicensed assistive personnel (UAP). The nurse can inform the UAP of the intended therapeutic effects and/or specific side effects of the medication and request the UAP to report specific client observations to the nurse for follow-up. In some long-term care settings, trained UAP may

administer certain medications to stable clients. It is important, however, for the nurse to remember that the medication knowledge of the UAP is limited and *assessment and evaluation of the effectiveness of the medication remain the responsibility of the nurse.*

Administering Oral Medications—continued

Equipment

- Client's MAR or computer printout
- Dispensing system
- Disposable medication cups: small paper or plastic cups for tablets and capsules, waxed or plastic calibrated medication cups for liquids
- Pill crusher/cutter
- Straws to administer medications that may discolor the teeth or to facilitate the ingestion of liquid medication for certain clients
- Drinking glass and water or juice
- Soft foods such as applesauce or pudding to use for crushed medications for clients who may choke on liquids

IMPLEMENTATION

Preparation

1. Know the reason why the client is receiving the medication, the drug classification, contraindications, usual dosage range, side effects, and nursing considerations for administering and evaluating the intended outcomes for the medication.
2. Check the MAR.
 - Check for the drug name, dosage, frequency, route of administration, and expiration date for administering the medication, if appropriate. **Rationale:** *Orders for certain medications (e.g., narcotics, antibiotics) expire after a specified time frame and they need to be reordered by the primary care provider.*
 - If the MAR is unclear or pertinent information is missing, compare the MAR with the prescriber's most recent written order.
 - Report any discrepancies to the charge nurse or the primary care provider, as agency policy dictates.
3. Verify the client's ability to take medication orally.
 - Determine whether the client can swallow, is NPO, is nauseated or vomiting, has gastric suction, or has diminished or absent bowel sounds.
4. Organize the supplies.
 - Gather the MAR(s) for each client together so that medications can be prepared for one client at a time. **Rationale:** *Organization of supplies saves time and reduces the chance of error.*

Performance

1. Perform hand hygiene and observe other appropriate infection prevention procedures.
2. Unlock the dispensing system.
3. Obtain the appropriate medication.
 - Read the MAR and take the appropriate medication from the shelf, drawer, or refrigerator. The medication may be dispensed in a bottle, box, or unit-dose package.
 - Compare the label of the medication container or unit-dose package against the order on the MAR or computer printout. **Rationale:** *This is a safety check to ensure that the right medication is given.* If these are not identical, recheck the prescriber's written order in the client's chart. If there is still a discrepancy, check with the nurse in charge or the pharmacist. ①
 - Check the expiration date of the medication. Return expired medications to the pharmacy. **Rationale:** *Outdated medications are not safe to administer.*
 - Use only medications that have clear, legible labels. **Rationale:** *This ensures accuracy.*
4. Prepare the medication.
 - Calculate the medication dosage accurately.
 - Prepare the correct amount of medication for the required dose, without contaminating the medication. **Rationale:** *Aseptic technique maintains drug cleanliness.*
 - While preparing the medication, recheck each prepared drug and container with the MAR again. **Rationale:** *This second safety check reduces the chance of error.*

① Compare the medication label to the MAR.

Tablets or Capsules

- Place packaged unit-dose capsules or tablets directly into the medicine cup. Do not remove the medication from the package until at the bedside. **Rationale:** *The wrapper keeps the medication clean. Not removing the medication facilitates identification of the medication in the event the client refuses the drug or assessment data indicate to hold the medication. Unopened unit-dose packages can usually be returned to the medication cart.*
- If using a stock container, pour the required number into the bottle cap, and then transfer the medication to the disposable cup without touching the tablets.
- Keep narcotics and medications that require specific assessments, such as pulse measurements, respiratory rate or depth, or blood pressure, separate from the others. **Rationale:** *This reminds the nurse to complete the needed assessment(s) in order to decide whether to give the medication or to withhold the medication if indicated.*
- Break only scored tablets if necessary to obtain the correct dosage. Use a cutting or splitting device if needed. Check the agency policy as to how unused portions of a medication are to be discarded. ②
- If the client has difficulty swallowing, check if the medication can be crushed. Some drug handbooks have an appendix that lists the "Do Not Crush" medications. The Institute for Safe Medication Practices (2013c) website provides an updated list of medications that should not be crushed. Some medications that should not be crushed include time-released and enteric-coated medications. An example of tablets that should not be crushed is oxycodone (OxyContin), a long-acting narcotic that normally lasts 12 hours after administration. If the tablet is crushed, the client gets a surge of action in the first 2 hours, and may then start having severe pain again in 4 to 6 hours, because the narcotic effect wears off too soon. The crushing of these tablets causes an uneven effect, and the long or sustained action of the medication is lost.

Administering Oral Medications—continued

2 A cutting device can be used to divide tablets.

- If it is acceptable, crush the tablets to a fine powder with a pill crusher or between two medication cups. Then, mix the powder with a small amount of soft food (e.g., custard, applesauce).

CLINICAL ALERT!

Check with the pharmacy before crushing tablets. Sustained-action, enteric-coated, buccal, or sublingual tablets should not be crushed.

Liquid Medication

- Thoroughly mix the medication before pouring. Discard any medication that has changed color or turned cloudy.
- Remove the cap and place it upside down on the countertop. **Rationale:** This avoids contaminating the inside of the cap.
- Hold the bottle so the label is next to your palm and pour the medication away from the label. **Rationale:** This prevents the label from becoming soiled and illegible as a result of spilled liquids. 3
- Place the medication cup on a flat surface at eye level and fill it to the desired level, using the *bottom* of the **meniscus** (crescent-shaped upper surface of a column of liquid) to align with the container scale. 4 **Rationale:** This method ensures accuracy of measurement.
- Before capping the bottle, wipe the lip with a paper towel. **Rationale:** This prevents the cap from sticking.
- When giving small amounts of liquids (e.g., less than 5 mL), prepare the medication in a sterile syringe without the needle or in a specially designed oral syringe 5. Label the syringe with the name of the medication and the route (PO).

3 Pouring a liquid medication from a bottle.

4 The bottom of the meniscus is the measuring guide.

Rationale: Any oral solution removed from the original container and placed into a syringe should be labeled to avoid medications being given by the wrong route (e.g., IV). This practice facilitates client safety and avoids tragic errors.

- Keep unit-dose liquids in their package and open them at the bedside.

Oral Narcotics

- If an agency uses a manual recording system for controlled substances, check the narcotic record for the previous drug count and compare it with the supply available. Some medications, including narcotics, are kept in plastic containers that are sectioned and numbered.
- Remove the next available tablet and drop it in the medicine cup.
- After removing a tablet, record the necessary information on the appropriate narcotic control record and sign it.
- Note:** Computer-controlled dispensing systems allow access only to the selected drug and automatically record its use.

5 Oral syringe.

Administering Oral Medications—continued

SAFETY ALERT!

SAFETY

2014 The Joint Commission National Patient Safety Goals (2013a)

GOAL 3: IMPROVE THE SAFETY OF USING MEDICATIONS

- Label all medications, medication containers, and other solutions on and off the sterile field in perioperative and other procedural settings.
- Medication containers include syringes, medicine cups, and basins.

Rationale: Medications or other solutions in unlabeled containers are unidentifiable. Errors, sometimes tragic, have resulted from medications and other solutions being removed from their original containers and placed into unlabeled containers. This unsafe practice neglects basic principles of safe medication management, yet it is routine in many organizations. The labeling of all medications, medication containers, and other solutions is a risk-reduction activity consistent with safe medication management. This practice addresses a recognized risk point in the administration of medications in perioperative and other procedural settings.

All Medications

- Place the prepared medication and MAR together on the medication cart.
 - Recheck the label on the container before returning the bottle, box, or envelope to its storage place. **Rationale:** This third check further reduces the risk of error.
 - Avoid leaving prepared medications unattended. **Rationale:** This precaution prevents potential mishandling errors.
 - Lock the medication cart before entering the client's room. **Rationale:** This is a safety measure because medication carts are not to be left open when unattended.
 - Check the room number against the MAR if agency policy does not allow the MAR to be removed from the medication cart. **Rationale:** This is another safety measure to ensure that the nurse is entering the correct client room.
5. Provide for client privacy.
 6. Prepare the client.
 - Introduce self and verify the client's identity using agency protocol. **Rationale:** This ensures that the right client receives the medication.
 - Assist the client to a sitting position or, if not possible, to a side-lying position. **Rationale:** These positions facilitate swallowing and prevent aspiration.
 - If not previously assessed, take the required assessment measures, such as pulse and respiratory rates or blood pressure. Take the apical pulse rate before administering digitalis preparations. Take blood pressure before giving antihypertensive drugs. Take the respiratory rate prior to administering narcotics. **Rationale:** Narcotics depress the respiratory center. If any of the findings are above or below the predetermined parameters, consult the primary care provider before administering the medication.

7. Explain the purpose of the medication and how it will help, using language that the client can understand. Include relevant information about effects; for example, tell the client receiving a diuretic to expect an increase in urine output. **Rationale:** Information can facilitate acceptance of and compliance with the therapy.

8. Administer the medication at the correct time.
 - Take the medication to the client within the guidelines of the agency
 - Give the client sufficient water or preferred juice to swallow the medication. Before using juice, check for any food and medication incompatibilities. **Rationale:** Fluids ease swallowing and facilitate absorption from the GI tract. Grapefruit juice may not be safe for clients who take certain medications. Liquid medications other than antacids or cough preparations may be diluted with 15 mL (1/2 oz) of water to facilitate absorption.
 - If the client is unable to hold the pill cup, use the pill cup to introduce the medication into the client's mouth, and give only one tablet or capsule at a time. **Rationale:** Putting the cup to the client's mouth maintains the cleanliness of the nurse's hands. Giving one medication at a time eases swallowing.
 - If an older child or adult has difficulty swallowing, ask the client to place the medication on the back of the tongue before taking the water. **Rationale:** Stimulation of the back of the tongue produces the swallowing reflex.
 - If the medication has an objectionable taste, ask the client to suck a few ice chips beforehand, or give the medication with juice, applesauce, or pudding if there are no contraindications. **Rationale:** The cold of the ice chips will desensitize the taste buds, and juices, applesauce, or pudding may mask the taste of the medication.
 - If the client says that the medication you are about to give is different from what the client has been receiving, do not give the medication without first checking the original order. **Rationale:** Most clients are familiar with the appearance of medications taken previously. Unfamiliar medications may signal a possible error.
 - Stay with the client until all medications have been swallowed. **Rationale:** The nurse must see the client swallow the medication before the drug administration can be recorded. The nurse may need to check the client's mouth to ensure that the medication was swallowed and not hidden inside the cheek. A primary care provider's order or agency policy is required for medications left at the bedside.
9. Document each medication given.
 - Record the medication given, dosage, time, any complaints or assessments of the client, and your signature.
 - If medication was refused or omitted, record this fact on the appropriate record; document the reason, when possible, and the nurse's actions according to agency policy.
10. Dispose of all supplies appropriately.
 - Replenish stock (e.g., medication cups) and return the cart to the appropriate place.
 - Discard used disposable supplies.

Evaluation

- Return to the client when the medication is expected to take effect (usually 30 minutes) to evaluate the effects of the medication on the client.
- Observe for desired effect (e.g., relief of pain or decrease in body temperature).
- Note any adverse effects or side effects (e.g., nausea, vomiting, skin rash, or change in vital signs).
- Relate to previous findings, if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Administering Oral Medications

- Knowledge of growth and development is essential for the nurse administering medications to infants and children.
- Nurses must know the range of safe medication dosages for infants and children.

INFANTS

- Oral medications can be effectively administered in several ways:
 - A syringe or dropper
 - A medication nipple that allows the infant to suck the medication
 - Mixed in small amounts of food
 - A spoon or medication cup, for older children.
- Never mix medications into foods that are essential, since the infant may associate the food with an unpleasant taste and refuse that food in the future. Never mix medications with formula.
- Place a small amount of liquid medication along the inside of the baby's cheek and wait for the infant to swallow before giving more to prevent aspiration or spitting out.
- When using a spoon, retrieve and refeed medication that is thrust outward by the infant's tongue.

CHILDREN

- Whenever possible, children should be given a choice between the use of a spoon, dropper, or syringe.
- Dilute the oral medication, if indicated, with a small amount of water. Many oral medications are readily swallowed if they are diluted with a small amount of water. If large quantities of water are used, the child may refuse to drink the entire amount and receive only a portion of the medication.
- Oral medications for children are usually prepared in sweetened liquid form to make them more palatable. Crush medications that are not supplied in liquid form and mix them with substances available on most pediatric units, such as honey, flavored syrup, jam, or a fruit puree.
- Necessary foods such as milk or orange juice should not be used to mask the taste of medications because the child may

- develop unpleasant associations and refuse that food in the future.
- Disguise disagreeable-tasting medications with sweet-tasting substances mentioned previously. However, present any altered medication to the child honestly and not as a food or a treat.
- Place the young child or toddler on your lap or a parent's lap in a sitting position.
- Administer the medication slowly with a measuring spoon, plastic syringe, or medicine cup.
- To prevent nausea, pour a carbonated beverage over finely crushed ice and give it before or immediately after the medication is administered.
- Follow medication with a drink of water, juice, a soft drink, or a Popsicle or frozen juice bar. This removes any unpleasant aftertaste.
- For children who take sweetened medications on a long-term basis, follow the medication administration with oral hygiene. These children are at high risk for dental caries.

OLDER ADULTS

- The physiological changes associated with aging influence medication administration and effectiveness. Examples include altered memory, less acute vision, decrease in renal function, less complete and slower absorption from the GI tract, and decreased liver function. Many of these changes enhance the possibility of cumulative effects and toxicity.
- Older adults usually require smaller dosages of drugs, especially sedatives and other central nervous system depressants.
- Older adults are mature adults capable of reasoning. The nurse, therefore, needs to explain the reasons for and the effects of the client's medications.
- Socioeconomic factors such as lack of transportation and decreased finances may influence obtaining medications when needed.
- An increase in marketing and availability of vitamins, herbs, and supplements alerts the nurse to include this information in a medication history.

Home Care Considerations Administering Medications**PATIENT-CENTERED CARE**

The nurse should instruct the client to:

- Learn the names of the medications as well as their actions and possible adverse effects. Carry a complete list of all prescriptions, OTC medications, and home remedies at all times.
- Keep all medications out of reach of children and pets.
- If using a syringe to administer the medication to an infant or child, remove and dispose of the plastic cap that fits on the end of the syringe. Infants and small children have been known to choke on these caps.
- Take the medications only as prescribed. Know which medications need to be taken on an empty stomach and which can be taken with food/meals. Immediately consult the nurse, pharmacist, or primary care provider about any problems with the medication.
- Always check the medication label to make sure the correct medication is being taken.
- Request labels printed with larger type on medication containers if labels are difficult to read.
- Check the expiration date and discard outdated medications. Previously, most people discarded old medicines by flushing them down the toilet. The U.S. Environmental Protection Agency (EPA) no longer recommends this. Inform the client to check with their local government. Many cities and towns have

- household hazardous waste facilities where they can take their old medicines. The expired medications may be placed in the trash if the following precautions are used: Keep the medication in the original container and mark out the person's name. Add a nontoxic but bad-tasting product (e.g., cayenne pepper, mustard) to the container to keep individuals or animals from eating it. Place in a sturdy container, tape the container shut, and have this container be the last thing put in the garbage can.
- Ask the pharmacist to substitute childproof caps with ones that are more easily opened, as necessary.
- If a dose or more is missed, do not take two or more doses; ask the pharmacist or primary care provider for directions.
- Do not crush or cut a tablet or capsule without first checking with the primary care provider or pharmacist. Doing so may affect the medication's absorption.
- Never stop taking the medication without first discussing it with the primary care provider.
- Always check with the pharmacist before taking any nonprescription medications. Some OTC medications can interact with the prescribed medication.

Additionally, the nurse can set up a medication plan to assist clients and family members to remember a schedule. Weekly pill containers (available at pharmacies) or a written plan may be helpful.

NASOGASTRIC AND GASTROSTOMY MEDICATIONS

For clients who cannot take anything by mouth (NPO) and have a **nasogastric tube** or a **gastrostomy tube** in place, an alternative route for administering medications is through the nasogastric or gastrostomy tube. A nasogastric (NG) tube is inserted by way of the nasopharynx and is placed into the client's stomach for the purpose of feeding the client or to remove gastric secretions. A gastrostomy tube is surgically placed directly into the client's stomach and provides another route for administering medications and nutrition (see Chapter 47 ∞). Guidelines for administering medications by nasogastric tubes and gastrostomy tubes are shown in the Practice Guidelines box.

PARENTERAL MEDICATIONS

Parenteral administration of medications is a common nursing procedure. Nurses give parenteral medications intradermally (ID), subcutaneously, intramuscularly (IM), or intravenously (IV). Because these medications are absorbed more quickly than oral medications and are irretrievable once injected, the nurse must prepare and administer them carefully and accurately. Administering parenteral drugs requires the same nursing knowledge as for oral and topical drugs; however, because injections are invasive procedures, aseptic technique must be used to minimize the risk of infection.

Equipment

To administer parenteral medications, nurses use syringes and needles to withdraw medication from ampules and vials.

SYRINGES

Syringes have three parts: the tip, which connects with the needle; the barrel, or outside part, on which the scales are printed; and the plunger, which fits inside the barrel (Figure 35–14 ■). When handling a syringe, the nurse may touch the outside of the barrel and the handle of the plunger; however, the nurse must *avoid letting any unsterile object touch the tip or inside of the barrel, the shaft of the plunger, or the shaft or tip of the syringe*.

Several kinds of syringes are available in differing sizes, shapes, and materials. Syringes range in sizes from 1 to 60 mL. A nurse typically uses a syringe ranging from 1 to 3 mL in size for injections (e.g., subcutaneous or intramuscular). A **hypodermic syringe** comes in 3- and 5-mL sizes. The choice of syringe depends on many factors,

Figure 35–14 ■ The three parts of a syringe.

PRACTICE GUIDELINES

Administering Medications by Nasogastric or Gastrostomy Tube

- Always check with the pharmacist to see if the client's medications come in a liquid form because these are less likely to cause tube obstruction.
- If medications do not come in liquid form, check to see if they may be crushed. (Note that enteric-coated, sustained-action, buccal, and sublingual medications should never be crushed.)
- Liquid medication must be further diluted with sterile water, especially if the liquid form is viscous.
- Crush a tablet into a fine powder and dissolve in at least 30 mL of warm sterile water. Cold liquids may cause client discomfort. Use only water for mixing and flushing. Some medications are mixed with other fluids, such as normal saline, in order to maximize dissolution. Nurses are encouraged to consult with a pharmacist.
- Sterile water is recommended for use in adult and neonatal/pediatric clients before and after medication administration (American Society for Parenteral and Enteral Nutrition, 2009, p. 156). ISMP (2010a) advises not to use tap water because it often contains chemical contaminants that might interact with the drug.
- Read medication labels carefully before opening a capsule. Open hard gelatin capsules and mix the powder with sterile water.
- Do not administer whole or undissolved medications because they will clog the tube.
- Assess tube placement prior to administration of medications. (See Chapter 47 ∞ for methods to verify tube placement.)
- Before giving the medication, aspirate all the stomach contents and measure the residual volume. Check agency policy if residual volume is greater than 100 mL.
- When administering the medication(s):
 - Remove the plunger from the syringe and connect the syringe to a pinched or kinked tube. **Rationale:** *Pinching or kinking the tube prevents excess air from entering the stomach and causing distention.*
 - Put 15 to 30 mL (5 to 10 mL for children) of sterile water into the syringe barrel to flush the tube before administering the first medication. Raise or lower the barrel of the syringe to adjust the flow as needed. Pinch or clamp the tubing before all the water is instilled to avoid excess air entering the stomach.
 - Pour liquid or dissolved medication into the syringe barrel and allow to flow by gravity into the enteral tube.
 - If you are giving several medications, administer each one separately and flush with at least 15 to 30 mL (5 mL for children) of tap water between each medication.
 - When you have finished administering all medications, flush with another 15 to 30 mL (5 to 10 mL for children) of warm water to clear the tube.
- If the tube is connected to suction, disconnect the suction and keep the tube clamped for 20 to 30 minutes after giving the medication to enhance absorption.

Figure 35-15 ■ Three kinds of syringes: A, 3-mL syringe marked in tenths (0.1) of milliliters and in minims; B, insulin syringe marked in 100 units; C, tuberculin syringe marked in tenths and hundredths (0.01) of 1 milliliter (mL) and in minims.

such as medication, location of injection, and type of tissue. Syringes ranging from 1 to 3 mL may have two scales marked on them: the minim and the milliliter. The milliliter scale is the one normally used; the minim scale is used for very small dosages (Figure 35-15 ■). The larger sized syringes (e.g., 10, 20, and 50 mL) are not used to administer drugs directly but can be useful for adding medications to IV solutions or for irrigating wounds.

An **insulin syringe** is similar to a hypodermic syringe, but the scale is specially designed for insulin: a 100-unit calibrated scale intended for use with U-100 insulin. This is the only syringe that should be used to administer insulin. Several low-dose insulin syringes are also available (e.g., 30-unit and 50-unit). These syringes frequently have a nonremovable needle. All insulin syringes are calibrated on the 100-unit scale in North America. The correct choice of syringe is based on the amount of insulin required (Figure 35-16 ■).

An insulin pen is an insulin injector device that looks like a pen and contains an insulin cartridge. The pen is easy to use: The client attaches a new needle for each injection, dials a dose, inserts the needle, and presses the injection button to deliver the insulin (Gebel, 2012). The parts of an insulin pen are shown in Figure 35-17 ■. Many clients use the insulin pen for accurate self-administration of insulin. Not all pens are the same. Each pen works only with specific types of insulins (Gebel, 2012, 2013). Clients have a choice between

Figure 35-16 ■ Different insulin syringes based on the amount of insulin required. Note the difference in the number of units of insulin per line.

a disposable or reusable pen. A disposable pen comes prefilled with a cartridge of insulin and is stored in the refrigerator until the time of use when it is kept at room temperature after opening. When the insulin is depleted, the pen is discarded. Clients who use a reusable pen insert an insulin cartridge, which is purchased separately. The cartridge is kept in a refrigerator until it is loaded into the pen. The pen, after being loaded, is kept at room temperature until the insulin is gone and then another cartridge is loaded into the pen (Gebel, 2012). Another difference among insulin pens is the dose amount. Some pens allow clients to inject half units of insulin and others can only dose in whole units.

Increasingly, many hospitals have considered the advantages of insulin pens and subsequently changed from nurses using a vial and syringe to an insulin pen for subcutaneous administration of insulin (Edgeworth, 2011). Some common problems have been encountered with the use of insulin pens in hospitals. These problems, however, can be corrected with training for all practitioners before they use insulin pen devices. Grissinger (2011) and Edgeworth (2011) describe the following common problems:

- **Needlestick injuries.** Nurses who held the insulin pen at an angle, instead of the correct 90° angle, were found to be at a higher risk

Figure 35-17 ■ Insulin pen. The dose selector knob dials the desired dose of insulin. Pressing the injection button administers the insulin.

A

B

Figure 35-18 ■ Tips of syringes: A, Luer-Lok syringe (note threaded tip); B, non-Luer-Lok syringe (note the smooth graduated tip).

of an accidental needlestick. Also, the skin area that needs to be pinched should be approximately 1 inch of skin between the fingers after the pinch is completed to avoid a needlestick.

- **Errors in technique.** Sometimes the nurse may see a “wet spot” on the skin after injection and then wonders if the client received the full dose. The buttons of some pens are difficult to push down causing the nurse to inadvertently lift the needle out of the skin and leave a wet spot. ISMP (2013b) directs users to remove the needle immediately after injection to decrease the risk of air entering the cartridge (p. 2). It is also important for the nurse and/or client to remember to roll the insulin suspension (i.e., NPH and regular mixture), if appropriate. Not doing so may result in inaccurate doses.
- **Using the pen like a vial.** Insulin should not be withdrawn from the pen cartridge as if it were a vial. This can produce an air bubble in the cartridge and cause an inaccurate dose for the next injection.
- **Using the same pen for more than one client.** The Centers for Disease Control and Prevention (CDC) (2012a) has received an increasing number of reports about improper use of insulin pens in hospitals. Specifically, that there has been inappropriate reuse and sharing of insulin pens. Insulin pens are designed to be used by a *single person* only. They are *never* to be used for more than one person because this creates a risk of bloodborne pathogen transmission. ISMP (2013b) states that “placing a new sterile needle on a pen previously used for one client is not enough to ensure pen sterility for delivery of a dose of insulin to another client” (p. 1).

The **tuberculin syringe** was originally designed to administer tuberculin solution. It is a narrow syringe, calibrated in tenths and hundredths of a milliliter (up to 1 mL) on one scale and in sixteenths of a minim (up to 1 minim) on the other scale. This type of syringe can also be useful in administering other drugs, particularly when small or precise measurement is indicated (e.g., pediatric dosages).

Syringes are made in other sizes as well (e.g., 10, 20, and 50 mL). These are not generally used to administer drugs directly but can be useful for adding medications to IV solutions or for irrigating wounds. The tip of a syringe varies and is classified as either a Luer-Lok or non-Luer-Lok. A Luer-Lok syringe has a tip that requires the needle to be twisted onto it to avoid accidental removal of the needle (Figure 35-18 ■). The non-Luer-Lok syringe has a smooth graduated tip, and needles are slipped onto it. The larger 50-mL non-Luer-Lok

Figure 35-19 ■ A 60-mL non-Luer-Lok syringe, which can be used for irrigation of tubes or wounds.

Figure 35-20 ■ Disposable plastic syringes and needles: *Top*, syringe with needle safety device; *middle*, with plastic cap over the needle; *bottom*, with plastic case over the needle and syringe.

syringe is often used for irrigation purposes (e.g., wounds, tubes). See Figure 35-19 ■.

Most syringes used today are made of plastic, are individually packaged for sterility in a paper wrapper or a rigid plastic container (Figure 35-20 ■), and are disposable. The syringe and needle may be packaged together or separately. Needleless systems are also available in which the needle is replaced by a plastic cannula.

A

B

C

D

Figure 35-21 ■ A, Syringe and prefilled sterile cartridge with needle; B, assembling the device; C, the cartridge slides into the syringe barrel; D, the top twists securing the cartridge into the unit.

Injectable medications are frequently supplied in disposable **prefilled unit-dose systems**. These are available as (a) prefilled syringes ready for use or (b) prefilled sterile cartridges and needles that require the attachment of a reusable holder (injection system) before use (Figure 35-21 ■). Examples of the latter system are the Tubex and Carpuject injection systems. The manufacturers provide specific directions for use. Because most prefilled cartridges are overfilled, excess medication must be ejected before the injection to ensure the right dosage. Because the needle is fused to the syringe, the nurse cannot change the gauge or length of the needle. The nurse, however, can transfer the medication into a regular syringe if the assessment of the client necessitates a different needle gauge or length. The Carpuject has a removable protective cap, which allows the prefilled cartridge to become a vial so that the nurse can withdraw the medication.

NEEDLES

Needles are made of stainless steel, and most are disposable. Reusable needles (e.g., for special procedures) need to be sharpened periodically before resterilization because the points become dull with use and are occasionally damaged or acquire burrs on the tips. A dull or damaged needle should *never* be used.

A needle has three discernible parts: the **hub**, which fits onto the syringe; the **cannula**, or **shaft**, which is attached to the hub; and the

bevel, which is the slanted part at the tip of the needle (Figure 35-22 ■). A disposable needle has a plastic hub. Needles used for injections have three variable characteristics:

1. **Slant or length of the bevel.** The bevel of the needle may be short or long. Longer bevels provide the sharpest needles and cause less discomfort. They are commonly used for subcutaneous and intramuscular injections. Short bevels are used for intradermal and IV injections because a long bevel can become occluded if it rests against the side of a blood vessel.
2. **Length of the shaft.** The shaft length of commonly used needles varies from 1/2 to 2 inches. The appropriate needle length is chosen according to the client's muscle development, the client's weight, and the type of injection.
3. **Gauge (or diameter) of the shaft.** The gauge varies from #18 to #30. The larger the gauge number, the smaller the diameter

Figure 35-22 ■ The parts of a needle.

BOX 35-8 Avoiding Puncture Injuries

Figure 35-23 ■ Dispose of used syringe and needle in a sharps container.

- Use appropriate puncture-proof disposal containers to dispose of uncapped needles and sharps (Figure 35-23 ■). These are provided in all client areas. Never throw sharps in wastebaskets. Sharps include any items that can cut or puncture skin such as:
 - Needles
 - Surgical blades
 - Lancets
 - Razors
 - Broken glass
 - Broken capillary pipettes
 - Exposed dental wires
 - Reusable items (e.g., large-bore needles, hooks, rasps, drill points)
 - ANY SHARP INSTRUMENT!
- Never bend or break needles before disposal.
- Never recap *used* needles (i.e., ones that have been inserted into clients) except under specified circumstances (e.g., when transporting a syringe to the laboratory for an arterial blood gas or blood culture).
- When recapping a needle (i.e., drawing up a medication into a syringe *prior* to administration):
- Use a safety mechanical device that firmly grips the needle cap and holds it in place until it is ready to recap (Figure 35-24 ■).

Figure 35-24 ■ A safety mechanical device that holds the needle cap in place until the nurse is ready to recap.

- Use a one-handed “scoop” method. This is performed by (a) placing the needle and syringe with needle horizontally on a flat surface, (b) inserting the needle into the cap, using one hand (Figure 35-25 ■), and then (c) using your other hand to pick up the cap and tighten it to the needle hub. Be careful not to contaminate the needle. If the needle becomes contaminated, replace the needle with a new one.

Figure 35-25 ■ Recapping a needle using the one-handed scoop method.

of the shaft. Smaller gauges produce less tissue trauma, but larger gauges are necessary for viscous medications, such as penicillin.

For an adult requiring a subcutaneous injection, it is appropriate to use a needle of #24 to #26 gauge and 3/8 to 5/8 inch long. Obese clients may require a 1-inch needle. For intramuscular injections, a longer needle (e.g., 1 to 1 1/2 in.) with a larger gauge (e.g., #20 to #22 gauge) is used. Slender adults and children usually require a shorter needle. The nurse must assess the client to determine the appropriate needle length.

PREVENTING NEEDLESTICK INJURIES

One of the most potentially hazardous procedures that health care personnel face is using and disposing of needles and sharps. Needlestick injuries present a major risk for infection with hepatitis B virus, human immunodeficiency virus (HIV), and many other pathogens. Standards have been set by the Occupational Safety and Health

Administration (OSHA) to prevent such injuries. Some of these are summarized in Box 35-8. If an accidental needlestick injury occurs, the nurse needs to follow specific steps outlined by OSHA.

Safety syringes have been designed in recent years to protect health care workers. Safety devices are categorized as either *passive* or *active*. The nurse does not need to activate the passive safety device. For example, for some syringes, after injection, the needle retracts immediately into the barrel (Figure 35-26 ■). In contrast, the active safety device requires the nurse to manually activate the safety feature. For example, the nurse activates a mechanism to retract the needle into the syringe barrel, or the nurse, after injection, manually pulls a plastic sheath or guard over the needle (Figure 35-27 ■).

Preparing Injectable Medications

Injectable medications can be prepared by withdrawing the medication from an ampule or vial into a sterile syringe, using prefilled

Figure 35-26 ■ Passive safety device. The needle retracts immediately into the barrel after injection.

Figure 35-27 ■ Active safety device. The nurse manually pulls the sheath or guard over the needle after injection.

Figure 35-28 ■ A needleless system can extract medicine from a vial.

syringes, or by using needleless injection systems. Figure 35–28 ■ shows an example of a needleless system used to access medication from a vial.

AMPULES AND VIALS

Ampules and vials (Figure 35–29 ■) are frequently used to package sterile parenteral medications. An **ampule** is a glass container usually designed to hold a single dose of a drug. It is made of clear glass and has a distinctive shape with a constricted neck. Ampules vary

Figure 35-29 ■ A, Ampules; B, vials.

in size from 1 to 10 mL or more. Most ampule necks have colored marks around them, indicating where they are prescored for easy opening.

To access the medication in an ampule, the ampule must be broken at its constricted neck. Traditionally, files have been used to score the ampule. Today plastic ampule openers are available that prevent injury from broken glass. The device consists of a plastic cap that fits over the top of an ampule. The head of the ampule, when broken, remains inside the cap and is placed into a sharps container (Figure 35–30 ■). If an ampule opener is not available, the nurse can clean the ampule neck with an alcohol swab and, using dry sterile gauze, snap off the top of the ampule. Once the ampule is broken, the fluid is aspirated into a syringe using a filter needle or filter straw (Figure 35–31 ■). Both prevent aspiration of any glass particles.

A **vial** is a small glass bottle with a sealed rubber cap. Vials come in different sizes, from single-use vials to multiple-dose vials. They usually have a metal or plastic cap that protects the rubber seal and

A

B

C

Figure 35-30 ■ A, Ampule opener; B, plastic opener is placed over top of ampule; C, top of ampule remains in opener after ampule is broken open.

A

B

Figure 35-31 ■ A filter needle, A, or a filter straw, B, prevents glass from being withdrawn with the medication.

must be removed to access the medication. To access the medication in a vial, the vial must be pierced with a needle. In addition, air must be injected into a vial before the medication can be withdrawn. Failure to inject air before withdrawing the medication leaves a vacuum within the vial that makes withdrawal difficult.

A single-use vial contains only one dose of medication and should only be used once. In contrast, a multidose vial is a bottle of liquid medication that contains more than one dose, such as insulin or vaccination vials. Recent investigations by the CDC have identified improper uses of syringes, needles, and medication vials that have resulted in disease transmission, such as hepatitis B (CDC, 2012b). Whenever possible, use of single-dose vials is preferred over multidose vials, especially when medications will be administered to multiple clients. If multidose vials must be used, both the needle or cannula and syringe used to access the vial must be sterile. The *One and Only* health campaign is aimed at raising awareness about safe injection practice. The slogan is: *One needle, One syringe, Only One time.*

Some drugs (e.g., penicillin) may be dispensed as powders in vials. A liquid (diluent) must be added to a powdered medication before it can be injected. The technique of adding a diluent to a powdered drug to prepare it for administration is called **reconstitution**. Powdered drugs usually have printed instructions (enclosed with each packaged vial) that describe the amount and kind of solvent to be added. Commonly used diluents are sterile water or sterile normal saline. Some preparations are supplied in individual-dose vials; others come in multidose vials. The following are two examples of the preparation of powdered drugs:

1. **Single-dose vial:** Instructions for preparing a single-dose vial state that 1.5 mL of sterile water is to be added to the sterile dry powder, thus providing a single dose of 2 mL. The volume of the drug powder was 0.5 mL. Therefore, the 1.5 mL of water plus the 0.5 mL of powder results in 2 mL of solution. In other instances, the addition of a solution does not increase the volume. Therefore, it is important to follow the manufacturer's directions.
2. **Multidose vial:** A dose of 750 mg of a certain drug is ordered for a client. On hand is a 10-g multidose vial. The directions for preparation read: "Add 8.5 mL of sterile water, and each milliliter

will contain 1.0 g or 1,000 mg.” To determine the amount to inject, the nurse does these calculations:

$$\begin{aligned} 1 \text{ mL} &= 1,000 \text{ mg} \\ x \text{ mL} &= 750 \text{ mg} \\ &\text{(cross multiply)} \\ x &= \frac{750 \times 1}{1,000} \\ x &= 0.75 \end{aligned}$$

The nurse will give 0.75 mL of the medication.

Glass and rubber particulate have been found in medications withdrawn from ampules and vials using a regular needle. As a result, it

is strongly recommended that the nurse use a filter needle when withdrawing medications from ampules and vials to prevent withdrawing glass and rubber particles. After drawing the medication into the syringe, the filter needle is replaced with the regular needle for injection. This prevents tracking of the medication through the client’s tissues during the insertion of the needle, which minimizes discomfort.

Skills 35–2 and 35–3 describe how to prepare medications from ampules and vials, respectively. Additionally, it is important to remember that when powdered drugs have been reconstituted, the date and time should be written on the label of the vial. Many of these drugs have to be used within a certain time period following reconstitution, so nurses need to know the expiration time after it has been reconstituted.

Preparing Medications from Ampules

ASSESSMENT

Assess

- Client allergies to medication
- Specific drug action, side effects, interactions, and adverse reactions
- Client’s knowledge of and learning needs about the medication
- Intended route of parenteral medication to determine appropriate size of syringe and needle for the client
- Ordered medication for clarity and expiration date

Perform appropriate assessments (e.g., vital signs, laboratory results) specific to the medication.

Determine if the assessment data influence administration of the medication (i.e., is it appropriate to administer the medication or does the medication need to be held and/or the primary care provider notified?).

PLANNING

DELEGATION

Preparing medications from ampules involves knowledge and use of sterile skills. Therefore, these techniques are not delegated to UAP.

Equipment

- Client’s MAR or computer printout
- Ampule of sterile medication
- File (if ampule is not scored) and small gauze square or plastic ampule opener
- Antiseptic swabs
- Syringe
- Needle for administering the medication
- Filter needle or straw for withdrawing medication from the ampule

IMPLEMENTATION

Preparation

1. Check the MAR.
 - Check the label on the ampule carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering medications. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
2. Organize the equipment.

Performance

1. Perform hand hygiene and observe other appropriate infection prevention procedures.
2. Prepare the medication ampule for drug withdrawal.
 - Flick the upper stem of the ampule several times with a fingernail. **Rationale:** *This will bring all medication down to the main portion of the ampule.*
 - Use an ampule opener or place a piece of sterile gauze or alcohol wipe between your thumb and the ampule neck or around the ampule neck, and break off the top by *bending* it toward you to ensure the ampule is broken away from yourself and away from others. **Rationale:** *The sterile gauze*

protects the fingers from the broken glass, and any glass fragments will spray away from the nurse. ①

or

- Place the antiseptic wipe packet over the top of the ampule before breaking off the top. **Rationale:** *This method ensures that all glass fragments fall into the packet and reduces the risk of cuts.*
 - Dispose of the top of the ampule in the sharps container.
3. Withdraw the medication.
 - Place the ampule on a flat surface.
 - Attach the filter needle/straw to the syringe. **Rationale:** *The filter needle/straw prevents glass particles from being withdrawn with the medication.*
 - Remove the cap from the filter needle and insert the needle into the center of the ampule. Do not touch the rim of the ampule with the needle tip or shaft. **Rationale:** *This will keep the needle sterile.* Withdraw the amount of drug required for the dosage.
 - With a single-dose ampule, hold the ampule slightly on its side, if necessary, to obtain more than the ordered amount of medication. ②

Preparing Medications from Ampules—continued

SKILL 35-2

A

A

B

1 A, Breaking the neck of an ampule using a gauze pad; B, breaking the neck of an ampule using an ampule opener.

- Dispose of the filter needle by placing in a sharps container.
- If giving an injection replace the filter needle with a regular needle, tighten the cap at the hub of the needle, and push solution into the needle, to the prescribed amount.

B

2 Withdrawing a medication A, from an ampule on a flat surface; and B, from an inverted ampule.

Preparing Medications from Vials

SKILL 35-3

PLANNING DELEGATION

Preparing medications from vials involves knowledge and use of sterile technique. Therefore, these techniques are not delegated to UAP.

IMPLEMENTATION

Preparation

- Follow the same preparation as described in Skill 35-2.

Performance

1. Perform hand hygiene and observe other appropriate infection prevention procedures.

Equipment

- Client's MAR or computer printout
- Vial of sterile medication
- Antiseptic swabs
- Safety needle and syringe
- Filter needle (check agency policy)
- Sterile water or normal saline, if drug is in powdered form

2. Prepare the medication vial for drug withdrawal.
 - Mix the solution, if necessary, by rotating the vial between the palms of the hands, not by shaking. **Rationale:** Some vials contain aqueous suspensions, which settle when

Preparing Medications from Vials—continued

they stand. In some instances, shaking is contraindicated because it may cause the mixture to foam.

- Remove the protective cap, or clean the rubber cap of a previously opened vial with an antiseptic wipe by rubbing in a circular motion. **Rationale:** *The antiseptic cleans the cap and reduces the number of microorganisms.*
3. Withdraw the medication.
- Attach a filter needle, as agency practice dictates, to draw up premixed liquid medications from multidose vials. **Rationale:** *Using the filter needle prevents any solid particles from being drawn up through the needle.*
 - Ensure that the needle is firmly attached to the syringe.
 - Remove the cap from the needle, then draw up into the syringe the amount of air equal to the volume of the medication to be withdrawn.
 - Carefully insert the needle into the upright vial through the center of the rubber cap, maintaining the sterility of the needle.
 - Inject the air into the vial, keeping the bevel of the needle above the surface of the medication. **1 Rationale:** *The air will allow the medication to be drawn out easily because negative pressure will not be created inside the vial. The bevel is kept above the medication to avoid creating bubbles in the medication.*
 - Withdraw the prescribed amount of medication using either of the following methods:
 - Hold the vial down (i.e., with the base lower than the top), move the needle tip so that it is below the fluid level, and withdraw the medication. Avoid drawing up the last drops of the vial. **2 Rationale:** *Proponents of this method say that keeping the vial in the upright position while withdrawing the medication allows particulate matter to precipitate out of the solution. Leaving the last few drops reduces the chance of withdrawing foreign particles.*

or

 - Invert the vial, ensure the needle tip is below the fluid level, and gradually withdraw the medication. **3 Rationale:** *Keeping the tip of the needle below the fluid level prevents air from being drawn into the syringe.*
 - Hold the syringe and vial at eye level to determine that the correct dosage of drug is drawn into the syringe. Eject air remaining at the top of the syringe into the vial.
 - When the correct volume of medication plus a little more (e.g., 0.25 mL) is obtained, withdraw the needle from the vial, and replace the cap over the needle using the scoop method, thus maintaining its sterility.
 - If necessary, tap the syringe barrel to dislodge any air bubbles present in the syringe. **Rationale:** *The tapping motion will cause the air bubbles to rise to the top of the syringe where they can be ejected out of the syringe.*
 - If giving an injection, replace the filter needle, if used, with a regular or safety needle of the correct gauge and length. Eject air from the new needle and verify correct medication volume before injecting the client.

Variation: Preparing and Using Multidose Vials

- Read the manufacturer's directions.
- Withdraw an equivalent amount of air from the vial before adding the diluent, unless otherwise indicated by the directions.
- Add the amount of sterile water or saline indicated in the directions.
- If a multidose vial is reconstituted, label the vial with the date and time it was prepared, the amount of drug contained in each milliliter of solution, and your initials. **Rationale:** *Time is an important factor to consider in the expiration of these medications.*

1 Injecting air into a vial.

2 Withdrawing a medication from a vial that is held with the base down.

3 Withdrawing a medication from an inverted vial.

- Once the medication is reconstituted, store it in a refrigerator or as recommended by the manufacturer.
- Discard vial if sterility is compromised or questionable.
- Remember to use a sterile syringe and needle/cannula for each access to the multidose vial.

MIXING MEDICATIONS IN ONE SYRINGE

Frequently, clients need more than one drug injected at the same time. To spare the client the experience of being injected twice, two drugs (if compatible) are often mixed in one syringe and given as one injection. It is common, for instance, to combine two types of insulin in this manner or to combine injectable preoperative medications such as morphine with atropine or scopolamine. Drugs can also be mixed in IV solutions. When uncertain about drug compatibilities, the nurse should consult a pharmacist or check a compatibility chart before mixing the drugs.

The nurse must also exercise caution when mixing short- and long-acting insulins, because they vary in content. Chemically, insulin is a protein that, when hydrolyzed in the body, yields a number of amino acids. Some insulin preparations contain an additional modifying protein, such as globulin or protamine, which slows absorption. This fact is particularly relevant when mixing two insulin preparations for injection because many insulin syringes have needles that cannot be changed. A vial of insulin that does not have the added protein (i.e., regular insulin) should *never* be contaminated with insulin that does have the added protein (i.e., Lente or NPH insulin). Skill 35–4 describes how to mix medications in one syringe.

Mixing Medications Using One Syringe

ASSESSMENT

Assess

- Client allergies to medications
- Specific drug action, side effects, interactions, and adverse reactions
- Client's knowledge of and learning needs about the medications

- Intended route of parenteral medication to determine appropriate size of syringe and needle for the client
 - Ordered medications for clarity and expiration date
- Determine that the two medications are compatible.

PLANNING

DELEGATION

Mixing medications in one syringe involves knowledge and use of aseptic technique. Therefore, this procedure is not delegated to UAP.

Equipment

- Client's MAR or computer printout
- Two vials of medication; one vial and one ampule; two ampules; or one vial or ampule and one cartridge
- Antiseptic swabs
- Sterile syringe and safety needle or insulin syringe and needle (If insulin is being given, use a small-gauge hypodermic needle, e.g., #26 gauge.)
- Additional sterile subcutaneous or intramuscular safety needle (optional)

IMPLEMENTATION

Preparation

1. Check the MAR.
 - Check the label on the medications carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering medications. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
 - Before preparing and combining the medications, ensure that the total volume of the injection is appropriate for the injection site.
2. Organize the equipment.

Performance

1. Perform hand hygiene and observe other appropriate infection prevention procedures.
2. Prepare the medication ampule or vial for drug withdrawal.
 - See Skill 35–2, *Performance* section, step 2, for an ampule.
 - Inspect the appearance of the medication for clarity. Note, however, that some medications are always cloudy. **Rationale:** *Preparations that have changed in appearance should be discarded.*
 - If using insulin, thoroughly mix the solution in each vial prior to administration. Rotate the vials between the palms of the hands. **Rationale:** *Mixing ensures an adequate concentration and thus an accurate dose. Shaking insulin vials can make the medication frothy, making precise measurement difficult.*
 - Clean the tops of the vials with antiseptic swabs.
3. Withdraw the medications.

Mixing Medications from Two Vials

- Take the syringe and draw up a volume of air equal to the volume of medications to be withdrawn from both vials A and B.
- Inject a volume of air equal to the volume of medication to be withdrawn into vial A. Make sure the needle does not touch the solution. **Rationale:** *This prevents cross contamination of the medications.*
- Withdraw the needle from vial A and inject the remaining air into vial B.
- Withdraw the required amount of medication from vial B. **Rationale:** *The same needle is used to inject air into and withdraw medication from the second vial. It must not be contaminated with the medication in vial A.*
- Using a newly attached sterile needle, withdraw the required amount of medication from vial A. Avoid pushing the plunger because that will introduce medication B into vial A. If using a syringe with a fused needle, withdraw the medication from vial A. The syringe now contains a mixture of medications from vials A and B. **Rationale:** *With this method, neither vial is contaminated by microorganisms or by medication from the other vial. Be careful to withdraw only the ordered amount and to not create air bubbles. Rationale:* *The syringe now contains two medications and an excess amount cannot be returned to the vial.*

See also the *Variation* later in this skill.

Mixing Medications from One Vial and One Ampule

- First prepare and withdraw the medication from the vial. **Rationale:** *Ampules do not require the addition of air prior to withdrawal of the drug.*

Mixing Medications Using One Syringe—continued

- Then withdraw the required amount of medication from the ampule.

Mixing Medications from One Cartridge and One Vial or Ampule

- First ensure that the correct dose of the medication is in the cartridge. Discard any excess medication and air.
- Draw up the required medication from a vial or ampule into the cartridge. Note that when withdrawing medication from a vial, an equal amount of air must first be injected into the vial.
- If the total volume to be injected exceeds the capacity of the cartridge, use a syringe with sufficient capacity to withdraw the desired amount of medication from the vial or ampule, and transfer the required amount from the cartridge to the syringe.

Variation: Mixing Insulins

The following is an example of mixing 10 units of regular insulin and 30 units of neutral protamine Hagedorn (NPH) insulin, which contains protamine.

- Inject 30 units of air into the NPH vial and withdraw the needle. (There should be no insulin in the needle.) The needle should not touch the insulin. ❶
- Inject 10 units of air into the regular insulin vial and immediately withdraw 10 units of regular insulin. ❷ and ❸ Always withdraw the regular insulin first. **Rationale:** *This minimizes the possibility of the regular insulin becoming contaminated with the additional protein in the NPH.*

- Reinsert the needle into the NPH insulin vial and withdraw 30 units of NPH insulin. ❹ (The air was previously injected into the vial.) Be careful to withdraw only the ordered amount and to not create air bubbles. If excess medication has been drawn up, discard the syringe and begin the procedure over again.

Rationale: *The syringe now contains two medications, and an excess amount cannot be returned to the vial because the syringe contains regular insulin, which, if returned to the NPH vial, would dilute the NPH with regular insulin. The NPH vial would not provide accurate future dosages of NPH insulin.*

By using this method, you avoid adding NPH insulin to the regular insulin.

CLINICAL ALERT!

One way to determine which insulin to *withdraw* first is to remember the saying “Clear before cloudy.” (Regular insulin is clear and NPH is cloudy due to the proteins in the insulin.)

SAFETY ALERT!

SAFETY

The ISMP (2012) considers insulin a high-alert medication, meaning that it can cause significant client harm if used in error. Check the health agency’s policy regarding administration because some agencies may require insulin doses to be checked by two nurses.

❸

❹

Intradermal Injections

An **intradermal (ID) injection** is the administration of a drug into the dermal layer of the skin just beneath the epidermis. Usually only a small amount of liquid is used, for example, 0.1 mL. This method of administration is frequently used for allergy testing and tuberculosis (TB) screening. Common sites for intradermal injections are the inner lower arm, the upper chest, and the back beneath the scapulae (Figure 35-32 ■). The left arm is commonly used for TB screening and the right arm is used for all other tests. The steps for administering an intradermal injection are described in Skill 35-5.

Subcutaneous Injections

Among the many kinds of drugs administered subcutaneously (just beneath the skin) are vaccines, insulin, and heparin. Common sites for subcutaneous injections are the outer aspect of the upper arms and the anterior aspect of the thighs. These areas are convenient and normally have good blood circulation. Other areas that can be used

Figure 35-32 ■ Body sites commonly used for intradermal injections.

Administering an Intradermal Injection for Skin Tests

PURPOSE

- To provide a medication that the client requires for allergy testing and TB screening

ASSESSMENT

Assess

- Appearance of injection site
 - Specific drug action and expected response
 - Client's knowledge of drug action and response
- Check agency protocol about sites to use for skin tests.

PLANNING

DELEGATION

The administration of intradermal injections is an invasive technique that involves the application of nursing knowledge, problem solving, and sterile technique. This technique is not delegated to UAP. The nurse, however, can inform the UAP about symptoms of allergic reactions and the necessity of reporting those observations immediately to the nurse.

Equipment

- Client's MAR or computer printout
- Vial or ampule of the correct medication
- Sterile 1-mL syringe calibrated into hundredths of a milliliter (i.e., tuberculin syringe) and a #25- to #27-gauge safety needle that is 1/4 to 5/8 inch long
- Alcohol swabs
- 2×2 sterile gauze square (optional)
- Clean gloves (according to agency protocol)
- Bandage (optional)
- Epinephrine on hand in case of allergic anaphylactic reaction

IMPLEMENTATION

Preparation

- Check the MAR.
 - Check the label on the medication carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering medications. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
- Organize the equipment.

PERFORMANCE

- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Prepare the medication from the vial or ampule for drug withdrawal.
 - See Skills 35-2 and 35-3.
- Prepare the client
 - Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. **Rationale:** *This ensures that the right client receives the medication.*
- Explain to the client that the medication will produce a small wheal, sometimes called a bleb. A wheal is a small raised area, like a blister. The client will feel a slight prick as the needle enters the skin. Some medications are absorbed slowly through the capillaries into the general circulation, and the bleb gradually disappears. Other drugs remain in the area and interact with the body tissues to produce redness and induration (hardening), which will need to be interpreted at a particular time (e.g., in 24 or 48 hours). This reaction will also gradually disappear. **Rationale:** *Information can facilitate acceptance of and compliance with the therapy.*
- Provide for client privacy.
- Select and clean the site.
 - Select a site (e.g., the forearm about a hand's width above the wrist and three or four finger widths below the antecubital space).
 - Avoid using sites that are tender, inflamed, or swollen and those that have lesions.
 - Apply gloves as indicated by agency policy.
 - Cleanse the skin at the site using a firm circular motion starting at the center and widening the circle outward. Allow the area to dry thoroughly.

- Prepare the syringe for the injection.
 - Remove the needle cap while waiting for the antiseptic to dry.
 - Expel any air bubbles from the syringe. Small bubbles that adhere to the plunger are of no consequence. **Rationale:** *A small amount of air will not harm the tissues.*
 - Grasp the syringe in your dominant hand, close to the hub, holding it between thumb and forefinger. Hold the needle almost parallel to the skin surface, with the bevel of the needle up. **Rationale:** *The possibility of the medication entering the subcutaneous tissue increases when using an angle greater than 15°.*
- Inject the fluid.
 - With the nondominant hand, pull the skin at the site until it is taut. For example, if using the ventral forearm, grasp the client's dorsal forearm and gently pull it to tighten the ventral skin. **Rationale:** *Taut skin allows for easier entry of the needle and less discomfort for the client.*
 - Insert the tip of the needle far enough to place the bevel through the epidermis into the dermis. The outline of the bevel should be visible under the skin surface.
 - Stabilize the syringe and needle. Inject the medication carefully and slowly so that it produces a small wheal on the skin. **Rationale:** *This verifies that the medication entered the dermis.* ①
 - Withdraw the needle quickly at the same angle at which it was inserted. Activate the needle safety device. Apply a bandage if indicated.
 - Do not massage the area. **Rationale:** *Massage can disperse the medication into the tissue or out through the needle insertion site.*
 - Dispose of the syringe and needle into the sharps container. **Rationale:** *Do not recap the needle in order to prevent needlestick injuries.*
 - Remove and discard gloves.
 - Perform hand hygiene.
 - Circle the injection site with ink to observe for redness or induration (hardening), per agency policy.
- Document all relevant information.
 - Record the testing material given, the time, dosage, route, site, and nursing assessments.

Administering an Intradermal Injection for Skin Tests—continued

1 A

1 B

1 C

1 For an intradermal injection: A, the needle enters the skin at a 5° to 15° angle; B, C, the medication forms a bleb or wheal under the epidermis.

EVALUATION

- Evaluate the client's response to the testing substance.
Rationale: Some medications used in testing may cause allergic reactions. Epinephrine may need to be used.
- Evaluate the condition of the site in 24 or 48 hours, depending on the test. Measure the area of redness and induration in millimeters at the largest diameter and document findings.

LIFESPAN CONSIDERATIONS Administering an Intradermal Injection

Children

- Children should be gently restrained during the procedure in order to prevent injury from a sudden movement.
- Make sure the child understands that the injection is not a punishment.
- Ask the child not to rub or scratch the injection site. Rubbing the site can interfere with test results by irritating the underlying tissue.

Home Care Considerations Administering an Intradermal Injection

PATIENT-CENTERED CARE

- Assess the client's knowledge about the intradermal injection and the reason for follow-up with the health care professional. Set up an appointment for the visit.
- Instruct and explain why the injection site should not be washed, rubbed, or scratched.

are the abdomen, the scapular areas of the upper back, and the upper ventrogluteal and dorsogluteal areas (Figure 35–33 ■). Only small doses (0.5 to 1 mL) of medication are usually injected via the subcutaneous route. Check agency policy.

The type of syringe used for subcutaneous injections depends on the medication being given. Generally a 1- or 2-mL syringe is used for most subcutaneous injections. However, if insulin is being administered, an insulin syringe is used; if heparin is being administered, a prefilled cartridge may be used.

Needle sizes and lengths are selected based on the client's body mass, the intended angle of insertion, and the planned site. Generally a #25-gauge, 5/8-inch needle is used for adults of normal

weight and the needle is inserted at a 45° angle; a 3/8-inch needle is used at a 90° angle. A child may need a 1/2-inch needle inserted at a 45° angle.

One method nurses use to determine length of needle is to pinch the tissue at the site and select a needle length that is half the width of the skinfold. To determine the angle of insertion, a general rule to follow relates to the amount of tissue that can be pinched or grasped at the site. A 45° angle is used when 1 inch of tissue can be grasped at the site; a 90° angle is used when 2 inches of tissue can be grasped.

When administering insulin to adults, the current standard needle gauge is #30 gauge with a short needle (4 to 6 mm). Most

Figure 35-33 ■ Body sites commonly used for subcutaneous injections.

clients prefer the shorter and thinner needles because they are less painful. The risk of injecting into the muscle is lessened with the shorter needle.

Subcutaneous injection sites need to be rotated in an orderly fashion to minimize tissue damage, aid absorption, and avoid discomfort. This is especially important for clients who must receive repeated injections, such as those with diabetes. Because insulin is absorbed at different rates at different parts of the body, the blood glucose levels of a client who has diabetes can vary when various sites are used. Insulin is absorbed most quickly when injected into the abdomen and then into the arms, and most slowly when injected into the thighs and buttocks. Rotate the injection sites weekly to prevent lipoatrophy and lipohypertrophy (Adams & Urban, 2013).

Nurses have traditionally been taught to aspirate by pulling back on the plunger after inserting the needle and before injecting the medication. The nurse could then determine whether the needle had entered a blood vessel. Absence of blood was believed to indicate that the needle was in subcutaneous tissue and not in the more vascular muscular tissue. According to the American Diabetes Association (ADA) (2004), routine aspiration is no longer recommended with insulin administration. Crawford and Johnson (2012) completed a recent review of evidence to answer the question of the need to aspirate for blood when administering an IM or subcutaneous injection. Their answer is “clearly ‘no’ for the injection of vaccines, immunizations, heparin, and insulin” (p. 25). It is likely, however, that students will observe that the practice of aspirating subcutaneous injections will vary among nurses.

The steps for administering a subcutaneous injection are described in Skill 35-6.

Administering a Subcutaneous Injection

PURPOSES

- To provide a medication the client requires (see specific drug action)
- To allow slower absorption of a medication compared with either the intramuscular or intravenous route

ASSESSMENT

Assess

- Allergies to medication
- Specific drug action, side effects, and adverse reactions
- Client's knowledge and learning needs about the medication
- Status and appearance of subcutaneous site for lesions, erythema, swelling, ecchymosis, inflammation, and tissue damage from previous injections
- Ability of client to cooperate during the injection
- Previous injection sites used

PLANNING

DELEGATION

The administration of subcutaneous injections is an invasive technique that involves the application of nursing knowledge, problem solving, and sterile technique. Therefore, this skill is not delegated to UAP. The nurse, however, can inform the UAP of the intended therapeutic effects and/or specific side effects of the medication and direct the UAP to report specific client observations to the nurse for follow-up.

Equipment

- Client's MAR or computer printout
- Vial or ampule of the correct sterile medication
- Syringe and needle (e.g., 3-mL syringe, #25-gauge needle or smaller, 3/8 or 5/8 in. long)
- Antiseptic swabs
- Dry sterile gauze for opening an ampule (optional)
- Clean gloves

Administering a Subcutaneous Injection—continued

IMPLEMENTATION

Preparation

- Check the MAR.
 - Check the label on the medication carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering medications. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
- Organize the equipment.

Performance

- Perform hand hygiene and observe other appropriate infection prevention procedures (e.g., clean gloves).
- Prepare the medication from the ampule or vial for drug withdrawal.
 - See Skill 35–2 (ampule) or 35–3 (vial).
 - If the medication is insulin or heparin, the dosage needs to be verified by another nurse. **Rationale:** *Double checking the dosage avoids medication errors.*

CLINICAL ALERT!

When asking another nurse to verify the dosage of insulin or heparin, leave the needle and syringe in the vial and ask “What dosage do I have in the syringe?” The nurse needs to then check the vial medication name and concentration as well as calculate the dosage. This is a safer and more accurate method of double checking than saying to another nurse “I have 10 units of insulin,” which “presets” the other nurse’s checking of the medication dosage and can lead to an error.

- Provide for client privacy.
- Prepare the client.
 - Prior to performing the procedure, introduce self and verify the client’s identity using agency protocol. **Rationale:** *This ensures that the right client receives the right medication.*
 - Assist the client to a position in which the arm, leg, or abdomen can be relaxed, depending on the site to be used. **Rationale:** *A relaxed position of the site minimizes discomfort.*
 - Obtain assistance in holding an uncooperative client. **Rationale:** *This prevents injury due to sudden movement after needle insertion.*
- Explain the purpose of the medication and how it will help, using language that the client can understand. Include relevant information about effects of the medication. **Rationale:** *Information can facilitate acceptance of and compliance with the therapy.*
- Select and clean the site.
 - Select a site free of tenderness, hardness, swelling, scarring, itching, burning, or localized inflammation. Select a site that has not been used frequently. **Rationale:** *These conditions could hinder the absorption of the medication and may also increase the likelihood of injury and discomfort at the injection site.*
 - Apply clean gloves.
 - As agency protocol indicates, clean the site with an antiseptic swab. Start at the center of the site and clean in a widening circle to about 5 cm (2 in.). Allow the area to dry thoroughly. **Rationale:** *The mechanical action of swabbing removes skin secretions, which contain microorganisms.*
 - Place and hold the swab between the third and fourth fingers of the nondominant hand, or position the swab on the client’s skin above the intended site. **Rationale:** *Using*

this technique keeps the swab readily accessible when the needle is withdrawn.

- Prepare the syringe for injection.
 - Remove the needle cap while waiting for the antiseptic to dry. Pull the cap straight off to avoid contaminating the needle by the outside edge of the cap. **Rationale:** *The needle will become contaminated if it touches anything but the inside of the cap, which is sterile.*
 - Dispose of the needle cap.
- Inject the medication.
 - Grasp the syringe in your dominant hand by holding it between your thumb and fingers. With palm facing to the side or upward for a 45° angle insertion, or with the palm downward for a 90° angle insertion, prepare to inject. ①
 - Using the nondominant hand, pinch or spread the skin at the site, and insert the needle using the dominant hand and a firm steady push. Recommendations vary about whether to pinch or spread the skin and at what angle to administer subcutaneous injections. The most important consideration is the depth of the subcutaneous tissue in the area to be injected. If the client has more than 1/2 inch of adipose tissue in the injection site, it would be safe to administer the injection at a 90° angle with the skin spread. If the client is thin or lean and lacks adipose tissue, the subcutaneous injection should be given with the skin pinched and at a 45° to 60° angle. One way to check that the pinch of skin is subcutaneous tissue is to ask the client to flex and extend the elbow. If any muscle is being held in the pinch, you will feel it contract and relax. If so, release the pinch and try again. ②

- Inserting a needle into the subcutaneous tissue using 90° and 45° angles.

- Administering a subcutaneous injection into pinched tissue.

Administering a Subcutaneous Injection—continued

- When the needle is inserted, move your nondominant hand to the end of the plunger. Some nurses find it easier to move the nondominant hand to the barrel of the syringe and the dominant hand to the end of the plunger.
 - Inject the medication by holding the syringe steady and depressing the plunger with a slow, even pressure.
Rationale: *Holding the syringe steady and injecting the medication at an even pressure minimizes discomfort for the client.*
 - It is recommended that with many subcutaneous injections, especially insulin, the needle should be embedded within the skin for 5 seconds after complete depression of the plunger to ensure complete delivery of the dose.
9. Remove the needle.
 - Remove the needle smoothly, pulling along the line of insertion while depressing the skin with your nondominant hand.
Rationale: *Depressing the skin places countertraction on it and minimizes the client's discomfort when the needle is withdrawn.*
 - If bleeding occurs, apply pressure to the site with dry sterile gauze until it stops. *Bleeding rarely occurs after subcutaneous injection.*
 10. Dispose of supplies appropriately.
 - Activate the needle safety device or discard the uncapped needle and attached syringe into designated receptacles.
Rationale: *Proper disposal protects the nurse and others from injury and contamination. The CDC recommends not capping the needle before disposal to reduce the risk of needlestick injuries.*
 - Remove and discard gloves.
 - Perform hand hygiene.
 11. Document all relevant information.
 - Document the medication given, dosage, time, route, and any assessments.
 - Many agencies prefer that medication administration be recorded on the medication record. The nurse's notes are used when prn medications are given or when there is a special problem.
 12. Assess the effectiveness of the medication at the time it is expected to act and document it.

VARIATION: ADMINISTERING A HEPARIN INJECTION

The subcutaneous administration of heparin requires special precautions because of the drug's anticoagulant properties.

- Select a site on the abdomen at least 2 inches away from the umbilicus and above the level of the iliac crests. Some agencies support the practice of subcutaneous injection of heparin in the thighs or arms as alternate sites to the abdomen. Avoid injecting into bruises, scars, masses, or areas of tenderness.
- Use a 3/8-inch, #25- or #26-gauge needle or smaller, and insert it at a 90° angle. If a client is very lean or wasted, use a needle longer than 3/8 inch and insert it at a 45° angle. The arms or thighs may be used as alternate sites.
- Do *not* aspirate when giving heparin by subcutaneous injection.
Rationale: *Aspiration can possibly damage the surrounding tissue and cause bleeding as well as ecchymoses (bruises).*
- Do not massage the site after the injection. **Rationale:** *Massaging could cause bleeding and ecchymoses and hasten drug absorption.*
- Alternate the sites of subsequent injections.

VARIATION: ADMINISTERING ENOXAPARIN (LOVENOX)

Lovenox is a low molecular weight heparin that is used to prevent deep venous thrombosis (DVT). Administration of Lovenox has special considerations also.

- Choose an area on the abdomen at least 2 inches from the umbilicus and above the level of the iliac crests.
- Lovenox syringes come prefilled. Check that the syringe is for the correct dosage. Every syringe comes with a small air bubble. Do *not* expel the air bubble unless you have to adjust the dose.
- Pinch an inch of the cleansed area on the abdomen to make a fold in the skin. Insert the full length of the needle at a 90° angle into the fold of the skin.
- Press the plunger with your thumb until the syringe is empty.
- Pull the needle straight out at the same angle that it was inserted and release the skinfold.
- Point the needle down and away from yourself and others and push down on the plunger to activate the safety shield (Sanofi-Aventis, 2012).

EVALUATION

- Conduct appropriate follow-up such as desired effect (e.g., relief of pain, sedation, lowered blood sugar, a prothrombin time within preestablished limits), any adverse effects (e.g., nausea, vomiting, skin rash), and clinical signs of side effects.
- Relate to previous findings if available.
- Report deviations from normal to the primary care provider.

Home Care Considerations Subcutaneous Injections

PATIENT-CENTERED CARE

- Store current bottle of insulin at room temperature to avoid painful injections, but keep extra supply in the refrigerator (ADA, 2013).
- If the client has impaired vision, consider prefilling syringes and storing them in an appropriate environment (e.g., the refrigerator) or obtaining prefilled medication syringes from pharmaceutical companies.
- For frequent injections, develop a plan for site rotation with the client and explain the reason for injection site rotation.
- For cost-saving measures, teach able clients to safely reuse disposable syringes. Clients with diabetes can be taught to use the same syringe two to three times. They should be instructed to change syringes when the needle appears dull. Clients should be encouraged to maintain needle asepsis, practice safe recapping, and assess for needle dullness with each injection (ADA, 2013). However, clients with poor personal hygiene, acute concurrent illness, open wounds on the hands, or decreased resistance to infection should be discouraged from reusing syringes.
- Explore with the client and primary care provider the appropriateness of the new inhaled version of insulin in place of the injectable version.
- For insulin-dependent clients, ensure that at least one knowledgeable support person can correctly inject insulin in an emergency situation and recognize and treat hypoglycemia.
- Teach the client and family how to safely dispose of needles. Do not throw needles in the garbage or flush used needles down the toilet. Put needles in recycling containers. The EPA (2012) recommends finding out what services are offered in the client's community. For example, some communities offer collection sites or have a disposal site set up that will accept used needles. Some even offer a pickup service that collects the container of used needles.
- The CDC website includes a list of needle disposal rules and needle disposal programs for each state.

Intramuscular Injections

Injections into muscle tissue, or **intramuscular (IM) injections**, are absorbed more quickly than subcutaneous injections because of the greater blood supply to the body muscles. Muscles can also take a larger volume of fluid without discomfort than subcutaneous tissues can, although the amount varies among individuals, chiefly based on muscle size and condition and the site used. An adult with well-developed muscles can usually safely tolerate up to 3 mL of medication in the gluteus medius and gluteus maximus muscles (Figure 35–34 ■). A volume of 1 to 2 mL is usually recommended for adults with less developed muscles. In the deltoid muscle, volumes of 0.5 to 1 mL are recommended.

Usually a 3- to 5-mL syringe is needed. The size of syringe used depends on the amount of medication being administered. The standard prepackaged intramuscular needle is 1 1/2 inches and #21 or #22 gauge. Several factors indicate the size and length of the needle to be used:

- The muscle
- The type of solution
- The amount of adipose tissue covering the muscle
- The age of the client.

For example, a smaller needle such as a #23- to #25-gauge needle 1 inch long is commonly used for the deltoid muscle. More viscous solutions require a larger gauge (e.g., #20 gauge). Clients who are quite obese may require a needle longer than 1 1/2 inches (e.g., 2 in.), and clients who are emaciated may require a shorter

Figure 35–34 ■ Lateral view of the right buttock showing the three gluteal muscles used for intramuscular injections.

needle (e.g., 1 in.). See Table 35–10 for a comparison of injection type information.

A major consideration in the administration of IM injections is the selection of a safe site located away from large blood vessels, nerves, and bone. Several body sites can be used for IM injections. These sites are discussed in detail next. Contraindications for using a specific site include tissue injury and the presence of nodules, lumps, abscesses, tenderness, or other pathology.

TABLE 35–10 Comparison of Injection Information

	Syringe Size	Needle Size	Needle Length	Volume of Fluid	Aspiration?	Common Sites	Common Uses
Intradermal (ID)	TB syringe	#25–#27 gauge	1/4–5/8 inch	0.1 mL	No	<ul style="list-style-type: none"> • Inner lower arm • Upper chest • Back beneath scapulae 	<ul style="list-style-type: none"> • Allergy testing • TB screening
Subcutaneous	1- to 2-mL syringe Insulin syringe	#25 gauge #30 gauge for insulin	Adult of normal weight: 5/8 inch needle inserted at 45° angle OR 3/8 inch needle inserted at 90° angle Insulin needle: 4–6 mm	0.5–1 mL	No	<ul style="list-style-type: none"> • Outer aspect of upper arms • Anterior aspect of thigh • Abdomen 	<ul style="list-style-type: none"> • Vaccines • Insulin • Heparin
Intramuscular (IM)	Deltoid: 1-mL syringe Ventrogluteal: 3- to 5-mL syringes*	Deltoid: #23–#25 gauge Ventrogluteal: #21 or #22 gauge	Deltoid: 1 inch Ventrogluteal: 1.5 inches	Deltoid: 0.5–1 mL Ventrogluteal: 3 mL max for adult with well-developed gluteal muscle 1–2 mL for adults with less developed gluteal muscle	Deltoid: No Ventrogluteal: No scientific evidence confirming or rejecting aspiration	Deltoid Ventrogluteal	Deltoid: Immunizations Ventrogluteal: Medication that requires large muscle for absorption and/or volume greater than 1 mL

*Size depends on amount of medication being administered.

VENTROGLUTEAL SITE

The ventrogluteal site is in the gluteus medius muscle, which lies over the gluteus minimus (see Figure 35–34). The ventrogluteal site is the *preferred* site for intramuscular injections because the area:

- Contains no large nerves or blood vessels.
- Provides the greatest thickness of gluteal muscle consisting of both the gluteus medius and gluteus minimus.
- Is sealed off by bone.
- Contains consistently less fat than the buttock area, thus eliminating the need to determine the depth of subcutaneous fat.

The ventrogluteal site is the safest site of choice for an IM injection of more than 1 mL in clients older than 7 months (Zimmerman, 2010). This is because it provides the greatest thickness of gluteal muscle and is free of penetrating nerves. Research on the ventrogluteal site being the best site spans several decades, but the use of this site for IM injections in clinical practice is infrequent.

The client position for the injection can be a back, prone, or side-lying position. The side-lying position, however, helps locate the ventrogluteal site more easily. Position the client on his or her side with the knee bent and raised slightly toward the chest. The trochanter will protrude, which facilitates locating the ventrogluteal site. To establish the exact site, the nurse places the heel of the hand on the client's greater trochanter, with the fingers pointing toward the client's head. The right hand is used for the left hip, and the left hand for the right hip. With the index finger on the client's anterior superior iliac spine, the nurse stretches the middle finger dorsally (toward the buttocks), palpating the crest of the ilium and then pressing below it. The triangle formed by the index finger, the third finger, and the crest of the ilium is the injection site (Figures 35–35 ■ and 35–36 ■). Figure 35–35 shows the landmarks and Figure 35–36 shows administering an IM injection into the ventrogluteal site while using the preferred Z-track method as shown in Skill 35–6.

VASTUS LATERALIS SITE

The vastus lateralis muscle is usually thick and well developed in both adults and children. It is recommended as the site of choice for intramuscular injections for infants and young children because it is the largest muscle mass (Ball, Bindler, & Cowen, 2012, p. 273). Because there are no major blood vessels or nerves in the area, it is desirable for

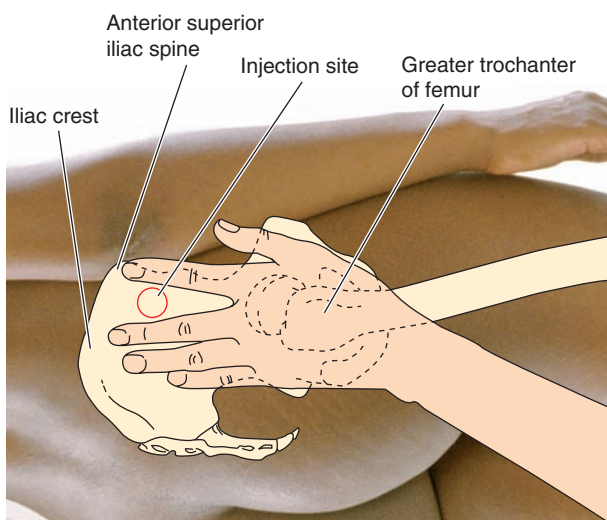

Figure 35–35 ■ Landmarks for the ventrogluteal site for an intramuscular injection.

Figure 35–36 ■ Administering an intramuscular injection into the ventrogluteal site using the Z-track method.

infants whose gluteal muscles are poorly developed. It is situated on the anterior lateral aspect of the infant's thigh (Figure 35–37 ■). The middle third of the muscle is suggested as the site. In the adult, the landmark is established by dividing the area between the greater trochanter of the femur and the lateral femoral condyle into thirds and selecting the middle third (Figures 35–38 ■ and 35–39 ■). The client can assume a back-lying or a sitting position for an injection into this site.

DORSOGLUTEAL SITE

Historically, the dorsogluteal site was primarily used for intramuscular injections. However, this site is close to the sciatic nerve and the superior gluteal nerve and artery. As a result, complications (e.g., numbness, pain, paralysis) occurred if the nurse injected a medication near or into the sciatic nerve. In addition, there tends to be more subcutaneous tissue at the dorsogluteal site. As a result, the medication may be injected into the subcutaneous tissue instead of the muscle, which can then affect the intended therapeutic effect.

Because of the above safety issues and, as stated previously, the ventrogluteal site is the *preferred* site for intramuscular injection. Cocoman and Murray (2010), based on a review of nursing literature and research, state that use of the dorsogluteal site should be avoided

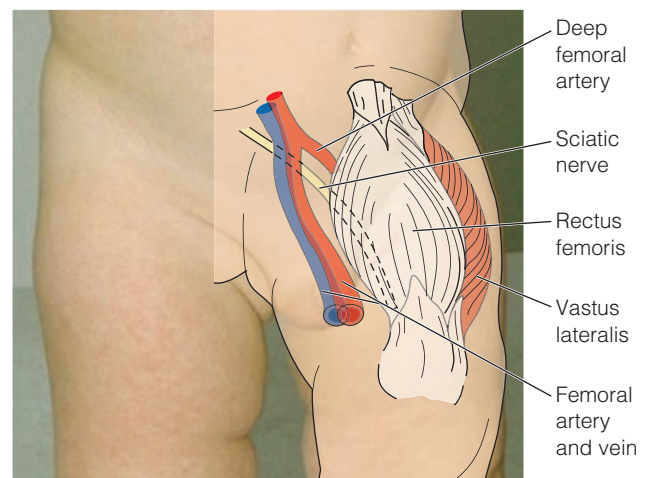

Figure 35–37 ■ The vastus lateralis muscle of an infant's upper thigh, used for intramuscular injections.

Figure 35-38 ■ Landmarks for the vastus lateralis site of an adult's right thigh, used for an intramuscular injection.

from injection practice because it presents an unacceptable risk for clients. Potera (2011) noted, however, that many older nurses still use the dorsogluteal site. Several reasons for this preference include ease of site identification, more experience with using the dorsogluteal site, less confidence using the ventrogluteal site, and lack of emphasis to use the ventrogluteal site over the dorsogluteal site when learning

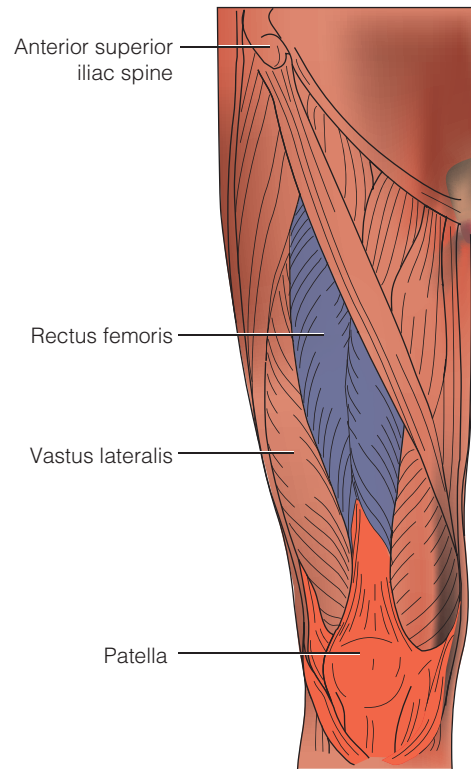

Figure 35-40 ■ Landmarks for the rectus femoris muscle of the upper right thigh, used for intramuscular injections.

about intramuscular injections. In contrast, younger nurses follow the recommended clinical practice of using the ventrogluteal site.

RECTUS FEMORIS SITE

The rectus femoris muscle, which belongs to the quadriceps muscle group, is used only occasionally for intramuscular injections. It is situated on the anterior aspect of the thigh (Figure 35-40 ■). Its chief advantage is that clients who administer their own injections can reach this site easily. Its main disadvantage is that an injection here may cause considerable discomfort for some people.

A

B

Figure 35-39 ■ A, Determining landmarks; B, administering an intramuscular injection by the Z-track method into the vastus lateralis site.

DELTOID SITE

The deltoid muscle is found on the lateral aspect of the upper arm. It is not used often for intramuscular injections because it is a relatively small muscle and is very close to the radial nerve and radial artery. It is sometimes considered for use in adults because of rapid absorption from the deltoid area, but no more than 1 mL of solution can be administered. This site is recommended for the administration of hepatitis B vaccine in adults.

The nurse locates the upper landmark for the deltoid site by placing four fingers across the deltoid muscle with the first finger on the acromion process. The top of the axilla is the line that marks the lower border landmark (Figure 35–41 ■). A triangle within these boundaries indicates the deltoid muscle about 5 cm (2 in.) below the acromion process (Figures 35–42 ■ and 35–43 ■).

Figure 35–43 ■ Administering an intramuscular injection into the deltoid site.

Firmly pressing the injection site for 10 seconds before inserting the needle is thought to reduce the sensory input from an injection, regardless of the site (Zimmerman, 2010).

INTRAMUSCULAR INJECTION TECHNIQUE

Skill 35–7 describes how to administer an IM injection using the Z-track technique, which is recommended for all IM injections (Nicoll & Hesby, 2002, p. 157). The Z-track method has been found to be a less painful technique, and it decreases leakage of irritating medications into the subcutaneous tissue (Barron & Cocoman, 2008; Nicoll & Hesby, 2002; Zimmerman, 2010). Although the Z-track technique is not always used in practice, research evidence supports its effectiveness and recommends its routine use.

Another aspect of IM injection technique is the practice of aspirating for blood prior to administering the injection. Is this practice based on tradition or evidence? Historically, nurses have been taught to aspirate for blood before all IM injections to prevent accidentally injecting the medication into a blood vessel. Aspiration technique consists of pulling the syringe plunger back for 5 to 10 seconds to create negative pressure in the tissue and look for blood return. One study, however, found that only 3% of the nurses in that study aspirated long enough to be of benefit (Hensel & Springmyer, 2011). Literature and integrative reviews of evidence indicate that the practice of aspiration before vaccination injections into the deltoid has no basis in scientific evidence (Crawford & Johnson, 2012; Hensel & Springmyer, 2011). Moreover, the American Academy of Pediatrics, the American Council on Immunization Practices, and the World Health Organization have stated that the practice of aspiration is unnecessary for vaccinations because there are no large vessels located at the recommended vaccination sites (Crawford & Johnson, 2012; Hensel & Springmyer, 2011).

The evidence, however, is not clear regarding aspiration at IM sites other than the deltoid (i.e., ventrogluteal). What is currently known is that there have been no major complications connected to the ventrogluteal site because this site avoids all major nerves and blood vessels (Zimmerman, 2010, p. 60). Hensel and Springmyer (2011) state that “the practice of aspirating for blood return with any IM injection may cease as the use of the ventrogluteal site increases” (p. 592). Further research is needed to examine the practice of aspirating with medications other than vaccinations.

Figure 35–41 ■ A method of establishing the deltoid muscle site for an intramuscular injection.

Figure 35–42 ■ Landmarks for the deltoid muscle of the upper arm, used for intramuscular injections.

Administering an Intramuscular Injection

PURPOSE

- To provide a medication the client requires (see specific drug action)

ASSESSMENT

Assess

- Client allergies to medication(s)
- Specific drug action, side effects, and adverse reactions
- Client's knowledge of and learning needs about the medication
- Tissue integrity of the selected site
- Client's age and weight to determine site and needle size
- Client's ability or willingness to participate

Determine whether the size of the muscle is appropriate to the amount of medication to be injected. An average adult's deltoid muscle can usually absorb 0.5 mL of medication, although some authorities believe 1 mL can be absorbed by a well-developed deltoid muscle. The gluteus medius muscle can often absorb 1 to 4 mL, although 4 mL may be very painful and may be contraindicated by agency protocol.

PLANNING

DELEGATION

The administration of IM injections is an invasive technique that involves the application of nursing knowledge, problem solving, and sterile technique. Delegation to UAP would be inappropriate. The nurse, however, can inform the UAP of the intended therapeutic effects and/or specific side effects of the medication and direct the UAP to report specific client observations to the nurse for follow-up.

Equipment

- Client's MAR or computer printout
- Sterile medication (usually provided in an ampule or vial or prefilled syringe)
- Syringe and needle of a size appropriate for the amount and type of solution to be administered
- Antiseptic swabs
- Clean gloves

IMPLEMENTATION

Preparation

- Check the MAR.
 - Check the label on the medication carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering the medication and dose. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
 - Confirm that the dose is correct.
- Organize the equipment.

Performance

- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Prepare the medication from the ampule or vial for drug withdrawal.
 - See Skill 35-2 (ampule) or 35-3 (vial).
 - Whenever feasible, change the needle on the syringe before the injection. **Rationale:** *Because the outside of a new needle is free of medication, it does not irritate subcutaneous tissues as it passes into the muscle.*
 - Invert the syringe needle uppermost and expel all excess air.
- Provide for client privacy.
- Prepare the client.
 - Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. **Rationale:** *This ensures that the right client receives the medication.*
 - Assist the client to a supine, lateral, prone, or sitting position, depending on the chosen site. If the target muscle is the gluteus medius (ventrogluteal site), have the client in the supine position flex the knee(s); in the lateral position, flex the upper leg; and in the prone position, toe in. **Rationale:** *Appropriate positioning promotes relaxation of the target muscle.*
 - Obtain assistance in holding an uncooperative client. **Rationale:** *This prevents injury due to sudden movement after needle insertion.*
- Explain the purpose of the medication and how it will help, using language that the client can understand. Include relevant information about effects of the medication. **Rationale:** *Information can facilitate acceptance of and compliance with the therapy.*
- Select, locate, and clean the site.
 - Select a site free of skin lesions, tenderness, swelling, hardness, or localized inflammation and one that has not been used frequently.

- If injections are to be frequent, alternate sites. Avoid using the same site twice in a row. **Rationale:** *This is to reduce the discomfort of intramuscular injections.* If necessary, discuss with the prescribing primary care provider an alternative method of providing the medication.
- Locate the exact site for the injection. See the discussion of sites earlier in this chapter.
- Apply clean gloves.
- Clean the site with an antiseptic swab. Using a circular motion, start at the center and move outward about 5 cm (2 in.).
- Transfer and hold the swab between the third and fourth fingers of your nondominant hand in readiness for needle withdrawal, or position the swab on the client's skin above the intended site. Allow skin to dry prior to injecting medication. **Rationale:** *This will help reduce the discomfort of the injection.*
- Prepare the syringe for injection.
 - Remove the needle cover and discard without contaminating the needle.
 - If using a prefilled unit-dose medication, take caution to avoid dripping medication on the needle prior to injection. If this does occur, wipe the medication off the needle with a sterile gauze. Some sources recommend changing the needle if possible. **Rationale:** *Medication left on the needle can cause pain when it is tracked through the subcutaneous tissue (Nicoll & Hesby, 2002).*
- Inject the medication using the Z-track technique.
 - Use the ulnar side of the nondominant hand to pull the skin approximately 2.5 cm (1 in.) to the side. Under some circumstances, such as for an emaciated client or an infant, the muscle may be pinched. **Rationale:** *Pulling the skin and subcutaneous tissue or pinching the muscle makes it firmer and facilitates needle insertion.* ①
 - Holding the syringe between the thumb and forefinger (as if holding a pen), pierce the skin quickly and smoothly at a 90° angle (see Figure 35-39), and insert the needle into the muscle. ② **Rationale:** *Using a quick motion lessens the client's discomfort.*
 - Hold the barrel of the syringe steady with your nondominant hand and aspirate by pulling back on the plunger with your dominant hand. ③ Aspirate for 5 to 10 seconds. **Rationale:** *If the needle is in a small blood vessel, it takes time for the blood to appear.* If blood appears in the syringe, withdraw the needle, discard the syringe, and prepare a new

Administering an Intramuscular Injection—continued

1 Inserting an intramuscular needle at a 90° angle using the Z-track method: A, skin pulled to the side; B, skin released. Note: When the skin returns to its normal position after the needle is withdrawn, a seal is formed over the intramuscular site. This prevents seepage of the medication into the subcutaneous tissues and subsequent discomfort.

injection. **Rationale:** This step determines whether the needle has been inserted into a blood vessel. Note, however, that as stated previously, the practice of aspiration immediately before the administration of an IM vaccine injection is not necessary. Aspiration should be used with the dorsogluteal site (last resort) because needle insertion is close to the gluteal artery. Currently there is no clear evidence with other sites. Thus, it is recommended that nursing students consult the policy manual at the institution where they are practicing to determine the recommended guidelines for IM injection technique.

- If blood does not appear, inject the medication steadily and slowly (approximately 10 seconds per milliliter) while holding the syringe steady if using the ventrogluteal site. **Rationale:** Injecting medication slowly promotes comfort and allows time for tissue to expand and begin absorption of the medication (Malkin, 2008; Zimmerman, 2010). Holding the syringe steady minimizes discomfort. One study found that rapidly injecting vaccines without aspiration caused less pain (Hensel & Springmyer, 2011).
 - After injection, wait 10 seconds if using the ventrogluteal site. **Rationale:** Waiting permits the medication to disperse into the muscle tissue, thus decreasing the client's discomfort.
9. Withdraw the needle.
 - Withdraw the needle smoothly at the same angle of insertion. **Rationale:** This minimizes tissue injury. Release the skin.
 - Apply gentle pressure at the site with a dry sponge. **Rationale:** Use of an alcohol swab may cause pain or a burning sensation.
 - It is not necessary to massage the area at the site of injection. **Rationale:** Massaging the site may cause the leakage of medication from the site and result in irritation.
 - If bleeding occurs, apply pressure with a dry sterile gauze until it stops.
 10. Activate the needle safety device or discard the uncapped needle and attached syringe into the proper receptacle.
 11. Remove and discard gloves.
 - Perform hand hygiene.
 12. Document all relevant information.
 - Include the time of administration, drug name, dose, route, and the client's reactions.
 13. Assess the effectiveness of the medication at the time it is expected to act.

2 Holding the syringe between the thumb and forefinger. Note that the nurse is using the Z-track technique.

3 In addition to pulling the skin to the side, the nondominant hand is holding the barrel of the syringe to prevent it from moving while the dominant hand aspirates by pulling back on the plunger.

Evaluation

- Conduct appropriate follow-up, such as
 - Desired effect (e.g., relief of pain or vomiting)
 - Any adverse reactions or side effects
 - Local skin or tissue reactions at injection site (e.g., redness, swelling, pain, or other evidence of tissue damage).
- Relate to previous findings, if available.
- Report significant deviation from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Intramuscular Injections**INFANTS**

- The vastus lateralis site is recommended as the site of choice for intramuscular injections for infants. There are no major blood vessels or nerves in this area, and it is the infant's largest muscle mass. It is situated on the anterior lateral aspect of the thigh.
- Obtain assistance to immobilize an infant or young child. The parent may hold the child. This prevents accidental injury during the procedure.

CHILDREN

- Use needles that will place medication in the main muscle mass; infants and children usually require smaller, shorter

needles (#22 to #25 gauge, 5/8 to 1 in. long) for intramuscular injections.

- The vastus lateralis is recommended as the site of choice for toddlers and children.
- For the older child and adolescent, the recommended sites are the same as for the adult: ventrogluteal or deltoid. Ask which arm they would like the injection in.

OLDER ADULTS

- Older clients may have a decreased muscle mass or muscle atrophy. A shorter needle may be needed. Assessment of an appropriate injection site is critical. Absorption of medication may occur more quickly than expected.

Intravenous Medications

Because IV medications enter the client's bloodstream directly by way of a vein, they are appropriate when a rapid effect is required. This route is also appropriate when medications are too irritating to tissues to be given by other routes. When an IV line is already established, this route is desirable because it avoids the discomfort of other par-enteral routes. Methods for administering medications intravenously include the following:

- Large-volume infusion of intravenous fluid
- Intermittent intravenous infusion (piggyback or tandem setups)
- Volume-controlled infusion (often used for children)
- Intravenous push (IVP) or bolus
- Intermittent injection ports (device).

In all of these methods, the client has an existing intravenous line or an IV access site such as a saline or heparin lock. Most agencies have procedures and policies about who may administer an IV medication. Chapter 52 ∞ describes the technique for performing a venipuncture and establishing an IV line.

With all IV medication administration, it is very important to observe clients closely for signs of adverse reactions. Because the drug enters the bloodstream directly and acts immediately, there is no way it can be withdrawn or its action terminated. Therefore, the nurse must take special care to avoid any errors about the preparation of the drug and the calculation of the dosage. When the administered drug is particularly potent, an antidote to the drug should be

available. In addition, assess the vital signs before, during, and after infusion of the drug.

Before adding any medications to an existing intravenous infusion, the nurse must check for the "rights" and check compatibility of the drug and the existing intravenous fluid. Be aware of any incompatibilities of the drug and the fluid that is infusing. For example, the drug phenytoin (Dilantin) is incompatible with glucose and will form a precipitate if injected through a port in an intravenous line with glucose/dextrose infusing.

LARGE-VOLUME INFUSIONS

Mixing a medication into a large-volume IV container is the safest and easiest way to administer a drug intravenously. The drugs are diluted in volumes of 250, 500, or 1,000 mL of compatible fluids. It may be necessary to consult a pharmacist to confirm compatibility. Fluids such as IV normal saline or Ringer's lactate are frequently used. Commonly added drugs are potassium chloride and vitamins. It may also be necessary to ensure the compatibility of some drugs with the plastic IV bag and tubing. A glass IV bottle and special tubing may be used in special situations. See Skill 35–8.

The main danger of infusing a large volume of fluid is circulatory overload (hypervolemia) (see Chapter 51 ∞).

The nurse adds the medication to the infusing fluid container or before it is hung for infusion. In many hospitals, the pharmacist adds the medication to the IV container. It is still the nurse's responsibility to check the IV label against the orders of the primary care provider.

Adding Medications to Intravenous Fluid Containers**PURPOSES**

- To provide and maintain a constant level of a medication in the blood
- To administer well-diluted medications at a continuous and slow rate

ASSESSMENT

- Inspect and palpate the IV insertion site for signs of infection, infiltration, or a dislocated catheter.
- Inspect the surrounding skin for redness, pallor, or swelling.
- Palpate the surrounding tissues for coldness and the presence of edema, which could indicate leakage of the IV fluid into the tissues.
- Take vital signs for baseline data for medication that is particularly potent.
- Determine if the client has allergies to the medication(s).
- Check the compatibility of the medication(s) and IV fluid.

Adding Medications to Intravenous Fluid Containers—continued

PLANNING DELEGATION

Adding medications to IV fluid containers involves the application of nursing knowledge and critical thinking. The nurse does not delegate this procedure to UAP. However, the nurse can inform the UAP of the intended therapeutic effects and/or specific side effects of the medication(s) in the IV and direct the UAP to report specific client observations to the nurse for follow-up.

IMPLEMENTATION

Preparation

1. Check the MAR.
 - Check the label on the medication carefully against the MAR to make sure that the correct medication is being prepared.
 - Follow the three checks for administering medications. Read the label on the medication (1) when it is taken from the medication cart, (2) before withdrawing the medication, and (3) after withdrawing the medication.
 - Confirm that the dosage and route is correct.
 - Verify which infusion solution is to be used with the medication.
 - Consult a pharmacist, if required, to confirm compatibility of the drugs and solutions being mixed.
2. Organize the equipment.

Performance

1. Perform hand hygiene and observe other appropriate infection prevention procedures.
2. Prepare the medication ampule or vial for drug withdrawal.
 - See Skill 35-2 (ampule) or 35-3 (vial).
 - Check the agency's practice for using a filter needle to withdraw premixed liquid medications from multidose vials or ampules.
3. Add the medication.

To New IV Container

- Locate the injection port. Clean the port with the antiseptic or alcohol swab. **1** **Rationale:** *This reduces the risk of*

Equipment
