Along with fecal seepage and constipation, symptoms include frequent but nonproductive desire to defecate and rectal pain. A generalized feeling of illness results; the client becomes anorexic, the abdomen becomes distended, and nausea and vomiting may occur.

The causes of fecal impaction are usually poor defecation habits and constipation. Also, the administration of medications such as anticholinergics and antihistamines will increase the client's risk in the development of a fecal impaction. The barium used in radiologic examinations of the upper and lower gastrointestinal tracts can also be a causative factor. Therefore, after these examinations, laxatives or enemas are usually given to ensure removal of the barium.

CLINICAL ALERT!

An older adult with a fecal impaction may show symptoms of delirium. Assess for fecal impaction if the client with constipation problems has a sudden change in mental status.

Digital examination of the impaction through the rectum should be done gently and carefully. Although digital rectal examination is within the scope of nursing practice, some agency policies require a primary care provider's order for digital manipulation and removal of a fecal impaction.

Although fecal impaction can generally be prevented, treatment of impacted feces is sometimes necessary. When fecal impaction is suspected, the client is often given an oil retention enema, a cleansing enema 2 to 4 hours later, and daily additional cleansing enemas, suppositories, or stool softeners. If these measures fail, manual removal is often necessary.

Diarrhea

Diarrhea refers to the passage of liquid feces and an increased frequency of defecation. It is the opposite of constipation and results from rapid movement of fecal contents through the large intestine. Rapid passage of chyme reduces the time available for the large intestine to reabsorb water and electrolytes. Some people pass stool with increased frequency, but diarrhea is not present unless the stool is relatively unformed and excessively liquid. The person with diarrhea finds

it difficult or impossible to control the urge to defecate. Diarrhea and the threat of incontinence are sources of concern and embarrassment. Often, spasmodic cramps are associated with diarrhea. Bowel sounds are increased. With persistent diarrhea, irritation of the anal region extending to the perineum and buttocks generally results. Fatigue, weakness, malaise, and emaciation are the results of prolonged diarrhea.

When the cause of diarrhea is irritants in the intestinal tract, diarrhea is thought to be a protective flushing mechanism. It can create serious fluid and electrolyte losses in the body, however, that can develop within frighteningly short periods of time, particularly in infants, small children, and older adults.

Clostridium difficile-associated disease, which produces mucoid and foul-smelling diarrhea, has been increasing in recent years. Clients at the highest risk for the development of *C. difficile* include immunosuppressed individuals, clients on chemotherapy, and those who have recently used antimicrobial agents, usually fluoroquinolones (Grossman & Mager, 2010). Older adults are at the greatest risk due to underlying disease(s) and greater exposure in hospitals and extended care facilities (Diggs & Surawicz, 2010). Infection control against *C. difficile* infection includes hand hygiene, contact precautions, and cleaning of surfaces with a bleach solution. All individuals involved in the care of the client need to be reminded to wash their hands with soap and water because alcohol-based hand gels are not effective against *C. difficile*. Also, wearing gloves when coming into contact with soiled linens is needed to prevent the spread of the bacteria and spores that exist with *C. difficile* (Grossman & Mager, 2010). Table 49–2 lists some of the major causes of diarrhea and the physiological responses of the body.

The irritating effects of diarrhea stool increase the risk for skin breakdown. Therefore, the area around the anal region should be kept clean and dry and be protected with zinc oxide or other ointment. In addition, a fecal collector can be used (see page 1231).

Bowel Incontinence

Bowel incontinence, also called **fecal incontinence**, refers to the loss of voluntary ability to control fecal and gaseous discharges through the anal sphincter. The incontinence may occur at specific times, such as after meals, or it may occur irregularly. Two types of bowel incontinence are described: partial and major. Partial incontinence is the inability to control flatus or to prevent minor soiling. Major incontinence is the inability to control feces of normal consistency.

TABLE 49–2 Major Causes of Diarrhea

Cause	Physiological Effect
Psychological stress (e.g., anxiety)	Increased intestinal motility and mucous secretion
Medications	Inflammation and infection of mucosa due to overgrowth of pathogenic intestinal microorganisms
Antibiotics	Irritation of intestinal mucosa
Iron	Irritation of intestinal mucosa
Cathartics	Incomplete digestion of food or fluid
Allergy to food, fluid, drugs	Increased intestinal motility and mucous secretion
Intolerance of food or fluid	Reduced absorption of fluids
Diseases of the colon (e.g., malabsorption syndrome, Crohn's disease)	Inflammation of the mucosa often leading to ulcer formation

Fecal incontinence is generally associated with impaired functioning of the anal sphincter or its nerve supply, such as in some neuromuscular diseases, spinal cord trauma, and tumors of the external anal sphincter muscle.

The prevalence of bowel incontinence increases with age. Seven percent of women under the age of 40 years' experience bowel incontinence. That percentage increases to 22% or more by the sixth decade of life. In nursing homes the rate exceeds 50% and a significant number experience both fecal and urinary incontinence (Gallagher & Thompson, 2012, p. 95). Bowel incontinence is an emotionally distressing problem that can ultimately lead to social isolation. Afflicted individuals withdraw into their homes or, if in the hospital, the confines of their room, to minimize the embarrassment associated with soiling. Several surgical procedures are used for the treatment of fecal incontinence. These include repair of the sphincter and bowel diversion or colostomy.

Flatulence

The three primary sources of flatus are (1) action of bacteria on the chyme in the large intestine, (2) swallowed air, and (3) gas that diffuses between the bloodstream and the intestine.

Most gases that are swallowed are expelled through the mouth by eructation (belching). However, large amounts of gas can accumulate in the stomach, resulting in gastric distention. The gases formed in the large intestine are chiefly absorbed through the intestinal capillaries into the circulation. **Flatulence** is the presence of excessive flatus in the intestines and leads to stretching and inflation of the intestines (intestinal distention). Flatulence can occur in the colon from a variety of causes, such as foods (e.g., cabbage, onions), abdominal surgery, or narcotics. If the gas is propelled by increased colon activity before it can be absorbed, it may be expelled through the anus. If excessive gas cannot be expelled through the anus, it may be necessary to insert a rectal tube to remove it.

Evidence-Based Practice Is There a Difference Between Two Methods of Ostomy Care Instruction?

EVIDENCE-BASED PRACTICE

First-time ostomy clients have a great deal of new knowledge and skills to learn about living with and caring for an ostomy. Crawford et al. (2012) described the traditional method of instruction for new ostomy clients at their institution. That is, a certified wound ostomy continence nurse (CWOCN) spent three individual hour-long sessions with each new ostomy client. This was time intensive for the nurses and resulted in fatigue for the postoperative ostomy clients. They wanted to investigate the use of a unique, self-designed, integrated method of teaching incorporating a DVD. A review of the literature found that individual instruction versus DVD instruction has been previously studied. Only one study, however, addressed the subject of nurse involvement along with a DVD method, and there were no studies concerning ostomy clients and DVD instruction. The purpose of their randomized controlled study was to compare two methods of ostomy care instruction to determine their effect on clients' knowledge, skills, and confidence related to ostomy care. Both methods of instruction included one-on-one sessions with a CWOCN at the client's bedside. The "nurse instruction" group received three one-on-one sessions and the "nurse instruction plus DVD" group received two one-on-one sessions plus one session of nurse-guided video instruction in between. A post-test experimental design was used to compare the two instructional methods.

The study setting was two acute care hospitals in the Midwest. Subjects included adult clients, 21 years or older, with new fecal ostomies, either a colostomy or ileostomy. All 68 clients were

independent in activities of daily living prior to their ostomy surgery. The subjects were randomly assigned to one of the instruction groups. A detailed instructional guide was prepared for the CWOCN investigators to ensure that all clients in the study received the same ostomy care information during the teaching sessions.

Three instruments were used to assess the subjects' knowledge, skills, and confidence in providing ostomy self-care. First was a knowledge test where scores were recorded as a percentage of correct answers. Direct observation was used to evaluate skills in four areas: emptying the pouch, caring for the stoma site, sizing and preparing pouching products, and applying the ostomy appliance. Finally, the subjects completed a visual analog scale indicating their levels of confidence in providing ostomy self-care. The results of the data analysis revealed that the nurse instruction plus DVD technique was as effective as the nurse instruction method.

IMPLICATIONS

This study confirmed the results of previous studies that found that video instruction was equally effective for increasing knowledge when compared to traditional instructional methods. It is important to remember that the authors designed an instructional method that incorporated DVD instruction as an adjunct to nurse instruction, not as a replacement for nurse instruction. The integrated DVD method offers flexibility in meeting the learning needs of the postoperative ostomy client and their family, especially after hospital discharge.

BOWEL DIVERSION OSTOMIES

An **ostomy** is an opening for the gastrointestinal, urinary, or respiratory tract onto the skin. There are many types of intestinal ostomies. A **gastrostomy** is an opening through the abdominal wall into the stomach. A **jejunostomy** opens through the abdominal wall into the jejunum, an **ileostomy** opens into the ileum (small bowel), and a **colostomy** opens into the colon (large bowel). Gastrostomies and jejunostomies are generally performed to provide an alternate feeding route. The purpose of bowel ostomies is to divert and drain fecal material. Bowel diversion ostomies are often classified according to (a) their status as permanent or temporary, (b) their anatomic location, and (c) the construction of the **stoma**, the opening created in the abdominal wall by the ostomy. A stoma is generally red in color and moist. Initially, slight bleeding may occur when the stoma is touched and this is considered normal. A person does not feel the stoma because there are no nerve endings in the stoma.

Permanence

Colostomies can be either temporary or permanent. Temporary colostomies are generally performed for traumatic injuries or inflammatory conditions of the bowel. They allow the distal diseased portion of the bowel to rest and heal. Permanent colostomies are performed to provide a means of elimination when the rectum or anus is nonfunctional as a result of a birth defect or a disease such as cancer of the bowel.

CLINICAL ALERT!

Surgery to reconnect the ends of the bowel of a temporary ostomy may be called a take-down.

Anatomic Location

An ileostomy generally empties from the distal end of the small intestine. A cecostomy empties from the cecum (the first part of the ascending colon). An ascending colostomy empties from the ascending colon, a transverse colostomy from the transverse colon, a descending colostomy from the descending colon, and a sigmoidostomy from the sigmoid colon (Figure 49-4 ■).

Figure 49-4 ■ The locations of bowel diversion ostomies.

The location of the ostomy influences the character and management of the fecal drainage. The farther along the bowel, the more formed the stool (because the large bowel reabsorbs water from the fecal mass) and the more control over the frequency of stomal discharge can be established. For example:

- An ileostomy produces liquid fecal drainage. Drainage is constant and cannot be regulated. Ileostomy drainage contains some digestive enzymes, which are damaging to the skin. For this reason, ileostomy clients must wear an appliance continuously and take special precautions to prevent skin breakdown. Compared to colostomies, however, odor is minimal because fewer bacteria are present.
- An ascending colostomy is similar to an ileostomy in that the drainage is liquid and cannot be regulated, and digestive enzymes are present. Odor, however, is a problem requiring control.
- A transverse colostomy produces a malodorous, mushy drainage because some of the liquid has been reabsorbed. There is usually no control.
- A descending colostomy produces increasingly solid fecal drainage. Stools from a sigmoidostomy are of normal or formed consistency, and the frequency of discharge can be regulated. People with a sigmoidostomy may not have to wear an appliance at all times, and odors can usually be controlled.

The length of time that an ostomy is in place also helps to determine the consistency of the stool, particularly with transverse and descending colostomies. Over time, the stool becomes more formed because the remaining functioning portions of the colon tend to compensate by increasing water reabsorption.

Surgical Construction of the Stoma

Stoma constructions are described as single, loop, divided, or double-barreled colostomies. The *single* stoma is created when one end of bowel is brought out through an opening onto the anterior abdominal wall. This is referred to as an *end* or *terminal colostomy*; the stoma is permanent (Figure 49-5 ■).

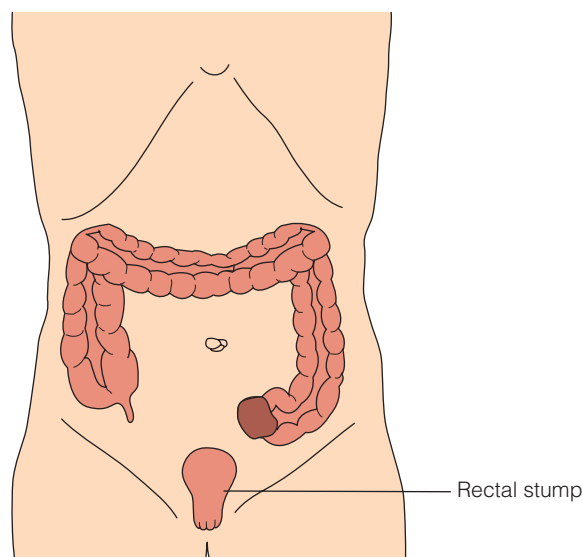

Figure 49-5 ■ End colostomy. The diseased portion of bowel is removed and a rectal pouch remains.

Figure 49-6 ■ Loop colostomy.
Courtesy of Cory Patrick Hartley, RN.

In the *loop colostomy*, a loop of bowel is brought out onto the abdominal wall and supported by a plastic bridge or by a piece of rubber tubing (Figure 49-6 ■). A loop stoma has two openings: the proximal or afferent end, which is active, and the distal or efferent end, which is inactive. The loop colostomy is usually performed in an emergency procedure and is often situated on the right transverse colon. It is a bulky stoma that is more difficult to manage than a single stoma.

The *divided colostomy* consists of two edges of bowel brought out onto the abdomen but separated from each other (Figure 49-7 ■). The opening from the digestive or proximal end is the colostomy. The distal end in this situation is often referred to as a mucous fistula, since this section of bowel continues to secrete mucus. The divided colostomy is often used in situations where spillage of feces into the distal end of the bowel needs to be avoided.

Figure 49-7 ■ Divided colostomy with two separated stomas.

Figure 49-8 ■ Double-barreled colostomy.

The *double-barreled colostomy* resembles a double-barreled shotgun (Figure 49-8 ■). In this type of colostomy, the proximal and distal loops of bowel are sutured together for about 10 cm (4 in.) and both ends are brought up onto the abdominal wall.

LIFESPAN CONSIDERATIONS Factors in Potential Bowel Elimination Problems

CHILDREN

- Successful toilet training can prevent many problems with elimination. The family should be assessed for “readiness to train.” Assess the child’s physical, cognitive, and interpersonal skills, and parental readiness. Does the child have sphincter control (usually by 18 to 24 months)? Does the child understand the meaning of toileting? Is the child able to express him- or herself and does the child demonstrate interest in learning? Are parents ready to work with the child?
- Encourage a regular toileting routine for children. When toilet training, ensure that toddlers can rest their feet comfortably on the floor or a footstool, and are not frightened or pressured while toileting.
- An acute episode of dehydration and constipation (often related to an illness) can lead to chronic stool problems. Constipation can cause painful defecation, which causes the child to withhold stool, leading to more severe constipation, more pain on defecation, more withholding, and so on. Breaking the cycle by helping ease defecation is important to prevent long-term problems.

OLDER ADULTS

- Poor fluid intake and inability to eat a high-fiber diet, due to swallowing or chewing difficulties, are often causes of constipation.
- Medications that are commonly taken by older adults such as antacids, many antihypertensives, antidepressants, diuretics, and narcotics for pain also contribute to constipation.
- Clients receiving tube feedings can experience diarrhea. To alleviate it, they require a change of formula, a change in its strength, or a change in the speed or temperature of tube feeding administration.
- Clients receiving laxative preparation for x-rays or other procedures may experience fluid and electrolyte imbalances due to diarrhea.
- Individuals with cognitive impairment, such as Alzheimer’s disease, may be unaware of what and when they eat or drink or of their bowel habits. It is important that caregivers monitor the person’s bowel elimination patterns.
- Individuals with impaired mobility may have difficulty getting to the bathroom or using a regular toilet. A raised toilet seat and other devices, such as bars to assist in ambulation, may be very helpful. The decrease in activity may also contribute to constipation.

ANATOMY & PHYSIOLOGY REVIEW

Small and Large Intestines

Review the figure and reflect back on your anatomy and physiology courses.

Small and large intestines.

From *Medical Terminology: A Living Language*, 5th ed., by B. F. Fremgen and S. S. Frucht, 2013, Upper Saddle River, NJ: Pearson Education, Inc.

QUESTIONS

1. What are the primary functions of the small intestine?
2. What are the primary functions of the large intestine?
3. What part of the small intestine connects to the colon?
4. What consistency would the stool be in a client with an ileostomy and why?
5. Compare and contrast the consistency of stool in a transverse colostomy and a descending colostomy.
6. How would you describe the stool discharged from a sigmoidostomy?

See student resource website for answers.

●○○ NURSING MANAGEMENT

Assessing

Assessment of fecal elimination includes taking a nursing history; performing a physical examination of the abdomen, rectum, and anus; and inspecting the feces. The nurse also should review any data obtained from relevant diagnostic tests.

Nursing History

A nursing history for fecal elimination helps the nurse ascertain the client's normal pattern. The nurse elicits a description of usual feces and any recent changes and collects information about any past or current problems with elimination, the presence of an ostomy, and factors influencing the elimination pattern.

Examples of questions to elicit this information are shown in the Assessment Interview. The number of questions to ask is adapted to the individual client, according to the client's responses in the first three categories. For example, questions about factors influencing elimination might be addressed only to clients who are experiencing problems.

When eliciting data about the client's defecation pattern, the nurse needs to understand that the time of defecation and the amount of feces expelled are as individual as the frequency of defecation.

Often, the patterns individuals follow depend largely on early training and on convenience.

Physical Examination

Physical examination of the abdomen in relation to fecal elimination problems includes inspection, auscultation, percussion, and palpation with specific reference to the intestinal tract. Auscultation precedes palpation because palpation can alter peristalsis. Examination of the rectum and anus includes inspection and palpation. Physical examination of the abdomen, rectum, and anus is discussed in Chapter 30 ∞.

Inspecting the Feces

Observe the client's stool for color, consistency, shape, amount, odor, and the presence of abnormal constituents. Table 49–1, earlier in this chapter, summarizes normal and abnormal characteristics of stool and possible causes.

Diagnostic Studies

Diagnostic studies of the gastrointestinal tract include direct visualization techniques, indirect visualization techniques, and laboratory tests for abnormal constituents (see Chapter 34 ∞).

ASSESSMENT INTERVIEW Fecal Elimination

DEFECATION PATTERN

- When do you usually have a bowel movement?
- Has this pattern changed recently?

DESCRIPTION OF FECES AND ANY CHANGES

- Have you noticed any changes in the color, texture (hard, soft, watery), shape, or odor of your stool recently?

FECAL ELIMINATION PROBLEMS

- What problems have you had or do you now have with your bowel movements (constipation, diarrhea, excessive flatulence, seepage, or incontinence)?
- When and how often does it occur?
- What do you think causes it (food, fluids, exercise, emotions, medications, disease, surgery)?
- What have you tried to solve the problem, and how effective was it?

FACTORS INFLUENCING ELIMINATION

- *Use of elimination aids.* What routines do you follow to maintain your usual defecation pattern? Do you use natural aids such as specific foods or fluids (e.g., a glass of hot lemon juice before breakfast), laxatives, or enemas to maintain elimination?

- *Diet.* What foods do you believe affect defecation? What foods do you typically eat? What foods do you avoid? Do you take meals at regular times?
- *Fluid.* What amount and kind of fluid do you take each day (e.g., 6 glasses of water, 2 cups of coffee)?
- *Exercise.* What is your usual daily exercise pattern? (Obtain specifics about exercise rather than asking whether it is sufficient; ideas of what is sufficient vary among individuals.)
- *Medications.* Have you taken any medications that could affect the intestinal tract (e.g., iron, antibiotics)?
- *Stress.* Are you experiencing any stress? Do you think this affects your defecation pattern? How?

PRESENCE AND MANAGEMENT OF OSTOMY

- What is your usual routine with your colostomy/ileostomy?
- What type of appliance do you wear and did you bring a spare with you?
- What problems, if any, do you have with it?
- How can the nurses help you manage your colostomy/ileostomy?

Diagnosing

NANDA International (Herdman & Kamitsuru, 2014) includes the following diagnostic labels for fecal elimination problems:

- *Bowel Incontinence*
- *Constipation*
- *Risk for Constipation*
- *Perceived Constipation*
- *Diarrhea*
- *Dysfunctional Gastrointestinal Motility*

Clinical application of selected diagnoses is shown at the end of the chapter in the Nursing Care Plan and Concept Map.

Fecal elimination problems may affect many other areas of human functioning and as a consequence may be the etiology of other NANDA diagnoses. Examples follow:

- *Risk for Deficient Fluid Volume* and/or *Risk for Electrolyte Imbalance* related to
 - a. Prolonged diarrhea
 - b. Abnormal fluid loss through ostomy
- *Risk for Impaired Skin Integrity* related to
 - a. Prolonged diarrhea
 - b. Bowel incontinence
 - c. Bowel diversion ostomy
- *Situational Low Self-Esteem* related to
 - a. Ostomy
 - b. Fecal incontinence
 - c. Need for assistance with toileting
- *Disturbed Body Image* related to
 - a. Ostomy
 - b. Bowel incontinence
- *Deficient Knowledge (Bowel Training, Ostomy Management)* related to lack of previous experience
- *Anxiety* related to
 - a. Lack of control of fecal elimination secondary to ostomy
 - b. Response of others to ostomy.

Planning

The major goals for clients with fecal elimination problems are to:

- Maintain or restore normal bowel elimination pattern.
- Maintain or regain normal stool consistency.
- Prevent associated risks such as fluid and electrolyte imbalance, skin breakdown, abdominal distention, and pain.

Appropriate preventive and corrective nursing interventions that relate to these must be identified. Specific nursing activities associated with each of these interventions can be selected to meet the client's individual needs. Examples of clinical applications of these using NANDA, NIC, and NOC designations are shown in the Nursing Care Plan at the end of the chapter.

Planning for Home Care

Clients who have bowel diversion ostomies, who wear pouches, or who have other ongoing elimination problems will need continuing care in the home setting. In preparation for discharge, the nurse needs to assess the client's and family's ability to meet specific care needs. The Home Care Assessment outlines the specific assessment data required before developing a home care plan. Using the assessment data, the nurse designs a teaching plan for the client and family (see Client Teaching).

Implementing

Promoting Regular Defecation

The nurse can help clients achieve regular defecation by attending to (a) the provision of privacy, (b) timing, (c) nutrition and fluids, (d) exercise, and (e) positioning. See Client Teaching for healthy habits related to bowel elimination.

Privacy

Privacy during defecation is extremely important to many people. The nurse should therefore provide as much privacy as possible for such clients but may need to stay with those who are too weak to be left alone. Some clients also prefer to wipe, wash, and dry themselves

Home Care Assessment Fecal Elimination

PATIENT-CENTERED CARE

CLIENT AND ENVIRONMENT

- *Self-care abilities for toileting:* ability to get to the toilet, to manipulate clothing for toileting, to perform toileting hygiene, and to flush the toilet
- *Mechanical aids required:* walker, cane, wheelchair, raised toilet seat, grab bars, bedpan, commode
- *Mechanical barriers that limit access to the toilet or are unsafe:* poor lighting, cluttered pathway to bathroom, narrow doorway for wheelchair, and so on
- *Bowel elimination problem:* alterations in characteristics of feces, diarrhea, constipation, incontinence, presence of ostomy, and methods of handling these
- *Level of knowledge:* planned bowel management or training program, prescribed medications, ostomy care, dietary alterations, and fluid and exercise requirements or restrictions
- *Facilities:* adequacy of bathroom facilities to facilitate toileting hygiene and ostomy care and to contain potentially infectious fecal effluent or stool

FAMILY

- *Caregiver availability and skills:* people able to assist with toileting, medications, ostomy care, or other prescribed therapeutic measures
- *Family role changes and coping:* effect on financial status, parenting and spousal roles, sexuality, social roles
- *Alternate potential primary or respite caregivers:* for example, other family members, volunteers, church members, paid caregivers or housekeeping services; available community respite care (adult day care, senior centers)

COMMUNITY

- Availability of and familiarity with possible sources of assistance: equipment and supply companies, financial assistance, home health agencies

CLIENT TEACHING

Fecal Elimination

FACILITATING TOILETING

- Ensure safe and easy access to the toilet. Make sure lighting is appropriate, scatter rugs are removed or securely fastened, and so on.
- Facilitate instruction as needed about transfer techniques.
- Suggest ways that garments can be adjusted to make disrobing easier for toileting (e.g., Velcro closing on clothing).

MONITORING BOWEL ELIMINATION PATTERN

- Instruct the client, if appropriate, to keep a record of time and frequency of stool passage, any associated pain, and color and consistency of the stool.

DIETARY ALTERATIONS

- Provide information about required food and fluid alterations to promote defecation or to manage diarrhea.

MEDICATIONS

- Discuss problems associated with overuse of laxatives, if appropriate, and the use of alternatives to laxatives, suppositories, and enemas.
- Discuss the addition of a fiber supplement if the client is taking a constipating medication.

MEASURES SPECIFIC TO ELIMINATION PROBLEM

- Provide instructions associated with specific elimination problems and treatment, such as:
 - Constipation
 - Diarrhea
 - Ostomy care.

COMMUNITY AGENCIES AND OTHER SOURCES OF HELP

- Make appropriate referrals to home care or community care for assistance with resources such as installation of grab bars and raised toilet seats, structural alterations for wheelchair access, homemaker or home health aide services to assist with ADLs, and an enterostomal therapy nurse for assistance with stoma care and selection of ostomy appliances.
- Provide information about companies where durable medical equipment (e.g., raised toilet seats, commodes, bedpans, urinals) can be purchased, rented, or obtained free of charge, and where medical supplies such as incontinence pads or ostomy irrigating supplies and appliances can be obtained.
- Suggest additional sources of information and help such as ostomy self-help and support groups or clubs.

CLIENT TEACHING

Healthy Defecation

- Establish a regular exercise regimen.
- Include high-fiber foods, such as vegetables, fruits, and whole grains, in the diet.
- Maintain fluid intake of 2,000 to 3,000 mL/day.
- Do not ignore the urge to defecate.
- Allow time to defecate, preferably at the same time each day.
- Avoid OTC medications to treat constipation and diarrhea.

after defecating. A nurse may need to provide water and a washcloth and towel for this purpose.

Timing

A client should be encouraged to defecate when the urge is recognized. To establish regular bowel elimination, the client and nurse

can discuss when mass peristalsis normally occurs and provide time for defecation. Many people have well-established routines. Other activities, such as bathing and ambulating, should not interfere with the defecation time.

Nutrition and Fluids

The diet a client needs for regular normal elimination varies, depending on the kind of feces the client currently has, the frequency of defecation, and the types of foods that the client finds assist with normal defecation.

For Constipation Increase daily fluid intake, and instruct the client to drink hot liquids, warm water with a squirt of fresh lemon, and fruit juices, especially prune juice. Include fiber in the diet, that is, foods such as raw fruit, bran products, and whole-grain cereals and bread.

For Diarrhea Encourage oral intake of fluids and bland food. Eating small amounts can be helpful because small amounts are more easily

CLIENT TEACHING

Managing Diarrhea

Drink at least 8 glasses of water per day to prevent dehydration. Consider drinking a few glasses of electrolyte replacement fluids a day.

- Eat foods with sodium and potassium. Most foods contain sodium. Potassium is found in meats and many vegetables and fruits, especially purple grape juice, tomatoes, potatoes, bananas, cooked peaches, and apricots.
- Increase foods containing soluble fiber, such as rice, oatmeal, and skinless fruits and potatoes.
- Avoid alcohol and beverages with caffeine, which aggravate the problem.
- Limit foods containing insoluble fiber, such as high-fiber whole-wheat and whole-grain breads and cereals, and raw fruits and vegetables.
- Limit fatty foods.
- Thoroughly clean and dry the perianal area after passing stool to prevent skin irritation and breakdown. Use soft toilet tissue to clean and dry the area. Apply a dimethicone-based cream or alcohol-free barrier film as needed.
- If possible, discontinue medications that cause diarrhea.
- When diarrhea has stopped, reestablish normal bowel flora by eating fermented dairy products, such as yogurt or buttermilk.
- Seek a primary care provider consultation right away if weakness, dizziness, or loose stools persist more than 48 hours.

absorbed. Excessively hot or cold fluids should be avoided because they stimulate peristalsis. In addition, highly spiced foods and high-fiber foods can aggravate diarrhea. See Client Teaching for details about managing diarrhea.

For Flatulence Limit carbonated beverages, the use of drinking straws, and chewing gum—all of which increase the ingestion of air. Gas-forming foods, such as cabbage, beans, onions, and cauliflower, should also be avoided.

Exercise

Regular exercise helps clients develop a regular defecation pattern. A client with weak abdominal and pelvic muscles (which impede normal defecation) may be able to strengthen them with the following isometric exercises:

- In a supine position, the client tightens the abdominal muscles as though pulling them inward, holding them for about 10 seconds and then relaxing them. This should be repeated 5 to 10 times, four times a day, depending on the client's health.
- Again in a supine position, the client can contract the thigh muscles and hold them contracted for about 10 seconds, repeating the exercise 5 to 10 times, four times a day. This helps the client confined to bed gain strength in the thigh muscles, thereby making it easier to use a bedpan.

Positioning

Although the squatting position best facilitates defecation, on a toilet seat the best position for most people seems to be leaning forward.

For clients who have difficulty sitting down and getting up from the toilet, an elevated toilet seat can be attached to a regular toilet. Clients then do not have to lower themselves as far onto the seat and do not have to lift as far off the seat. Elevated toilet seats can be purchased for use in the home.

Figure 49-9 ■ A commode with overlying seat.

A bedside **commode**, a portable chair with a toilet seat and a receptacle beneath that can be emptied, is often used for the adult client who can get out of bed but is unable to walk to the bathroom. Some commodes have wheels and can slide over the base of a regular toilet when the waste receptacle is removed, thus providing clients the privacy of a bathroom. Some commodes have a seat and can be used as a chair (Figure 49-9 ■). Potty chairs are available for children.

Clients restricted to bed may need to use a **bedpan**, a receptacle for urine and feces. Female clients use a bedpan for both urine and feces; male clients use a bedpan for feces and a urinal for urine. The two main types of bedpans are the regular high-back pan and the slipper, or fracture, pan (Figure 49-10 ■). The slipper pan has a low back and is used for clients unable to raise their buttocks because of physical problems or therapy that contraindicates such movement. Many older adults benefit from the use of a slipper pan. See Practice Guidelines for the techniques of giving and removing a bedpan.

Teaching About Medications

The most common categories of medications affecting fecal elimination are cathartics and laxatives, antidiarrheals, and antiflatulents.

Cathartics and Laxatives

Cathartics are drugs that induce defecation. They can have a strong, purgative effect. A laxative is mild in comparison to a cathartic, and it produces soft or liquid stools that are sometimes accompanied by abdominal cramps. Examples of cathartics are castor oil, cascara,

Figure 49-10 ■ *Left*, The high-back or regular bedpan; *right*, the slipper or fracture pan.

PRACTICE GUIDELINES

Giving and Removing a Bedpan

- Provide privacy.
- Wear clean gloves.
- If the bedpan is metal, warm it by rinsing it with warm water.
- Adjust the bed to a height appropriate to prevent back strain.
- Elevate the side rail on the opposite side to prevent the client from falling out of bed.
- Ask the client to assist by flexing the knees, resting the weight on the back and heels, and raising the buttocks, or by using a trapeze bar, if present.
- Help lift the client as needed by placing one hand under the lower back, resting your elbow on the mattress, and using your forearm as a lever.
- Lubricate the back of the bedpan with a small amount of hand lotion or liquid soap to reduce tissue friction and shearing.
- Place a regular bedpan so that the client's buttocks rest on the smooth, rounded rim. Place a slipper pan with the flat, low end under the client's buttocks (Figure 49-11 ■).
- For the client who cannot assist, obtain the assistance of another nurse to help lift the client onto the bedpan or place the client on his or her side, place the bedpan against the buttocks (Figure 49-12 ■), and roll the client back onto the bedpan.
- To provide a more normal position for the client's lower back, elevate the client's bed to a semi-Fowler's position, if permitted. If elevation is contraindicated, support the client's back with pillows as needed to prevent hyperextension of the back.
- Cover the client with bed linen to maintain comfort and dignity.
- Provide toilet tissue, place the call light within reach, lower the bed to the low position, elevate the side rail if indicated, and leave the client alone.
- Answer the call light promptly.

Figure 49-11 ■ Placing a slipper pan under the buttocks.

Figure 49-12 ■ Placing a regular bedpan against the client's buttocks.

PRACTICE GUIDELINES

Giving and Removing a Bedpan—*continued*

- Do not leave anyone on a bedpan longer than 15 minutes unless they are able to remove the pan themselves. Lengthy stays on a bedpan can cause skin breakdown.
- When removing the bedpan, return the bed to the position used when giving the bedpan, hold the bedpan steady to prevent spillage of its contents, cover the bedpan, and place it on the adjacent chair.
- If the client needs assistance, apply gloves and wipe the client's perineal area with several layers of toilet tissue. If a specimen is to be collected, discard the soiled tissue into a moisture-proof receptacle other than the bedpan. For female clients, clean from the urethra toward the anus to prevent transferring rectal microorganisms into the urinary meatus.
- Wash the perineal area of dependent clients with soap and water as indicated and thoroughly dry the area.
- For all clients, offer warm water, soap, a washcloth, and a towel to wash the hands.
- Assist the client to a comfortable position, empty and clean the bedpan, and return it to the bedside.
- Remove and discard your gloves and wash your hands.
- Spray the room with air freshener as needed to control odor unless contraindicated because of respiratory problems or allergies.
- Document color, odor, amount, and consistency of urine and feces, and the condition of the perineal area.

phenolphthalein, and bisacodyl. Table 49–3 describes the different types of laxatives.

Laxatives are contraindicated in the client who has nausea, cramps, colic, vomiting, or undiagnosed abdominal pain. Clients need to be informed about the dangers of laxative use. Continual use of laxatives to encourage bowel evacuation weakens the bowel's natural responses to fecal distention, resulting in chronic constipation. To eliminate chronic laxative use, it is usually necessary to teach the client about dietary fiber, regular exercise, taking sufficient fluids,

and establishing regular defecation habits. In addition, any medication regimen should be examined to see whether it could cause constipation.

Some laxatives are given in the form of **suppositories**. These act in various ways: by softening the feces, by releasing gases such as carbon dioxide to distend the rectum, or by stimulating the nerve endings in the rectal mucosa. The best results can be obtained by inserting the suppository 30 minutes before the client's usual defecation time or when the peristaltic action is greatest, such as after breakfast.

TABLE 49–3 Types of Laxatives

Type	Action	Examples	Pertinent Teaching Information
Bulk forming	Increases the fluid, gaseous, or solid bulk in the intestines.	Psyllium hydrophilic mucilloid (Metamucil), methylcellulose (Citrucel)	May take 12 or more hours to act. Sufficient fluid must be taken. Safe for long-term use.
Osmotic/saline	Draws water into the intestine by osmosis, distends bowel, and stimulates peristalsis. Almost no water or electrolytes are absorbed as solution moves through the intestines and the large fluid volume flushes feces from the colon (Daniels & Schmelzer, 2013).	Four major types of osmotic laxatives: lactulose, sodium phosphate (tablet form only requiring a prescription; OsmoPrep, Visicol), magnesium salts (magnesium citrate), and sodium sulfate (SUPREP) Electrolyte-free polyethylene glycol 3350 (PEG 3350) (MiraLAX) PEG-ES (GoLYTELY; NuLYTELY)	May be rapid acting. Can cause fluid and electrolyte imbalance, particularly in older people and children with cardiac and renal disease. Use caution when giving to older adults. A laxative that is helpful in the treatment of constipation. It is a powder that is tasteless when mixed in a flavored liquid such as juice. Used for cleaning of the colon before colonoscopy. Requires drinking a large volume (4 L), which may be difficult for clients to tolerate. Has an unpleasant taste.
Stimulant/irritant	Irritates the intestinal mucosa or stimulates nerve endings in the wall of the intestine, causing rapid propulsion of the contents.	Bisacodyl (Dulcolax, Correctol), senna (Senokot, Ex-Lax), cascara, castor oil	Acts more quickly than bulk-forming agents. Fluid is passed with the feces. May cause cramps. Use only for short periods of time. Prolonged use may cause fluid and electrolyte imbalance.
Stool softener or surfactant	Softens and delays the drying of the stool; causes more water and fat to be absorbed into the stool.	Docusate sodium (Colace) Docusate calcium (Surfak)	Slow-acting; may take several days.
Lubricant	Lubricates the stool and colon mucosa.	Mineral oil (Haley's M-O)	Prolonged use inhibits the absorption of some fat-soluble vitamins.

BOX 49–2 Guidelines for Using Antidiarrheal Medications

- If the diarrhea persists for more than 3 or 4 days, determine the underlying cause. Using a medication such as an opiate when the cause is an infection, toxin, or poison may prolong diarrhea.
- Long-term use of OTC medications (e.g., loperamide hydrochloride [Imodium]) can produce dependence.
- Some antidiarrheal agents can cause drowsiness (e.g., diphenoxylate hydrochloride [Lomotil]) and should not be used when driving an automobile or running machinery.
- Kaolin-pectin preparations (e.g., Kaopectate) may absorb nutrients.
- Bulk laxatives and other absorbents may be used to help bind toxins and absorb excess bowel liquid.
- Bismuth preparations (e.g., Pepto-Bismol), often used to treat “traveler’s diarrhea,” may contain aspirin and should not be given to children and teenagers with chickenpox, influenza, and other viral infections.

Antidiarrheal Medications

These medications slow the motility of the intestine or absorb excess fluid in the intestine. Guidelines for using antidiarrheals are shown in Box 49–2.

Antiflatulent Medications

Antiflatulent agents such as simethicone do not decrease the formation of flatus but they do coalesce the gas bubbles and facilitate their passage by belching through the mouth or expulsion through the anus. A combination of simethicone and loperamide (Imodium Advanced) is effective in relieving abdominal bloating and gas associated with acute diarrhea; however, no convincing evidence has been shown for common flatulence (“Relief from intestinal gas,” 2013). **Carminatives** are herbal oils known to act as agents that help expel gas from the stomach and intestines. Suppositories can also be given to relieve flatus by increasing intestinal motility.

Decreasing Flatulence

There are a number of ways to reduce or expel flatus, including exercise, moving in bed, ambulation, and avoiding gas-producing foods. Movement stimulates peristalsis and the escape of flatus and reabsorption of gases in the intestinal capillaries.

Certain medication can decrease flatulence. Probiotics may be helpful in the management of flatulence and bloating. Because each probiotic is a different mixture of bacteria, they need to be treated as different medications. Recent studies have shown different probiotics to be helpful for various gastrointestinal disorders (Lacy, Gabbard, & Crowell, 2011). Bismuth subsalicylate (Pepto-Bismol) can be effective; however, it should not be used as a continuous treatment because it contains aspirin and could cause salicylate toxicity. Alpha-galactosidase (Beano) is effective for reducing flatulence caused by eating fermentable carbohydrates (e.g., beans, bran, fruit).

Administering Enemas

An **enema** is a solution introduced into the rectum and large intestine. The action of an enema is to distend the intestine and sometimes to irritate the intestinal mucosa, thereby increasing peristalsis and the excretion of feces and flatus. The enema solution should be at 37.7°C (100°F) because a solution that is too cold or too hot is uncomfortable and causes cramping. Enemas are classified into four groups: cleansing, carminative, retention, and return-flow enemas.

Cleansing Enema

Cleansing enemas are intended to remove feces. They are given chiefly to:

- Prevent the escape of feces during surgery.
- Prepare the intestine for certain diagnostic tests such as x-ray or visualization tests (e.g., colonoscopy).
- Remove feces in instances of constipation or impaction.

Cleansing enemas use a variety of solutions. Table 49–4 lists commonly used solutions.

Hypertonic solutions exert osmotic pressure, which draws fluid from the interstitial space into the colon. The increased volume in the colon stimulates peristalsis and hence defecation. A commonly used hypertonic enema is the commercially prepared Fleet phosphate enema. Hypotonic solutions (e.g., tap water) exert a lower osmotic pressure than the surrounding interstitial fluid, causing water to move from the colon into the interstitial space. Before the water moves from the colon, it stimulates peristalsis and defecation. Because the water moves out of the colon, the tap water enema should not be repeated because of the danger of circulatory

TABLE 49–4 Commonly Used Enema Solutions

Solution	Constituents	Action	Time to Take Effect	Adverse Effects
Hypertonic	90–120 mL of solution (e.g., sodium phosphate [Fleet])	Draws water into the colon.	5–10 min	Retention of sodium
Hypotonic	500–1,000 mL of tap water	Distends colon, stimulates peristalsis, and softens feces.	15–20 min	Fluid and electrolyte imbalance; water intoxication
Isotonic	500–1,000 mL of normal saline	Distends colon, stimulates peristalsis, and softens feces.	15–20 min	Possible sodium retention
Soapsuds	500–1,000 mL (3–5 mL soap to 1,000 mL water)	Irritates mucosa, distends colon.	10–15 min	Irritates and may damage mucosa
Oil (mineral, olive, cottonseed)	90–120 mL	Lubricates the feces and the colonic mucosa.	0.5–3 h	

overload when the water moves from the interstitial space into the circulatory system.

SAFETY ALERT!

SAFETY

Special precautions must be used to alert nurses to possible contraindications when Fleet enemas are prescribed for clients with renal failure. The label on the Fleet enema warns that using more than one enema every 24 hours can be harmful. Clients and family may underestimate the risks for a client with decreased renal function because a Fleet enema can be obtained over the counter in stores (Cohen, 2012).

Isotonic solutions, such as physiological (normal) saline, are considered the safest enema solutions to use. They exert the same osmotic pressure as the interstitial fluid surrounding the colon. Therefore, there is no fluid movement into or out of the colon. The instilled volume of saline in the colon stimulates peristalsis. Soapsuds enemas stimulate peristalsis by increasing the volume in the colon and irritating the mucosa. Only pure soap (i.e., Castile soap) should be used in order to minimize mucosa irritation.

Some enemas are large volume (i.e., 500 to 1,000 mL) for an adult and others are small volume (90 to 120 mL), including hypertonic solutions. The amount of solution administered for a high-volume enema will depend on the age and medical condition of the individual. For example, clients with certain cardiac or renal diseases would be adversely affected by significant fluid retention that might result from large-volume hypotonic enemas.

Cleansing enemas may also be described as high or low. A high enema is given to cleanse as much of the colon as possible. The client changes from the left lateral position to the dorsal recumbent position and then to the right lateral position during administration so that the solution can follow the large intestine. The low enema is used to clean the rectum and sigmoid colon only. The client maintains a left lateral position during administration.

The force of flow of the solution is governed by (a) the height of the solution container, (b) size of the tubing, (c) viscosity of the fluid, and (d) resistance of the rectum. The higher the solution container is held above the rectum, the faster the flow and the greater the force (pressure) in the rectum. During most adult enemas, the solution container should be no higher than 30 cm (12 in.) above the rectum. During a high cleansing enema, the solution container is usually held 30 to 49 cm (12 to 18 in.) above the rectum because the fluid is instilled farther to clean the entire bowel.

Carminative Enema

A carminative enema is given primarily to expel flatus. The solution instilled into the rectum releases gas, which in turn distends the rectum and the colon, thus stimulating peristalsis. For an adult, 60 to 80 mL of fluid is instilled.

Retention Enema

A retention enema introduces oil or medication into the rectum and sigmoid colon. The liquid is retained for a relatively long period (e.g., 1 to 3 hours). An oil retention enema acts to soften the feces and to lubricate the rectum and anal canal, thus facilitating passage of the feces. Antibiotic enemas are used to treat infections locally, anthelmintic enemas to kill helminths such as worms and intestinal parasites, and nutritive enemas to administer fluids and nutrients to the rectum.

Return-Flow Enema

A return-flow enema, also called a Harris flush, is occasionally used to expel flatus. Alternating flow of 100 to 200 mL of fluid into and out of the rectum and sigmoid colon stimulates peristalsis. This process is repeated five or six times until the flatus is expelled and abdominal distention is relieved.

From a holistic perspective, it is important for the nurse to remember that clients may perceive this type of procedure as a significant violation of personal space. Cultural sensitivity pertaining to personal space, gender of the caregiver, and the potential meaning of the structures and fluids found in this private area of the body needs to be considered. Keep in mind the client's potential discomfort with the gender of the caregiver and try to accommodate the client's preferences whenever possible. When it is not possible to honor the client's wishes, respectfully explain the circumstances. A gentle, matter-of-fact approach is often most helpful. Also, insertion of anything foreign into an orifice of a client's body may trigger memories of past abuse. Monitor the client for emotional responses to the procedure (both subtle and extreme) because this could indicate a history of trauma and require appropriate referral for counseling. Simply asking the client to describe the experience will give the nurse more information for possible referral.

Skill 49-1 describes how to administer an enema.

CLINICAL ALERT!

Some clients may wish to administer their own enemas. If this is appropriate, the nurse validates the client's knowledge of correct technique and assists as needed.

Administering an Enema

PURPOSE

- To achieve one or more of the following actions: cleansing, carminative, retention, or return-flow

ASSESSMENT

Assess

- When the client last had a bowel movement and the amount, color, and consistency of the feces
- Presence of abdominal distention
- Whether the client has sphincter control
- Whether the client can use a toilet or commode or must remain in bed and use a bedpan

Administering an Enema—continued

PLANNING

Before administering an enema, determine that there is a primary care provider's order. At some agencies, a primary care provider must order the type of enema and the time to give it, for example, the morning of an examination. At other agencies, enemas are given at the nurse's discretion (i.e., as necessary on a prn order). In addition, determine the presence of kidney or cardiac disease that contraindicates the use of a hypotonic or hypertonic solution.

DELEGATION

Administration of some enemas may be delegated to unlicensed assistive personnel (UAP). However, the nurse must ensure the personnel are competent in the use of standard precautions. Abnormal findings such as inability to insert the rectal tip, client inability to retain the solution, or unusual return from the enema must be validated and interpreted by the nurse.

IMPLEMENTATION

Preparation

- Lubricate about 5 cm (2 in.) of the rectal tube (some commercially prepared enema sets already have lubricated nozzles).
Rationale: *Lubrication facilitates insertion through the sphincter and minimizes trauma.*
- Run some solution through the connecting tubing of a large-volume enema set and the rectal tube to expel any air in the tubing, then close the clamp. **Rationale:** *Air instilled into the rectum, although not harmful, causes unnecessary distention.*

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments. Indicate that the client may experience a feeling of fullness while the solution is being administered. Explain the need to hold the solution as long as possible.
 - Perform hand hygiene and observe other appropriate infection prevention procedures.
 - Apply clean gloves.
 - Provide for client privacy.
 - Assist the adult client to a left lateral position, with the right leg as acutely flexed as possible ①, with the linen-saver pad under the buttocks. **Rationale:** *This position facilitates the flow of solution by gravity into the sigmoid and descending colon, which are on the left side. Having the right leg acutely flexed provides for adequate exposure of the anus.*
 - Insert the enema tube.
 - For clients in the left lateral position, lift the upper buttock.
- ② **Rationale:** *This ensures good visualization of the anus.*

① Assuming a left lateral position for an enema. Note the commercially prepared enema.

Equipment

- Disposable linen-saver pad
- Bath blanket
- Bedpan or commode
- Clean gloves
- Water-soluble lubricant if tubing not prelubricated
- Paper towel

Large-Volume Enema

- Solution container with tubing of correct size and tubing clamp
- Correct solution, amount, and temperature

Small-Volume Enema

- Prepackaged container of enema solution with lubricated tip

② Inserting the enema tube.

③ Inserting the enema tube following the direction of the rectum.

- Insert the tube smoothly and slowly into the rectum, directing it toward the umbilicus. ③ **Rationale:** *The angle follows the normal contour of the rectum. Slow insertion prevents spasm of the sphincter.*
- Insert the tube 7 to 10 cm (3 to 4 in.). **Rationale:** *Because the anal canal is about 2.5 to 5 cm (1 to 2 in.) long in the adult, insertion to this point places the tip of the tube beyond the anal sphincter into the rectum.*

Administering an Enema—continued

- If resistance is encountered at the internal sphincter, ask the client to take a deep breath, then run a small amount of solution through the tube. **Rationale:** *This relaxes the internal anal sphincter.*
 - Never force tube or solution entry. If instilling a small amount of solution does not permit the tube to be advanced or the solution to freely flow, withdraw the tube. Check for any stool that may have blocked the tube during insertion. If present, flush it and retry the procedure. You may also perform a digital rectal examination to determine if there is an impaction or other mechanical blockage. If resistance persists, end the procedure and report the resistance to the primary care provider and nurse in charge.
7. Slowly administer the enema solution.
- Raise the solution container, and open the clamp to allow fluid flow.
- or
- Compress a pliable container by hand.
 - During most low enemas, hold or hang the solution container no higher than 30 cm (12 in.) above the rectum. **Rationale:** *The higher the solution container is held above the rectum, the faster the flow and the greater the force (pressure) in the rectum.* During a high enema, hang the solution container about 30 to 49 cm (12 to 18 in.). **Rationale:** *Fluid must be instilled farther for a high enema to clean the entire bowel.* See agency protocol.
 - Administer the fluid slowly. If the client complains of fullness or pain, lower the container or use the clamp to stop the flow for 30 seconds, and then restart the flow at a slower rate. **Rationale:** *Administering the enema slowly and stopping the flow momentarily decreases the likelihood of intestinal spasm and premature ejection of the solution.*
 - If you are using a plastic commercial container, roll it up as the fluid is instilled. This prevents subsequent suctioning of the solution. 4
 - After all the solution has been instilled or when the client cannot hold any more and feels the desire to defecate (the urge to defecate usually indicates that sufficient fluid has been administered), close the clamp, and remove the enema tube from the anus.
 - Place the enema tube in a disposable towel as you withdraw it.
8. Encourage the client to retain the enema.
- Ask the client to remain lying down. **Rationale:** *It is easier for the client to retain the enema when lying down than when sitting or standing, because gravity promotes drainage and peristalsis.*
 - Request that the client retain the solution for the appropriate amount of time, for example, 5 to 10 minutes for a cleansing enema or at least 30 minutes for a retention enema.
9. Assist the client to defecate.
- Assist the client to a sitting position on the bedpan, commode, or toilet. A sitting position facilitates the act of defecation.
 - Ask the client who is using the toilet not to flush it. The nurse needs to observe the feces.

4 Rolling up a commercial enema container.

- If a specimen of feces is required, ask the client to use a bedpan or commode.
 - Remove and discard gloves.
 - Perform hand hygiene.
10. Document the type and volume, if appropriate, of enema given. Describe the results.

SAMPLE DOCUMENTATION

8/2/2015 1000. States last BM five days ago. Abdomen distended and firm. Bowel sounds hypoactive. Fleet enema, given per order, resulted in large amount of firm brown stool. States he "feels better." _____ M. Lopez, RN

Variation: Administering an Enema to an Incontinent Client

Occasionally a nurse needs to administer an enema to a client who is unable to control the external sphincter muscle and thus cannot retain the enema solution for even a few minutes. In that case, after the enema tube is inserted, the client assumes a supine position on a bedpan. The head of the bed can be elevated slightly, to 30 degrees if necessary for easier breathing, and pillows used to support the client's head and back.

Variation: Administering a Return-Flow Enema

For a return-flow enema, the solution (100 to 200 mL for an adult) is instilled into the client's rectum and sigmoid colon. Then the solution container is lowered so that the fluid flows back out through the rectal tube into the container, pulling the flatus with it. The inflow–outflow process is repeated five or six times (to stimulate peristalsis and the expulsion of flatus), and the solution is replaced several times during the procedure if it becomes thick with feces.

Document the type of solution; length of time the solution was retained; the amount, color, and consistency of the returns; and the relief of flatus and abdominal distention in the client record using forms or checklists supplemented by narrative notes when appropriate.

EVALUATION

- Perform a detailed follow-up based on findings that deviated from expected or normal for the client. Relate findings to

previous assessment data if available. Report significant deviations from expected to the primary care provider.

LIFESPAN CONSIDERATIONS Administering an Enema**INFANTS/CHILDREN**

- Provide a careful explanation to the parents and child before the procedure. An enema is an intrusive procedure and therefore threatening to the child.
- The enema solution should be isotonic (usually normal saline). Some hypertonic commercial solutions (e.g., Fleet phosphate enema) can lead to hypovolemia and electrolyte imbalances. In addition, the osmotic effect of the enema may produce diarrhea and subsequent metabolic acidosis.
- Infants and small children do not exhibit sphincter control and need to be assisted in retaining the enema. The nurse administers the enema while the infant or child is lying with the buttocks over the bedpan, and the nurse firmly presses the buttocks together to prevent the immediate expulsion of the solution. Older children can usually hold the solution if they understand what to do and are not required to hold it for too long a period. It may be necessary to ensure that the bathroom is available for an ambulatory child before starting the procedure or to have a bedpan ready.
- Enema temperature should be 37.7°C (100°F) unless otherwise ordered.
- Large-volume enemas consist of 50 to 200 mL in children less than 18 months old; 200 to 300 mL in children 18 months to 5 years; and 300 to 500 mL in children 5 to 12 years old.

- For infants and small children, the dorsal recumbent position is frequently used. Position them on a small padded bedpan with support for the back and head. Secure the legs by placing a diaper under the bedpan and then over and around the thighs. Place the underpad under the client's buttocks to protect the bed linen, and drape the client with the bath blanket.
- Insert the tube 5 to 7.5 cm (2 to 3 in.) in the child and only 2.5 to 3.75 cm (1 to 1.5 in.) in the infant.
- For children, lower the height of the solution container appropriately for the age of the child. See agency protocol.
- To assist a small child in retaining the solution, apply firm pressure over the anus with tissue wipes, or firmly press the buttocks together.

OLDER ADULTS

- Older adults may fatigue easily.
- Older adults may be more susceptible to fluid and electrolyte imbalances. Use tap water enemas with great caution.
- Monitor the client's tolerance during the procedure, watching for vagal episodes (e.g., slow pulse) and dysrhythmias.
- Protect older adults' skin from prolonged exposure to moisture.
- Assist older clients with perineal care as indicated.

Home Care Considerations Administering an Enema**PATIENT-CENTERED CARE**

Teach the caregiver or client the following:

- To make a saline solution, mix 1 teaspoon of table salt with 500 mL of tap water.

- Use enemas only as directed. Do not rely on them for regular bowel evacuation.
- Prior to administration, make sure a bedpan, commode, or toilet is nearby.

Digital Removal of a Fecal Impaction

Digital removal involves breaking up the fecal mass digitally and removing it in portions. Because the bowel mucosa can be injured during this procedure, some agencies restrict and specify the personnel permitted to conduct digital disimpactions. Rectal stimulation is also contraindicated for some people because it may cause an excessive vagal response resulting in cardiac arrhythmia. Before disimpaction it is suggested an oil retention enema be given and held for 30 minutes. After a disimpaction, the nurse can use various interventions to remove remaining feces, such as a cleansing enema or the insertion of a suppository.

CLINICAL ALERT!

Clients with a history of cardiac disease and/or dysrhythmias may be at risk with digital stimulation to remove an impaction. If in doubt, the nurse should check with the primary care provider before performing the procedure.

Because manual removal of an impaction can be painful, the nurse may use, if the agency permits, 1 to 2 mL of lidocaine (Xylocaine) gel on a gloved finger inserted into the anal canal as far as the nurse can reach. The lidocaine will anesthetize the anal canal and rectum and should be inserted 5 minutes before the disimpaction.

Disimpacting the client requires great sensitivity and a caring, yet matter-of-fact, approach. Be aware of personal facial expressions or anything that may convey distaste or disgust to the client. When dealing with fecal matter, many clients feel a sense of shame that relates to childhood

experiences that may have been traumatic in some way. Control issues may also be triggered, and can manifest in many ways. Confusion and negative feelings are easily triggered in both client and nurse. Awareness and an ability to discuss these issues with a client, when appropriate, are important to providing sensitive care. Self-awareness will help the nurse be more therapeutically present to the client.

For digital removal of a fecal impaction:

1. If indicated, obtain assistance from a second person who can comfort the client during the procedure.
2. Ask the client to assume a right or left side-lying position, with the knees flexed and the back toward the nurse. When the person lies on the right side, the sigmoid colon is uppermost; thus, gravity can aid removal of the feces. Positioning on the left side allows easier access to the sigmoid colon.
3. Place a disposable absorbent pad under the client's buttocks and a bedpan nearby to receive stool.
4. Drape the client for comfort and to avoid unnecessary exposure of the body.
5. Apply clean gloves and liberally lubricate the gloved index finger.
6. Gently insert the index finger into the rectum and move the finger along the length of the rectum.
7. Loosen and dislodge stool by gently massaging around it. Break up stool by working the finger into the hardened mass, taking care to avoid injury to the mucosa of the rectum.
8. Carefully work stool downward to the end of the rectum and remove it in small pieces. Continue to remove as much fecal

material as possible. Periodically assess the client for signs of fatigue, such as facial pallor, diaphoresis, or change in pulse rate. Manual stimulation should be minimal.

9. Following disimpaction, assist the client to clean the anal area and buttocks. Then assist the client onto a bedpan or commode for a short time because digital stimulation of the rectum often induces the urge to defecate.

Bowel Training Programs

For clients who have chronic constipation, frequent impactions, or fecal incontinence, bowel training programs may be helpful. The program is based on factors within the client's control and is designed to help the client establish normal defecation. Such matters as food and fluid intake, exercise, and defecation habits are all considered. Before beginning such a program, clients must understand it and want to be involved. The major phases of the program are as follows:

- Determine the client's usual bowel habits and factors that help and hinder normal defecation.
- Design a plan with the client that includes the following:
 - a. Fluid intake of about 2,500 to 3,000 mL/day
 - b. Increase in fiber in the diet
 - c. Intake of hot drinks, especially just before the usual defecation time
 - d. Increase in exercise.
- Maintain the following daily routine for 2 to 3 weeks:
 - a. Administer a cathartic suppository (e.g., Dulcolax) 30 minutes before the client's defecation time to stimulate peristalsis.
 - b. When the client experiences the urge to defecate, assist the client to the toilet or commode or onto a bedpan. Note the length of time between the insertion of the suppository and the urge to defecate.
 - c. Provide the client with privacy for defecation and a time limit; 30 to 40 minutes is usually sufficient.
 - d. Teach the client to lean forward at the hips, to apply pressure on the abdomen with the hands, and to bear down for defecation. These measures increase pressure on the colon. Straining should be avoided because it can cause hemorrhoids.
- Provide positive feedback when the client successfully defecates. Refrain from negative feedback if the client fails to defecate.
- Offer encouragement to the client and convey that patience is often required. Many clients require weeks or months of training to achieve success.

Fecal Incontinence Pouch

To collect and contain large volumes of liquid feces, the nurse may place a fecal incontinence collector pouch around the anal area (Figure 49–13 ■). The purpose of the pouch is to prevent progressive perianal skin irritation and breakdown and frequent linen changes necessitated by incontinence. In many agencies, the pouch is replacing the traditional approach to this problem; that is, inserting a large Foley catheter into the client's rectum and inflating the balloon to keep it in place—a practice that may damage the rectal sphincter and rectal mucosa. A rectal catheter also increases peristalsis and incontinence by stimulating sensory nerve fibers in the rectum.

A fecal collector is secured around the anal opening and may or may not be attached to drainage. Pouches are best applied before the perianal skin becomes excoriated. If perianal skin excoriation is

Figure 49–13 ■ A drainable fecal collector pouch.

present, the nurse either (a) applies a dimethicone-based moisture-barrier cream or alcohol-free barrier film to the skin to protect it from feces until it heals and then applies the pouch, or (b) applies a skin barrier or hydrocolloid barrier underneath the pouch to achieve the best possible seal.

Nursing responsibilities for clients with a rectal pouch include (a) regular assessment and documentation of the perianal skin status, (b) changing the bag every 72 hours or sooner if there is leakage, (c) maintaining the drainage system, and (d) providing explanations and support to the client and support people.

Some clients (e.g., post-stroke, post-trauma, quadriplegia, or paraplegia) may be treated for fecal incontinence with surgical repair of a damaged sphincter or an artificial bowel sphincter. The artificial sphincter consists of three parts: a cuff around the anal canal, a pressure-regulating balloon, and a pump that inflates the cuff (Figure 49–14 ■). The cuff is inflated to close the sphincter,

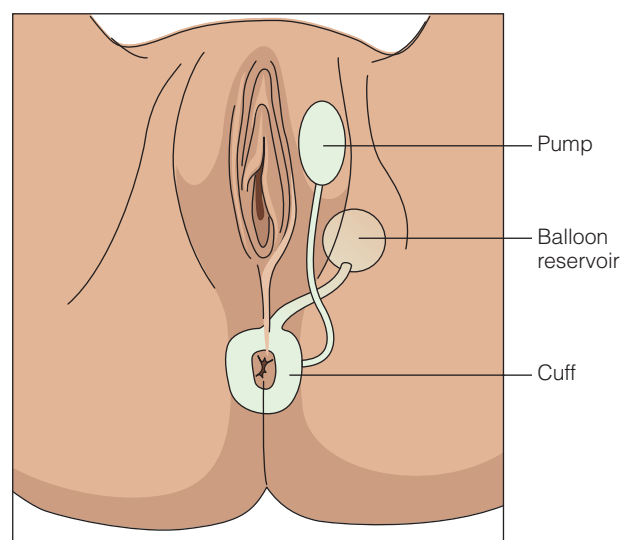

Figure 49–14 ■ Inflatable artificial sphincter.

maintaining continence. To have a bowel movement, the client deflates the cuff. The cuff automatically reinflates in 10 minutes. Management of this device is usually specific to the device; contact the manufacturing company for details.

Administering enemas and rectal medications may be harmful with this device in place. Ensure safety of these practices with the device instruction guide provided by the device manufacturer.

Ostomy Management

Clients with fecal diversions need considerable psychological support, instruction, and physical care. This section is limited to the nurse's physical interventions of stoma assessment, application of an appliance to collect feces and protect skin, and promotion of self-care. Many agencies have access to a wound ostomy continence nurse (WOCN) to assist these clients. If possible, clients should meet with the WOCN prior to the surgery to assist in the placement of the colostomy. National organizations (e.g., United Ostomy Associations of America) have support groups whose mission is to improve the quality of life of people who have, or will have, an ostomy. Members of local chapters of such an organization have been known to meet and visit with a client who has a new ostomy. It is common for a client with a new ostomy to feel frightened and alone. Talking with another person who has gone through a similar experience may help the client realize that he or she is not alone and others are willing to listen and help.

Stoma and Skin Care

Care of the stoma and skin is important for all clients who have ostomies. The fecal material from a colostomy or ileostomy is irritating to the peristomal skin. This is particularly true of stool from an ileostomy, which contains digestive enzymes. It is important to assess the peristomal skin for irritation each time the appliance is changed. Any irritation or skin breakdown needs to be treated immediately. The skin is kept clean by washing off any excretion and drying thoroughly.

An ostomy appliance should protect the skin, collect stool, and control odor. The appliance consists of a skin barrier and a pouch. Some clients may prefer to also wear an adjustable ostomy belt, which attaches to an ostomy pouch to hold the pouch firmly in place (Figure 49–15 ■).

Appliances can be one piece where the skin barrier is already attached to the pouch (Figure 49–16 A ■), or an appliance can consist of two pieces: a separate pouch with a flange and a separate skin barrier with a flange where the pouch fastens to the barrier at the flange (Figure 49–16 B). The pouch can be removed without removing the skin barrier when using a two-piece appliance. Pouches can be closed

Figure 49–15 ■ Adjustable ostomy belt.

or drainable (Figure 49–17 ■). A drainable pouch usually has a clip where the end of the pouch is folded over the clamp and clipped (Figure 49–18 ■). Newer drainable pouches have an integrated closure system instead of a clamp. The client folds up the end of the pouch three times and presses firmly to seal the pouch. Drainable pouches are usually used by people who need to empty the pouch more than twice a day.

Closed pouches are often used by people who have a regular stoma discharge (e.g., sigmoid colostomy) and only have to empty the pouch 1 or 2 times a day. Some people find it easier to change a closed pouch than emptying a drainable pouch, which requires some dexterity.

Odor control is essential to clients' self-esteem. As soon as clients are ambulatory, they can learn to work with the ostomy in the bathroom to avoid odors at the bedside. Selecting the appropriate kind of appliance promotes odor control. An intact appliance contains odors. Most pouches contain odor-barrier material. Some pouches also have a pouch filter that allows gas out of the pouch but not the odor.

Ostomy appliances can provide a leakproof seal for about 3 to 7 days (Avent, 2012). The pouch should be changed on a routine basis,

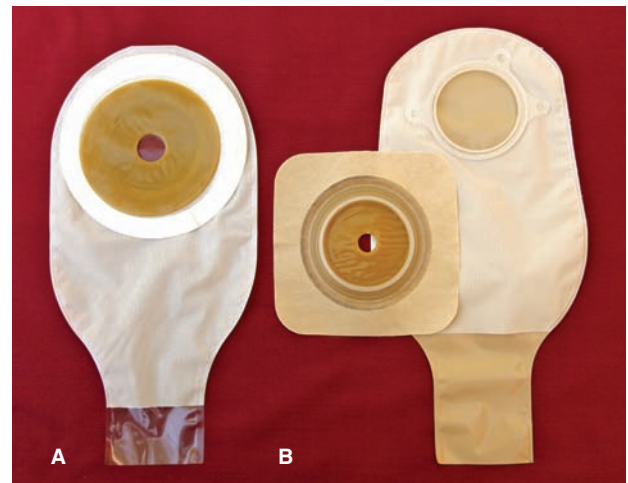

Figure 49–16 ■ A, A one-piece ostomy appliance or pouching system; B, a two-piece ostomy appliance or pouching system.

Figure 49–17 ■ A, A closed pouch; B, a drainable pouch.

Figure 49–18 ■ Applying a pouch clamp.

before leakage occurs. The most common routine for changing the appliance is twice weekly (Hollister, Inc., 2011). Some manufacturers recommend removing the pouch and skin barrier twice a week to clean and inspect the peristomal skin unless stool leaks onto the peristomal skin, necessitating a change. If the skin is erythematous, eroded, denuded, or ulcerated, the pouch should be changed every 24 to 48 hours to allow appropriate treatment of the skin. More frequent changes are recommended if the client complains of pain or discomfort.

The type of ostomy and amount of output influence how often the pouch is emptied. The pouch is emptied when it is one third to one half full. If the pouch overfills, it can cause separation of the skin barrier from the skin and allow stool to come in contact with the skin. This results in the entire appliance needing to be removed and a new one applied.

Skill 49–2 explains how to change a bowel diversion ostomy appliance.

Changing a Bowel Diversion Ostomy Appliance

PURPOSES

- To assess and care for the peristomal skin
- To collect stool for assessment of the amount and type of output
- To minimize odors for the client's comfort and self-esteem

ASSESSMENT

Determine the following:

- The type of ostomy and its placement on the abdomen. Surgeons often draw diagrams when there are two stomas. If there is more than one stoma, it is important to confirm which is the functioning stoma.
- The type and size of appliance currently used and the special barrier substance applied to the skin, according to the nursing care plan.

Assess

- *Stoma color:* The stoma should appear red, similar in color to the mucosal lining of the inner cheek and slightly moist. Very pale or darker-colored stomas with a dusky bluish or purplish hue indicate impaired blood circulation to the area. Notify the surgeon immediately.
- *Stoma size and shape:* Most stomas protrude slightly from the abdomen. New stomas normally appear swollen, but swelling generally decreases over 2 or 3 weeks or for as long as

6 weeks. Failure of swelling to recede may indicate a problem, for example, blockage.

- *Stomal bleeding:* Slight bleeding initially when the stoma is touched is normal, but other bleeding should be reported.
- *Status of peristomal skin:* Any redness and irritation of the peristomal skin—the 5 to 13 cm (2 to 5 in.) of skin surrounding the stoma—should be noted. Transient redness after removal of adhesive is normal.
- *Amount and type of feces:* Assess the amount, color, odor, and consistency. Inspect for abnormalities, such as pus or blood.
- *Complaints:* Complaints of burning sensation under the skin barrier may indicate skin breakdown. The presence of abdominal discomfort and/or distention also needs to be determined.
- Learning needs of the client and family members regarding the ostomy and self-care.
- The client's emotional status, especially strategies used to cope with the body image changes and the ostomy.

PLANNING

Review features of the appliance to ensure that all parts are present and functioning correctly.

DELEGATION

Care of a *new* ostomy is not delegated to UAP. However, aspects of ostomy function are observed during usual care and may be recorded by a WOCN in addition to the unit nurse. Abnormal findings must be validated and interpreted by the nurse. In some agencies, UAP may remove and replace *well-established* ostomy appliances.

Equipment

- Clean gloves
- Bedpan
- Moisture-proof bag (for disposable pouches)
- Cleaning materials, including warm water, mild soap (optional), washcloth, towel
- Tissue or gauze pad
- Skin barrier (optional)
- Stoma measuring guide
- Pen or pencil and scissors
- New ostomy pouch with optional belt
- Tail closure clamp
- Deodorant for pouch (optional)

Continued on page 1234

Changing a Bowel Diversion Ostomy Appliance—continued

IMPLEMENTATION

Preparation

- Determine the need for an appliance change.
 - Assess the used appliance for leakage of stool. **Rationale:** *Stool can irritate the peristomal skin.*
 - Ask the client about any discomfort at or around the stoma. **Rationale:** *A burning sensation may indicate breakdown beneath the faceplate of the pouch.*
 - Assess the fullness of the pouch. **Rationale:** *The weight of an overly full bag may loosen the skin barrier and separate it from the skin, causing the stool to leak and irritate the peristomal skin.*
- If there is pouch leakage or discomfort at or around the stoma, change the appliance.
- Select an appropriate time to change the appliance.
 - Avoid times close to meal or visiting hours. **Rationale:** *Ostomy odor and stool may reduce appetite or embarrass the client.*
 - Avoid times immediately after meals or the administration of any medications that may stimulate bowel evacuation. **Rationale:** *It is best to change the pouch when drainage is least likely to occur.*
 - The best time to change a pouching system is first thing in the morning or 2 to 4 hours after meals, when the bowel is least active (Scemons, 2013, p. 37).

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the results will be used in planning further care or treatments. Changing an ostomy appliance should not cause discomfort, but it may be distasteful to the client. Communicate acceptance and support to the client. It is important to change the appliance competently and quickly. Include support people as appropriate.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Apply clean gloves.
- Provide for client privacy preferably in the bathroom, where clients can learn to deal with the ostomy as they would at home.
- Assist the client to a comfortable sitting or lying position in bed or preferably a sitting or standing position in the bathroom. **Rationale:** *Lying or standing positions may facilitate smoother pouch application, that is, avoid wrinkles.*
- Unfasten the belt if the client is wearing one.
- Empty the pouch and remove the ostomy skin barrier.
 - Empty the contents of a drainable pouch through the bottom opening into a bedpan or toilet. **Rationale:** *Emptying before removing the pouch prevents spillage of stool onto the client's skin.*
 - If the pouch uses a clamp, do not throw it away because it can be reused.
 - Assess the consistency, color, and amount of stool.
 - Peel the skin barrier off slowly, beginning at the top and working downward, while holding the client's skin taut. **Rationale:** *Holding the skin taut minimizes client discomfort and prevents abrasion of the skin.*
 - Discard the disposable pouch in a moisture-proof bag.
- Clean and dry the peristomal skin and stoma.
 - Use toilet tissue to remove excess stool.
 - Use warm water, mild soap (optional), and a washcloth to clean the skin and stoma. ❶ Check agency practice on the use of soap. **Rationale:** *Soap is sometimes not advised because it can be irritating to the skin. If soap is allowed, do not use deodorant or moisturizing soaps. **Rationale:** They may interfere with the adhesives in the skin barrier.*

❶ Cleaning the skin.

Courtesy of Cory Patrick Hartley, RN.

❷ A guide for measuring the stoma.

Courtesy of Cory Patrick Hartley, RN.

- Dry the area thoroughly by patting with a towel. **Rationale:** *Excess rubbing can abrade the skin.*
- Assess the stoma and peristomal skin.
 - Inspect the stoma for color, size, shape, and bleeding.
 - Inspect the peristomal skin for any redness, ulceration, or irritation. Transient redness after the removal of adhesive is normal.
 - Place a piece of tissue or gauze over the stoma, and change it as needed. **Rationale:** *This absorbs any seepage from the stoma while the ostomy appliance is being changed.*
 - Prepare and apply the skin barrier (peristomal seal).
 - Use the guide ❷ to measure the size of the stoma.
 - On the backing of the skin barrier, trace a circle the same size as the stomal opening.
 - Cut out the traced stoma pattern to make an opening in the skin barrier. ❸ Make the opening no more than 1/8 inch larger than the stoma (Piras & Hurley, 2011). **Rationale:** *This allows space for the stoma to expand slightly when functioning and minimizes the risk of stool contacting peristomal skin.*
 - Remove the backing to expose the sticky adhesive side. The backing can be saved and used as a pattern when making an opening for future skin barriers.

Changing a Bowel Diversion Ostomy Appliance—continued

3 The nurse is making a stoma opening on a disposable one-piece pouch.

5 Pressing the skin barrier of a disposable one-piece pouch for 30 seconds to activate the adhesives in the skin barrier.

4 Centering the skin barrier over the stoma.

Courtesy of Cory Patrick Hartley, RN.

For a One-Piece Pouching System

- Center the one-piece skin barrier and pouch over the stoma, and gently press it onto the client's skin for 30 seconds. 4,
- 5 **Rationale:** *The heat and pressure help activate the adhesives in the skin barrier.*

For a Two-Piece Pouching System

- Center the skin barrier over the stoma and gently press it onto the client's skin for 30 seconds.
 - Remove the tissue over the stoma before applying the pouch.
 - Snap the pouch onto the flange or skin barrier wafer.
 - For drainable pouches, close the pouch according to the manufacturer's directions.
 - Remove and discard gloves. Perform hand hygiene.
12. Document the procedure in the client record using forms or checklists supplemented by narrative notes when appropriate.

EVALUATION

- Relate findings to previous data if available. Adjust the teaching plan and nursing care plan as needed. Reinforce the teaching each time the care is performed. Encourage and support self-care as soon as possible because clients should be able to perform self-care by discharge. **Rationale:** *Client learning is facilitated by consistent nursing interventions.*
- Perform detailed follow-up based on findings that deviated from expected or normal for the client. Report significant deviations from normal to the primary care provider.

Record pertinent assessments and interventions. Report any increase in stoma size, change in color indicative of circulatory impairment, and presence of skin irritation or erosion. Record on the client's chart discoloration of the stoma, the appearance of the peristomal skin, the amount and type of drainage, the client's reaction to the procedure, the client's experience with the ostomy, and skills learned by the client.

SAMPLE DOCUMENTATION

8/3/2015 0900 Colostomy bag changed. Moderate to large amount of semi-formed brown stool. Stoma reddish color. No redness or irritation around stoma. Client looked at stoma today and started asking questions as to how she will be able to change the pouch when she is home. Asked if she would like to do the next changing of the pouch. Stated "yes." _____ G. Hsu, RN

Variation: Emptying a Drainable Pouch

- Empty the pouch when it is one third to one half full of stool or gas. **Rationale:** *Emptying before it is overfull helps avoid breaking the seal with the skin and stool then coming in contact with the skin.*
- While wearing gloves, hold the pouch outlet over a bedpan or toilet. Lift the lower edge up.
- Unclamp or unseal the pouch.
- Drain the pouch. Loosen feces from sides by moving fingers down the pouch.
- Clean the inside of the tail of the pouch with a tissue or a premoistened towelette.
- Apply the clamp or seal the pouch.
- Dispose of used supplies.
- Remove and discard gloves.
- Perform hand hygiene.
- Document the amount, consistency, and color of stool.

Home Care Considerations Changing an Ostomy Appliance

PATIENT-CENTERED CARE

- Provide the client with the names and phone numbers of a WOCN, supply vendor, and other resource people to contact when needed. Provide pertinent Internet resources for information and support.
- Inform the client of signs to report to a health care provider (e.g., peristomal redness, skin breakdown, and changes in stomal color).
- Provide client and family education regarding care of the ostomy and appliance when traveling.
- Educate the client and family regarding infection control precautions, including proper disposal of used pouches since these cannot be flushed down a toilet.
- Younger clients may have special concerns about odor and appearance. Provide information about ostomy care and community support groups. A visit from someone who has had an ostomy under similar circumstances may be helpful.

Colostomy Irrigation

A colostomy irrigation, similar to an enema, is a form of stoma management used only for clients who have a sigmoid or descending colostomy. The purpose of irrigation is to distend the bowel sufficiently to stimulate peristalsis, which stimulates evacuation. When a regular evacuation pattern is achieved, the wearing of a colostomy pouch is unnecessary. Currently, colostomy irrigations are not routinely taught to most clients. Routine daily irrigations for control of the time of elimination ultimately become the client’s decision. Some clients prefer to control the time of elimination through rigid dietary regulation and not be bothered with irrigations, which can take up to an hour to complete. When regulation by irrigation is chosen, it should be done at the same time each day. Control by irrigations also necessitates some control of the diet. For example, laxative foods that might cause an unexpected evacuation need to be avoided.

For most clients, a relatively small amount of fluid (300 to 500 mL) stimulates evacuation. For others, up to 1,000 mL may be needed because a colostomy has no sphincter and the fluid tends to return as it is instilled. This problem is reduced by the use of a cone on the irrigating catheter. The cone helps to hold the fluid within the

bowel during the irrigation. Clients who choose to practice colostomy irrigation need to be motivated to master the procedure. In addition, good manual dexterity and eyesight, along with uninterrupted time (approximately 60 minutes) is needed (Williams, 2011). These requirements may deter clients from using this alternative method of regaining bowel control.

Evaluating

The goals established during the planning phase are evaluated according to specific desired outcomes, also established in that phase. If outcomes are not achieved, the nurse should explore the reasons. The nurse might consider some or all of the following questions:

- Were the client’s fluid intake and diet appropriate?
- Was the client’s activity level appropriate?
- Are prescribed medications or other factors affecting the gastrointestinal function?
- Do the client and family understand the provided instructions well enough to comply with the required therapy?
- Were sufficient physical and emotional support provided?

NURSING CARE PLAN Altered Bowel Elimination

Assessment Data

NURSING ASSESSMENT

Mrs. Emma Brown is a 78-year-old widow of 9 months. She lives alone in a low-income housing complex for older adults. Her two children live with their families in a city approximately 150 miles away. She has always enjoyed cooking for her family; however, now that she is alone, she does not cook for herself. As a result, she has developed irregular eating patterns and tends to prepare soup-and-toast meals. She gets little exercise and has had bouts of insomnia since her husband’s death. For the past month, Mrs. Brown has been having a problem with constipation. She states she has a bowel movement about every 3 to 4 days and her stools are hard and painful to excrete. Mrs. Brown decides to attend the health fair sponsored by the housing complex and seeks assistance from the county public health nurse.

Physical Examination

Height: 162 cm (5’4”)
 Weight: 65 kg (143 lb)
 Temperature: 36.2°C (97.2°F)
 Pulse: 82 beats/min
 Respirations: 20/min
 Blood pressure: 128/74 mmHg
 Active bowel sounds, abdomen slightly distended

Diagnostic Data

CBC: Hgb 10.8
 Urinalysis negative

Nursing Diagnosis

Constipation related to low-fiber diet and inactivity (as evidenced by infrequent, hard stools; painful defecation; abdominal distention)

Desired Outcomes

Bowel Elimination [0501], not compromised as evidenced by:

- Ease of stool passage
- Stool soft and formed
- Passage of stool without aids

NURSING CARE PLAN Altered Bowel Elimination—continued

Nursing Interventions*/Selected Activities	Rationale
CONSTIPATION/IMPACTION MANAGEMENT [0450]	
Identify factors (e.g., medications, bed rest, diet) that may cause or contribute to constipation.	<i>Assessing causative factors is an essential first step in teaching and planning for improved bowel elimination.</i>
Encourage increased fluid intake, unless contraindicated.	<i>Sufficient fluid intake is necessary for the bowel to absorb sufficient amounts of liquid to promote proper stool consistency.</i>
Evaluate medication profile for gastrointestinal side effects.	<i>Constipation is a common side effect of many drugs including narcotics and antacids.</i>
Teach Mrs. Brown how to keep a food diary.	<i>An appraisal of food intake will help identify if Mrs. Brown is eating a well-balanced diet and consuming adequate amounts of fluid and fiber. Excessive meat or refined food intake will produce small, hard stools.</i>
Instruct Mrs. Brown on a high-fiber diet, as appropriate.	<i>Fiber absorbs water, which adds bulk and softness to the stool and speeds up passage through the intestines.</i>
Instruct her on the relationship of diet, exercise, and fluid intake to constipation and impaction.	<i>Fiber without adequate fluid can aggravate, not facilitate, bowel function.</i>
Exercise Promotion [0200]	
Encourage verbalization of feelings about exercise or need for exercise.	<i>Perceptions of the need for exercise may be influenced by misconceptions, cultural and social beliefs, fears, or age.</i>
Determine Mrs. Brown's motivation to begin/continue an exercise program.	<i>Individuals who have been successful in an exercise program can assist Mrs. Brown by providing incentive and enhancing motivation. For example, a walking partner may be beneficial.</i>
Inform Mrs. Brown about the health benefits and physiological effects of exercise.	<i>Activity influences bowel elimination by improving muscle tone and stimulating peristalsis.</i>
Instruct her about appropriate types of exercise for her level of health, in collaboration with a primary care provider.	<i>Any individual beginning an exercise program should consult a primary care provider primarily for a cardiac evaluation. Mrs. Brown's age and lack of activity should be considered in planning the level of activity.</i>
Assist Mrs. Brown to set short-term and long-term goals for the exercise program.	<i>Realistic goal setting provides direction and motivation.</i>

Evaluation

Outcome not met. Mrs. Brown has kept a food diary and is able to identify the need for more fluid and fiber, but has not consistently included fiber in her diet. She has started a walking program with a neighbor but is only able to walk for 10 minutes at a time twice a week. She states her last bowel movement was 3 days ago.

*The NOC # for desired outcomes and the NIC # for nursing interventions are listed in brackets following the appropriate outcome or intervention. Outcomes, interventions, and activities selected are only a sample of those suggested by NOC and NIC and should be further individualized for each client.

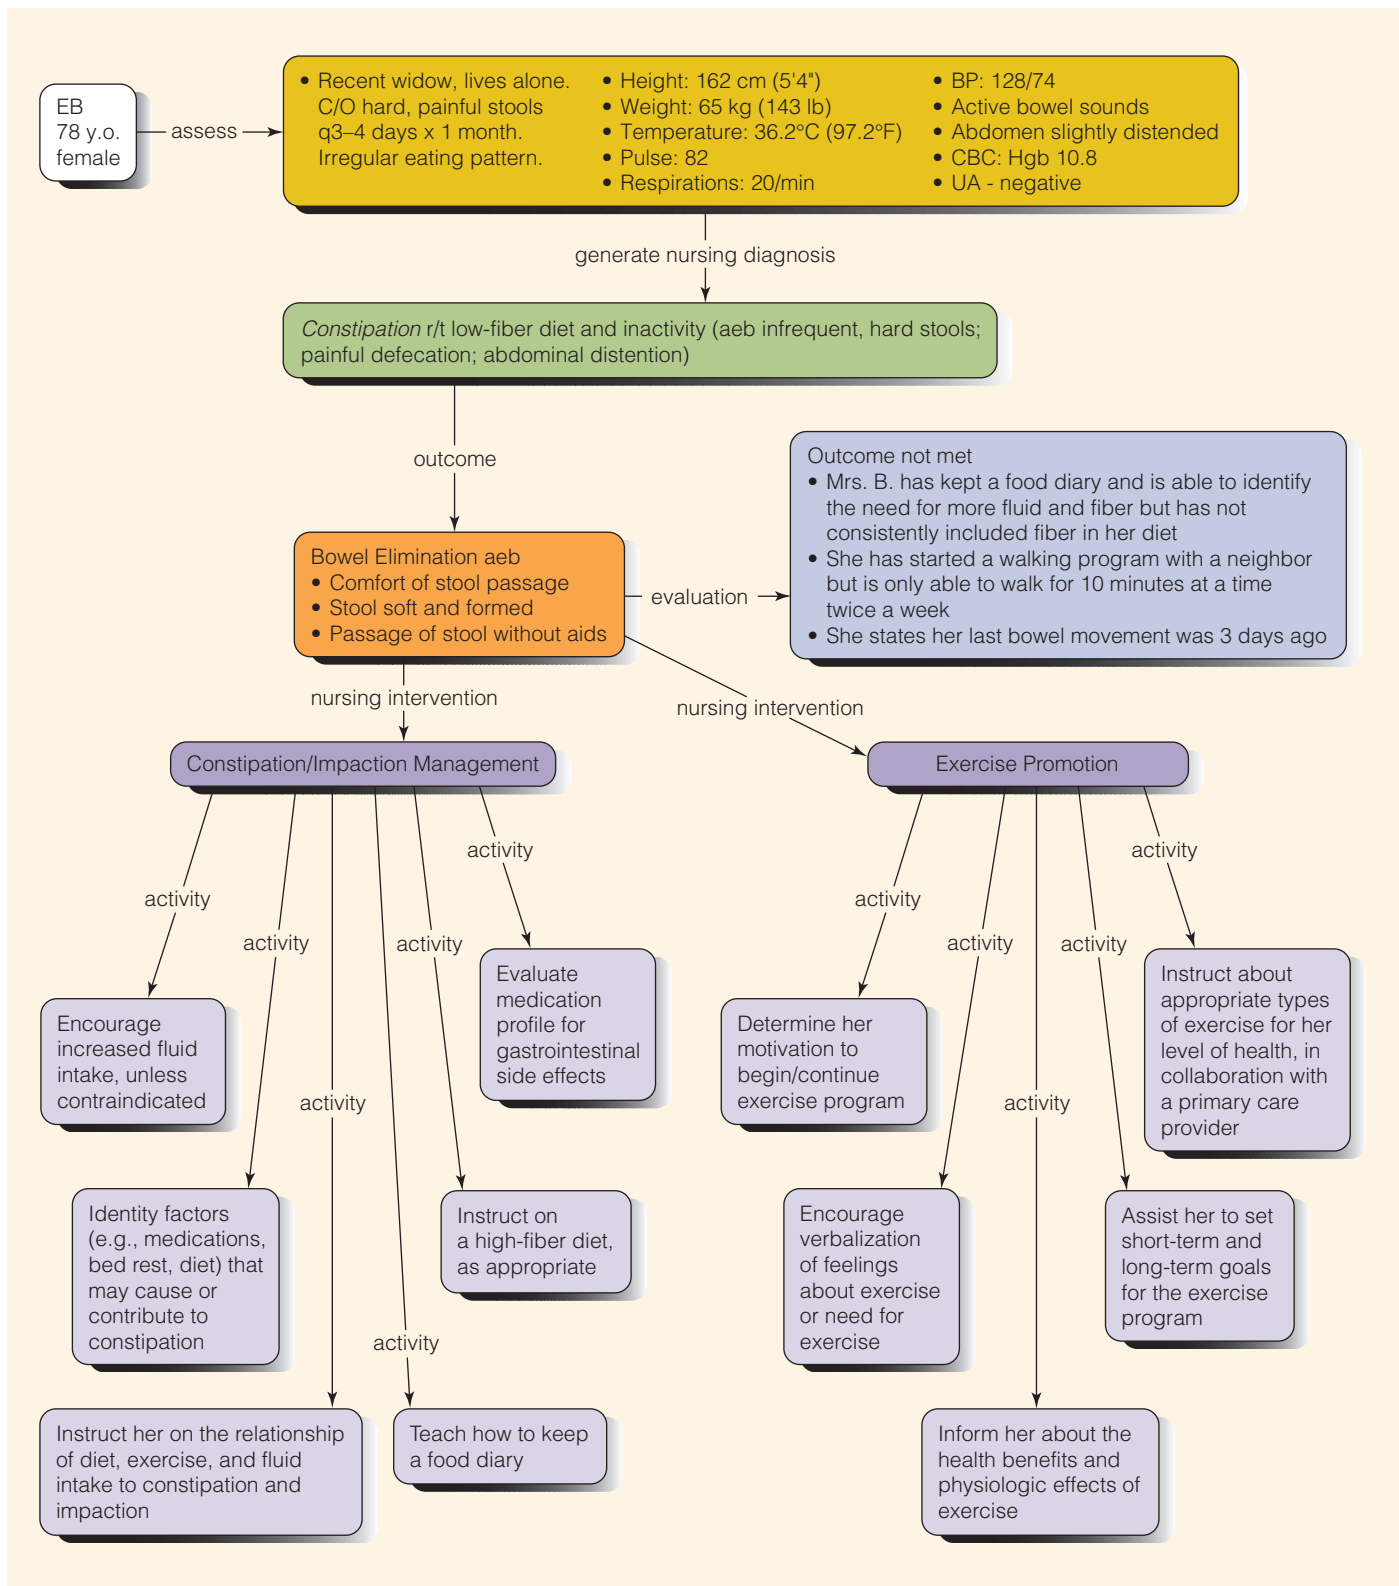

APPLYING CRITICAL THINKING

1. You learn that Mrs. Brown's stools have been liquid, in very small amounts, and at infrequent intervals, generally occurring when she feels the urge to defecate. What additional data are important to obtain from her?
2. What nursing intervention is most appropriate before making suggestions to correct or prevent the problem she is experiencing?
3. What suggestions can you give her about maintaining a regular bowel pattern?
4. Explain why cathartics and laxatives are generally contraindicated for people in Mrs. Brown's situation.

See Critical Thinking Possibilities on student resource website.

CONCEPT MAP

Altered Bowel Elimination

Chapter 49 Review

CHAPTER HIGHLIGHTS

- Primary functions of the large intestine are the absorption of water and nutrients, the mucoid protection of the intestinal wall, and fecal elimination.
- Patterns of fecal elimination vary greatly among people, but a regular pattern of fecal elimination with formed, soft stools is essential to health and a sense of well-being.
- Various factors affect defecation: developmental level, diet, fluid intake, activity and exercise, psychological factors, defecation habits, medications, diagnostic and medical procedures, pathologic conditions, and pain.
- Common fecal elimination problems include constipation, diarrhea, bowel incontinence, and flatulence. Each has specific defining characteristics and contributing causes that often relate to or are identical to the factors that affect defecation.
- Lack of exercise, irregular defecation habits, and overuse of laxatives are all thought to contribute to constipation. Sufficient fluid and fiber intake are required to keep feces soft.
- An adverse effect of constipation is straining during defecation, during which the Valsalva maneuver may be used. Cardiac problems may ensue.
- An adverse effect of prolonged diarrhea is fluid and electrolyte imbalance.
- Assessment relative to fecal elimination includes a nursing history; physical examination of the abdomen, rectum, and anus; and in some situations, visualization studies and inspection and analysis of stool for abnormal constituents such as blood.
- A nursing history includes data about the client's defecating pattern, description of feces and any changes, problems associated with elimination, and data about possible factors altering bowel elimination.
- When inspecting the client's stool, the nurse must observe its color, consistency, shape, amount, odor, and the presence of abnormal constituents.
- A function of the nurse is to assist clients with diet and bowel preparation before endoscopic and radiographic studies of the large intestine.
- NANDA-approved nursing diagnoses that relate specifically to altered bowel elimination include *Bowel Incontinence*, *Risk for Constipation*, *Constipation*, *Perceived Constipation*, *Diarrhea*, and *Dysfunctional Gastrointestinal Motility*. However, because altered elimination patterns affect several areas of human functioning, diagnoses such as *Risk for Deficient Fluid Volume*, *Risk for Electrolyte Imbalance*, *Risk for Impaired Skin Integrity*, *Situational Low Self-Esteem*, *Disturbed Body Image*, *Deficient Knowledge*, and *Anxiety* may also apply.
- Normal defecation is often facilitated in both well and ill clients by providing privacy, teaching clients to attend to defecation urges promptly, assisting clients to normal sitting positions whenever possible, encouraging appropriate food and fluid intake, and scheduling regular exercise.
- Nursing strategies include administering cathartics and antidiarrheals; administering cleansing, carminative, retention, or return-flow enemas; applying protective skin agents; monitoring fluid and electrolyte balance; and instructing clients in ways to promote normal defecation.
- The purpose of an enema is to increase peristalsis and the excretion of feces and flatus. Enemas are classified into four groups: cleansing, carminative, retention, and return-flow enemas.
- Digital removal of an impaction should be carried out gently because of vagal nerve stimulation and subsequent depressed cardiac rate. A primary care provider's order is often necessary.
- Clients who have bowel diversion ostomies require special care, with attention to psychological adjustment, diet, and stoma and skin care. A variety of stoma management methods is available to these clients, depending on the type and position of the ostomy.

TEST YOUR KNOWLEDGE

1. Clients should be taught that repeatedly ignoring the sensation of needing to defecate could result in which of the following?
 1. Constipation
 2. Diarrhea
 3. Incontinence
 4. Hemorrhoids
2. Which statement provides evidence that an older adult who is prone to constipation is in need of further teaching?
 1. "I need to drink one and a half to two quarts of liquid each day."
 2. "I need to take a laxative such as Milk of Magnesia if I don't have a BM every day."
 3. "If my bowel pattern changes on its own, I should call you."
 4. "Eating my meals at regular times is likely to result in regular bowel movements."
3. A client is scheduled for a colonoscopy. The nurse will provide information to the client about which type of enema?
 1. Oil retention
 2. Return flow
 3. High, large volume
 4. Low, small volume
4. The nurse is most likely to report which finding to the primary care provider for a client who has an established colostomy?
 1. The stoma extends 1/2 in. above the abdomen.
 2. The skin under the appliance looks red briefly after removing the appliance.
 3. The stoma color is a deep red-purple.
 4. The ascending colostomy delivers liquid feces.
5. Which goal is the most appropriate for clients with diarrhea related to ingestion of an antibiotic for an upper respiratory infection?
 1. The client will wear a medical alert bracelet for antibiotic allergy.
 2. The client will return to his or her previous fecal elimination pattern.
 3. The client will verbalize the need to take an antidiarrheal medication prn.
 4. The client will increase intake of insoluble fiber such as grains, rice, and cereals.

6. A client with a new stoma who has not had a bowel movement since surgery last week reports feeling nauseous. What is the appropriate nursing action?
1. Prepare to irrigate the colostomy.
 2. After assessing the stoma and surrounding skin, notify the surgeon.
 3. Assess bowel sounds and administer antiemetic.
 4. Administer a bulk-forming laxative, and encourage increased fluids and exercise.
7. The nurse assesses a client's abdomen several days after abdominal surgery. It is firm, distended, and painful to palpate. The client reports feeling "bloated." The nurse consults with the surgeon, who orders an enema. The nurse prepares to give what kind of enema?
1. Soapsuds
 2. Retention
 3. Return flow
 4. Oil retention
8. Which of the following is most likely to validate that a client is experiencing intestinal bleeding?
1. Large quantities of fat mixed with pale yellow liquid stool
 2. Brown, formed stools
 3. Semisoft black-colored stools
 4. Narrow, pencil-shaped stool
9. Which nursing diagnoses is/are most applicable to a client with fecal incontinence? Select all that apply.
1. *Bowel Incontinence*
 2. *Risk for Deficient Fluid Volume*
 3. *Disturbed Body Image*
 4. *Social Isolation*
 5. *Risk for Impaired Skin Integrity*
10. A student nurse is assigned to care for a client with a sigmoidostomy. The student will assess which ostomy site?

See Answers to Test Your Knowledge in Appendix A.

READINGS AND REFERENCES

Suggested Readings

Daniels, G., & Schmelzer, M. (2013). Giving laxatives safely and effectively. *MEDSURG Nursing*, 22(5), 290–302.

This article provides information about the modes of action of various laxatives and strategies to help medical-surgical nurses increase medication effectiveness and prevent adverse effects.

Toner, F., & Claros, E. (2012). Preventing, assessing, and managing constipation in older adults. *Nursing*, 42(12), 32–39. doi:10.1097/01.NURSE.0000422642.83383.17

The authors point out that half of all older adults suffer from constipation. They provide comprehensive information on understanding the pathophysiology, the classifications of constipation, the Rome II diagnostic criteria, treating constipation, possible complications, and nursing considerations.

50 Oxygenation

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Outline the structure and function of the respiratory system.
2. Describe the processes of breathing (ventilation) and gas exchange (respiration).
3. Explain the role and function of the respiratory system in transporting oxygen and carbon dioxide to and from body tissues.
4. Describe the mechanisms for respiratory regulation.
5. Identify factors influencing respiratory function.
6. Identify four major types of conditions that can alter respiratory function.
7. Describe nursing assessments for oxygenation status.
8. Describe nursing measures to promote respiratory function and oxygenation.
9. Explain the use of therapeutic measures such as medications, inhalation therapy, oxygen therapy, artificial airways, airway suctioning, and chest tubes to promote respiratory function.
10. State outcome criteria for evaluating client responses to measures that promote adequate oxygenation.
11. Verbalize the steps used in:
 - a. Administering oxygen by cannula, face mask, or face tent.
 - b. Oropharyngeal, nasopharyngeal, and nasotracheal suctioning.
 - c. Suctioning a tracheostomy or endotracheal tube.
 - d. Providing tracheostomy care.
12. Recognize when it is appropriate to delegate aspects of oxygen therapy, suctioning, and tracheostomy care.
13. Demonstrate appropriate documentation and reporting of oxygen therapy, suctioning, and tracheostomy care.

INTRODUCTION

Oxygen, a clear, odorless gas that constitutes approximately 21% of the air we breathe, is necessary for proper functioning of all living cells. The absence of oxygen can lead to cellular, tissue, and organism death. Cellular metabolism produces carbon dioxide, which must be eliminated from the body to maintain normal acid–base balance. Delivery of oxygen and removal of carbon dioxide require the integration of several systems including the hematologic, cardiovascular, and respiratory systems. The respiratory system provides the essential first process in this integrated system, that is, movement and transfer of gases between the atmosphere and the blood (Patton & Tibodeau, 2010). Impaired function of the system can significantly

affect our ability to breathe, transport gases, and participate in everyday activities.

Respiration is the process of gas exchange between the individual and the environment and involves four components:

1. Ventilation or breathing, the movement of air in and out of the lungs as we inhale and exhale
2. Alveolar-capillary gas exchange, which involves the diffusion of oxygen and carbon dioxide between the alveoli and the pulmonary capillaries
3. Transport of oxygen and carbon dioxide between the tissues and the lungs
4. Movement of oxygen and carbon dioxide between the systemic capillaries and the tissues.

STRUCTURE AND PROCESSES OF THE RESPIRATORY SYSTEM

The structure of the respiratory system facilitates gas exchange and protects the body from foreign matter such as particulates and pathogens. The four processes of the respiratory system include pulmonary ventilation, alveolar gas exchange, transport of oxygen and carbon dioxide, and systemic diffusion.

Structure of the Respiratory System

The respiratory system (Figure 50–1 ■) is divided structurally into the upper respiratory system and the lower respiratory system. The mouth, nose, pharynx, and larynx compose the upper respiratory system. The lower respiratory system includes the trachea and lungs, with the bronchi, bronchioles, alveoli, pulmonary capillary network, and pleural membranes.

Air enters through the nose, where it is warmed, humidified, and filtered. Hairs at the entrance of the nares trap large particles in the air,

and smaller particles are filtered and trapped as air changes direction on contact with the nasal turbinates and septum. Irritants in the nasal passages initiate the sneeze reflex. A large volume of air rapidly exits through the nose and mouth during a sneeze, helping to clear nasal passages.

Inspired air passes from the nose through the pharynx. The pharynx is a shared pathway for air and food. It includes both the nasopharynx and the oropharynx, which are richly supplied with lymphoid tissue that traps and destroys pathogens entering with the air.

The larynx is a cartilaginous structure that can be identified externally as the Adam's apple. In addition to its role in providing for speech, the larynx is important for maintaining airway patency and protecting the lower airways from swallowed food and fluids. During swallowing, the inlet to the larynx (the epiglottis) closes, routing food to the esophagus. The epiglottis is open during breathing, allowing air to move freely into the lower airways. Below the larynx, the trachea leads to the right and left main bronchi (primary bronchi) and the other conducting airways of the lungs. Within the lungs, the

Figure 50–1 ■ A, Organs of the respiratory tract; B, respiratory bronchioles, alveolar ducts, and alveoli.

BOX 50-1 The Cough Reflex

- Nerve impulses are sent through the vagus nerve to the medulla.
- A large inspiration of approximately 2.5 L occurs.
- The epiglottis and glottis (vocal cords) close.
- A strong contraction of abdominal and internal intercostal muscles dramatically raises the pressure in the lungs.
- The epiglottis and glottis open suddenly.
- Air rushes outward with great velocity.
- Mucus and any foreign particles are dislodged from the lower respiratory tract and are propelled up and out.

primary bronchi divide repeatedly into smaller and smaller bronchi, ending with the terminal bronchioles. Together these airways are known as the bronchial tree. The trachea and bronchi are lined with mucosal epithelium. These cells produce a thin layer of mucus, the “mucous blanket,” that traps pathogens and microscopic particulate matter. These foreign particles are then swept upward toward the larynx and throat by cilia, tiny hairlike projections on the epithelial cells. The cough reflex is triggered by irritants in the larynx, trachea, or bronchi and is described in Box 50-1.

After air passes through the trachea and bronchi, it enters the respiratory bronchioles and alveoli where all gas exchange occurs. This gas exchange or respiratory zone of the lungs includes the respiratory bronchioles (which have scattered air sacs in their walls), the alveolar ducts, and the alveoli (see Figure 50-1). Alveoli have very thin walls, composed of a single layer of epithelial cells covered by a thick mesh of pulmonary capillaries. The alveolar and capillary walls form the **respiratory membrane** (also known as the alveolar/capillary membrane), where gas exchange occurs between the air on the alveolar side and the blood on the capillary side. The airways move air to and from the alveoli; the right ventricle and pulmonary vascular system transport blood to the capillary side of the membrane. For example, deoxygenated blood leaves the right heart through the pulmonary artery and enters the lungs and capillaries. Oxygenated blood returns via capillaries to the pulmonary vein to the heart (Figure 50-2 ■). The thin, highly permeable membrane of the respiratory membrane (estimated to be not more than 0.0004 mm thick) is essential to normal gas exchange. Thus, fluid or other materials in the alveoli interfere with the respiratory process.

The outer surface of the lungs is covered by a thin, double layer of tissue known as the pleura. The parietal pleura lines the thorax and surface of the diaphragm. It doubles back to form the visceral pleura, covering the external surface of the lungs. Between these pleural layers is a potential space that contains a small amount of pleural fluid, a serous lubricating solution. This fluid prevents friction during the movements of breathing and serves to keep the layers adherent through its surface tension.

Pulmonary Ventilation

The first process of the respiratory system, ventilation of the lungs, is accomplished through the act of breathing: inspiration (inhalation) as air flows into the lungs, and expiration (exhalation) as air moves out of the lungs. Adequate ventilation depends on several factors:

- Clear airways
- An intact central nervous system (CNS) and respiratory center

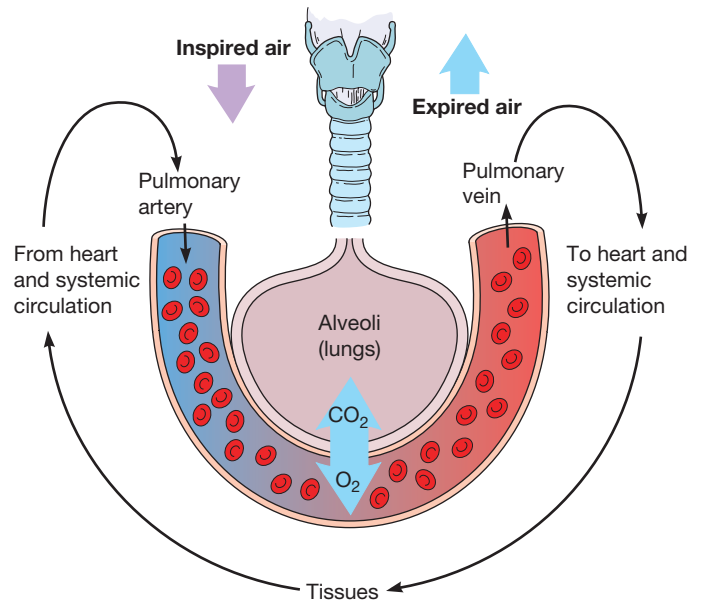

Figure 50-2 ■ Gas exchange occurs between the air on the alveolar side and the blood on the capillary side.

- An intact thoracic cavity capable of expanding and contracting
- Adequate pulmonary compliance and recoil.

A number of mechanisms, including ciliary action and the cough reflex, work to keep airways open and clear. In some cases, however, these defenses may be overwhelmed. The inflammation, edema, and excess mucous production that occur with some types of pneumonia may clog small airways, impairing ventilation of distal alveoli.

The respiratory centers of the medulla and pons in the brain-stem control breathing. Severe head injury or drugs that depress the central nervous system (e.g., opiates or barbiturates) can affect the respiratory centers, impairing the drive to breathe.

Expansion and recoil of the lungs occur passively in response to changes in pressures within the thoracic cavity and the lungs themselves. The **intrapleural pressure** (pressure in the pleural cavity surrounding the lungs) is always slightly negative in relation to atmospheric pressure. This negative pressure is essential because it creates the suction that holds the visceral pleura and the parietal pleura together as the chest cage expands and contracts. The recoil tendency of the lungs is a major factor in creating this negative pressure. The intrapleural fluid also contributes by causing the pleura to adhere together, much as a film of water can cause two glass slides to stick together.

The **intrapulmonary pressure** (pressure within the lungs) always equalizes with atmospheric pressure. Inspiration occurs when the diaphragm and intercostal muscles contract, increasing the size of the thoracic cavity. The volume of the lungs increases, decreasing intrapulmonary pressure. Air then rushes into the lungs to equalize this pressure with atmospheric pressure. Conversely, when the diaphragm and intercostal muscles relax, the volume of the lungs decreases, intrapulmonary pressure rises, and air is expelled. Normal elastic recoil of the thorax and lungs is essential to exhalation. Disease processes such as chronic obstructive pulmonary disease (COPD) that reduce this elasticity result in forced expirations and may impair the body's ability to expel carbon dioxide.

ANATOMY & PHYSIOLOGY REVIEW

The Respiratory System

The larynx, trachea, bronchi, and lungs with an expanded view showing the structures of an alveolus and the pulmonary blood vessels.

From *Medical Terminology: A Word-Building Approach*, 7th ed. (Figure 11.5), by J. Rice, 2012, Upper Saddle River, NJ: Pearson Education, Inc. Reproduced by permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

QUESTIONS

1. Pneumonia occurs when microorganisms get into the lower respiratory tract and overwhelm the body's defenses. Name at least two normal defense mechanisms present in the *upper* airway that help prevent microorganisms getting into the lower respiratory tract.
2. Microorganisms can travel past the upper respiratory tract defense mechanisms. What defense mechanisms are

present in the *lower* respiratory tract that may help the client?

3. The microorganisms have quickly multiplied and overpowered the client's defense mechanisms. The client has pneumonia and the alveoli are filled with infectious fluid. How will this affect gas exchange at the respiratory or alveolar/capillary membrane?

See student resource website for answers.

The degree of chest expansion during normal breathing is minimal, requiring little energy expenditure. In adults, approximately 500 mL of air is inspired and expired with each breath. This is known as **tidal volume**. Breathing during strenuous exercise or some types of heart disease requires greater chest expansion and effort. At this time, more than 1,500 mL of air may be moved with each breath. Accessory muscles of respiration, including the anterior neck muscles, intercostal muscles, and muscles of the abdomen, are employed. Active use of these muscles and noticeable effort in breathing are seen in clients with obstructive pulmonary disease.

Diseases such as muscular dystrophy, or trauma such as spinal cord injury, can affect the muscles of respiration, impairing the ability of the thoracic cavity to expand and contract. A gunshot wound or other chest trauma interferes with the crucial atmospheric and intrapleural pressure gradients, causing the lung to collapse.

Lung compliance, the expansibility or stretchability of lung tissue, plays a significant role in the ease of ventilation. At birth, the fluid-filled lungs are stiff and resistant to expansion, much as a new balloon is difficult to inflate. With each subsequent breath, the alveoli become more compliant and easier to inflate, just as a balloon becomes easier to inflate after several tries. Lung compliance tends to decrease with aging, making it more difficult to expand alveoli and increasing the risk for **atelectasis**, or collapse of a portion of the lung.

In contrast to lung compliance is **lung recoil**, the continual tendency of the lungs to collapse away from the chest wall. Just as lung compliance is necessary for normal inspiration, lung recoil is necessary for normal expiration. Although elastic fibers in lung tissue contribute to lung recoil, the surface tension of fluid lining the alveoli has the greatest effect on recoil. Fluid molecules tend to draw together, reducing the size of alveoli. **Surfactant**, a lipoprotein produced by specialized alveolar cells, acts like a detergent, reducing the surface tension of alveolar fluid. Without surfactant, lung expansion is exceedingly difficult and the lungs collapse. Premature infants whose lungs are not yet capable of producing adequate surfactant often develop respiratory distress syndrome.

Alveolar Gas Exchange

After the alveoli are ventilated, the second phase of the respiratory process—the diffusion of oxygen from the alveoli and into the pulmonary blood vessels—begins. **Diffusion** is the movement of gases or other particles from an area of greater pressure or concentration to an area of lower pressure or concentration.

Pressure differences in the gases on each side of the respiratory membrane obviously affect diffusion. When the pressure of oxygen is greater in the alveoli than in the blood, oxygen diffuses into the blood. The **partial pressure** (the pressure exerted by each individual gas in a mixture according to its concentration in the mixture) of oxygen (PO_2) in the alveoli is about 100 mmHg (sometimes referred to as **torr**, which is the same as millimeters of mercury), whereas the PO_2 in the venous blood of the pulmonary arteries is about 60 mmHg or torr. These pressures rapidly equalize, however, so that the arterial oxygen pressure also reaches about 100 mmHg. By contrast, carbon dioxide in the venous blood entering the pulmonary capillaries has a partial pressure of about 45 mmHg (PCO_2), whereas that in the alveoli has a partial pressure of about 40 mmHg. Therefore, carbon dioxide diffuses from the blood into the alveoli, where it can be eliminated with expired air. Partial pressures of oxygen and carbon dioxide are further defined by whether they derive from arterial or venous blood.

For example, the partial pressure of oxygen in arterial blood is called PaO_2 while the partial pressure of oxygen in venous blood is called PvO_2 . However, blood for partial pressures (blood gases) are usually obtained from arterial blood. Therefore, the abbreviation “ PO_2 ” is commonly used for arterial blood oxygen partial pressure.

Transport of Oxygen and Carbon Dioxide

The third part of the respiratory process involves the transport of respiratory gases. Oxygen needs to be transported from the lungs to the tissues, and carbon dioxide must be transported from the tissues back to the lungs. Normally most of the oxygen (97%) combines loosely with **hemoglobin** (oxygen-carrying red pigment) in the red blood cells (RBCs) and is carried to the tissues as **oxyhemoglobin** (the compound of oxygen and hemoglobin). Various factors influence the tendency of oxygen to bind with and release from hemoglobin. As oxygen diffuses from capillary blood into tissues, the decreasing partial pressure of oxygen stimulates the hemoglobin to release its attached oxygen molecules. Additionally, changes in blood pH affect the hemoglobin's ability to bind with and release oxygen. The small amount of oxygen not bound to hemoglobin is dissolved and transported in the plasma as the PaO_2 .

Several factors affect the rate of oxygen transport from the lungs to the tissues:

1. Cardiac output
2. Number of erythrocytes and blood hematocrit
3. Exercise.

Any pathologic condition that decreases cardiac output (e.g., damage to the heart muscle, blood loss, or pooling of blood in the peripheral blood vessels) diminishes the amount of oxygen delivered to the tissues. The heart compensates for inadequate output by increasing its pumping rate or heart rate; however, with severe damage or blood loss, this compensatory mechanism may not restore adequate blood flow and oxygen to the tissues.

The second factor influencing oxygen transport is the number of **erythrocytes** or red blood cells (RBCs) and the hematocrit. The **hematocrit** is the percentage of the blood that is erythrocytes. In men, the number of circulating erythrocytes normally averages about 5 million per cubic milliliter of blood, and in women, about 4.5 million per cubic milliliter. Normally the hematocrit is about 40% to 54% in men and 37% to 50% in women. Excessive increases in the blood hematocrit raise the blood viscosity, reducing the cardiac output and therefore reducing oxygen transport. Excessive reductions in the blood hematocrit, such as occur in anemia, reduce oxygen transport.

Exercise also has a direct influence on oxygen transport. In well-trained athletes, oxygen transport can be increased up to 20 times the normal rate, due in part to an increased cardiac output and to increased use of oxygen by the cells.

Carbon dioxide, continually produced in the processes of cell metabolism, is transported from the cells to the lungs in three ways. The majority (about 65%) is carried inside the RBCs as bicarbonate (HCO_3^-) and is an important component of the bicarbonate buffer system (see Chapter 52 ). A moderate amount of carbon dioxide (30%) combines with hemoglobin as carbaminohemoglobin for transport. Smaller amounts (5%) are transported in solution in the plasma and as carbonic acid (the compound formed when carbon dioxide combines with water).

Systemic Diffusion

The fourth process of respiration is diffusion of oxygen and carbon dioxide between the capillaries and the tissues and cells down to a concentration gradient similar to diffusion at the alveolar-capillary level. As cells consume oxygen, the partial pressure of oxygen in the tissues decreases, causing the oxygen at the arterial end of the capillary to diffuse into the cells. When cells consume more oxygen during exercise or stress, the pressure gradient increases and diffusion is enhanced, allowing the cells to regulate their own flow of oxygen. Carbon dioxide from metabolic processes accumulates in the tissues and diffuses into the capillaries where the partial pressure of carbon dioxide is lower. In reduced blood flow states such as shock, capillary blood flow may decrease, interfering with tissue oxygen delivery.

RESPIRATORY REGULATION

Respiratory regulation includes both neural and chemical controls to maintain the correct concentrations of oxygen, carbon dioxide, and hydrogen ions in body fluids. The nervous system of the body adjusts the rate of alveolar ventilations to meet the needs of the body so that PO_2 and PCO_2 remain relatively constant. The body's "respiratory center" is actually a number of groups of neurons located in the medulla oblongata and pons of the brain.

A chemosensitive center in the medulla oblongata is highly responsive to increases in blood CO_2 or hydrogen ion concentration. By influencing other respiratory centers, this center can increase the activity of the inspiratory center and the rate and depth of respirations. In addition to this direct chemical stimulation of the respiratory center in the brain, special neural receptors sensitive to decreases in O_2 concentration are located outside the central nervous system in the carotid bodies (just above the bifurcation of the common carotid arteries) and aortic bodies located above and below the aortic arch. Decreases in arterial oxygen concentrations stimulate these chemoreceptors, and they in turn stimulate the respiratory center to increase ventilation. Of the three blood gases (hydrogen, oxygen, and carbon dioxide) that can trigger chemoreceptors, increased carbon dioxide concentration normally has the strongest effect on stimulating respiration.

However, in clients with certain chronic lung ailments such as **emphysema**, oxygen concentrations, not carbon dioxide concentrations, play a major role in regulating respiration. For some clients, decreased oxygen concentrations are the main stimuli for respiration because the chronically elevated carbon dioxide levels that occur with emphysema "desensitize" the central chemoreceptors. This is sometimes called the hypoxic drive. Increasing the concentration of oxygen depresses the respiratory rate. Thus, oxygen must be administered cautiously to these clients and often at low flow rates. Current theory, however, is that only a small percentage of individuals with COPD actually have depressed CO_2 chemoreceptors. Low-flow oxygen therapy may not be enough for many clients with COPD, and chronic hypoxemia shortens survival and quality of life (Makic, Martin, Burns, Philbrick, & Rauen, 2013).

CLINICAL ALERT!

Oxygen is considered a drug and must be carefully prescribed based on individual client conditions.

FACTORS AFFECTING RESPIRATORY FUNCTION

Factors that influence oxygenation affect the cardiovascular system as well as the respiratory system. These factors include age, environment, lifestyle, health status, medications, and stress.

Age

Developmental factors have important influences on respiratory function. At birth, profound changes occur in the respiratory systems. The fluid-filled lungs drain, the PCO_2 rises, and the neonate takes a first breath. The lungs gradually expand with each subsequent breath, reaching full inflation by 2 weeks of age. Changes of aging that affect the respiratory system of older adults become especially important if the system is compromised by changes such as infection, physical or emotional stress, surgery, anesthesia, or other procedures. These types of changes are seen:

- Chest wall and airways become more rigid and less elastic.
- The amount of exchanged air is decreased.
- The cough reflex and cilia action are decreased.
- Mucous membranes become drier and more fragile.
- Decreases in muscle strength and endurance occur.
- If osteoporosis is present, adequate lung expansion may be compromised.
- A decrease in efficiency of the immune system occurs.
- Gastroesophageal reflux disease is more common in older adults and increases the risk of aspiration. The aspiration of stomach contents into the lungs often causes bronchospasm by setting up an inflammatory response.

Environment

Altitude, heat, cold, and air pollution affect oxygenation. The higher the altitude, the lower the PO_2 an individual breathes. As a result, the person at high altitudes has increased respiratory and cardiac rates and increased respiratory depth, which usually become most apparent when the individual exercises.

Healthy people exposed to air pollution, such as smog or secondhand tobacco smoke, may experience stinging of the eyes, headache, dizziness, and coughing. People who have a history of existing lung disease and altered respiratory function experience varying degrees of respiratory difficulty in a polluted environment. Some are unable to perform self-care in such an environment.

Lifestyle

Physical exercise or activity increases the rate and depth of respirations and hence the supply of oxygen in the body. Sedentary people, by contrast, lack the alveolar expansion and deep-breathing patterns of people with regular activity and are less able to respond effectively to respiratory stressors.

Certain occupations predispose an individual to lung disease. For example, silicosis is seen more often in sandstone blasters and potters than in the rest of the population; asbestosis in asbestos workers; anthracosis in coal miners; and organic dust disease in farmers and agricultural employees who work with moldy hay.

Health Status

In the healthy person, the respiratory system can provide sufficient oxygen to meet the body's needs. Diseases of the respiratory system, however, can adversely affect the oxygenation of the blood.

Medications

A variety of medications can decrease the rate and depth of respirations. The most common medications having this effect are the benzodiazepine sedative-hypnotics and anti-anxiety drugs (e.g., diazepam [Valium], lorazepam [Ativan], midazolam [Versed]), barbiturates (e.g., phenobarbital), and opioids such as morphine. When administering these, the nurse must carefully monitor respiratory status, especially when the medication is begun or when the dose is increased. Older clients are at high risk of respiratory depression and, hence, usually require reduced dosages.

Stress

When stress and stressors are encountered, both psychological and physiological responses can affect oxygenation. Some people may hyperventilate in response to stress. When this occurs, arterial PO_2 rises and PCO_2 falls. The person may experience light-headedness and numbness and tingling of the fingers, toes, and around the mouth as a result.

Physiologically, the sympathetic nervous system is stimulated and epinephrine is released during stress. Epinephrine causes the bronchioles to dilate, increasing blood flow and oxygen delivery to active muscles. Although these responses are adaptive in the short term, when stress continues they can be destructive, increasing the risk of cardiovascular disease.

ALTERATIONS IN RESPIRATORY FUNCTION

Respiratory function can be altered by conditions that affect:

- Patency (open airway)
- The movement of air into or out of the lungs
- The diffusion of oxygen and carbon dioxide between the alveoli and the pulmonary capillaries
- The transport of oxygen and carbon dioxide via the blood to and from the tissue cells.

Conditions Affecting the Airway

A completely or partially obstructed airway can occur anywhere along the upper or lower respiratory passageways. An upper airway obstruction—that is, in the nose, pharynx, or larynx—can occur when a foreign object such as food is present, when the tongue falls back into the oropharynx when a person is unconscious, or when secretions collect in the passageways. In the latter instance, the respirations will sound gurgly or bubbly as the air attempts to pass through the secretions. Lower airway obstruction involves partial or complete occlusion of the passageways in the bronchi and lungs most often due to increased accumulation of mucus or inflammatory exudate.

Assessing for and maintaining a patent airway is a nursing responsibility, one that often requires immediate action. Partial obstruction of the upper airway passages is indicated by a low-pitched snoring sound during inhalation. Complete obstruction is indicated

by extreme inspiratory effort that produces no chest movement and an inability to cough or speak. Such a client, in an effort to obtain air, may also exhibit marked sternal and intercostal retractions. Lower airway obstruction is not always as easy to observe. **Stridor**, a harsh, high-pitched sound, may be heard during inspiration. The client may have altered arterial blood gas levels, restlessness, dyspnea, and **adventitious breath sounds** (abnormal breath sounds). See Table 30–8, page 556.

Conditions Affecting Movement of Air

The term *breathing patterns* refers to the rate, volume, rhythm, and relative ease or effort of respiration. Normal respiration (**eupnea**) is quiet, rhythmic, and effortless. **Tachypnea** (rapid respirations) is seen with fevers, metabolic acidosis, pain, and hypoxemia. **Bradypnea** is an abnormally slow respiratory rate, which may be seen in clients who have taken drugs such as morphine or sedatives, who have metabolic alkalosis, or who have increased intracranial pressure (e.g., from brain injuries). **Apnea** is the absence of any breathing.

Hypoventilation, that is, inadequate alveolar ventilation, may be caused by either slow or shallow breathing, or both. Hypoventilation may occur because of diseases of the respiratory muscles, drugs, or anesthesia. Hypoventilation may lead to increased levels of carbon dioxide (**hypercarbia** or **hypercapnia**) or low levels of oxygen (hypoxemia).

Hyperventilation is the increased movement of air into and out of the lungs. During hyperventilation, the rate and depth of respirations increase and more CO_2 is eliminated than is produced. One particular type of hyperventilation that accompanies metabolic acidosis is **Kussmaul's breathing**, by which the body attempts to compensate for increased metabolic acids by blowing off acid in the form of CO_2 . Hyperventilation can also occur in response to stress or anxiety.

Other abnormal breathing patterns may create breathing irregularities. Irregular rhythms include:

- **Cheyne-Stokes respirations:** marked rhythmic waxing and waning of respirations from very deep to very shallow with short periods of apnea commonly caused by chronic diseases, increased intracranial pressure, or drug overdose
- **Biot's (cluster) respirations:** shallow breaths interrupted by apnea; may be seen in clients with CNS disorders.

Orthopnea is the inability to breathe easily unless sitting upright or standing. Difficulty breathing or the feeling of being *short of breath* (SOB) is called **dyspnea**. Dyspnea may occur with varying levels of exertion or at rest. The client with dyspnea will generally have observable (objective) signs such as flaring of the nostrils, labored-appearing breathing, increased heart rate, cyanosis, and diaphoresis. Dyspnea has many causes, most of which stem from cardiac or respiratory disorders. Because treatment is aimed at removing the underlying cause, it is important for the nurse to conduct a thorough history of the onset, duration, and precipitating and relieving factors of the client's dyspnea plus a comprehensive physical examination.

Conditions Affecting Diffusion

Impaired diffusion may affect levels of gases in the blood, particularly oxygen, which does not diffuse as readily as carbon dioxide. **Hypoxemia**, or reduced oxygen levels in the blood, may be caused

LIFESPAN CONSIDERATIONS Respiratory Development

INFANTS

- Respiratory rates are highest and most variable in newborns. The respiratory rate of a neonate is 40 to 80 breaths per minute.
- Infant respiratory rates average about 30 per minute.
- Because of rib cage structure, infants rely almost exclusively on diaphragmatic movement for breathing. This is seen as abdominal breathing, as the abdomen rises and falls with each breath.

CHILDREN

- The respiratory rate gradually decreases, averaging around 25 per minute in the preschooler and reaching the adult rate of 12 to 18 per minute by late adolescence.
- During infancy and childhood, viral upper respiratory infections (e.g., colds) are common and, fortunately, usually not serious. Infants and preschoolers also are at risk for airway obstruction by foreign objects such as coins and small toys. Cystic fibrosis is a congenital disorder that affects the lungs, causing them to become congested with thick, tenacious (sticky) mucus. Asthma is another chronic disease often identified in childhood. The airways of the asthmatic child react to stimuli such as allergens, exercise, or cold air by constricting, becoming edematous, and producing excessive mucus. Airflow is impaired, and the child may wheeze as air moves through narrowed air passages.

OLDER ADULTS

- Older adults are at increased risk for acute respiratory diseases such as pneumonia and chronic diseases such as emphysema and chronic bronchitis. COPD may affect older adults, particularly after years of exposure to cigarette smoke or industrial pollutants. Obstructive airway changes are accelerated with the genetic deficiency of the enzyme alpha₁-antitrypsin.

- Pneumonia may not present with the usual symptoms of a fever, but will present with atypical symptoms, such as confusion, weakness, loss of appetite, and increase in heart rate and respirations.

Nursing interventions should be directed toward achieving optimal respiratory effort, gas exchange, self-care habits, and wellness. Additionally, nurses play an important role in chronic disease management by assisting clients to cope with and minimize the effects of illnesses such as COPD.

- Always encourage wellness and prevention of disease by reinforcing the need for good nutrition, exercise, and immunizations, such as for influenza and pneumonia.
- Increase fluid intake, if not contraindicated by other problems, such as cardiac or renal impairment.
- In hospitalized and immobile clients, encourage ambulation and frequent changing of positions to allow for better lung expansion and air and fluid movement.
- Teach the client to use deep-breathing and coughing techniques for better lung expansion and airway clearance. (See Client Teaching throughout this chapter.)
- Pace activities to conserve energy.
- Encourage the client to eat more frequent, smaller meals to decrease gastric distention, which can cause pressure on the diaphragm.
- Teach the client to avoid extreme hot or cold temperatures, which can further tax the respiratory system.
- Teach actions and side effects of drugs, inhalers, and treatments.

CLINICAL MANIFESTATIONS

Hypoxia

- Rapid pulse
- Rapid, shallow respirations and dyspnea
- Increased restlessness or light-headedness
- Flaring of the nares
- Substernal or intercostal retractions
- Cyanosis

by conditions that impair diffusion at the alveolar-capillary level such as pulmonary edema or atelectasis (collapsed alveoli) or by low hemoglobin levels. The cardiovascular system compensates for hypoxemia by increasing the heart rate and cardiac output, to attempt to transport adequate oxygen to the tissues. If the cardiovascular system is unable to compensate or hypoxemia is severe, tissue **hypoxia** (insufficient oxygen anywhere in the body) results, potentially causing cellular injury or death. Clinical Manifestations lists signs of hypoxia.

Cyanosis (bluish discoloration of the skin, nail beds, and mucous membranes due to reduced hemoglobin-oxygen saturation) may be present with hypoxemia or hypoxia. Cyanosis requires two conditions: The blood must contain about 5 g or more of unoxygenated hemoglobin per 100 mL of blood, and the surface blood capillaries must be dilated. Factors that interfere with either of these conditions (e.g., severe anemia or the administration of epinephrine) will eliminate cyanosis as a sign even if the client is experiencing hypoxia.

Adequate oxygenation is essential for cerebral functioning. The cerebral cortex can tolerate hypoxia for only 3 to 5 minutes before permanent damage occurs. The face of the acutely hypoxic person

usually appears anxious, tired, and drawn. The person usually assumes a sitting position, often leaning forward slightly to permit greater expansion of the thoracic cavity.

With chronic hypoxemia, the client often appears fatigued and is lethargic. The client's fingers and toes may be clubbed as a result of long-term lack of oxygen in the arterial blood supply. With clubbing, the base of the nail becomes swollen and the ends of the fingers and toes increase in size. The angle between the nail and the base of the nail increases to more than 180 degrees. See Figure 30–10, page 530.

Conditions Affecting Transport

Once oxygen moves into the lungs and diffuses into the capillaries, the cardiovascular system transports the oxygen to all body tissues, and transports CO₂ from the cells back to the lungs where it can be exhaled from the body. Conditions that decrease cardiac output, such as congestive heart failure or hypovolemia, affect tissue oxygenation and also the body's ability to compensate for hypoxemia.

●○● NURSING MANAGEMENT

Assessing

Nursing assessment of oxygenation status includes a history, physical examination, and review of relevant diagnostic data.

Nursing History

A comprehensive nursing history relevant to oxygenation status should include data about current and past respiratory problems; lifestyle; presence of cough, **sputum** (coughed-up material), or pain; medications for breathing; and presence of risk factors for impaired

ASSESSMENT INTERVIEW Oxygenation

CURRENT RESPIRATORY PROBLEMS

- Have you noticed any changes in your breathing pattern (e.g., shortness of breath, difficulty breathing, need to be in upright position to breathe, or rapid and shallow breathing)?
- If so, which of your activities might cause these symptom(s) to occur?
- How many pillows do you use to sleep at night?

HISTORY OF RESPIRATORY DISEASE

- Have you had colds, allergies, asthma, tuberculosis, bronchitis, pneumonia, or emphysema?
- How frequently have these occurred? How long did they last? And how were they treated?
- Have you been exposed to any pollutants?

LIFESTYLE

- Do you smoke? If so, how much? If not, did you smoke previously, and when did you stop?
- Does any member of your family smoke?
- Is there cigarette smoke or other pollutants (e.g., fumes, dust, coal, asbestos) in your workplace?
- Do you use alcohol? If so, how many drinks (mixed drinks, glasses of wine, or beers) do you usually have per day or per week?
- Describe your exercise patterns. How often do you exercise and for how long?

PRESENCE OF COUGH

- How often and how much do you cough?
- Is it productive, that is, accompanied by sputum, or nonproductive, that is, dry?
- Does the cough occur during certain activity or at certain times of the day?

DESCRIPTION OF SPUTUM

- When is the sputum produced?
- What is the amount, color, thickness, odor?
- Is it ever tinged with blood?

PRESENCE OF CHEST PAIN

- How does going outside in the heat or the cold affect you?
- Do you experience any pain with breathing or activity?
- If so, where is the pain located?
- Describe the pain. How does it feel?
- Does it occur when you breathe in or out?
- How long does it last, and how does it affect your breathing?
- Do you experience any other symptoms when the pain occurs (e.g., nausea, shortness of breath or difficulty breathing, light-headedness, palpitations)?
- What activities precede your pain?
- What do you do to relieve the pain?

PRESENCE OF RISK FACTORS

- Do you have a family history of lung cancer, cardiovascular disease (including strokes), or tuberculosis?
- The nurse should also note the client's weight, activity pattern, and dietary assessment. Risk factors include obesity, sedentary lifestyle, and diet high in saturated fats.

MEDICATION HISTORY

- Have you taken or do you take any over-the-counter or prescription medications for breathing (e.g., bronchodilator, inhalant, narcotic)?
- If so, which ones? What are the dosages, times taken, and results, including side effects?

oxygenation status. Examples of interview questions to elicit this information are shown in the Assessment Interview.

Physical Examination

In assessing a client's oxygenation status, the nurse uses all four physical examination techniques: inspection, palpation, percussion, and auscultation. The nurse first observes the rate, depth, rhythm, and quality of respirations, noting the position the client assumes for breathing. The nurse also inspects for variations in the shape of the thorax that may indicate adaptation to chronic respiratory conditions. For example, clients with emphysema frequently develop a *barrel chest*.

The nurse palpates the thorax for bulges, tenderness, or abnormal movements. Palpation is also used to detect vocal (tactile) fremitus. The thorax can be percussed for diaphragmatic excursion (the movement of the diaphragm during maximal inspiration and expiration). However, this is not commonly done in acute care and long-term care settings. The nurse frequently auscultates the chest to assess if the client's breath sounds are normal or abnormal. See Chapter 30 , Skill 30-11 on page 556 for more information.

Diagnostic Studies

The primary care provider may order various diagnostic tests to assess respiratory status, function, and oxygenation. Included are sputum specimens, throat cultures, visualization procedures (see Chapter 34 ) , venous and arterial blood specimens, and pulmonary function tests.

Measurement of arterial blood gases is an important diagnostic procedure (see Chapter 52 ). Specimens of arterial blood are

normally taken by specialty nurses, respiratory therapists, or medical technicians. Blood for these tests is taken directly from the radial, brachial, or femoral arteries or from catheters placed in these arteries. Because of the relatively high pressure of the blood in these arteries, it is important to prevent hemorrhaging by applying pressure to the puncture site for about 5 minutes after removing the needle. Frequently the noninvasive measurement of oxygen saturation (using a device placed on the fingertip) is sufficient for attaining a measurement of oxygenation of the arterial blood.

Pulmonary Function Tests

Pulmonary function tests measure lung volume and capacity. Clients undergoing pulmonary function tests, which are usually carried out by a respiratory therapist, do not require an anesthetic. The client breathes into a machine. The tests are painless, but the client's cooperation is essential. It requires the ability to follow directions and some hand-eye coordination. Nurses need to explain the tests to clients beforehand and help them to rest afterward because the tests are often tiring. Table 50-1 describes the measurements taken, and Figure 50-3  shows their relationships and normal adult values.

Diagnosing

NANDA International (Herdman & Kamitsuru, 2014) includes the following diagnostic labels for clients with oxygenation problems:

- **Ineffective Airway Clearance:** inability to clear secretions or obstructions from the respiratory tract to maintain a clear airway.

TABLE 50–1 Pulmonary Volumes and Capacities

Measurement	Description
Tidal volume (V_T)	Volume inhaled and exhaled during normal quiet breathing
Inspiratory reserve volume (IRV)	Maximum amount of air that can be inhaled over and above a normal breath
Expiratory reserve volume (ERV)	Maximum amount of air that can be exhaled following a normal exhalation
Residual volume (RV)	The amount of air remaining in the lungs after maximal exhalation
Total lung capacity (TLC)	The total volume of the lungs at maximum inflation; calculated by adding the V_T , IRV, ERV, and RV
Vital capacity (VC)	Total amount of air that can be exhaled after a maximal inspiration; calculated by adding the V_T , IRV, and ERV
Inspiratory capacity	Total amount of air that can be inhaled following normal quiet exhalation; calculated by adding the V_T and IRV
Functional residual capacity (FRC)	The volume left in the lungs after normal exhalation; calculated by adding the ERV and RV
Minute volume (MV)	The total volume or amount of air breathed in 1 minute

A clinical example using this nursing diagnosis is shown in the Nursing Care Plan and Concept Map at the end of the chapter.

- **Ineffective Breathing Pattern:** inspiration and/or expiration that does not provide adequate ventilation.
- **Impaired Gas Exchange:** excess or deficit in oxygenation and/or carbon dioxide elimination at the alveolar-capillary membrane.
- **Activity Intolerance:** insufficient physiological or psychological energy to endure or complete required or desired daily activities.

The preceding nursing diagnoses may also be the etiology of several other nursing diagnoses, such as these:

- **Anxiety** related to ineffective airway clearance and feeling of suffocation
- **Fatigue** related to ineffective breathing pattern
- **Fear** related to chronic disabling respiratory illness
- **Powerlessness** related to inability to maintain independence in self-care activities because of ineffective breathing pattern
- **Insomnia** related to orthopnea and required O_2 therapy
- **Social Isolation** related to activity intolerance and inability to travel to usual social activities.

Planning

The overall outcomes/goals for a client with oxygenation problems are to:

- Maintain a patent airway.
- Improve comfort and ease of breathing.
- Maintain or improve pulmonary ventilation and oxygenation.
- Improve the ability to participate in physical activities.
- Prevent risks associated with oxygenation problems such as skin and tissue breakdown, syncope, acid–base imbalances, and feelings of hopelessness and social isolation.

These outcomes provide direction for planning interventions and as criteria for evaluating client progress.

A clinical example of desired outcomes, interventions, and activities is provided in the Nursing Care Plan and Concept Map at the end of the chapter.

Planning for Home Care

To provide for continuity of care, the nurse needs to consider the client’s learning needs and needs for assistance with care in the home.

Figure 50–3 ■ The relationship of lung volumes and capacities. Volumes (mL) shown are for an average adult male; female volumes are 20% to 25% smaller.

Home Care Assessment Oxygenation

PATIENT-CENTERED CARE

CLIENT

- *Self-care abilities*: ability to ambulate and perform ADLs independently
- *Exercise and activity pattern*: type and regularity of usual exercise, perceived and actual energy for desired and required leisure activities
- *Assistive devices required*: supplemental oxygen, humidifier, nebulizer treatments, or inhalers; walker, cane, or wheelchair; grab bars, shower chair, and other devices to promote safety and minimize energy expenditure; scale to monitor weight on a regular basis
- *Home environment for factors that impair airway clearance, gas exchange, or activity tolerance*: indoor pollutants such as cigarette smoke, dust, and allergens such as pets; lack of humidity in the air; and barriers such as stairs
- *Current level of knowledge*: importance of avoiding smoking and other pollutants; dietary salt and other restrictions (if appropriate); recommended activities; medications; need to limit exposure to respiratory infections; use of prescribed nebulizer, multidose inhaler, powdered dose inhaler, or home oxygen; activity level

FAMILY

- *Caregiver availability, skills, and responses*: ability and willingness to provide care as needed (help with ADLs, providing meals, assisting with transportation and shopping, caring for dependents; performing treatments such as percussion and postural drainage)
- *Family role changes and coping*: effect on financial status, parenting and spousal roles, sexuality, social roles
- *Alternate potential primary or respite caregivers*: for example, other family members, volunteers, church members, paid caregivers, or housekeeping services; available community respite care (e.g., adult day care, senior centers)

COMMUNITY

- *Environment*: usual temperature and humidity, presence of air pollutants such as automobile exhaust, industrial smoke and pollutants, smoke from field burning
- *Current knowledge of and experience with community resources*: medical and assistive equipment and supply companies, respiratory and physical therapy services, home health agencies, local pharmacies, available financial assistance, support and educational organizations such as the local lung association, COPD support groups

Planning incorporates an assessment of the client's and family's knowledge and abilities for self-care, financial resources, and evaluation of the need for referrals and for home health services. The Home Care Assessment outlines a home care assessment related to the client's oxygenation problems and needs. Client Teaching: Home Care Oxygenation addresses the learning needs of the client and family.

Implementing

Examples of nursing interventions to facilitate pulmonary ventilation may include ensuring a patent airway, positioning, encouraging deep breathing and coughing, and ensuring adequate hydration. Other nursing interventions helpful to ventilation are suctioning, lung inflation techniques, administration of analgesics before deep breathing

CLIENT TEACHING**Home Care Oxygenation****MAINTAINING AIRWAY CLEARANCE AND EFFECTIVE GAS EXCHANGE**

- Emphasize to the client and family the importance of not smoking or lighting any flammable materials (e.g., candles) in the same room. Refer them to smoking cessation programs as needed. For family members resistant to not smoking, emphasize the need to avoid smoking inside the home.
- Instruct the client in effective coughing techniques such as controlled coughing or "huff" coughing (see *Client Teaching: Forced Expiratory Technique (Huff Coughing)* in the *Implementing* section).
- Discuss the significance of changes in sputum, including the amount and characteristics such as color, viscosity, and odor. Instruct the client when to contact a health care provider.
- Teach the client to maintain a fluid intake of 2,500 to 3,000 mL (2.5 to 3 qt) per day if not contraindicated due to other health conditions such as heart failure or renal disease.
- Instruct the client of the rationale for using and how to use nebulizers or inhalers if prescribed; see Chapter 35 , pages 820–823.
- Teach the client and family how to use home oxygen delivery systems emphasizing safety considerations.

PROMOTING EFFECTIVE BREATHING

- Teach relaxation techniques such as progressive muscle relaxation, meditation, and visualization. Use DVDs as needed.
- Help the client identify specific factors that affect breathing such as stress, exposure to allergens or air pollution, and exposure to cold. Assist with identifying possible interventions and measures to avoid these factors.

MEDICATIONS

- Teach the client about prescribed medications, including the rationale for the medications, the dose, the desired and possible adverse effects, and any precautions about using a medication with food, beverages, or other medications.

SPECIFIC MEASURES FOR OXYGENATION PROBLEMS

- Provide instructions and rationale for specific procedures and problems such as:
 - a. Suctioning oropharyngeal and nasopharyngeal cavities
 - b. Caring for a temporary or permanent tracheostomy
 - c. Preventing the spread of tuberculosis and other respiratory infections to family members and others.

REFERRALS

- Make appropriate referrals to home health agencies or community social services for assistance in obtaining medical and assistive equipment such as grab bars, respiratory and physical therapy services, and home health or housekeeping services to assist with ADLs.

COMMUNITY AGENCIES AND OTHER SOURCES OF HELP

- Provide information about where durable medical equipment can be purchased, rented, or obtained free of charge; how to access home oxygen equipment and support services and physical and occupational therapy services; and where to obtain supplies such as tracheostomy supplies or nutritional supplements.
- Suggest additional sources of information such as the American Lung Association and the Asthma and Allergy Foundation of America.

and coughing, postural drainage, and percussion and vibration. Nursing strategies to facilitate the diffusion of gases through the alveolar membrane include encouraging coughing, deep breathing, and suitable activity. A client's nursing care plan should also include appropriate dependent nursing interventions such as oxygen therapy, tracheostomy care, and maintenance of a chest tube.

Promoting Oxygenation

Most people in good health give little thought to their respiratory function. Changing position frequently, ambulating, and exercising usually maintain adequate ventilation and gas exchange.

Client Teaching lists other ways to promote healthy breathing.

When people become ill, however, their respiratory functions may be inhibited for such reasons as pain and immobility. Shallow respirations inhibit both diaphragmatic excursion and lung distensibility. The result of inadequate chest expansion is pooling of respiratory secretions, which ultimately harbor microorganisms and promote infection. Additionally, shallow respirations may potentiate alveolar collapse, which may cause decreased diffusion of gases and subsequent hypoxemia. This situation is often compounded by giving narcotics for pain, because narcotics further depress the rate and depth of respiration.

Interventions by the nurse to maintain the normal respirations of clients include:

- Positioning the client to allow for maximum chest expansion
- Encouraging or providing frequent changes in position
- Encouraging deep breathing and coughing
- Encouraging ambulation
- Implementing measures that promote comfort, such as giving pain medications.

The semi-Fowler's or high-Fowler's position allows maximum chest expansion in clients who are confined to bed, particularly those with dyspnea. The nurse also encourages clients to turn from side to side frequently, so that alternate sides of the chest are permitted maximum expansion. Clients with severe pneumonia or other pulmonary disease in one lung, if positioned laterally, should be generally positioned with the "good lung down" to improve diffusion of oxygen to the blood from functioning alveoli. Dyspneic clients often sit in bed and lean over their overbed tables (which are raised to a suitable height), usually with a pillow for support. This orthopneic position is an adaptation of the high-Fowler's position. Some clients also sit upright

CLIENT TEACHING

Promoting Healthy Breathing

- Sit straight and stand erect to permit full lung expansion.
- Exercise regularly.
- Breathe through the nose.
- Breathe in to expand the chest fully.
- Do not smoke cigarettes, cigars, or pipes.
- Eliminate or reduce the use of household pesticides and irritating chemical substances.
- Do not incinerate garbage in the house.
- Avoid exposure to secondhand smoke.
- Use building materials that do not emit vapors.
- Make sure furnaces, ovens, and wood stoves are correctly ventilated.
- Support a pollution-free environment.

and lean on their arms or elbows, which is called the tripod position. The advantage to these positions is that each one forces the diaphragm down and forward and stabilizes the chest, which reduces the work of breathing. Also, a client in the orthopneic position can press the lower part of the chest against the table to help in exhaling (Figure 50–4 ■).

Deep Breathing and Coughing

The nurse can facilitate respiratory functioning by encouraging deep-breathing exercises and coughing to remove secretions from the airways. When coughing raises secretions high enough, the client may either **expectorate** (spit out) or swallow them. Swallowing the secretions is not harmful but does not allow the nurse to view the secretions for documentation purposes or to obtain a specimen for testing.

Clients with conditions that increase secretions or impair mobilization of secretions such as chest surgery, COPD, or cystic fibrosis often require encouragement to cough and breathe deeply. Specialized breathing exercises may be prescribed for clients with chronic obstructive diseases as part of their pulmonary rehabilitation. These generally require collaboration with other health care providers. One technique, pursed-lip breathing, may help alleviate dyspnea (Fachiano, Snyder, & Núñez, 2011). The client is taught to breathe in normally through the nose and exhale through pursed lips as if about to whistle, and blow slowly and purposefully, tightening the abdominal muscles to assist with exhalation. Clients may practice by slowly blowing a ping-pong ball across a table or visualizing that they are trying to make a candle flame waver.

Normal forceful coughing is highly effective, but some clients may lack the strength or ability to cough normally. Normal forceful coughing involves the client inhaling deeply and then coughing twice while exhaling. Alternative cough techniques such as forced expiratory technique, or huff coughing, may be taught as alternatives for those clients who are unable to perform a normal forceful cough. A client with a pulmonary condition (e.g., COPD) is instructed to exhale through pursed lips and to exhale with a "huff" sound in mid-exhalation. The huff cough helps prevent the high expiratory pressures that collapse diseased airways. This cough technique is described in Client Teaching.

Hydration

Adequate hydration maintains the moisture of the respiratory mucous membranes. Normally, respiratory tract secretions are thin and are therefore moved readily by ciliary action. However, when the client is dehydrated or when the environment has a low humidity, the respiratory secretions can become thick and tenacious. Fluid intake should be as great as the client can tolerate. See Chapter 52 ∞ for normal daily fluid intake.

Humidifiers are devices that add water vapor to inspired air. Room humidifiers provide cool mist to room air. Nebulizers are used to deliver humidity and medications. They may be used with oxygen delivery systems to provide moistened air directly to the client. Their purposes are to prevent mucous membranes from drying and becoming irritated and to loosen secretions for easier expectoration.

Medications

A number of types of medications can be used for clients with oxygenation problems.

Bronchodilators, anti-inflammatory drugs, expectorants, and cough suppressants are some medications that may be used to treat

Figure 50-4 ■ Two sitting “tripod” positions that help assist with breathing.

CLIENT TEACHING

Forced Expiratory Technique (Huff Coughing)

- After using a bronchodilator treatment (if prescribed), inhale deeply and hold your breath for a few seconds.
- Cough twice while exhaling. The first cough loosens the mucus; the second expels secretions.
- For huff coughing, lean forward and exhale sharply with a “huff” sound mid-exhalation. This technique helps keep your airways open while moving secretions up and out of the lungs.
- Inhale by taking rapid short breaths in succession (“sniffing”) to prevent mucus from moving back into smaller airways.
- Rest and breathe slowly between coughs.
- Try to avoid prolonged episodes of coughing because these may cause fatigue and hypoxia.

respiratory problems. Bronchodilators, including sympathomimetic drugs and xanthines, reduce bronchospasm, opening tight or congested airways and facilitating ventilation. These drugs may be administered orally or intravenously, but the preferred route is by inhalation to prevent many systemic side effects.

Because drugs used to dilate the bronchioles and improve breathing are usually drugs that enhance the sympathetic nervous

system, clients must be monitored for side effects of increased heart rate, blood pressure, anxiety, and restlessness. This is especially important in older adults, who may also have cardiac problems. Some over-the-counter drugs for respiratory problems have these same effects, so clients should be cautioned about taking them without checking with their primary care provider.

Another class of drugs used is the *anti-inflammatory drugs*, such as glucocorticoids. They can be given orally, intravenously, or by inhaler. They work by decreasing the edema and inflammation in the airways and allowing a better air exchange. If both bronchodilators and anti-inflammatory drugs are ordered by inhaler, the client should be instructed to use the bronchodilator inhaler first and then the anti-inflammatory inhaler. If the bronchioles are dilated first, more tissue is exposed on which the anti-inflammatory drugs can act. Newer formulations may combine a long-acting bronchodilator with an inhaled corticosteroid to improve client adherence to therapy because they require less time and less frequent dosing.

Another class of drugs is the *leukotriene modifiers*. These medications suppress the effects of leukotrienes on the smooth muscle of the respiratory tract. Leukotrienes cause bronchoconstriction, mucous production, and edema of the respiratory tract.

Expectorants help “break up” mucus, making it more liquid and easier to expectorate. Guaifenesin is a common expectorant found

A

B

Figure 50-5 ■ A, Flow-oriented SMI; B, volume-oriented SMI.

in many prescription and nonprescription cough syrups. When frequent or prolonged coughing interrupts sleep, a cough suppressant such as codeine may be prescribed.

Other medications can be used to improve oxygenation by improving cardiovascular function. The *digitalis glycosides* act directly on the heart to improve the strength of contraction and slow the heart rate. *Beta-adrenergic stimulating agents* such as dobutamine similarly increase cardiac output, thus improving O₂ transport. *Beta-adrenergic blocking agents* such as propranolol affect the sympathetic nervous system to reduce the workload of the heart. These drugs, however, can negatively affect people with asthma or COPD because they may constrict airways by blocking beta-2 adrenergic receptors.

Incentive Spirometry

Incentive spirometers (Figure 50-5 ■), also referred to as *sustained maximal inspiration devices (SMIs)*, measure the flow of air inhaled through the mouthpiece and are used to:

- Improve pulmonary ventilation.
- Counteract the effects of anesthesia or hypoventilation.
- Loosen respiratory secretions.
- Facilitate respiratory gaseous exchange.
- Expand collapsed alveoli.

SMIs are designed to mimic natural sighing or yawning by encouraging the client to take long, slow, deep breaths. The two general types

Evidence-Based Practice Can Breathing Exercises Have Beneficial Effects on Dyspnea, Exercise Capacity, and Health-Related Quality of Life for Clients with COPD?

EVIDENCE-BASED PRACTICE

Some studies have reported positive short-term physiological effects (e.g., improvement in gas exchange and ventilation) of breathing exercises in people with COPD; however, their effects on dyspnea, exercise capacity, and well-being are unclear. Holland, Hill, Jones, and McDonald (2012) conducted a review of literature to determine whether breathing exercises designed to retrain the breathing pattern could reduce dyspnea, increase exercise capacity, and improve well-being for people with COPD. They identified research trials using the Cochrane Airways Group Specialized Register of trials. The search resulted in a total of 16 randomized controlled trials (RCTs) that compared breathing exercises to no breathing exercises or another intervention in clients with COPD. The studies were conducted and published between 1965 and 2012, with 13 of the studies published since 2000. The size of the studies varied from 21 to 324 participants with a total of 1,233 participants, most of whom had severe COPD. The breathing techniques used in the research studies included pursed-lip breathing, diaphragmatic breathing, pranayama yoga breathing, changing the breathing pattern using computerized

feedback to slow the respiratory rate and increase exhalation time, or combinations of these techniques.

The authors concluded that breathing exercises appeared to be safe for people with COPD. Yoga breathing, pursed-lip breathing, and diaphragmatic breathing improved the distance walked in 6 minutes. They found that the effects of breathing exercises on dyspnea and well-being were variable. The authors noted that the “study quality was generally low” and recommended the need for additional rigorously designed RCTs to evaluate breathing exercises in people with COPD.

IMPLICATIONS

The authors state that there is currently no evidence to suggest that breathing exercises have benefits exceeding those delivered through the whole-body exercise training involved in pulmonary rehabilitation. Individuals with COPD who do not want to go through pulmonary rehabilitation or who do not have access to a pulmonary rehabilitation program may choose to perform breathing exercises.

DRUG CAPSULE

Sympathomimetics albuterol (Proventil, Ventolin)**CLIENT WITH RESPIRATORY MEDICATIONS THAT CAUSE BRONCHODILATION BY STIMULATING BETA-2 ADRENERGIC RECEPTORS IN THE LUNG**

The beta-2 adrenergic agonists are called sympathomimetic drugs because they “mimic” the action of sympathetic stimulation to the beta-2 receptors in the smooth muscle of the lung. At therapeutic levels these drugs promote bronchodilation and so relieve bronchospasm.

Sympathomimetic agents are useful in the treatment of bronchospasm in reversible obstructive airway diseases such as asthma and bronchitis. They are also useful in preventing exercise-induced bronchospasm.

Drugs that block the parasympathetic nervous system (anticholinergics) such as ipratropium (Atrovent) may be used alone or in combination (Combivent) with sympathomimetic agents to provide additional bronchodilation.

NURSING RESPONSIBILITIES

- Most inhaled sympathomimetics have a very rapid onset and short duration of action, so they are useful for relief of acute attacks but not for prophylaxis.
- Monitor the client’s respiratory status while administering sympathomimetics. This includes respiratory rate, lung sounds, oxygen saturation, and subjective symptoms.

- These medications should be used with caution in clients with conditions such as cardiac disease, vascular disease, hypertension, hyperthyroidism, and pregnancy.
- Monitor the client for common side effects including increased heart rate (due to sympathetic stimulation of the heart) and tremors.
- Monitor for other side effects that occur with excessive dosing, which may include CNS stimulation, gastrointestinal upset, hypertension, and sweating.

CLIENT AND FAMILY TEACHING

- Caution the client to use the least amount of medication needed to get relief for the shortest time period necessary. This will help prevent adverse effects.
- Counsel the client to report immediately any chest pain and/or changes in heart rate or rhythm.
- Teach the client and/or family how to use the delivery system. This will most often be a metered-dose inhaler (MDI) or dry powder inhaler (DPI) or nebulizer.
- Teach the client to record the frequency and intensity of symptoms.

Note: Prior to administering any medication, review all aspects with a current drug handbook or other reliable source.

DRUG CAPSULE

Glucocorticosteroids Inhaled: fluticasone (Flovent)**CLIENT WITH RESPIRATORY MEDICATIONS THAT SUPPRESS INFLAMMATION**

Glucocorticosteroids are administered to clients with oxygenation problems to suppress inflammation. They can be administered either by inhalation, orally, or intravenously. The route of administration depends on the severity of the client’s disorder and the individual’s response. Glucocorticosteroids (steroids) are well absorbed from the respiratory tract so giving them by inhalation is often effective. Steroids suppress the inflammatory response in the airways by decreasing synthesis and release of inflammatory mediators, decreasing activity of inflammatory cells, and decreasing edema.

NURSING RESPONSIBILITIES

- Glucocorticosteroids are intended for preventive therapy. They will not be useful in an acute attack.
- If the client is also taking a sympathomimetic medication, delivery of inhaled corticosteroids (ICS) to the respiratory tract may be enhanced by administering the sympathomimetic first (and waiting 3 to 5 minutes).
- It is important to monitor the client’s respiratory status while administering steroids. This includes respiratory rate, lung sounds, oxygen saturation, and subjective symptoms.
- These medications should be used with caution or not at all in clients with conditions such as allergy, pregnancy, lactation, and systemic infections.

- Monitor the client for side effects of the medications. Most commonly this could be an increase in heart rate (due to sympathetic stimulation of the heart) and tremors.
- The client should be monitored for other side effects, which will usually only occur with excessive dosing and may include CNS stimulation, gastrointestinal upset, hypertension, and sweating.

CLIENT AND FAMILY TEACHING

- Caution the client to use the least amount needed to get relief for the shortest time period necessary. This will help prevent adverse effects. Alternate-day therapy may be recommended to decrease adrenal suppression.
- Make sure the client understands that these drugs are *not* for acute attacks. They are intended to be preventive therapy.
- Teach the client and/or family how to use the delivery system. This will most often be a metered-dose inhaler (MDI) or dry powder inhaler (DPI) or nebulizer.
- Counsel the client to rinse the mouth after using ICS to decrease the risk of oropharyngeal or esophageal fungal infections (thrush).
- Counsel the client to report adverse effects such as sore throat, hoarseness, and pharyngeal and laryngeal fungal infections.
- Teach the client to record the frequency and intensity of symptoms.

Note: Prior to administering any medication, review all aspects with a current drug handbook or other reliable source.

CLIENT TEACHING

Using Cough Medications

- Do not take cough medications in excessive amounts because of adverse side effects.
- If you have diabetes mellitus, avoid cough syrups that contain sugar or alcohol; these can disturb metabolism.
- When a cough medicine does not act as expected, consult a health care professional.
- Be aware of side effects (e.g., drowsiness) that can make the operation of machinery dangerous.

of spirometers are the flow-oriented spirometer and the volume-oriented spirometer.

The flow-oriented spirometer consists of one or more clear plastic chambers containing freely movable colored balls or disks. The ball or disks are elevated as the client inhales. The longer the inspiratory flow is maintained, the larger the volume, so the client is encouraged to take slow deep breaths. This type of spirometer does not measure the specific volume of air inhaled.

Volume-oriented spirometers measure the inhalation volume maintained by the client. When the client inhales, a piston-like plate or accordion-pleated cylinder rises as the client inspires, and markings on the side indicate the volume of inspiration achieved by the client.

When using an SMI, the client should be assisted into a position, preferably an upright sitting position in bed or on a chair, that facilitates maximum ventilation. Client Teaching lists instructions for clients in the use of incentive spirometers.

Percussion, Vibration, and Postural Drainage

Percussion, vibration, and postural drainage (PVD) are performed according to a primary care provider's order by nurses, respiratory therapists, physical therapists, or an interdisciplinary team of these health care team members. Percussion, sometimes called *clapping*, is forceful striking of the skin with cupped hands. Mechanical percussion cups and vibrators are also available. When the hands are used, the fingers and thumb are held together and flexed slightly to form a cup, as one would to scoop up water. Percussion over congested lung areas can mechanically dislodge tenacious secretions from the bronchial walls. Cupped hands trap the air against the

Figure 50-6 ■ Percussing the upper posterior chest.

chest. The trapped air then sets up vibrations through the chest wall to the secretions.

To percuss a client's chest, follow these steps:

- Cover the area with a towel or gown to reduce discomfort.
- Ask the client to breathe slowly and deeply to promote relaxation.
- Alternately flex and extend the wrists rapidly to slap the chest (Figure 50-6 ■).
- Percuss each affected lung segment for 1 to 2 minutes.

When done correctly, the percussion action should produce a hollow, popping sound. Percussion is avoided over the breasts, sternum, spinal column, and kidneys.

Vibration is a series of vigorous quiverings produced by hands that are placed flat against the client's chest wall. Vibration is used after percussion to increase the turbulence of the exhaled air and thus loosen thick secretions. It is often done alternately with percussion.

To vibrate the client's chest, the nurse follows these steps:

- Place hands, palms down, on the chest area to be drained, one hand over the other with the fingers together and extended (Figure 50-7 ■). Alternatively, the hands may be placed side by side.
- Ask the client to inhale deeply and exhale slowly through the nose or pursed lips.

Figure 50-7 ■ Vibrating the upper posterior chest.

CLIENT TEACHING

Using an Incentive Spirometer

- Hold or place the spirometer in an upright position. A tilted *flow-oriented* device requires less effort to raise the balls or disks; a *volume-oriented* device will not function correctly unless upright.
- Exhale normally.
- Seal the lips tightly around the mouthpiece.
- Take in a slow, deep breath to elevate the balls or cylinder, and then hold the breath for 2 seconds initially, increasing to 6 seconds (optimum), to keep the balls or cylinder elevated if possible.
- For a flow-oriented device, avoid brisk, low-volume breaths that snap the balls to the top of the chamber. Greater lung expansion is achieved with a very slow inspiration than with a brisk, shallow breath, even though it may not elevate the balls or keep them elevated while you hold your breath. Sustained elevation of the balls or cylinder ensures adequate ventilation of the alveoli (lung air sacs).
- If you have difficulty breathing only through the mouth, a nose clip can be used.
- Remove the mouthpiece and exhale normally.
- Cough after the incentive effort. Deep ventilation may loosen secretions, and coughing can facilitate their removal.
- Relax and take several normal breaths before using the spirometer again.
- Repeat the procedure several times and then four or five times hourly. Practice increases inspiratory volume, maintains alveolar ventilation, and prevents atelectasis (collapse of the air sacs).
- Clean the mouthpiece with water and shake it dry.

- During the exhalation, tense all the hand and arm muscles, and using mostly the heel of the hand, vibrate (shake) the hands, moving them downward. Stop the vibrating when the client inhales.
- Vibrate during five exhalations over one affected lung segment.
- After each vibration, encourage the client to cough and expectorate secretions into the sputum container.

Postural drainage is the drainage by gravity of secretions from various lung segments. Secretions that remain in the lungs or respiratory airways promote bacterial growth and subsequent infection. They also can obstruct the smaller airways and cause atelectasis. Secretions in the major airways, such as the trachea and the right and left main bronchi, are usually coughed into the pharynx, where they can be expectorated, swallowed, or effectively removed by suctioning.

A wide variety of positions is necessary to drain all segments of the lungs, but not all positions are required for every client. Only those positions that drain specific affected areas are used. The lower lobes require drainage most frequently because the upper lobes drain by gravity. Before postural drainage, the client may be given a bronchodilator medication or nebulization therapy to loosen secretions. Postural drainage treatments are scheduled two or three times daily, depending on the degree of lung congestion. The best times include before breakfast, before lunch, in the late afternoon, and before bedtime. It is best to avoid hours shortly after meals because postural drainage at these times can be tiring and can induce vomiting.

The nurse needs to evaluate the client's tolerance of postural drainage by assessing the stability of the client's vital signs, particularly the pulse and respiratory rates, and by noting signs of intolerance, such as pallor, diaphoresis, dyspnea, nausea, and fatigue. Some clients do not react well to certain drainage positions, and the nurse must make appropriate adjustments. For example, some become dyspneic in Trendelenburg's position and require only a moderate tilt or a shorter time in that position.

The sequence for PVD is usually as follows: positioning, percussion, vibration, and removal of secretions by coughing or suction. Each position is usually assumed for 10 to 15 minutes, although beginning treatments may start with shorter times and gradually increase.

Following PVD, the nurse should auscultate the client's lungs, compare the findings to the baseline data, and document the amount, color, and character of expectorated secretions.

Today, kinetic therapy beds with modalities such as vibration and percussion therapy are widely available. These beds provide continuous lateral rotational therapy (CLRT) along with vibration and percussion modules that are programmed to perform for a specific amount of time.

Mucus Clearance Devices

A **mucus clearance device (MCD)** is used for clients with excessive secretions such as cystic fibrosis, COPD, and bronchiectasis (Wang, Zhang, & Li, 2010). The Flutter™ mucus clearance device is an example of one of these devices. The Flutter MCD is a small, handheld device with a hard plastic mouthpiece at one end and a perforated cover at the other end. Inside the device is a steel ball that sits in a circular cone shape (Figure 50–8 ■). The client inhales slowly and then, keeping the cheeks firm, exhales fast through the device, causing the steel ball to move up and down. This movement causes vibrations that loosen mucus from the airways and assist its movement up the airways to be expectorated.

Figure 50–8 ■ Flutter mucus clearance device.

Oxygen Therapy

The medical administration of supplemental oxygen is considered to be a process similar to that of administering medications and requires similar nursing actions. Determining the effectiveness of oxygen therapy involves several measures, including checking vital signs and peripheral blood oxygen saturation (pulse oximetry). Supplemental oxygen is indicated for clients who have hypoxemia due to the reduced ability for diffusion of oxygen through the respiratory membrane, hyperventilation, or substantial loss of lung tissue due to tumors or surgery. Others who may require oxygen are those with severe anemia or blood loss, or similar conditions in which there are inadequate numbers of RBCs or hemoglobin to carry the oxygen.

Oxygen therapy is prescribed by the primary care provider, who specifies the concentration, method of delivery, and depending on the method, liter flow per minute (L/min). The order may also call for the nurse to titrate the oxygen to achieve a desired saturation level as measured by pulse oximetry. When administering oxygen as an *emergency measure*, the nurse may initiate the therapy, and then contact the primary care provider for an order.

Oxygen is supplied in two ways in health care facilities: by portable systems (cylinders or tanks) and from wall outlets. Long-term care or assisted living facilities may use similar oxygen supplies or those used more commonly in the home.

Clients who require oxygen therapy in the home may use small cylinders of oxygen, oxygen in liquid form, or an oxygen concentrator. Portable oxygen delivery systems are available to increase the client's independence. Home oxygen therapy services are readily available in most communities. These services generally supply the oxygen and delivery devices, training for the client and family, equipment maintenance, and emergency services should a problem occur.

Oxygen administered from a cylinder or wall-outlet system is dry. Dry gases dehydrate the respiratory mucous membranes. Humidifying devices that add water vapor to inspired air are thus an essential adjunct of oxygen therapy, particularly for liter flows over 4 L/min (Figure 50–9 ■). These devices provide 20% to 40%

humidity. A humidifier bottle is attached below the flow meter gauge so that the oxygen passes through water and then through the specific oxygen tubing and equipment prescribed for the client (e.g., nasal cannula or mask).

Humidifiers prevent mucous membranes from drying and becoming irritated and loosen secretions for easier expectoration. Oxygen passing through water picks up water vapor before it reaches the client. The more bubbles created during this process, the more water vapor is produced. Very low liter flows (e.g., 1 to 2 L/min by nasal cannula) do not require humidification. When a client is breathing very low flow oxygen, enough atmospheric air is inhaled (which naturally has water vapor in it) to prevent mucosal drying.

Oxygen cylinders need to be handled and stored with caution and strapped securely in wheeled transport devices or stands to prevent possible falls and outlet breakages. They should be placed away from traffic areas and heaters.

A regulator that releases oxygen at a safe level and at a desirable rate must be attached before the oxygen supply is used. On a cylinder, the contents gauge indicates the pressure or amount of oxygen remaining in the tank and the flow meter or flow indicator indicates the gas flow in liters per minute. A flow meter is also required for wall-outlet systems.

To use an oxygen wall-outlet system, carry out these steps:

- Attach the flow meter to the wall outlet, exerting firm pressure. The flow meter should be in the off position (Figure 50–10 ■).

Figure 50–9 ■ An oxygen humidifier attached to a wall outlet oxygen flow meter.

- Fill the humidifier bottle with distilled or tap water in accordance with agency protocol. This can be done before coming to the bedside. Some humidifier bottles come prefilled by the manufacturer.
- Attach the humidifier bottle to the base of the flow meter (if indicated).
- Attach the prescribed oxygen tubing and delivery device to the humidifier.
- Regulate the flow meter to the prescribed level. The line for the prescribed flow rate (e.g., 2 L/min) should be in the middle of the ball of the flow meter (Figure 50–11 ■).

Safety precautions are essential during oxygen therapy (Box 50–2). Although oxygen by itself will not burn or explode, it does facilitate combustion. For example, a bed sheet ordinarily burns slowly when ignited in the atmosphere; however, if saturated with free-flowing oxygen and ignited by a spark, it will burn rapidly and explosively. The greater the concentration of oxygen, the more rapidly fires start and burn, and such fires are difficult to extinguish. Because oxygen is colorless, odorless, and tasteless, people are often unaware of its presence. It is important to teach clients about this aspect of oxygen therapy.

Figure 50–10 ■ Insert flow meter into the wall unit.

Figure 50–11 ■ This flow meter is set to deliver 2 L/min.

BOX 50-2 Oxygen Therapy Safety Precautions

- For home oxygen use or when the facility permits smoking, teach family members and roommates to smoke only outside or in provided smoking rooms away from the client and oxygen equipment.
- Place cautionary signs reading “No Smoking: Oxygen in Use” on the client’s door, at the foot or head of the bed, and on the oxygen equipment.
- Instruct the client and visitors about the hazard of smoking with oxygen in use.
- Make sure that electric devices (such as razors, hearing aids, radios, televisions, and heating pads) are in good working order to prevent the occurrence of short-circuit sparks.
- Avoid materials that generate static electricity, such as woolen blankets and synthetic fabrics. Cotton blankets should be used, and clients and caregivers should be advised to wear cotton fabrics.
- Avoid the use of volatile, flammable materials, such as oils, greases, alcohol, ether, and acetone (e.g., nail polish remover), near clients receiving oxygen.
- Be sure that electric monitoring equipment, suction machines, and portable diagnostic machines are all electrically grounded.
- Make known the location of fire extinguishers, and make sure personnel are trained in their use.

Like any medication, oxygen is not completely harmless to the client. Clients can receive an inadequate amount or an excessive amount of oxygen and both can lead to a decline in the client’s condition. An inadequate amount of oxygen (hypoxia) will lead to cell death, and if left untreated can ultimately lead to death. Excessive amounts of oxygen can lead to pulmonary tissue damage, increased duration of mechanical ventilation, and longer ICU and hospital stays (Blakeman, 2013; Kallet, 2012; Martin & Grocott, 2013). Oxygen toxicity can develop from breathing greater than 50% oxygen for 12 hours (Kallet, 2012). The lowest concentration needed to achieve the desired blood oxygen saturation (e.g., greater than 90% or a level prescribed by the primary care provider) should be used.

Oxygen Delivery Systems

Low-flow and high-flow systems are available to deliver oxygen to the client. The choice of system depends on the client’s oxygen needs, comfort, and developmental considerations. Low-flow systems deliver oxygen via small-bore tubing. Low-flow administration devices include nasal cannulas, face masks, oxygen tents, and transtracheal catheters. Because with these types of devices room air is also inhaled along with the supplemental oxygen, the fraction of inspired oxygen (FiO_2) will vary depending on the respiratory rate, tidal volume, and liter flow.

High-flow systems supply all the oxygen required during ventilation in precise amounts, regardless of the client’s respirations. The high-flow system used to deliver a precise and consistent FiO_2 is the Venturi mask with large-bore tubing.

Cannula

The nasal cannula (nasal prongs) is the most common and inexpensive device used to administer oxygen (Figure 50–12 ■). The nasal cannula is easy to apply and does not interfere with the client’s ability to eat or talk. It also is relatively comfortable, permits some freedom of movement, and is well tolerated by the client. It delivers a relatively low concentration of oxygen (24% to 45%) at flow rates of 2 to 6 L/min. Above 6 L/min, the client tends to swallow air and the FiO_2 is not increased. Limitations of the plain nasal cannula include inability to deliver higher concentrations of oxygen, and that it can be drying and irritating to mucous membranes.

Reservoir nasal cannulas are oxygen-conserving devices and are also called Oxymizer oxygen-conserving devices. They are used primarily in the home setting. The reservoir nasal cannula stores oxygen in the reservoir while the client breathes out and then delivers a 100% oxygen bolus when the client breathes in. As a result it delivers a higher oxygen concentration at a lower flow rate than the plain nasal cannula because it conserves oxygen. It can deliver FiO_2 of 0.5 or greater, while providing the same benefits of a plain nasal cannula. The two styles of reservoir nasal cannulas (Oxymizers) are the mustache and pendant styles (see Figure 50–12 B and C). Humidification is not necessary with the reservoir nasal cannula, because it collects

Figure 50–12 ■ A, Nasal cannula; B, mustache reservoir nasal cannula; C, pendant reservoir nasal cannula.

water vapor while the client breathes out and returns it when the client breathes in.

Administering oxygen by cannula is detailed in Skill 50–1.

Face Mask

Face masks that cover the client's nose and mouth may be used for oxygen inhalation. Most masks are made of clear, pliable plastic that can be molded to fit the face. They are held to the client's head with elastic bands. Some have a metal clip that can be bent over the bridge of the nose for a snug fit. Exhalation ports on the sides of the mask allow exhaled carbon dioxide to escape.

Some masks have reservoir bags, which provide higher oxygen concentrations to the client. A portion of the client's expired air is directed into the bag. Because this air comes from the upper respiratory passages (e.g., the trachea and bronchi), where it does not take part in gaseous exchange, its oxygen concentration remains the same as that of inspired air.

A variety of oxygen masks are marketed:

- The simple face mask delivers oxygen concentrations from 40% to 60% at liter flows of 5 to 8 L/min, respectively (Figure 50–13 A ■).
- The partial rebreather mask delivers oxygen concentrations of 40% to 60% at liter flows of 6 to 10 L/min, respectively. The

oxygen reservoir bag that is attached allows the client to rebreathe about the first third of the exhaled air in conjunction with oxygen (Figure 50–13 B). Thus, it increases the FiO_2 by recycling expired oxygen. The partial rebreather bag must not totally deflate during inspiration to avoid carbon dioxide buildup. If this problem occurs, the nurse increases the liter flow of oxygen so that the bag remains one third to one half full.

- The nonrebreather mask delivers the highest oxygen concentration possible—95% to 100%—by means other than intubation or mechanical ventilation, at liter flows of 10 to 15 L/min. One-way valves on the mask and between the reservoir bag and the mask prevent the room air and the client's exhaled air from entering the bag so only the oxygen in the bag is inspired (Figure 50–13 C). In some cases, one of the side valves is removed so that the client can still inhale room air if the oxygen supply is accidentally cut off. To prevent carbon dioxide buildup, the nonrebreather bag must not totally deflate during inspiration. If it does, the nurse can correct this problem by increasing the liter flow of oxygen.

A

B

C

D

Figure 50–13 ■ A, A simple face mask; B, a partial rebreather mask; C, a nonrebreather mask D, a Venturi mask.

- The Venturi mask delivers oxygen concentrations varying from 24% to 40% or 50% at liter flows of 4 to 10 L/min (Figure 50–13 D). The Venturi mask has wide-bore tubing and color-coded jet adapters that correspond to a precise oxygen concentration and liter flow. For example, in some cases, a blue adapter delivers a 24% concentration of oxygen at 4 L/min, and a green adapter delivers a 35% concentration of oxygen at 8 L/min. However, colors and concentrations may vary by manufacturers so the equipment must be examined carefully. Other manufacturers use a dial or setting for the desired concentration. Turning the oxygen source flow rate higher than specified by the equipment manufacturer will not increase the concentration delivered to the client.

Initiating oxygen by mask is much the same as initiating oxygen by cannula, except that the nurse must find a mask of appropriate size. Smaller sizes are available for children. Administering oxygen by mask or face tent is detailed in Skill 50–1. Limitations of masks include difficulty in achieving a proper fit and poor tolerance by some clients who may complain of feeling hot or “smothering.”

Face Tent

Face tents (Figure 50–14 ■) can replace oxygen masks when masks are poorly tolerated by clients. Face tents provide varying concentrations of oxygen, for example, 30% to 50% concentration of oxygen at 4 to 8 L/min. Frequently inspect the client’s facial skin for dampness or chafing, and dry and treat as needed. As with face masks, the client’s facial skin must be kept dry.

Transtracheal Catheter

A transtracheal catheter is placed through a surgically created tract in the lower neck directly into the trachea. Once the tract has matured (healed), the client removes and cleans the catheter two to four times per day. Oxygen applied to the catheter at greater than 1 L/min should be humidified, and high flow rates, as much as 15 to 20 L/min, can be administered (Figure 50–15 ■).

Noninvasive Positive Pressure Ventilation (NPPV)

In certain circumstances clients require mechanical assistance to maintain adequate breathing. This assistance may be accomplished by the use of **noninvasive positive pressure ventilation (NPPV)**, delivery of air or oxygen under pressure without the need

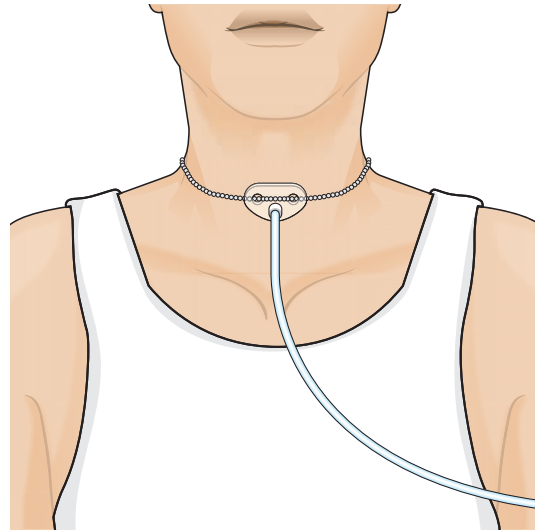

Figure 50–15 ■ Transtracheal catheter.

for an invasive tube such as an endotracheal tube or tracheostomy tube. Conditions requiring noninvasive ventilation include acute and chronic respiratory failure, pulmonary edema, COPD, and obstructive sleep apnea.

This discussion focuses on the use of noninvasive ventilation devices in the treatment of sleep apnea due to the prevalence of this condition. Sleep apnea affects 12 million Americans. When breathing stops (apnea), the person’s carbon dioxide level rises, breathing is stimulated, and then it resumes. There are varying types of sleep apnea but obstructive sleep apnea (OSA) is the most common. Risk factors include male gender, obesity, and age over 40; however, it can affect anyone at any age, including children. OSA can lead to a number of health problems including hypertension, fatigue, memory problems, other cardiovascular disease, and headaches. If an underlying cause can be treated, OSA may be reduced or eliminated.

The most common and least invasive treatment for OSA is positive pressure ventilation. A mask fitted over the client’s nose during sleep provides air under pressure during inhalation and exhalation so that the airway is kept open and cannot collapse. This mask and pump system is called continuous positive airway pressure (CPAP) (Figure 50–16 ■). A variation of CPAP is bilevel positive airway

Figure 50–14 ■ An oxygen face tent.

Figure 50–16 ■ A CPAP machine in use in the client’s home. Custom Medical Stock Photo, Inc.

pressure (BiPap) in which the pressure delivered during exhalation is less than the pressure delivered during inhalation.

The nurse's primary role in caring for clients using CPAP or BiPAP devices is to ensure optimal functioning and use of the device since it may need to be used nightly for the remainder

of their lives. There may be significant issues with adherence to CPAP therapy due to discomfort or other barriers, so the nurse should provide client education and support and also collaborate with the respiratory therapist and other involved health care providers.

Administering Oxygen by Cannula, Face Mask, or Face Tent

Before administering oxygen, check (a) the order for oxygen, including the administering device and the liter flow rate (L/min) or the percentage of oxygen; (b) the levels of oxygen (PaO₂) and carbon dioxide (PaCO₂) in the client's arterial blood (PaO₂ is normally 80 to

100 mmHg; PaCO₂ is normally 35 to 45 mmHg); and (c) whether the client has COPD. *Note:* If the client has not had arterial blood gases ordered, oxygen saturation should be checked using a noninvasive oximeter.

PURPOSES

Cannula

- To deliver a relatively low concentration of oxygen when only minimal O₂ support is required
- To allow uninterrupted delivery of oxygen while the client ingests food or fluids

Face Mask

- To provide moderate O₂ support and a higher concentration of oxygen and/or humidity than is provided by cannula
- To provide a high flow of O₂ when attached to a Venturi system

Face Tent

- To provide high humidity
- To provide oxygen when a mask is poorly tolerated

ASSESSMENT

See also Skill 30–11, Assessing the Thorax and Lungs, on pages 556–559.

Assess

- Skin and mucous membrane color: Note whether cyanosis is present, presence of mucus, sputum production, and impedance of airflow.
- Breathing patterns: Note depth of respirations and presence of tachypnea, bradypnea, or orthopnea.
- Chest movements: Note whether there are any intercostal, substernal, suprasternal, supraclavicular, or tracheal retractions during inspiration or expiration.
- Chest wall configuration (e.g., kyphosis, unequal chest expansion, barrel chest).
- Lung sounds audible by auscultating the chest and by ear.
- Presence of clinical signs of hypoxemia: tachycardia, tachypnea, restlessness, dyspnea, cyanosis, and confusion. Tachycardia and tachypnea are often early signs. Confusion is a later sign of severe oxygen deprivation.
- Presence of clinical signs of hypercarbia (hypercapnia): restlessness, hypertension, headache, lethargy, tremor.

- Presence of clinical signs of oxygen toxicity: tracheal irritation and cough, dyspnea, and decreased pulmonary ventilation.

Determine

- Vital signs, especially pulse rate and quality, and respiratory rate, rhythm, and depth.
- Whether the client has COPD. A high carbon dioxide level in the blood is the normal stimulus to breathe. However, people with COPD may have a chronically high carbon dioxide level, and their stimulus to breathe is hypoxemia. During continuous oxygen administration, arterial blood gas levels of oxygen (PaO₂) and carbon dioxide (PaCO₂) are measured periodically to monitor hypoxemia.
- Results of diagnostic studies such as chest x-ray.
- Hemoglobin, hematocrit, and complete blood count.
- Oxygen saturation levels.
- Arterial blood gases levels, if available.
- Pulmonary function tests, if available.

PLANNING

Consult with a respiratory therapist as needed in the beginning and during ongoing care of clients receiving ordered oxygen therapy. In many agencies, the therapist establishes the initial equipment and client teaching.

DELEGATION

Initiating the administration of oxygen is considered similar to administering a medication and is not delegated to unlicensed assistive personnel (UAP). However, reapplying the oxygen delivery device may be performed by the UAP, and many aspects of the client's response to oxygen therapy are observed during usual care and may be recorded by individuals other than the nurse. Abnormal findings must be validated and interpreted by the nurse. The nurse is also responsible for ensuring that the correct delivery method is being used.

INTERPROFESSIONAL PRACTICE

Administering oxygen may be within the scope of practice for specific health care providers. For example, in addition to nurses, respiratory therapists are involved in the care of clients receiving oxygen therapy. Although the respiratory therapist may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

Equipment

Cannula

- Oxygen supply with a flow meter and adapter
- Humidifier with distilled water or tap water according to agency protocol
- Nasal cannula and tubing
- Tape (optional)
- Padding for the elastic band

Administering Oxygen by Cannula, Face Mask, or Face Tent—continued

Face Mask

- Oxygen supply with a flow meter and adapter
- Humidifier with distilled water or tap water according to agency protocol
- Prescribed face mask of the appropriate size
- Padding for the elastic band

IMPLEMENTATION

Preparation

1. Determine the need for oxygen therapy, and verify the order for the therapy.
 - Perform a respiratory assessment to develop baseline data if not already available.
2. Prepare the client and support people.
 - Assist the client to a semi-Fowler's position if possible.

Rationale: *This position permits easier chest expansion and hence easier breathing.*

 - Explain that oxygen is not dangerous when safety precautions are observed. Inform the client and support people about the safety precautions connected with oxygen use.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Discuss how the effects of the oxygen therapy will be used in planning further care or treatments.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy, if appropriate.
4. Set up the oxygen equipment and the humidifier.
 - Attach the flow meter to the wall outlet or tank. The flow meter should be in the off position.
 - If needed, fill the humidifier bottle. (This can be done before coming to the bedside.)
 - Attach the humidifier bottle to the base of the flow meter.
 - Attach the prescribed oxygen tubing and delivery device to the humidifier.
5. Turn on the oxygen at the prescribed rate and ensure proper functioning.
 - Check that the oxygen is flowing freely through the tubing. There should be no kinks in the tubing, and the connections should be airtight. There should be bubbles in the humidifier as the oxygen flows through. You should feel the oxygen at the outlets of the cannula, mask, or tent.
 - Set the oxygen at the flow rate ordered.
6. Apply the appropriate oxygen delivery device.

Cannula

- Put the cannula over the client's face, with the outlet prongs fitting into the nares and the tubing hooked around the ears (see Figure 50-12 A).
- If the cannula will not stay in place, tape it at the sides of the face.
- Pad the tubing and band over the ears and cheekbones as needed.

Face Mask

- Guide the mask toward the client's face, and apply it from the nose downward.

Face Tent

- Oxygen supply with a flow meter and adapter
- Humidifier with distilled water or tap water according to agency protocol
- Face tent of the appropriate size

- Fit the mask to the contours of the client's face (see Figure 50-13 A). **Rationale:** *The mask should mold to the face so that very little oxygen escapes into the eyes or around the cheeks and chin.*
- Secure the elastic band around the client's head so that the mask is comfortable but snug.
- Pad the band behind the ears and over bony prominences. **Rationale:** *Padding will prevent irritation from the mask.*

Face Tent

- Place the tent over the client's face, and secure the ties around the head (see Figure 50-14).
7. Assess the client regularly.
 - Assess the client's vital signs, level of anxiety, color, and ease of respirations, and provide support while the client adjusts to the device. Some clients may complain of claustrophobia.
 - Assess the client in 15 to 30 minutes, depending on the client's condition, and regularly thereafter.
 - Assess the client regularly for clinical signs of hypoxia, tachycardia, confusion, dyspnea, restlessness, and cyanosis. Review oxygen saturation or arterial blood gas results if they are available.

Nasal Cannula

- Assess the client's nares for encrustations and irritation. Apply a water-soluble lubricant as required to soothe the mucous membranes.
- Assess the top of the client's ears for any signs of irritation from the cannula tubing. If present, padding with a gauze pad may help relieve the discomfort.

Face Mask or Tent

- Inspect the facial skin frequently for dampness or chafing, and dry and treat it as needed.
8. Inspect the equipment on a regular basis.
 - Check the liter flow and the level of water in the humidifier in 30 minutes and whenever providing care to the client.
 - Be sure that water is not collecting in dependent loops of the tubing.
 - Make sure that safety precautions are being followed.
 9. Document findings in the client record using forms or checklists supplemented by narrative notes when appropriate.

SAMPLE DOCUMENTATION

9/16/15 0930 Returned from physical therapy with c/o dyspnea. Resp. 26/min, shallow. P-92, BP 160/98, SpO₂ 92%. Skin warm, no cyanosis. Lung sounds clear, no retractions. O₂ per nasal cannula applied @ 2 L/min. _____ P. Isola, RN
 9/16/15 1000 No further c/o of dyspnea. Resp. 20/min, P 88, BP 152/92, SpO₂ 96%. O₂ per nasal cannula continues @ 2 L/min. _____ P. Isola, RN

EVALUATION

- Perform follow-up based on findings that deviated from expected or normal for the client. Relate findings to previous data if available (e.g., check oxygen saturation to evaluate adequate oxygenation).
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Oxygen Delivery Equipment**INFANTS****Oxygen Hood**

- An oxygen hood is a rigid plastic dome that encloses an infant's head. It provides precise oxygen levels and high humidity.
- The gas should not be allowed to blow directly into the infant's face, and the hood should not rub against the infant's neck, chin, or shoulder.

CHILDREN**Oxygen Tent**

- The tent consists of a rectangular, clear, plastic canopy with outlets that connect to an oxygen or compressed air source and to a humidifier that moisturizes the air or oxygen.
- Because the enclosed tent becomes very warm, some type of cooling mechanism is provided to maintain the temperature at 20°C to 21°C (68°F to 70°F).
- Cover the child with a gown or a cotton blanket. Some agencies provide gowns with hoods, or a small towel may be

wrapped around the head. *The child needs protection from chilling and from the dampness and condensation in the tent.*

- Flood the tent with oxygen by setting the flow meter at 15 L/min for about 5 minutes. Then, adjust the flow meter according to orders. *Flooding the tent quickly increases the oxygen to the desired level.*
- The tent can deliver approximately 30% oxygen.
- Children may fight having a mask placed on their faces. They are often fearful when placed in oxygen tents or hoods. These are normal responses that vary based on experience, developmental stage, degree of threat to body image, and attachment/abandonment issues. Providing safe toys and a beloved blanket or pillow to hold can help, as can fostering the parent-child bond even though separated by the plastic. Encourage parents to interact with their child around and through the tubing and tent.

Home Care Considerations Home Care Oxygen Equipment**PATIENT-CENTERED CARE**

Three major oxygen systems for home care use are available in most communities: cylinders or tanks of compressed gas, liquid (cryogenic) oxygen, and oxygen concentrators.

1. **Cylinders ("green tanks"):** These are the system of choice for clients who need oxygen episodically (e.g., on a prn basis). Advantages are that cylinders deliver all liter flows (1 to 15 L/min), and oxygen evaporation does not occur during storage. Disadvantages are that the cylinders are heavy and awkward to move, the supply company must be notified when a refill is needed, and they are costly for the high-use client. A size "D" tank weighs about 8 pounds and stores 425 L of oxygen (Figure 50-17 ■); an "E" tank holds 680 L and is transported on wheels. The large "H" tank weighs 150 pounds. The gauge on a full tank reads a pressure of at least 2,000 pounds per square inch (psi), and a tank is considered empty when it reads less than 500 psi.
2. **Liquid oxygen:** Liquid systems have two parts—a large stationary container and a portable unit with a small lightweight tank that is refilled from the stationary unit. Liquid reservoirs store oxygen at -212°C (-350°F) in a smaller amount of space than compressed gas. Advantages are that these reservoirs are lighter in weight and cleaner in appearance than cylinders and they are not as difficult to operate. Disadvantages of liquid oxygen are that many home care medical supply and service companies are not able to handle it, oxygen evaporation occurs when the unit is not used, only low flows (1 to 4 L/min) can be used or freezing occurs, and the portable unit designed to be carried over the shoulder weighs 8 to 10 pounds, a possible burden to the typical COPD client. A wheeled cart can be used to carry the unit but may be awkward.
3. **Oxygen concentrators:** Concentrators are electrically powered systems that manufacture oxygen from room air. At 1 L/min, such a system can deliver a concentration of about 95% oxygen, but the concentration drops when the flow rate increases (e.g., 75% concentration at 4 L/min). Advantages are that they are more attractive in appearance, resembling furniture rather than medical equipment; they eliminate the need for regular delivery of oxygen or refilling of cylinders; because the supply of oxygen is constant, they alleviate the client's anxiety about running out of oxygen; and they are the most economical system when continuous use is required. Major disadvantages of

Figure 50-17 ■ Using a portable oxygen system at home.
Aaron Haupt/Getty Images

Home Care Considerations Home Care Oxygen Equipment—*continued*

PATIENT-CENTERED CARE

a concentrator are that it is expensive; it lacks real portability (small units weigh 28 pounds); it tends to be noisy; it is powered by electricity (an emergency backup unit, for example, an oxygen tank, must be provided for clients for whom a power failure could be life threatening); and heat produced by the concentrator motor is a problem for those who live in trailers, small houses, or warm climates, where air conditioners are required. The oxygen concentrator must also be checked periodically with an O₂ analyzer to ensure that it is providing an adequate delivery of oxygen.

Another type of oxygen concentrator is the *oxygen enricher*. It uses a plastic membrane that allows water vapor to pass through with the oxygen, thus eliminating the need for a humidifying device. It is also thought to filter out bacteria present in the air. The enricher provides an O₂ concentration of 40% at all flow rates, it tends to be quieter than the concentrator, there is less chance of combustion (since the gas is only 40% oxygen), it has only two moving parts (thus decreasing the risk of

something going wrong), and a nebulizer can be operated off the enricher because of the high flow rate.

Social services or the case manager needs to ensure that the client has appropriate help in choosing a reputable home oxygen vendor. Services furnished should include:

- A 24-hour emergency service
- Trained personnel to make the initial delivery and instruct the client in safe, appropriate use of the oxygen and maintenance of the equipment
- At least monthly follow-up visits to check the equipment and reinstruct the client as necessary
- A regular cost review to ensure that the system is the most cost effective one for that client, with routine notification of the primary care provider or home care professional if it seems that another system is more appropriate.

The nurse needs to also ensure that the client knows about the financial reimbursements available from Medicare and Medicaid or other insurance agencies.

Artificial Airways

Artificial airways are inserted to maintain a patent air passage for clients whose airways have become or may become obstructed. A patent airway is necessary so that air can flow to and from the lungs. Four of the more common types of airways are oropharyngeal, nasopharyngeal, endotracheal, and tracheostomy.

Oropharyngeal and Nasopharyngeal Airways

Oropharyngeal and nasopharyngeal airways are used to keep the upper air passages open when secretions or the tongue may obstruct them (e.g., in a client who is sedated, is semicomatose, or has an altered level of consciousness). These airways are easy to insert and have a low risk of complications. Sizes vary and should be appropriate to the size and age of the client. The nasopharyngeal airway should be well lubricated with water-soluble gel prior to inserting. The oropharyngeal airway may be lubricated with water or saline, if necessary.

Oropharyngeal airways (Figure 50–18 ■) stimulate the gag reflex and are only used for clients with altered levels of consciousness (e.g., because of general anesthesia, overdose, or head injury). To insert the airway:

- Place the client in a supine or semi-Fowler's position.
- Apply clean gloves.
- Hold the lubricated airway by the outer flange, with the distal end pointing up or curved upward.

Figure 50–18 ■ An oropharyngeal airway in place.

- Open the client's mouth and insert the airway along the top of the tongue.
- When the distal end of the airway reaches the soft palate at the back of the mouth, rotate the airway 180 degrees downward, and slip it past the uvula into the oral pharynx.
- If not contraindicated, place the client in a side-lying position or with the head turned to the side to allow secretions to drain out of the mouth.
- The oropharynx may be suctioned as needed by inserting the suction catheter alongside the airway.
- Remove and discard gloves.
- Perform hand hygiene.
- Do not tape the airway in place; remove it when the client begins to cough or gag.
- Provide mouth care at least every 2 to 4 hours, keeping suction available at the bedside.
- As appropriate for the client's condition, remove the airway every 8 hours to assess the mouth and provide oral care. Reinsert the airway immediately.

Nasopharyngeal airways are tolerated better by alert clients. They are inserted through the nares, terminating in the oropharynx (Figure 50–19 ■). When caring for a client with a nasopharyngeal airway, provide frequent oral and nares care, reinserting the airway

Figure 50–19 ■ A nasopharyngeal airway in place.

Figure 50-20 ■ An endotracheal tube (ETT).

in the other naris every 8 hours or as ordered to prevent necrosis of the mucosa.

Endotracheal Tubes

Endotracheal tubes (ETTs) are most commonly inserted in clients who have had general anesthetics or for those in emergency situations where mechanical ventilation is required. An ETT is inserted by an anesthesiologist, primary care provider, certified registered nurse anesthetist (CRNA), or respiratory therapist with specialized education. It is inserted through the mouth or the nose and into the trachea, using a laryngoscope as a guide (Figure 50-20 ■). The tube terminates just superior to (above) the bifurcation of the trachea into the bronchi. The tube may have an air-filled cuff to prevent air leakage around it. Because an ETT passes through the epiglottis and glottis, the client is unable to speak while it is in place. Nursing interventions for clients with ETTs are shown in Box 50-3.

Tracheostomy

Clients who need airway support due to a temporary or permanent condition may have a tracheostomy. A tracheostomy is an opening

Figure 50-21 ■ A tracheostomy tube in place.

into the trachea through the neck. A tube is usually inserted through this opening and an artificial airway is created. A tracheostomy is performed using one of two techniques: the traditional open surgical method or via a percutaneous insertion. The percutaneous method can be done at the bedside in a critical care unit. The open technique is done in an operating room where a surgical incision is made in the trachea just below the larynx. A curved tracheostomy tube is inserted to extend through the stoma into the trachea (Figure 50-21 ■). Tracheostomy tubes are available in different sizes and may be plastic, silicone, or metal, and cuffed, uncuffed, or fenestrated. A fenestrated tracheostomy tube has an opening that allows air to pass through to the vocal cords, thus allowing the client to communicate.

Tracheostomy tubes have an outer cannula that is inserted into the trachea and a flange that rests against the neck. The flange allows the tube to be secured in place with tracheostomy tapes/twill ties or Velcro collars (Figure 50-22 ■). All tubes also have an obturator, which is used to insert the outer cannula and is then removed. The obturator, along with a spare tracheostomy tube of the same size and smaller, is kept at the client's bedside in case the tube becomes dislodged and needs to be reinserted. Some tracheostomy tubes have an

BOX 50-3 Nursing Interventions for Clients with Endotracheal Tubes

- Perform hand hygiene before and after contact with the client. Wear gloves when handling respiratory secretions or objects contaminated with respiratory secretions.
- Assess the client's respiratory status at least every 2 hours, or more frequently if indicated. Include respiratory rate, rhythm, depth, equality of chest excursion, and lung sounds; level of consciousness; oxygen saturation, percentage of oxygen used and by what means (e.g., ventilator); and skin color in your assessment.
- Frequently assess nasal and oral mucosa for redness and irritation. Report any abnormal findings to the primary care provider.
- Secure the endotracheal tube with tape or a commercially prepared holder to prevent movement of the tube farther into or out of the trachea. Assess the position of the tube frequently. Notify the primary care provider immediately if the tube is dislodged out of the airway. If the tube advances into a main bronchus, it will need to be repositioned to ensure ventilation of both lungs.
- Unless contraindicated, elevate the head of the bed 30° to 45°.
- Using sterile technique, suction the endotracheal tube as needed to remove excessive secretions. Perform subglottic suctioning before deflating the cuff of the endotracheal tube or before moving the tube. Wear goggles when performing suctioning.
- Closely monitor cuff pressure, maintaining a pressure of 20 to 25 mmHg (or as recommended by the tube manufacturer) to minimize the risk of tracheal tissue necrosis. If recommended, deflate the cuff periodically.
- Provide oral hygiene and nasal care every 2 to 4 hours. Use an oropharyngeal airway to prevent the client from biting down on an oral endotracheal tube. Move oral endotracheal tubes to the opposite side of the mouth every 8 hours or per agency protocol, taking care to maintain the position of the tube in the trachea. *This prevents irritation to the oral mucosa.*
- Provide humidified air or oxygen because the endotracheal tube bypasses the upper airways, which normally moisten the air.
- If the client is on mechanical ventilation, ensure that all alarms are enabled at all times because the client cannot call for help should an emergency occur.
- Communicate frequently with the client, providing a note pad or picture board for the client to use in communicating.
- Inform the client and family that an endotracheal tube is usually used as a short-term artificial airway. Instruct the client and family not to manipulate the tube and to call for the nurse if the client is uncomfortable.

Figure 50–22 ■ Components of a tracheostomy tube.

inner cannula that is inserted and locked into place inside the outer cannula. The purpose of the inner cannula is to prevent tube obstruction by allowing regular cleaning or replacement. Many plastic inner cannulas are cleaned with a solution of full or half-strength hydrogen peroxide and sterile water. Some facilities, however, recommend using normal saline only. Morris, Whitmer, and McIntosh (2013) note that it is important to check the manufacturer's instructions for cleaning tracheostomy tubes because silicone tubes and metal tubes can be damaged by using hydrogen peroxide (p. 21). The outer cannula of the tracheostomy tube remains in place to maintain a patent airway.

CLINICAL ALERT!

Some inner cannulas are disposable. These cannulas have a different method of attachment than the nondisposable tubes. Also, the different types of disposable tubes are not interchangeable.

Cuffed tracheostomy tubes are surrounded by an inflatable cuff that produces an airtight seal between the tube and the trachea. This seal prevents aspiration of oropharyngeal secretions and air leakage between the tube and the trachea. Cuffed tubes are often used immediately after a tracheostomy and are essential when ventilating a tracheostomy client with a mechanical ventilator. Children do not require cuffed tubes, because their tracheas are resilient enough to seal the air space around the tube.

Low-pressure cuffs (Figure 50–23 ■) are commonly used to distribute a low, even pressure against the trachea, thus decreasing the risk of tracheal tissue necrosis. They do not need to be deflated periodically to reduce pressure on the tracheal wall. Foam cuffed tracheostomy tubes (Figure 50–24 ■) do not require injected air; instead, when the port is opened, ambient air enters the balloon, which then conforms to the client's trachea. Air is removed from the cuff prior to insertion or removal of the tube.

The nurse provides tracheostomy care for the client with a new or recent tracheostomy to maintain patency of the tube and reduce the risk of infection. Initially a tracheostomy may need to be suctioned (see the section on suctioning that follows) and cleaned as often as every 1 to 2 hours. After the initial inflammatory response subsides, tracheostomy care may only need to be done once or twice a day, depending on the client. For a client with a new tracheostomy, sterile technique should be used when providing tracheostomy care

Figure 50–23 ■ A tracheostomy tube with a low-pressure cuff.

Figure 50–24 ■ A tracheostomy tube with a foam cuff.

in order to prevent infection. After the stoma has healed, clean gloves can be used while changing the dressing and tie tapes. Skill 50–4 later in this chapter describes tracheostomy care.

When the client breathes through a tracheostomy, air is no longer heated, humidified, and filtered as it is when passing through the upper airways; therefore, special precautions are necessary. Humidity may be provided with a mist collar (Figure 50–25 ■). Clients with long-term tracheostomies may use a heat moisture exchange device known as a “Swedish nose” that fits onto the connector of the inner cannula (Barnett, 2012) (Figure 50–26 ■). They may also wear a stoma protector such as a 4×4 gauze held in place with a cotton tie over the stoma or a light scarf to filter air as it enters the tracheostomy.

Suctioning

When clients have difficulty handling their secretions or an artificial airway is in place, suctioning may be necessary to clear air passages. **Suctioning** is the aspiration of secretions through a catheter connected to a suction machine or wall suction outlet. Even though the

Figure 50–25 ■ A tracheostomy mist collar.

Figure 50–26 ■ Heat moisture exchange device.

upper airways (the oropharynx and nasopharynx) are not sterile, sterile technique is recommended for all suctioning to avoid introducing pathogens into the airways. It is best to check the agency’s policy because some facilities may use clean rather than sterile technique for nasopharyngeal and oropharyngeal suctioning.

Oropharyngeal and nasopharyngeal suctioning removes secretions from the upper respiratory tract. Nasotracheal suctioning provides closer access to the trachea and requires sterile technique. Skill 50–2 outlines oropharyngeal, nasopharyngeal, and nasotracheal suctioning.

Suction catheters may be either open tipped or whistle tipped (Figure 50–27 ■). The whistle-tipped catheter is less irritating to respiratory tissues, although the open-tipped catheter may be more effective for removing thick mucous plugs. An oral suction tube, or Yankauer suction tube, is used to suction the oral cavity. Alert clients can be taught how to use this method of oral suctioning themselves (Figure 50–28 ■). Most suction catheters have a thumb port on the side to control the suction. The catheter is connected to suction tubing, which in turn is connected to a collection chamber and suction control gauge (Figure 50–29 ■).

Figure 50–27 ■ Types of suction catheters: A, open tipped; B, whistle tipped.

Figure 50–28 ■ Oral (Yankauer) suction tube.

Figure 50–29 ■ A wall suction unit.

The nurse decides when suctioning is needed by assessing the client for signs of respiratory distress or evidence that the client is unable to cough up and expectorate secretions. Dyspnea, bubbling or rattling (adventitious) breath sounds, poor skin color (pallor, duskiness, or cyanosis), restlessness, tachycardia, or decreased oxygen saturation (SpO₂) levels (also called O₂ sat) may indicate the need for suctioning. Good nursing judgment and critical thinking are necessary, because suctioning irritates mucous membranes, can increase secretions

if performed too frequently, and can cause the client's O₂ saturation to drop further, put the client in bronchospasm, and if the client has a head injury, cause the intracranial pressure to increase. In other words, suctioning is based on clinical need versus a fixed schedule.

In addition to removing secretions that obstruct the airway and facilitating ventilation, suctioning can be performed to obtain secretions for diagnostic purposes and to prevent infection that may result from accumulated secretions.

Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning

PURPOSES

- To remove secretions that obstruct the airway
- To facilitate ventilation
- To obtain secretions for diagnostic purposes
- To prevent infection that may result from accumulated secretions

ASSESSMENT

Assess for clinical signs indicating the need for suctioning:

- Restlessness, anxiety
- Noisy respirations
- Adventitious (abnormal) breath sounds when the chest is auscultated
- Change in mental status
- Skin color
- Rate and pattern of respirations
- Pulse rate and rhythm
- Decreased oxygen saturation

PLANNING

DELEGATION

Oral suctioning using a Yankauer suction tube can be delegated to UAP and to the client or family, if appropriate, since this is not a sterile procedure. The nurse needs to review the procedure and important points such as not applying suction during insertion of the tube to avoid trauma to the mucous membrane. Oropharyngeal suctioning uses a suction catheter and, although not a sterile procedure, should be performed by a nurse or respiratory therapist. Suctioning can stimulate the gag reflex, hypoxia, and dysrhythmias that may require problem solving. In contrast, nasopharyngeal and nasotracheal suctioning use sterile technique and require application of knowledge and problem solving and should be performed by the nurse or respiratory therapist.

INTERPROFESSIONAL PRACTICE

Suctioning a client may be within the scope of practice for specific health care providers. For example, in addition to nurses, respiratory therapists may help suction a client. Although the respiratory therapist may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Inform the client that suctioning will relieve breathing difficulty and that the procedure is painless but may be uncomfortable and stimulate the cough, gag, or sneeze reflex. **Rationale:** *Knowing that the procedure will relieve breathing problems is often reassuring and enlists the client's cooperation.*
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client.
 - Position a conscious person who has a functional gag reflex in the semi-Fowler's position with the head turned to one side for oral suctioning or with the neck hyperextended for nasal suctioning. **Rationale:** *These positions facilitate the insertion of the catheter and help prevent aspiration of secretions.*
 - Position an unconscious client in the lateral position, facing you. **Rationale:** *This position allows the tongue to fall forward, so that it will not obstruct the catheter on insertion. The lateral position also facilitates drainage of secretions from the pharynx and prevents the possibility of aspiration.*
 - Place the towel or moisture-resistant pad over the pillow or under the chin.

Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning—continued

- Prepare the equipment.
 - Turn the suction device on and set to appropriate negative pressure on the suction gauge. The amount of negative pressure should be high enough to clear secretions but not too high. **Rationale:** *Too high of a pressure can cause the catheter to adhere to the tracheal wall and cause irritation or trauma.* A rule of thumb is to use the lowest amount of suction pressure needed to clear the secretions.

For Oral and Oropharyngeal Suction

- Apply clean gloves.
- Moisten the tip of the Yankauer or suction catheter with sterile water or saline. **Rationale:** *This reduces friction and eases insertion.*
- Pull the tongue forward, if necessary, using gauze.
- Do not apply suction (that is, leave your finger off the port) during insertion. **Rationale:** *Applying suction during insertion causes trauma to the mucous membrane.*
- Advance the catheter about 10 to 15 cm (4 to 6 in.) along one side of the mouth into the oropharynx. **Rationale:** *Directing the catheter along the side prevents gagging.*
- It may be necessary during oropharyngeal suctioning to apply suction to secretions that collect in the mouth and beneath the tongue.
- Remove and discard gloves.
- Perform hand hygiene.

For Nasopharyngeal and Nasotracheal Suction

- Open the lubricant.
- Open the sterile suction package.
 - Set up the cup or container, touching only the outside.
 - Pour sterile water or saline into the container.
 - Apply the sterile gloves, or apply an unsterile glove on the nondominant hand and then a sterile glove on the dominant hand. **Rationale:** *The sterile gloved hand maintains the sterility of the suction catheter, and the unsterile glove prevents the transmission of the microorganisms to the nurse.*
- With your sterile gloved hand, pick up the catheter and attach it to the suction unit. ①
- Test the pressure of the suction and the patency of the catheter by applying your sterile gloved finger or thumb to the port or open branch of the Y-connector (the suction control) to create suction.
 - If needed, apply or increase supplemental oxygen.
- Lubricate and introduce the catheter.
 - Lubricate the catheter tip with sterile water, saline, or water-soluble lubricant. **Rationale:** *This reduces friction and eases insertion.*
 - Remove oxygen with the nondominant hand, if appropriate.

① Attaching the catheter to the suction unit.

- Without applying suction, insert the catheter into either naris and advance it along the floor of the nasal cavity. **Rationale:** *This avoids the nasal turbinates.*
 - Never force the catheter against an obstruction. If one nostril is obstructed, try the other.
- Perform suctioning.
 - Apply your finger to the suction control port to start suction, and gently rotate the catheter. **Rationale:** *Gentle rotation of the catheter ensures that all surfaces are reached and prevents trauma to any one area of the respiratory mucosa due to prolonged suction.*
 - Apply suction for 5 to 10 seconds while slowly withdrawing the catheter, then remove your finger from the control and remove the catheter. **Rationale:** *Intermittent suction reduces the occurrence of trauma or irritation to the trachea and nasopharynx.*
 - A suction attempt should last only 10 to 15 seconds. During this time, the catheter is inserted, the suction applied and discontinued, and the catheter removed.
 - Rinse the catheter and repeat suctioning as above if necessary.
 - Rinse and flush the catheter and tubing with sterile water or saline.
 - Relubricate the catheter, and repeat suctioning until the air passage is clear.
 - Allow sufficient time between each suction for ventilation and oxygenation. Limit suctioning to 5 minutes in total. **Rationale:** *Applying suction for too long may cause secretions to increase or may decrease the client's oxygen supply.*
 - Encourage the client to breathe deeply and to cough between suctionings. Use supplemental oxygen, if appropriate. **Rationale:** *Coughing and deep breathing help carry secretions from the trachea and bronchi into the pharynx, where they can be reached with the suction catheter. Deep breathing and supplemental oxygen replenish the oxygen supply that was decreased during the suctioning process.*
 - Obtain a specimen if required.
 - Use a sputum trap ② as follows:
 - Attach the suction catheter to the tubing of the sputum trap.
 - Attach the suction tubing to the sputum trap air vent.
 - Suction the client. The sputum trap will collect the mucus during suctioning.
 - Remove the catheter from the client. Disconnect the sputum trap tubing from the suction catheter. Remove the suction tubing from the trap air vent.
 - Connect the tubing of the sputum trap to the air vent. **Rationale:** *This retains any microorganisms in the sputum trap.*
 - Connect the suction catheter to the tubing.
 - Flush the catheter to remove secretions from the tubing.
 - Promote client comfort.
 - Offer to assist the client with oral or nasal hygiene.
 - Assist the client to a position that facilitates breathing.
 - Dispose of equipment and ensure availability for the next suction.
 - Dispose of the catheter, gloves, water, and waste container.
 - Rinse the suction tubing as needed by inserting the end of the tubing into the used water container.
 - Wrap the catheter around your sterile gloved hand and hold the catheter as the glove is removed over it for disposal.
 - Perform hand hygiene.
 - Empty and rinse the suction collection container as needed or indicated by protocol. Change the suction tubing and container daily.

Oropharyngeal, Nasopharyngeal, and Nasotracheal Suctioning —continued

2 A sputum collection trap.

- Ensure that supplies are available for the next suctioning (suction kit, gloves, water or normal saline).
13. Assess the effectiveness of suctioning.
 - Auscultate the client's breath sounds to ensure they are clear of secretions. Observe skin color, dyspnea, level of anxiety, and oxygen saturation levels.
 14. Document relevant data.
 - Record the procedure: the amount, consistency, color, and odor of sputum (e.g., foamy, white mucus; thick, green-tinged mucus; or blood-flecked mucus) and the client's respiratory status before and after the procedure. This may include lung sounds, rate and character of breathing, and oxygen saturation.
 - If the procedure is carried out frequently (e.g., every hour), it may be appropriate to record only once, at the end of the shift; however, the frequency of the suctioning must be recorded.

SAMPLE DOCUMENTATION

12/12/2015 0830 Producing large amounts of thick, tenacious white mucus to back of oral pharynx but unable to expectorate into tissue. Uses Yankauer suction tube as needed. O₂ sat increased from 89% before suctioning to 93% after suctioning. RR also decreased from 26 to 18–20 after suctioning. Lungs clear to auscultation throughout all lobes. Continuous O₂ at 2 L/min via n/c. Will continue to reassess q hour. _____ L. Webb, RN

EVALUATION

- Conduct appropriate follow-up, such as appearance of secretions suctioned; breath sounds; respiratory rate, rhythm, and depth; pulse rate and rhythm; and skin color.
- Compare findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Suctioning

INFANTS

A bulb syringe is used to remove secretions from an infant's nose or mouth. Care needs to be taken to avoid stimulating the gag reflex.

CHILDREN

A catheter is used to remove secretions from an older child's mouth or nose.

OLDER ADULTS

Older adults often have cardiac and/or pulmonary disease, thus increasing their susceptibility to hypoxemia related to suctioning. Watch closely for signs of hypoxemia. If noted, stop suctioning and hyperoxygenate.

Home Care Considerations Suctioning

PATIENT-CENTERED CARE

- Teach clients and families that the most important aspect of infection control is frequent hand washing.
- Airway suctioning in the home is considered a clean procedure.
- The catheter or Yankauer should be flushed by suctioning recently boiled or distilled water to rinse away mucus, followed by the suctioning of air through the device to dry the internal surface and, thus, discourage bacterial growth. The outer surface of the device may be wiped with alcohol or hydrogen peroxide. The suction catheter or Yankauer should be allowed to dry and then be stored in a clean, dry area.
- Suction catheters treated in the manner described above may be reused. It is recommended that catheters be discarded after 24 hours. Yankauer suction tubes may be cleaned, boiled, and reused.

Following endotracheal intubation or a tracheostomy, the trachea and surrounding respiratory tissues are irritated and react by producing excessive secretions. Sterile suctioning is necessary to remove these secretions from the trachea and bronchi to maintain a patent airway. The frequency of suctioning depends on the client's health and how recently the intubation was done. Additionally,

suctioning may be necessary in clients who have increased secretions because of pneumonia or inability to clear secretions because of altered level of consciousness.

Suctioning is associated with several complications: hypoxemia, trauma to the airway, nosocomial or health care-associated infection, and cardiac dysrhythmia, which is related to the hypoxemia.

The following techniques are used to minimize or decrease these complications:

- **Suction only as needed.** Because suctioning the client with an ETT or tracheostomy is uncomfortable for the client and potentially hazardous because of hypoxemia, it should be performed only when indicated and not on a fixed schedule.
- **Sterile technique.** Infection of the lower respiratory tract can occur during tracheal suctioning. The nurse using sterile technique during the suctioning process can prevent this complication.
- **No saline instillation.** Instilling normal saline into the airway has been a common practice and a routine part of the suctioning procedure. It was thought that the saline would facilitate removal of secretions and improve the client's oxygenation status. Research, however, has shown that saline instillation does *not* facilitate removal of secretions and causes adverse effects such as hypoxemia and increased risk of pneumonia (Ntoumenopoulos, 2013; Pierson, 2013).
- **Hyperinflation.** This involves giving the client breaths that are greater than the tidal volume set on the ventilator through the ventilator circuit or via a manual resuscitation bag. Three to five breaths are delivered before and after each pass of the suction catheter.
- **Hyperventilation.** This involves increasing the number of breaths the client is receiving. This can be done through the ventilator or using a manual resuscitation bag.
- Both hyperinflation and hyperventilation help prevent suction hypoxemia; however, they should be used with caution because they can cause injury as a result of overdistention of the lungs (Hess, MacIntyre, Mishoe, Galvin, & Adams, 2012).
- **Hyperoxygenation.** This can be done with a manual resuscitation bag or through the ventilator and is performed by increasing

the oxygen flow (usually to 100%) before suctioning and between suction attempts. This is the best technique to avoid suction-related hypoxemia.

To prevent hypoxia when tracheostomy and endotracheal suctioning are administered, the outer diameter of the suction catheter should not exceed one half the internal diameter of the tracheostomy or ETT (Nance-Floyd, 2011). A rule of thumb to determine suction catheter size is to double the millimeter size of the artificial airway. For example, an artificial airway (e.g., tracheostomy) diameter of 8 mm $\times 2 = 16$. A size 16 French suction catheter would be the largest size catheter that would be safe to use.

The nurse uses sterile techniques to prevent infection of the respiratory tract (Skill 50-3). The traditional method of suctioning an ETT or tracheostomy is sometimes referred to as the *open method*. If a client is connected to a ventilator, the nurse disconnects the client from the ventilator, suctions the airway, reconnects the client to the ventilator, and discards the suction catheter. Drawbacks to the open airway suction system include the nurse needing to wear personal protective equipment (e.g., goggles or face shield, gown) to avoid exposure to the client's sputum and the potential cost of one-time catheter use, especially if the client requires frequent suctioning.

With the *closed airway/tracheal suction system (in-line suctioning)* (Figure 50-30 ■), the suction catheter attaches to the ventilator tubing and the client does not need to be disconnected from the ventilator. The nurse is not exposed to any secretions because the suction catheter is enclosed in a plastic sheath. The catheter can be reused as many times as necessary until the system is changed. The nurse needs to inquire about the agency's policy for changing the closed suction system.

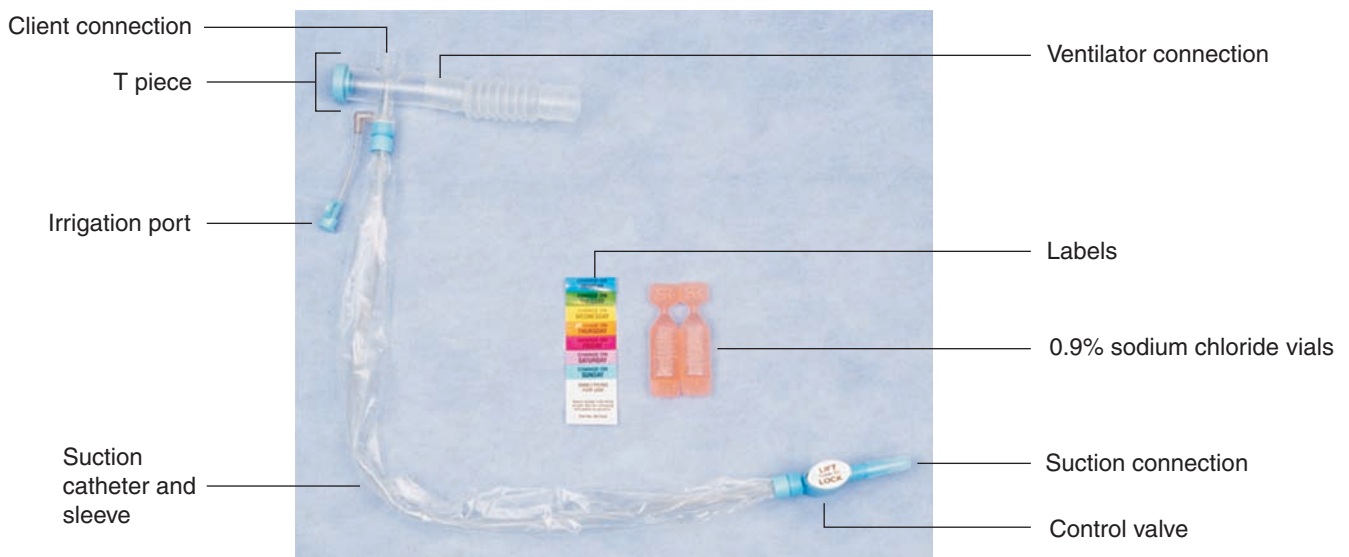

Figure 50-30 ■ A closed airway suction (in-line) system.

Suctioning a Tracheostomy or Endotracheal Tube

PURPOSES

- To maintain a patent airway and prevent airway obstructions
- To promote respiratory function (optimal exchange of oxygen and carbon dioxide into and out of the lungs)
- To prevent pneumonia that may result from accumulated secretions

ASSESSMENT

Assess the client for the presence of adventitious (abnormal) breath sounds. Assess the client's cough reflex and note the client's ability or inability to remove the secretions through coughing.

PLANNING

DELEGATION

Suctioning a tracheostomy or endotracheal tube is a sterile, invasive technique requiring application of scientific knowledge and problem solving. This skill is performed by a nurse or respiratory therapist and is not delegated to UAP.

Equipment

- Resuscitation bag (bag valve mask) connected to 100% oxygen
- Sterile towel (optional)
- Equipment for suctioning (see Skill 50-2)
- Goggles and mask if necessary
- Gown (if necessary)
- Sterile gloves
- Moisture-resistant bag

INTERPROFESSIONAL PRACTICE

Suctioning a client with a tracheostomy or endotracheal tube may be within the scope of practice for specific health care providers. For example, in addition to nurses, respiratory therapists may suction a client with a tracheostomy or endotracheal tube. Although the respiratory therapist may verbally communicate their findings and plan to the health care team members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Preparation

Determine if the client has been suctioned previously and, if so, review the documentation of the procedure. This information can be very helpful in preparing the nurse for both the physiological and psychological impact of suctioning on the client.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Inform the client that suctioning usually causes some intermittent coughing and that this assists in removing the secretions.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client.
 - If not contraindicated, place the client in the semi-Fowler's position to promote deep breathing, maximum lung expansion, and productive coughing. **Rationale:** *Deep breathing oxygenates the lungs, counteracts the hypoxic effects of suctioning, and may induce coughing. Coughing helps to loosen and move secretions.*
5. Prepare the equipment for an open suction system—see *Variation* section for a closed suction system.
 1. Attach the resuscitation apparatus to the oxygen source.
 - a. Adjust the oxygen flow to 100%.
 - b. Open the sterile supplies:
 - i. Suction kit or catheter
 - ii. Sterile basin/container.
 - c. Pour sterile normal saline or water into sterile basin.
 - d. Place the sterile towel, if used, across the client's chest below the tracheostomy.
 - e. Turn on the suction, and set the pressure in accordance with agency policy. The suction pressure should be set at

1 Attaching the resuscitation apparatus to the oxygen source.

what is needed to adequately remove secretions. Hess et al. (2012) state that the suction pressure “should *not* exceed 100 mm Hg in infants, 125 mm Hg in children, and 150 mm Hg in adults” (p. 413). Nance-Floyd (2011) recommends using suction pressure of up to 120 mmHg for open system suctioning and up to 160 mmHg for closed system suctioning (p. 15).

- Apply goggles, mask, and gown if necessary.

Suctioning a Tracheostomy or Endotracheal Tube—continued

- Apply sterile gloves. Some agencies recommend putting a sterile glove on the dominant hand and an unsterile glove on the nondominant hand to protect the nurse.
 - Holding the catheter in the dominant hand and the connector in the nondominant hand, attach the suction catheter to the suction tubing (see Figure 1 in Skill 50-2).
6. Flush and lubricate the catheter.
- Using the dominant hand, place the catheter tip in the sterile saline solution.
 - Using the thumb of the nondominant hand, occlude the thumb control and suction a small amount of the sterile solution through the catheter. **Rationale:** *This determines that the suction equipment is working properly and lubricates the outside and the lumen of the catheter. Lubrication eases insertion and reduces tissue trauma during insertion. Lubricating the lumen also helps prevent secretions from sticking to the inside of the catheter.*
7. If the client does not have copious secretions, hyperventilate the lungs with a resuscitation bag before suctioning.
- Summon an assistant, if one is available, for this step.
 - Using your nondominant hand, turn on the oxygen to 12 to 15 L/min.
 - If the client is receiving oxygen, disconnect the oxygen source from the tracheostomy tube using your nondominant hand.
 - Attach the resuscitator to the tracheostomy or ETT. 2
 - Compress the Ambu bag three to five times, as the client inhales. This is best done by a second person who can use both hands to compress the bag.
 - Observe the rise and fall of the client's chest to assess the adequacy of each ventilation.
 - Remove the resuscitation device and place it on the bed or the client's chest with the connector facing up.

Variation: Using a Ventilator to Provide Hyperventilation

If the client is on a ventilator, use the ventilator for hyperventilation and hyperoxygenation. Newer models have a mode that provides 100% oxygen for 2 minutes and then switches back to the previous oxygen setting as well as a manual breath or sigh button. **Rationale:** *The use of ventilator settings provides more consistent delivery of oxygenation and hyperinflation than a resuscitation device.*

8. If the client has copious secretions, do not hyperventilate with a resuscitator. *Instead:*
- Keep the regular oxygen delivery device on and increase the liter flow or adjust the FiO_2 to 100% for several breaths before suctioning. **Rationale:** *Hyperventilating a client who has copious secretions can force the secretions deeper into the respiratory tract.*

3 Inserting the catheter into the trachea through the tracheostomy tube. **Note:** Suction is not applied while inserting the catheter.

9. Quickly but gently insert the catheter *without* applying any suction.
- With your nondominant thumb off the suction port, quickly but gently insert the catheter into the trachea through the tracheostomy tube. 3 **Rationale:** *To prevent tissue trauma and oxygen loss, suction is not applied during insertion of the catheter.*
 - Insert the catheter about 0.5 to 1 cm past the distal end of the tube for an open system, and 1 to 2 cm past the distal end for a closed system (Nance-Floyd, 2011) or until the client coughs. If you feel resistance, withdraw the catheter about 1 to 2 cm (0.4 to 0.8 in.) before applying suction. **Rationale:** *Resistance usually means that the catheter tip has reached the bifurcation of the trachea. Withdrawing the catheter will prevent damaging the mucous membranes at the bifurcation.*
10. Perform suctioning.
- Apply suction for 5 to 10 seconds by placing the nondominant thumb over the thumb port. **Rationale:** *Suction time is restricted to 10 seconds or less to minimize oxygen loss.*
 - Rotate the catheter by rolling it between your thumb and forefinger while slowly withdrawing it. **Rationale:** *This prevents tissue trauma by minimizing the suction time against any part of the trachea.*
 - Withdraw the catheter completely, and release the suction.
 - Hyperventilate the client.
 - Suction again, if needed.
11. Reassess the client's oxygenation status and repeat suctioning.
- Observe the client's respirations and skin color. Check the client's pulse if necessary, using your nondominant hand. If the client is on a cardiac monitor, assess the rate and rhythm.
 - Encourage the client to breathe deeply and to cough between suctionings.
 - Allow 2 to 3 minutes with oxygen, as appropriate between suctionings when possible. **Rationale:** *This provides an opportunity for reoxygenation of the lungs.*
 - Flush the catheter and repeat suctioning until the air passage is clear and the breathing is relatively effortless and quiet.
 - After each suction, pick up the resuscitation bag with your nondominant hand and ventilate the client with no more than three breaths.

2 Attaching the resuscitator to the tracheostomy tube.

Suctioning a Tracheostomy or Endotracheal Tube—continued

12. Dispose of equipment and ensure availability for the next suction.
 - Flush the catheter and suction tubing.
 - Turn off the suction and disconnect the catheter from the suction tubing.
 - Wrap the catheter around your sterile hand and peel the glove off so that it turns inside out over the catheter. Remove the other glove.
 - Discard the gloves and the catheter in the moisture-resistant bag.
 - Perform hand hygiene.
 - Replenish the sterile fluid and supplies so that the suction is ready for use again. **Rationale:** *Clients who require suctioning often require it quickly, so it is essential to leave the equipment at the bedside ready for use.*
 - Be sure that the ventilator and oxygen settings are returned to presuctioning settings. **Rationale:** *On some ventilators this is automatic, but always check. It is very dangerous for clients to be left on 100% oxygen.*
13. Provide for client comfort and safety.
 - Assist the client to a comfortable, safe position that aids breathing. If the person is conscious, a semi-Fowler's position is frequently indicated. If the person is unconscious, Sims' position aids in the drainage of secretions from the mouth.
14. Document relevant data.
 - Record the suctioning, including the amount and description of suction returns and any other relevant assessments.

SAMPLE DOCUMENTATION

12/13/2015 1000 Coarse crackles in RLL and LLL. Requires suctioning about every 1–2 hrs. Obtained large amount of pinkish-tinged, white thin mucus via ETT. Breath sounds clearer after suctioning. SpO₂ increased from 90% before suctioning to 95% after suctioning. Client signals when he wants to be suctioned. ——— C. Holmes, RN

EVALUATION

- Perform a follow-up examination of the client to determine the effectiveness of the suctioning (e.g., respiratory rate, depth, and character; breath sounds; color of skin and nail beds; character and amount of secretions suctioned; changes in vital signs [e.g., heart rate, oxygen saturation]).
- Relate findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

Variation: Closed Airway/Tracheal Suction System (In-Line Catheter)

- If a catheter is not already attached, apply clean gloves, aseptically open a new closed catheter set, and attach the ventilator connection on the T piece to the ventilator tubing. Attach the client connection to the ETT or tracheostomy.
- Attach one end of the suction connecting tubing to the suction connection port of the closed system and the other end of the connecting tubing to the suction device.
- Turn suction on, occlude or kink tubing, and depress the suction control valve (on the closed catheter system) to set suction to the appropriate level. Release the suction control valve.
- Use the ventilator to hyperoxygenate and hyperinflate the client's lungs.
- Unlock the suction control mechanism if required by the manufacturer.
- Advance the suction catheter enclosed in its plastic sheath with the dominant hand. Steady the T piece with the nondominant hand.
- Depress the suction control valve and apply continuous suction for no more than 10 seconds and gently withdraw the catheter.
- Repeat as needed remembering to provide hyperoxygenation and hyperinflation as needed.
- When completed suctioning, withdraw the catheter into its sleeve and close the access valve, if appropriate. **Rationale:** *If the system does not have an access valve on the client connector, the nurse needs to observe for the potential of the catheter migrating into the airway and partially obstructing the artificial airway.*
- Flush the catheter by instilling normal saline into the irrigation port and applying suction. Repeat until the catheter is clear.
- Close the irrigation port and close the suction valve.
- Remove and discard gloves.
- Perform hand hygiene.

LIFESPAN CONSIDERATIONS Suctioning a Tracheostomy or Endotracheal Tube

INFANTS AND CHILDREN

Have an assistant gently restrain the child to keep the child's hands out of the way. The assistant should maintain the child's head in the midline position.

OLDER ADULTS

- Health care–associated pneumonia and ventilator-associated pneumonia (VAP) can occur because of infected secretions

in the upper airway. Oral antiseptic rinses (e.g., chlorhexidine gluconate) reduce the rate of nosocomial pneumonia in critically ill clients (Booker, Murff, Kitko, & Jablonski, 2013).

- Do a thorough lung assessment before and after suctioning to determine effectiveness of suctioning and to be aware of any special problems.

Home Care Considerations Suctioning a Tracheostomy or Endotracheal Tube

PATIENT-CENTERED CARE

- Whenever possible, the client should be encouraged to clear the airway by coughing.
- Clients may need to learn to suction their secretions if they cannot cough effectively.
- Clean gloves should be used when endotracheal suctioning is performed in the home environment.
- The nurse needs to instruct the caregiver on how to determine the need for suctioning and the correct process and rationale underlying the practice of suctioning to avoid potential complications of suctioning.
- Stress the importance of adequate hydration as it thins secretions, which can aid in the removal of secretions by coughing or suctioning.

Providing Tracheostomy Care

PURPOSES

- To maintain airway patency
- To maintain cleanliness and prevent infection at the tracheostomy site
- To facilitate healing and prevent skin excoriation around the tracheostomy incision
- To promote comfort

ASSESSMENT

Assess

- Respiratory status including ease of breathing, rate, rhythm, depth, lung sounds, and oxygen saturation level
- Pulse rate
- Character and amount of secretions from tracheostomy site
- Presence of drainage on tracheostomy dressing or ties
- Appearance of incision (note any redness, swelling, purulent discharge, or odor)

PLANNING

DELEGATION

Tracheostomy care involves application of scientific knowledge, sterile technique, and problem solving, and therefore needs to be performed by a nurse or respiratory therapist.

INTERPROFESSIONAL PRACTICE

Providing tracheostomy care may be within the scope of practice for specific health care providers. For example, in addition to nurses, respiratory therapists may help provide tracheostomy care for a client. Although the respiratory therapist may verbally communicate their findings and plan to the health care members, the nurse must also know where to locate their documentation in the client's medical record.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Provide for a means of communication, such as eye blinking or raising a finger, to indicate pain or distress. Follow through by carefully observing the client throughout the procedure, offering periodic eye contact, caring touch, and verbal reassurance.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy.
4. Prepare the client and the equipment.
 - Assist the client to a semi-Fowler's or Fowler's position to promote lung expansion.
 - Suction the tracheostomy tube, if needed. (See Skill 50-3.)
 - If suctioning was required, allow the client to rest and restore oxygenation.
 - Open the tracheostomy kit or sterile basins.
 - Establish a sterile field.
 - Open other sterile supplies as needed including sterile applicators, suction kit, tracheostomy dressing, and disposable inner cannula, if applicable.
 - Pour the soaking solution and sterile normal saline into separate containers.
 - Apply clean gloves.
 - Remove the oxygen source.
 - Unlock the inner cannula (if present) and remove it by gently pulling it out toward you in line with its curvature. Place the inner cannula in the soaking solution, if not a disposable inner cannula. **Rationale:** *This moistens and loosens dried secretions.*
 - Based on the client's respiratory assessments, place oxygen source over or near the outer cannula. **Rationale:** *This prevents oxygen desaturation by maintaining oxygen to the client.*

Equipment

- Sterile disposable tracheostomy cleaning kit or supplies including sterile containers, sterile nylon brush and/or pipe cleaners, sterile applicators, gauze squares
- Disposable inner cannula if applicable
- Towel or drape to protect bed linens
- Sterile suction catheter kit (suction catheter and sterile container for solution)
- Sterile normal saline (Some agencies may use a mixture of hydrogen peroxide and sterile normal saline. Check agency protocol for soaking solution.)
- Sterile gloves (two pairs—one pair is for suctioning if needed.)
- Clean gloves
- Moisture-proof bag
- Commercially prepared sterile tracheostomy dressing or sterile 4×4 gauze dressing
- Cotton twill ties or Velcro collar
- Clean scissors

1 Cleaning the inner cannula with a brush.

- Remove the soiled tracheostomy dressing. Place the soiled dressing in your gloved hand and peel the glove off so that it turns inside out over the dressing. Remove and discard the gloves and the dressing.
 - Perform hand hygiene.
 - Apply sterile gloves. Keep your dominant hand sterile during the procedure.
5. Clean the inner cannula. (See the *Variation* section for using a disposable inner cannula.)
 - Remove the inner cannula from the soaking solution.
 - Clean the lumen and entire inner cannula thoroughly using the brush or pipe cleaners moistened with sterile normal saline. 1 Inspect the cannula for cleanliness by holding it at eye level and looking through it into the light.
 - Rinse the inner cannula thoroughly in the sterile normal saline.

Providing Tracheostomy Care—continued

2 Using an applicator stick to clean the tracheostomy site.

- After rinsing, gently tap the cannula against the inside edge of the sterile saline container. Use a pipe cleaner folded in half to dry only the inside of the cannula; do not dry the outside. **Rationale:** *This removes excess liquid from the cannula and prevents possible aspiration by the client, while leaving a film of moisture on the outer surface to lubricate the cannula for reinsertion.*
6. Replace the inner cannula, securing it in place.
 - Insert the inner cannula by grasping the outer flange and inserting the cannula in the direction of its curvature.
 - Lock the cannula in place by turning the lock (if present) into position to secure the flange of the inner cannula to the outer cannula.
 7. Clean the incision site and tube flange.
 - Using sterile applicators or gauze dressings moistened with normal saline, clean the incision site. 2 Handle the sterile supplies with your dominant hand. Use each applicator or gauze dressing only once and then discard. **Rationale:** *This avoids contaminating a clean area with a soiled gauze dressing or applicator.*
 - Hydrogen peroxide may be used (usually in a half-strength solution mixed with sterile normal saline; use a separate sterile container if this is necessary) to remove crusty secretions around the tracheostomy site. Do not use directly on the site. Check agency policy. Thoroughly rinse the cleaned area using gauze squares moistened with sterile normal saline. **Rationale:** *Hydrogen peroxide can be irritating to the skin and inhibit healing if not thoroughly removed.*
 - Clean the flange of the tube in the same manner.
 - Thoroughly dry the client's skin and tube flanges with dry gauze squares.
 8. Apply a sterile dressing.
 - Use a commercially prepared split-gauze tracheostomy dressing of nonraveling material. 3 Never use cotton-filled gauze squares or cut the 4x4 gauze. **Rationale:** *Cotton lint or gauze fibers can be aspirated by the client, potentially creating a tracheal abscess.* Newer products include a nonadhesive hydrocellular dressing, which is a cushioned pad that absorbs large amounts of secretions. 4
 - Place the dressing under the flange of the tracheostomy tube.
 - While applying the dressing, ensure that the tracheostomy tube is securely supported. **Rationale:** *Excessive movement of the tracheostomy tube irritates the trachea.*
 9. Change the tracheostomy ties or Velcro collar.
 - Change as needed to keep the skin clean and dry.

3 A commercially prepared tracheostomy dressing of nonraveling material.

4 A nonadhesive hydrocellular tracheostomy dressing. Courtesy Covidien

- Twill tape and specially manufactured Velcro ties are available. Twill tape is inexpensive and readily available; however, it is easily soiled and can trap moisture, which leads to irritation of the skin of the neck. Velcro ties are becoming more commonly used. 5 They are wider, more comfortable, and cause less skin abrasion.

Providing Tracheostomy Care—continued

5 A Velcro tracheostomy tie.

- For client safety, the literature recommends a two-person technique when changing the securing device to prevent tube dislodgement. This involves one person holding the tracheostomy tube in place while the other changes the securing device.

Two-Strip Method (Twill Tape)

- Cut two unequal strips of twill tape, one approximately 25 cm (10 in.) long and the other about 50 cm (20 in.) long. **Rationale:** *Cutting one tape longer than the other allows them to be fastened at the side of the neck for easy access and to avoid the pressure of a knot on the skin at the back of the neck.*
- Cut a 1-cm (0.5-in.) lengthwise slit approximately 2.5 cm (1 in.) from one end of each strip. To do this, fold the end of the tape back onto itself about 2.5 cm (1 in.), then cut a slit in the middle of the tape from its folded edge.
- Leaving the old ties in place, thread the slit end of one clean tape through the eye of the tracheostomy flange from the bottom side; then thread the long end of the tape through the slit, pulling it tight until it is securely fastened to the flange. **Rationale:** *Leaving the old ties in place while securing the clean ties prevents inadvertent dislodging of the tracheostomy tube. Securing tapes in this manner avoids the use of knots, which can come untied or cause pressure and irritation.*
- If old ties are very soiled or it is difficult to thread new ties onto the tracheostomy flange with old ties in place, have an assistant apply a sterile glove and hold the tracheostomy in place while you replace the ties. **Rationale:** *This is very important because movement of the tube during this procedure may cause irritation and stimulate coughing. Coughing can dislodge the tube if the ties are undone.*
- Repeat the process for the second tie.
- Ask the client to flex the neck. Slip the longer tape under the client's neck, place a finger between the tape and the client's neck, 6 and tie the tapes together at the side of the neck. **Rationale:** *Flexing the neck increases its circumference the way coughing does. Placing a finger under the tie prevents making the tie too tight, which could interfere with coughing or place pressure on the jugular veins.*
- Tie the ends of the tapes using square knots. Cut off any long ends, leaving approximately 1 to 2 cm (0.5 in.). **Rationale:** *Square knots prevent slippage and loosening. Adequate ends beyond the knot prevent the knot from inadvertently untying.*
- Once the clean ties are secured, remove the soiled ties and discard.

6 Placing a finger underneath the tie tape before tying it.

One-Strip Method (Twill Tape)

- Cut a length of twill tape 2.5 times the length needed to go around the client's neck from one tube flange to the other.
- Thread one end of the tape into the slot on one side of the flange.
- Bring both ends of the tape together. Take them around the client's neck, keeping them flat and untwisted.
- Thread the end of the tape next to the client's neck through the slot from the back to the front.
- Have the client flex the neck. Tie the loose ends with a square knot at the side of the client's neck, allowing for slack by placing one finger under the ties as with the two-strip method. Cut off long ends.
- Tape and pad the tie knot.
- Place a folded 4x4 gauze square under the tie knot, and apply tape over the knot. **Rationale:** *This reduces skin irritation from the knot and prevents confusing the knot with the client's gown ties.*
- Check the tightness of the ties.
- Frequently check the tightness of the tracheostomy ties and position of the tracheostomy tube. **Rationale:** *Swelling of the neck may cause the ties to become too tight, interfering with coughing and circulation. Ties can loosen in restless clients, allowing the tracheostomy tube to extrude from the stoma.*

Velcro Collar Method

- Thread one piece of the collar with the Velcro end into the slot on one side of the flange.
 - Take the collar around the back of the client's neck, keeping it flat.
 - Thread the other piece of the collar with the Velcro end into the slot on the other side of the flange.
 - Take the second piece of the collar around the back of the client's neck, keeping it flat.
 - Have the client flex the neck and secure the two pieces of the collar together with the Velcro, allowing space for one to two fingers between the collar and the client's neck.
 - Check the tightness of the collar as with the tie method.
10. Remove and discard sterile gloves.
 - Perform hand hygiene.
 11. Document all relevant information.
 - Record suctioning, tracheostomy care, and the dressing change, noting your assessments.

Providing Tracheostomy Care—continued

SAMPLE DOCUMENTATION

12/11/2015 0900 Respirations 18–20/min. Lung sounds clear. Able to cough up secretions requiring little suctioning. Inner cannula changed. Trach dressing changed. Minimal amount of serosanguinous drainage present. Trach incision area pink to reddish in color 0.2 cm around entire opening. No broken skin noted in the reddened area. _____ J. Garcia, RN

- Using a gloved hand, unlock the current inner cannula (if present) and remove it by gently pulling it out toward you in line with its curvature.
- Check the cannula for amount and type of secretions and discard properly.
- Pick up the new inner cannula touching only the outer locking portion.
- Insert the new inner cannula into the tracheostomy.
- Lock the cannula in place by turning the lock (if present) or clipping in place.

Variation: Using a Disposable Inner Cannula

- Check policy for frequency of changing inner cannula because standards vary among institutions.
- Open a new cannula package.

EVALUATION

- Perform appropriate follow-up such as determining character and amount of secretions, drainage from the tracheostomy, appearance of the tracheostomy incision, pulse rate and respiratory status compared to baseline data, and complaints of pain or discomfort at the tracheostomy site.
- Relate findings to previous assessment data if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Tracheostomy Care

INFANTS AND CHILDREN

- An assistant should always be present while tracheostomy care is performed.
- Always keep a sterile, packaged tracheostomy tube taped to the child's bed so that if the tube dislodges, a new one is available for immediate reintubation.

OLDER ADULTS

Older adult skin is fragile and prone to breakdown. Care of the skin at the tracheostomy stoma is very important.

Home Care Considerations Tracheostomy Care

PATIENT-CENTERED CARE

- For tracheostomies older than 1 month, clean technique (rather than sterile technique) is used for tracheostomy care.
- Stress the importance of good hand hygiene to the caregiver.
- Tap water may be used for rinsing the inner cannula.
- Teach the caregiver the tracheostomy care procedure and observe a return demonstration. Periodically reassess caregiver knowledge and/or tracheostomy care technique.
- Inform the caregiver of the signs and symptoms that may indicate an infection of the stoma site or lower airway.
- Names and telephone numbers of health care personnel who can be reached for emergencies or advice must be available to the client and/or caregiver.
- If the tracheostomy is permanent, provide contact information for available support groups.

Chest Tubes and Drainage Systems

If the thin, double-layered pleural membrane is disrupted by lung disease, surgery, or trauma, the negative pressure between the pleural layers may be lost. The lung then collapses because it is no longer drawn outward as the diaphragm and intercostal muscles contract during inhalation. When air collects in the pleural space, it is known as a **pneumothorax**. A **hemothorax** is the accumulation of blood in the pleural space, and a **pleural effusion** exists when there is excessive fluid in the pleural space. The air, blood, or fluid in the pleural space places pressure on lung tissue and interferes with lung expansion. Chest tubes may be inserted into the pleural cavity to restore negative pressure and drain collected fluid or blood. Because air rises, chest tubes for pneumothorax often are placed in the upper anterior thorax, whereas chest tubes used to drain blood and fluid generally are placed in the lower lateral chest wall.

When chest tubes are inserted, they must be connected to a sealed drainage system or a one-way valve that allows air and fluid to be

removed from the chest cavity but prevents air from entering from the outside. Sterile disposable drainage systems are used to prevent outside air from entering the chest tube. These systems typically have a suction control chamber, a water-seal chamber, and a closed collection chamber, for drainage (Figure 50–31 ■). With the water-seal system, when the client inhales, the water prevents air from entering the system from the atmosphere. During exhalation, however, air can exit the chest cavity, bubbling up through the water. Suction can be added to the system to facilitate removing air and secretions from the chest cavity. The drainage system should always be kept below the level of the client's chest to prevent fluid and drainage from being drawn back into the chest cavity.

A Heimlich valve may be used for ambulatory clients (Figure 50–32 ■). The Heimlich valve is a one-way flutter valve that allows air to escape from the chest cavity, but prevents air from reentering. The arrow on the housing of the valve should always point away from the client. At each assessment, observe the inner valve carefully for movement during exhalation, indicating airflow

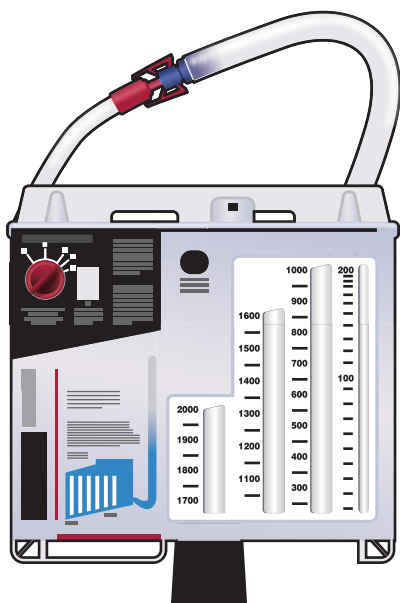

Figure 50-31 ■ A disposable chest drainage system.

Figure 50-33 ■ The Pneumostat is an example of a device often used for clients with a pneumothorax. It has a one-way valve and a small collection chamber.

Figure 50-32 ■ Heimlich chest drain valve.

through the device. The Heimlich valve is not designed to collect fluid. Another device, attached to the chest tube and called the Pneumostat, also has a one-way valve and, unlike the Heimlich valve, a small built-in collection chamber. It is used exclusively for clients with a pneumothorax who usually have small amounts of fluid (Figure 50-33 ■).

Nursing responsibilities regarding drainage systems include the following:

- Monitor and maintain the patency and integrity of the drainage system.
- Assess the client's vital signs, oxygen saturation, cardiovascular status, and respiratory status. Check the breath sounds bilaterally and check for symmetry of breath sounds.
- Observe the dressing site at least every 4 hours. Inspect the dressing for excessive and abnormal drainage, such as bleeding or foul-smelling discharge. Palpate around the dressing site, and listen for a crackling sound indicative of subcutaneous emphysema.

- Subcutaneous emphysema, which is air in the subcutaneous tissues, can result from a poor seal at the chest tube insertion site.*
- Determine level of discomfort with and without activity and medicate the client for pain if indicated.
 - Encourage deep-breathing exercises and coughing every 2 hours (this may be contraindicated in clients who have had a lung removed). Have the client sit upright to perform the exercises, and splint the chest around the tube insertion site with a pillow or with a hand to minimize discomfort.
 - Reposition the client every 2 hours. When the client is lying on the affected side, place rolled towels beside the tubing. *Frequent position changes promote drainage, prevent complications, and provide comfort. Rolled towels prevent occlusion of the chest tube by the client's weight.*
 - Assist the client with range-of-motion exercises of the affected shoulder three times per day to maintain joint mobility.
 - Ensure that the connections are securely taped and that the chest tube is secured to the client's chest wall.
 - Keep the collection device below the client's chest level.
 - Frequently check the water-seal and suction control chambers. The water can evaporate and water may need to be added to the chamber. The water-seal level should fluctuate with respiratory effort.
 - Assess the drainage in the tubing and collection chamber. The drainage is measured at regularly scheduled times (check agency policy). Mark the date and time at the fluid level on the drainage chamber. The unit is not replaced until almost full.
 - Avoid aggressive chest tube manipulation (e.g., milking or stripping the tube). Milking can create excessive negative pressure that can harm the pleural membranes and/or surrounding tissues and cause the client pain (Durai, Hoque, & Davies, 2010).

- Avoid clamping the chest tube because this increases the risk of a tension pneumothorax. You can clamp the tube for a moment to replace the drainage unit or to locate the source of an air leak, but never when transporting a client or for any extended period of time.
- If the tube becomes disconnected from the collecting system, submerge the end in 2.5 cm (1 in.) of sterile saline or water *to maintain the seal*. If the chest tube is inadvertently pulled out, the wound should be immediately covered with a dry sterile dressing. If you can hear air leaking out of the site, ensure that the dressing is not occlusive. *If the air cannot escape, this would lead to a tension pneumothorax. A tension pneumothorax occurs when there is buildup of air in the pleural space and it cannot escape, causing increased pressure. This pressure can eventually compromise cardiovascular function.*
- When transporting and ambulating the client:
 - a. Keep the water-seal unit below chest level and upright.
 - b. Disconnect the drainage system from the suction apparatus before moving the client and make sure the air vent is open.
- Use standard precautions and personal protective equipment while manipulating the system and assisting with insertion or removal.

Chest tube insertion and removal require sterile technique and must be done without introducing air or microorganisms into the pleural cavity. Removal of a chest tube is a brief but quite painful procedure. Medicate the client before the removal. Remove the dressing around the tube and prepare the dressing that will cover the insertion site. This will be an occlusive dressing if there is no purse-string suture around the insertion site to prevent air from entering the chest. Generally, the primary care provider performs the removal but, in some areas, specially trained nurses may be permitted to do so.

Evaluating

Using the goals and desired outcomes identified in the planning stage of the nursing process, the nurse collects data to evaluate the effectiveness of interventions. If outcomes are not achieved, the nurse, client, and support person if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome “Respirations unlabored and rate is within expected range” is not met, examples of questions that need to be considered include the following:

- What is the client’s perception of the problem?
- Is the client complaining of shortness of breath or difficulty breathing?
- Is the client taking medications or performing treatments such as percussion, vibration, and postural drainage as prescribed?
- Has the client been exposed to an upper respiratory infection that is affecting breathing?
- Do other factors need to be considered, such as the client’s psychological stress level?

Examples of questions to consider if the outcome “Able to complete ADLs without fatigue” is not met include the following:

- What other factors may be affecting the client’s ability to complete ADLs?
- Is the client getting adequate sleep? If not, what is interfering with the client’s rest?
- Are there assistive devices (e.g., a shower chair, clothing that is easy to put on) that could help the client achieve this goal?
- Does the client need help with housework and other ADLs?
- Is the client’s diet adequate to meet nutritional needs?

NURSING CARE PLAN Ineffective Airway Clearance

Assessment Data

Nursing Assessment

Johti Singh is a 39-year-old secretary who was admitted to the hospital with an elevated temperature, fatigue, rapid, labored respirations; and mild dehydration. The nursing history reveals that Ms. Singh has had a “bad cold” for several weeks that just wouldn’t go away. She has been dieting for several months and skipping meals. Ms. Singh mentions that in addition to her full-time job as a secretary she is attending college classes two evenings a week. She has smoked one package of cigarettes per day since she was 18 years old. Chest x-ray confirms pneumonia.

Physical Examination

Height: 167.6 cm (5’6”)
 Weight: 54.4 kg (120 lb)
 Temperature: 39.4°C (103°F)
 Pulse: 68 beats/min
 Respirations: 24/min
 Blood pressure: 118/70 mmHg
 Skin pale; cheeks flushed
 Chills; use of accessory muscles; inspiratory crackles with diminished breath sounds right base; expectorating thick, yellow sputum

Diagnostic Data

Chest x-ray: right lobar infiltration
 WBC: 14,000
 pH: 7.49
 PaCO₂: 33 mmHg
 HCO₃⁻: 20 mEq/L
 PaO₂: 80 mmHg
 O₂ SAT: 88%

Nursing Diagnosis

Ineffective Airway Clearance related to thick sputum, secondary to pneumonia (as evidenced by rapid respirations, diminished and adventitious breath sounds, thick yellow sputum)

Desired Outcomes*

Respiratory Status: Airway

Patency [0410] as evidenced by:

- No deviation from normal range for respiratory rate
- No accumulation of sputum
- No adventitious breath sounds

NURSING CARE PLAN Ineffective Airway Clearance—continued

Nursing Interventions*/Selected Activities	Rationale
Cough Enhancement [3250]	
Assist Ms. Singh to a sitting position with head slightly flexed, shoulders relaxed, and knees flexed.	<i>Lying flat causes the abdominal organs to shift toward the chest, crowding the lungs and making it more difficult to breathe.</i>
Encourage her to take several deep breaths.	<i>Deep breathing promotes oxygenation before controlled coughing.</i>
Encourage her to take a deep breath, hold for 2 seconds, and cough two or three times in succession.	<i>Controlled coughing is accomplished by closure of the glottis and the explosive expulsion of air from the lungs by the work of abdominal and chest muscles.</i>
Encourage use of incentive spirometry, as appropriate.	<i>Breathing exercises help maximize ventilation.</i>
Promote systemic fluid hydration, as appropriate.	<i>Adequate fluid intake enhances liquefaction of pulmonary secretions and facilitates expectoration of mucus.</i>
Respiratory Monitoring [3350]	
Monitor rate, rhythm, depth, and effort of respirations.	<i>Provides a basis for evaluating adequacy of ventilation.</i>
Note chest movement, watching for symmetry, use of accessory muscles, and supraclavicular and intercostal muscle retractions.	<i>Presence of nasal flaring and use of accessory muscles during respirations may occur in response to ineffective ventilation.</i>
Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds.	<i>As fluid and mucus accumulate, abnormal breath sounds can be heard including crackles and diminished breath sounds resulting from fluid-filled air spaces and diminished lung volume.</i>
Auscultate lung sounds after treatments to note results.	<i>Assists in evaluating prescribed treatments and client outcomes.</i>
Monitor client's ability to cough effectively.	<i>Respiratory tract infections alter the amount and character of secretions. An ineffective cough compromises airway clearance and prevents mucus from being expelled.</i>
Monitor client's respiratory secretions.	<i>People with pneumonia commonly produce rust-colored, purulent sputum.</i>
Institute respiratory therapy treatments (e.g., nebulizer) as needed.	<i>A variety of respiratory therapy treatments may be used to open constricted airways and liquefy secretions.</i>
Monitor for increased restlessness, anxiety, and air hunger.	<i>These clinical manifestations would be early indicators of hypoxia.</i>
Note changes in SpO ₂ , tidal volume, and arterial blood gas values, as appropriate.	<i>Evaluates the status of oxygenation, ventilation, and acid-base balance.</i>
Evaluation	
Outcome partially met. Ms. Singh coughs and deep breathes purposefully q1–2h during the day. Her fluid intake is approximately 1,500 mL each day. Cough continues to be productive of moderately thick, rusty-colored sputum. Inspiratory crackles remain present in right lower lobe.	

*The NOC # for desired outcomes and the NIC # for nursing interventions are listed in brackets following the appropriate outcome or intervention. Outcomes, interventions and activities selected are only a sample of those by NOC and NIC and should be further individualized for each client.

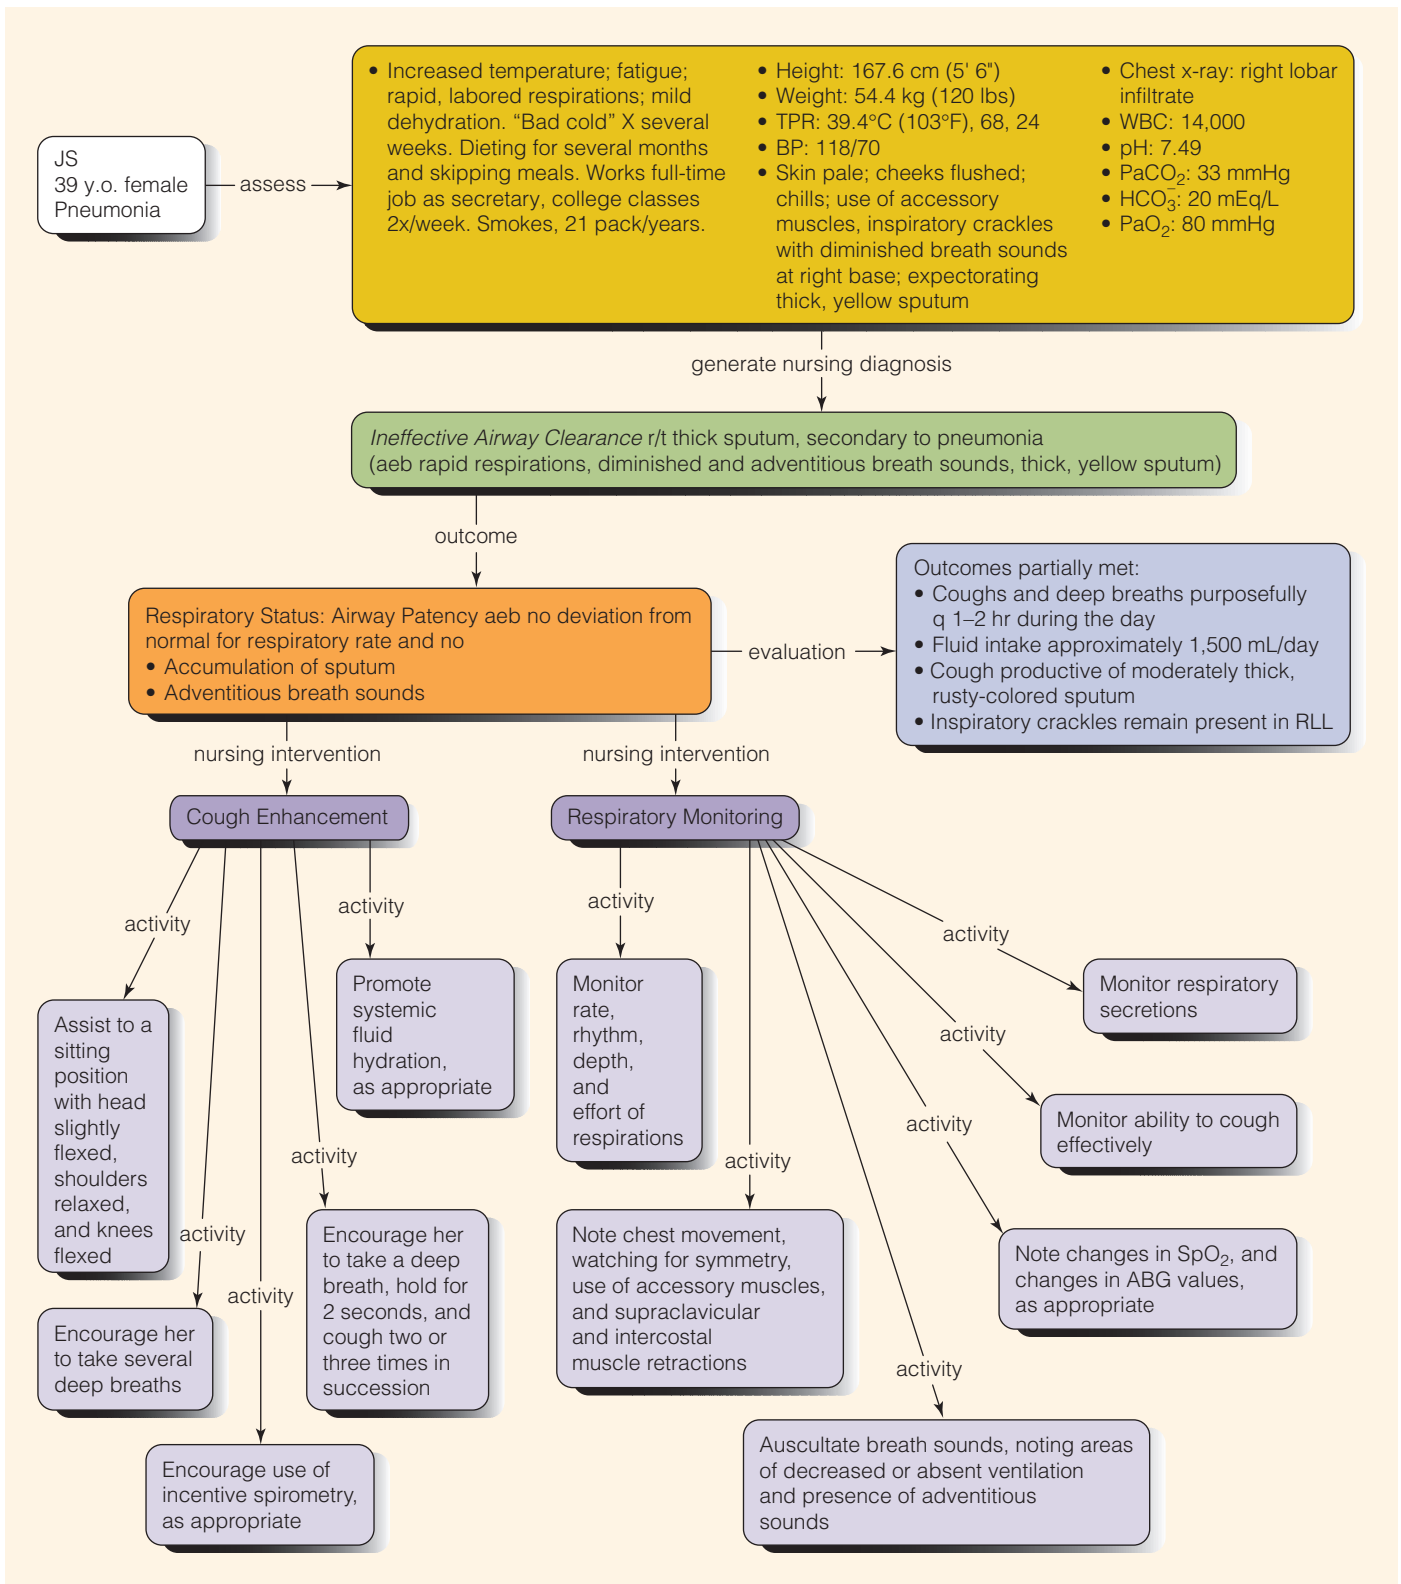

Applying Critical Thinking

1. What factors may have led the medical staff to suspect that Ms. Singh had more than a very bad cold? Would you have come to the same conclusion?
2. The care plan appropriately focuses on the acute care of this client. Once she is significantly improved, the nurse will perform discharge teaching. What areas should be included?
3. The client already has some signs of respiratory distress. What signs might indicate that her condition was deteriorating into a more emergency situation? How would you handle this?
4. It appears that the client's sputum has not been cultured. In caring for this client, what infection control guidelines would be needed?
5. Ms. Singh's oxygen order is for a face mask at 6 L/min. She repeatedly pulls it off and you find it lying in the sheets. How might you intervene?

See Critical Thinking Possibilities on student resource website.

CONCEPT MAP

Ineffective Airway Clearance

Chapter 50 Review

CHAPTER HIGHLIGHTS

- Respiration is the process of gas exchange between the individual and the environment.
- The respiratory system contributes to effective respiration through pulmonary ventilation (the movement of air between the atmosphere and the lungs), the diffusion of oxygen and carbon dioxide across the pulmonary membrane, transport of oxygen from the tissues to the lungs and carbon dioxide from the tissues to the lungs, and transport of oxygen and carbon dioxide between the systemic capillaries and the tissues.
- Alveoli and the capillaries that surround them form the respiratory membrane, where gas exchange between the lungs and the blood occurs.
- Effective pulmonary ventilation, or breathing, requires clear airways, an intact central nervous system and respiratory center, an intact thoracic cavity and musculature, and adequate pulmonary compliance (stretch) and recoil.
- Gas exchange occurs by diffusion, as gas molecules move from an area of higher concentration to an area of lower concentration. At the respiratory membrane, oxygen moves from the alveolus into the blood, while carbon dioxide moves from the blood into the alveolus.
- Most oxygen (97%) is carried to the tissues loosely combined with hemoglobin in red blood cells (RBCs). Anemia, which is too few RBCs or low hemoglobin levels, impairs oxygen transportation.
- Respiratory regulation includes both neural and chemical controls to maintain the correct concentrations of oxygen, carbon dioxide, and hydrogen ions in body fluids. The body's "respiratory center" is located in the medulla oblongata and pons of the brain.
- Respiratory rates normally are highest in neonates and infants, gradually slowing to adult ranges.
- Aging affects the respiratory system: The chest wall becomes more rigid and lungs less elastic.
- Other factors affecting oxygenation include the environment, lifestyle, health status, medications, and stress.
- Respiratory function can be altered by conditions that affect the patency of the airway, movement of air into or out of the lungs, diffusion of oxygen and carbon dioxide between the alveoli and the pulmonary capillaries, and the transport of oxygen and carbon dioxide via the blood to and from the tissue cells.
- Hypoxia, insufficient oxygen in the tissues, can result from impaired ventilation (hypoventilation) or impaired diffusion, or from impaired oxygen transportation to the tissues because of anemia or decreased cardiac output.
- Airway obstruction interferes with ventilation. A low-pitched snoring sound, stridor, and abnormal breath sounds may accompany partial airway obstruction. Extreme inspiratory effort with no chest movement indicates complete upper airway obstruction.
- Normal respirations are quiet and unlabored; altered respiratory patterns include tachypnea, bradypnea, hyperventilation, hypoventilation, and dyspnea. Shortness of breath is a subjective sensation of not getting enough air.
- The nursing history includes questions about current or past respiratory problems and about lifestyle, presence of symptoms such as cough or shortness of breath, smoking and other risk factors, and medications.
- Diagnostic tests that may be performed to assess oxygenation include sputum and throat culture specimens; blood tests such as arterial blood gases; pulmonary function tests; and visualization procedures such as x-rays, lung scans, laryngoscopy, and bronchoscopy.
- Nursing diagnoses for the client with problems of oxygenation include *Ineffective Airway Clearance*, *Ineffective Breathing Pattern*, *Impaired Gas Exchange*, and *Activity Intolerance*. These problems also may be the etiology for several other nursing diagnoses, including *Anxiety*, *Fatigue*, *Fear*, *Powerlessness*, *Insomnia*, and *Social Isolation*.
- In discharge and home care planning, the nurse assesses the client's self-care abilities and need for assistive devices, home environment, compliance with medical regimen, and knowledge level. The ability of the family or support people to provide assistance and financial support and to cope with the changes is also assessed, as are community factors such as the environment and resources.
- The nurse teaches the client about home care activities to maintain a patent airway and gas exchange and to promote healthy breathing. Dietary modifications, prescribed medications, and specific procedures also are taught, and the nurse makes referrals to community agencies as needed.
- Nursing interventions to promote oxygenation include promoting healthy breathing, deep breathing and coughing, and hydration; administering medications; implementing measures to clear secretions (e.g., incentive spirometry, percussion, vibration, postural drainage, and mucus clearing devices); initiating and monitoring oxygen therapy; initiating or assisting with procedures to maintain the airway (e.g., artificial airways and suctioning); providing tracheostomy care; and monitoring chest drainage systems.
- The effectiveness of nursing interventions is evaluated by using the goals and desired outcomes identified in the planning stage of the nursing process. If a goal is not met, the nurse asks pertinent questions to assess the reason for not meeting the goal.

TEST YOUR KNOWLEDGE

1. A client with chronic pulmonary disease has a bluish tinge around the lips. The nurse charts which term to most accurately describe the client's condition?
 1. Hypoxia
 2. Hypoxemia
 3. Dyspnea
 4. Cyanosis
2. To prevent postoperative complications, the nurse assists the client with coughing and deep-breathing exercises. This is best accomplished by implementing which of the following?
 1. Coughing exercises 1 hour before meals and deep breathing 1 hour after meals
 2. Forceful coughing as many times as tolerated
 3. Huff coughing every 2 hours or as needed
 4. Diaphragmatic and pursed-lip breathing 5 to 10 times, four times a day

3. The nurse is preparing to perform tracheostomy care. Prior to beginning the procedure the nurse performs which action?
 1. Tells the client to raise two fingers to indicate pain or distress.
 2. Changes the twill tape holding the tracheostomy in place.
 3. Cleans the incision site.
 4. Checks the tightness of the ties and knot.
4. Which action by the nurse represents proper nasopharyngeal/nasotracheal suction technique?
 1. Lubricate the suction catheter with petroleum jelly before and between insertions.
 2. Apply suction intermittently while inserting the suction catheter.
 3. Rotate the catheter while applying suction.
 4. Hyperoxygenate with 100% oxygen for 30 minutes before and after suctioning.
5. Which client statement informs the nurse that his teaching about the proper use of an incentive spirometer was effective?
 1. "I should breathe out as fast and hard as possible into the device."
 2. "I should inhale slowly and steadily to keep the balls up."
 3. "I should use the device three times a day, after meals."
 4. "The entire device should be washed thoroughly in sudsy water once a week."
6. While a client with chest tubes is ambulating, the connection between the tube and the water seal dislodges. Which action by the nurse is most appropriate?
 1. Assist the client to ambulate back to bed.
 2. Reconnect the tube to the water seal.
 3. Assess the client's lung sounds with a stethoscope.
 4. Have the client cough forcibly several times.
7. The nurse makes the assessment that which client has the greatest risk for a problem with the transport of oxygen from the lungs to the tissues? A client who has
 1. Anemia.
 2. An infection.
 3. A fractured rib.
 4. A tumor of the medulla.
8. Which term does the nurse document to best describe a client experiencing shortness of breath when lying down who must assume an upright or sitting position to breathe more comfortably and effectively?
 1. Dyspnea
 2. Hyperpnea
 3. Orthopnea
 4. Acapnea
9. A client with emphysema is prescribed corticosteroid therapy on a short-term basis for acute bronchitis. The client asks the nurse how the steroids will help him. The nurse responds by saying that the corticosteroids will do which of the following?
 1. Promote bronchodilation.
 2. Help the client to cough.
 3. Prevent respiratory infection.
 4. Decrease inflammation in the airways.
10. The nurse is planning to perform percussion and postural drainage. Which is an important aspect of planning the client's care?
 1. Percussion and postural drainage should be done before lunch.
 2. The order should be coughing, percussion, positioning, and then suctioning.
 3. A good time to perform percussion and postural drainage is in the morning after breakfast when the client is well rested.
 4. Percussion and postural drainage should always be preceded by 3 minutes of 100% oxygen.

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Outline the structure and physiology of the cardiovascular system.
2. Identify major risk factors for the development of cardiovascular disease and related health promotion objectives from *Healthy People 2020*.
3. Describe three major alterations in cardiovascular function.
4. Outline the nursing management of a client with cardiovascular disease.
5. Describe the critical nature of cardiopulmonary resuscitation.
6. Verbalize the steps used in:
 - a. Applying a sequential compression device.
7. Recognize when it is appropriate to delegate aspects of applying a sequential compression device to unlicensed assistive personnel.
8. Demonstrate appropriate documentation and reporting when applying a sequential compression device.

INTRODUCTION

The circulatory, or cardiovascular, system is responsible for the transport of oxygen, fluids, electrolytes, and products of metabolism via the blood to and from tissues.

PHYSIOLOGY OF THE CARDIOVASCULAR SYSTEM

The respiratory and cardiovascular systems are closely linked and dependent on one another to deliver oxygen to the tissues of the body. Alterations in function of either system can affect the other and lead to tissue hypoxia (lack of oxygen).

The heart and the blood vessels make up the cardiovascular system. Together with blood, it is the major transport system of the body, bringing oxygen and nutrients to the cells and removing wastes for disposal. The heart serves as the system's pump, moving blood through the vessels to the tissues.

The Heart

The heart is a hollow, cone-shaped organ about the size of a fist. It is located in the mediastinum, between the lungs and underlying the sternum. It is enclosed by a double layer of fibrous membrane known as the **pericardium**. The parietal, or outermost, pericardium serves to protect the heart and anchor it to surrounding structures. The visceral pericardium adheres to the surface of the heart, forming the heart's

outermost layer, the **epicardium**. The heart wall contains two additional layers: the **myocardium**, cardiac muscle cells that form the bulk of the heart and contract with each beat, and the **endocardium**, which lines the inside of the heart's chambers and great vessels (Figure 51-1 ■).

Four hollow chambers within the heart, two upper **atria** and two lower **ventricles**, are separated longitudinally by the interventricular **septum**, forming two parallel pumps. The atria and ventricles are separated from one another by the **atrioventricular (AV) valves**, the tricuspid valve on the right and the bicuspid or mitral valve on the left. The valves are named for the number of cusps (or leaflets) present on the valve. The ventricles, in turn, are separated from the great vessels (the pulmonary arteries and aorta) by the **semilunar valves** (named for their crescent moon shape): the pulmonary (also called the pulmonic) valve on the right and the aortic valve on the left. The valves serve to direct the flow of blood, allowing it to move from the atria to the ventricles, and the ventricles to the great vessels, but preventing backflow (Figure 51-2 ■).

Deoxygenated blood from the veins enters the right side of the heart through the superior and inferior venae cavae (singular is vena cava). From there, it flows into the right ventricle, which pumps it through the pulmonary artery into the lungs for gas exchange across the alveolar-capillary membrane. Freshly oxygenated blood returns to the left atrium via the pulmonary veins. From here, the blood enters the left ventricle to be pumped out for systemic circulation through the aorta (Figure 51-3 ■).

Figure 51-1 ■ The layers of the heart: the epicardium, the myocardium, and the endocardium.

CORONARY CIRCULATION

The heart muscle moves blood to the lungs and peripheral tissues but does not receive oxygen or nourishment from the blood within its chambers. Instead, it is supplied by a network of vessels known as coronary circulation or more commonly as the **coronary arteries**. The coronary arteries originate at the base of the aorta, branching out to encircle and penetrate the myocardium. These arteries fill during ventricular relaxation, bringing oxygen-rich blood to the myocardium (Figure 51-4 ■). If these arteries become clogged with atherosclerotic plaques or are obstructed by a blood clot, the myocardium is deprived of oxygen, and the client may develop chest pain (angina) or

experience a myocardial infarction (heart attack). The cardiac veins drain the deoxygenated blood from the myocardium into the coronary sinus, which empties into the right atrium.

CARDIAC CYCLE

With each heartbeat, the myocardium goes through a cycle of contraction (systole) and relaxation (diastole). **Systole** is when the heart ejects (propels) the blood into pulmonary and systemic circulation. **Diastole** is when the ventricles fill with blood. The diastolic phase of the cardiac cycle is twice as long as the systolic phase. This is important because diastole (or ventricular filling) is largely a passive

1. The sinoatrial (SA) node fires a stimulus across the walls of both left and right atria causing them to contract.
2. The stimulus arrives at the atrioventricular (AV) node.
3. The stimulus is directed to follow the AV bundle (Bundle of His).
4. The stimulus now travels through the apex of the heart through the bundle branches.
5. The Purkinje fibers distribute the stimulus across both ventricles causing ventricular contraction.

Figure 51-3 ■ The functioning of the heart valves and blood flow through the heart.

From *Medical Terminology: A Word-Building Approach*, 7th ed. (p. 264), by J. Rice, 2012. Reproduced by permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

Figure 51-4 ■ The coronary arteries supply the heart muscle with oxygenated blood.

TABLE 51-1 Cardiac Cycle and Heart Sounds

Sound	Phase of Cardiac Cycle
S ₁ —first sound	Beginning of ventricular systole; the sound is caused by closure of the atrioventricular valves—the tricuspid and the mitral.
S ₂ —second sound	Beginning of ventricular diastole; the sound is caused by closure of the semilunar valves—the aortic and pulmonic.

process. The longer diastolic phase allows this filling to occur. At the end of the diastolic phase, the atria contract, adding additional volume to the ventricles. This volume is sometimes called *atrial kick*. The relationship between the phases of the cardiac cycle and normal heart sounds is described in Table 51-1.

CARDIAC CONDUCTION SYSTEM

Cardiac muscle contraction is a mechanical event that occurs in response to electrical stimulation. Cardiac muscle is unique in

1. The sinoatrial (SA) node fires a stimulus across the walls of both left and right atria causing them to contract.
2. The stimulus arrives at the atrioventricular (AV) node.
3. The stimulus is directed to follow the AV bundle (Bundle of His).
4. The stimulus now travels through the apex of the heart through the bundle branches.
5. The Purkinje fibers distribute the stimulus across both ventricles causing ventricular contraction.

Figure 51–5 ■ The conduction system of the heart. The impulse is initiated by the SA node, then travels to the AV node, the bundle of His, bundle branches, and finally to the Purkinje fibers.

From *Medical Terminology: A Word-Building Approach*, 7th ed. (p. 268), by J. Rice, 2012. Reproduced by permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

that, unlike skeletal muscle, it can generate electrical impulses and contractions independently of the nervous system. This unique property of heart muscle is called **automaticity**. A network of specialized cells and pathways known as the cardiac conduction system normally controls the electrical activity and contractions of the heart.

The primary pacemaker of the heart is the **sinoatrial (SA or sinus) node**, located where the superior vena cava enters the right atrium. The SA node normally initiates electrical impulses that are conducted throughout the heart and result in ventricular contraction. In adults, it usually discharges impulses at a regular rate of 60 to 100 times per minute, the “normal” heart rate. The impulse then spreads throughout the atria via the interatrial pathways. These conduction pathways converge and narrow through the **atrioventricular (AV) node**, slightly delaying transmission of the impulse to the ventricles. This delay allows the atria to contract slightly before ventricular contraction occurs. From the AV node, the impulse then progresses down through the intraventricular septum to the ventricular conduction pathways: the **bundle of His**, the right and left bundle branches, and the **Purkinje fibers**. These fibers terminate in ventricular muscle, stimulating contraction (Figure 51–5 ■).

CARDIAC OUTPUT

As the ventricles contract during systole, blood flows out of the ventricles through the aorta and pulmonary artery into systemic and pulmonary circulation. The heart muscle then relaxes (the diastolic phase), allowing the ventricles to refill and cardiac muscle to be perfused. This repeated contraction and relaxation of the heart is known as the cardiac cycle. The cycle is repeated 60 to 100 times a minute in an adult, stimulated by impulses generated by the SA node.

With each contraction, a certain amount of blood, known as the stroke volume, is ejected from the ventricles into circulation. In adults, the average stroke volume is about 70 mL per beat. **Cardiac output (CO)** is the amount of blood pumped by the ventricles in 1 minute. Cardiac output is calculated by multiplying the **stroke volume (SV)**, the amount of blood ejected with each contraction, times the heart rate (HR). Thus, $SV \times HR = CO$. Normal cardiac output is 4 to 8 L/min. Cardiac output is an important indicator of how well the heart is functioning as a pump. If CO is poor, oxygen and nutrients do not reach cells as needed, impairing tissue perfusion. Cardiac output is affected by several factors, as discussed next.

HEART RATE An increased heart rate increases CO, even if the stroke volume does not change. Conversely, CO decreases when the heart rate falls if stroke volume remains constant. There are physiological limits to the increase in CO that occurs with increased heart rate. Very rapid heart rates, more than 150 beats per minute in an adult, may not allow adequate time for the ventricles to fill, causing CO to fall. Heart rate is influenced by many factors including the autonomic nervous system, blood pressure, hormones such as thyroid hormone, and some medications.

PRELOAD **Preload** is the degree to which muscle fibers in the ventricle are stretched at the end of the relaxation period (diastole). Preload largely depends on the amount of blood returning to the heart from venous circulation; increased volume causes increased stretch, leading to more forceful contraction of cardiac muscle fibers. This physiological relationship is referred to as the Frank-Starling law of the heart, which states that the length of ventricular muscle fibers (stretch) at the end of diastole directly affects the strength (force) of contraction. For example, exercise increases venous return and therefore increases preload; in response, the heart contracts more forcefully, causing stroke volume and cardiac output to increase during exercise.

CONTRACTILITY **Contractility** is the natural ability of cardiac muscle fibers to shorten or contract. Stroke volume decreases if contractility is poor, reducing cardiac output. Contractility is affected by the autonomic nervous system and certain drugs. Drugs that affect contractility are called inotropic drugs; positive inotropic drugs increase contractility, and negative inotropic drugs decrease contractility. See the Drug Capsule on digoxin in Chapter 29 ∞ to learn more about this positive inotropic medication.

AFTERLOAD **Afterload** is the resistance that the ventricle must overcome during systole to eject blood into circulation. The right ventricle ejects blood into the pulmonary circulation, and the left ventricle ejects blood through the aortic valve to the systemic circulation. Blood flows from an area of higher pressure to an area of lower pressure. To move blood into the circulatory system, the ventricles must generate sufficient pressure to overcome vascular resistance or the pressure within the arteries, known as *afterload*. The right ventricle pumps blood into the low-pressure, low-resistance pulmonary vascular system; therefore, the pressures generated by the right ventricle are fairly low. The left ventricle, by contrast, pumps blood into the higher pressure systemic arterial system, generating much higher pressures and requiring more work. The higher the afterload, the harder the heart has to work to eject its contents, resulting in increased myocardial oxygen demand. For example, systemic vasoconstriction increases the arterial blood pressure and afterload, increasing the cardiac workload; vasodilation, on the other hand, reduces arterial pressure and the workload of the heart. Table 51–2 summarizes the factors related to cardiac function.

Blood Vessels

With each cardiac contraction, blood is ejected into a closed system of blood vessels that transport blood to the tissues and return it to the heart. The heart supports two circulatory systems: the low-pressure pulmonary system and the higher pressure systemic system.

TABLE 51–2 Factors Related to Cardiac Function

Indicator	Definition
Cardiac output (CO)	Amount of blood ejected from the heart each minute; $CO = SV \times HR$
Stroke volume (SV)	Amount of blood ejected from the heart with each beat
Heart rate (HR)	Number of beats each minute
Contractility	Inotropic state of the myocardium, strength of contraction
Preload	Left ventricular end diastolic volume, stretch of the myocardium
Afterload	Resistance against which the heart must pump

Deoxygenated blood from the right ventricle enters the pulmonary system through the pulmonary arteries. The pulmonary arteries subdivide into lobar arteries. These lobar arteries follow the main bronchi into the lungs, then branch out to form arterioles and the dense capillary networks that encompass the alveoli. Oxygen diffuses into the blood from the alveoli, and carbon dioxide diffuses into the alveoli from the blood. This diffusion occurs across the alveolar–capillary membrane. The blood then returns to the left side of the heart via venules and the pulmonary veins. Note that the pulmonary vascular system is the only part of the circulatory system in which arteries (which transport blood away from the heart) carry deoxygenated blood, and veins (which transport blood toward the heart) contain oxygenated blood.

The muscular left ventricle of the heart pumps oxygenated blood into the aorta. The blood then moves into major arteries that branch from the aorta and into successively smaller arteries, arterioles, and finally into the thin-walled capillary beds of organs and tissues. It is in the capillary beds that oxygen and nutrients are exchanged for metabolic waste products. The deoxygenated blood then returns to the heart through a series of venules and veins that become progressively larger until they empty into the superior and inferior venae cavae.

With the exception of capillaries, blood vessel walls have three distinct layers, or tunics. The innermost layer, the tunica intima, is smooth endothelium that facilitates blood flow. The tunica media is made up of elastic fibers and smooth muscle cells innervated by the autonomic nervous system. This allows vessels to constrict or dilate, depending on the needs of the body. The tunica media of arteries is thicker and more muscular than that of veins, a feature that helps maintain blood pressure and continuous circulation to the tissues. The outermost layer of blood vessels is the tunica adventitia, a layer of connective tissue that supports, protects, and anchors the vessel to surrounding tissues. Capillaries contain only one thin layer of tunica intima, allowing gases and molecules to diffuse between the blood and the tissues.

ARTERIAL CIRCULATION

Arterial circulation moves blood from the heart to the tissues, maintaining a constant flow to the capillary beds despite the intermittent pumping action of the heart.

Blood flow, the volume of blood flowing through a given vessel, organ, or the entire circulatory system over a specific period, is determined by pressure differences and resistance. Blood always moves

ANATOMY & PHYSIOLOGY REVIEW

Preload and Afterload

From *Medical Language*, 3rd ed., by S. M. Turley, © 2014. Reproduced with permission of Pearson Education, Inc. Upper Saddle River, New Jersey.

QUESTIONS

Preload is affected by the amount of blood returning to the heart from the venous circulation. Review the figure.

1. Which side of the heart is primarily affected by preload?
2. What could cause an *increase* of venous blood return to the heart?
3. When would an increase in preload have a positive effect/outcome for the client?
4. When does an increase in preload have a negative effect/outcome for the client?
5. What medication classification decreases preload? (*Hint*: Think about what could cause a decrease in venous return of volume to the heart.)

Afterload is the resistance against which the heart must pump. Review the figure.

6. Which side of the heart is primarily affected by afterload?
7. What can cause an increase in afterload (e.g., what can cause the left side of the heart to work harder)?
8. Based on the physiology, afterload can be decreased by medications that would have what physiological result/outcome?

See student resource website for answers.

from an area of higher pressure to an area of lower pressure. The greater the difference between pressures, the greater the blood flow. **Blood pressure (BP)** is the force exerted on arterial walls by the blood flowing within the vessel. See Chapter 29 ∞ for a further explanation of blood pressure. Mean arterial pressure (MAP) maintains blood flow to the tissues throughout the cardiac cycle. It is a product of cardiac output times **peripheral vascular resistance (PVR)**, or $CO \times PVR = MAP$.

Resistance is opposition to flow; peripheral vascular resistance impedes or opposes blood flow to the tissues. PVR is determined by:

- The viscosity, or thickness, of the blood
- Blood vessel length
- Blood vessel diameter.

VENOUS RETURN

In contrast to the high-pressure arterial system, venous pressure is too low to adequately return blood from peripheral tissues to the heart without assistance. The fall in intrathoracic pressure that occurs

with breathing draws blood upward toward the heart, an adaptation known as the respiratory pump. Skeletal muscle activity contributes to the muscular pump, as muscle contractions move blood toward the heart. Venous valves are vital in making these pumps work; once blood passes a valve, it cannot flow backward away from the heart. Figure 51–6 ■ depicts the relationship between arteries and veins and the entire circulatory system.

Blood

Blood serves as the transport medium within the cardiovascular system, bringing oxygen and nutrients from the environment (via the lungs and gastrointestinal system) to the cells. Blood is a complex mixture of living elements (the blood cells) suspended in fluid (the plasma). Its primary functions are:

- Transporting oxygen, nutrients, and hormones to the cells, and metabolic wastes from the cells for elimination
- Regulating body temperature, pH, and fluid volume
- Preventing infection and blood loss.

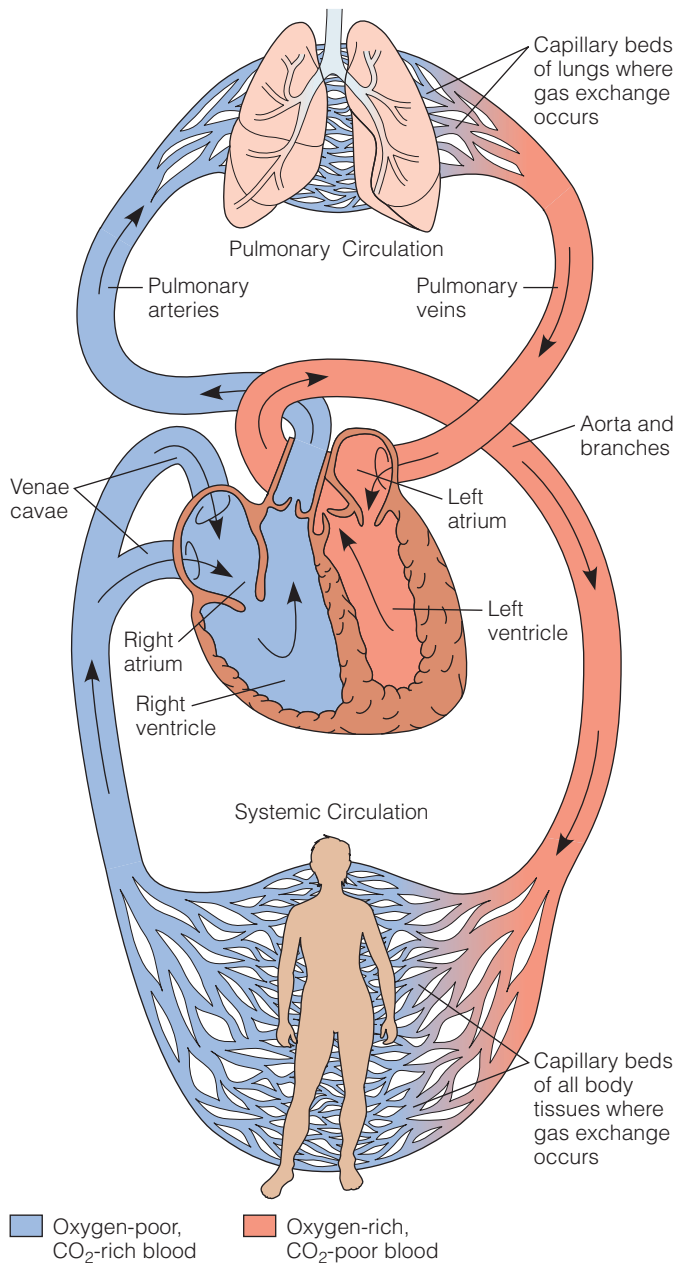

Figure 51–6 ■ The heart and blood vessels. The left side of the heart pumps oxygenated blood into the arteries. Deoxygenated blood returns via the venous system into the right side of the heart.

As previously noted in Chapter 50 ∞, most oxygen is transported bound to hemoglobin. **Hemoglobin** is a major component of red blood cells (erythrocytes), the predominant cell present in blood. Hemoglobin binds easily with oxygen, releasing it to body tissues. When all four heme groups of the hemoglobin molecule are bound to oxygen, it is said to be fully saturated. Oxygen binding is affected by several factors, including PO_2 , temperature, pH, and PCO_2 . Up to a certain point (about 70 mmHg), the higher the PO_2 , the greater the affinity of hemoglobin for oxygen and the more saturated the hemoglobin molecules. The relationships between oxygen binding and temperature, pH, and PCO_2 are the opposite: At higher temperatures, greater hydrogen ion concentrations (lower pH), and higher PCO_2 levels, the affinity of hemoglobin for oxygen decreases, and hemoglobin releases its oxygen molecules. Because of hemoglobin's importance

in oxygen transportation, anemia (too few red blood cells [RBCs] that contain too little or abnormal hemoglobin) interferes with oxygen delivery to the tissues, leading to fatigue and activity intolerance.

LIFESPAN CONSIDERATIONS

At birth, profound changes occur in the cardiovascular system. As the lungs expand, pressure in the pulmonary vascular system falls, changing pressure relationships within the heart. The foramen ovale (an opening between the two atria of the fetal heart) closes as pressure on the right side of the heart falls and pressure on the left side increases. Arterial PO_2 rises and arterial PCO_2 falls, prompting closure of the ductus arteriosus (a short vessel between the pulmonary artery and aorta of the fetus).

Pulse rates are highest and most variable in newborns. The resting heart rate for a neonate ranges from 100 to 170 beats/min immediately after birth and then the average heart rate is 120 beats/min (Ball, Bindler, & Cowen, 2014, p. 195). The heart rate decreases to 80 to 130 in infants up to 2 years of age, and continues to decrease throughout early childhood until reaching the adult rate of 60 to 100 by about age 10 years. Irregular heart rates are common in infants and young children, often increasing and decreasing with each breath. This pattern of irregularity is known as sinus arrhythmia, a normal variation in heart rate.

As the conversion from fetal circulation occurs, and pressure in the left side of the heart rises, arterial blood pressure increases. Immediately after birth (1 to 3 days of age) BP averages about 60/40 to 80/45 mmHg. By 1 month BP is about 90/55, and it rises gradually to 110/65 by approximately 16 years of age (Ball, Bindler, & Cowen, 2010, p. 256). With aging, BP may again rise as arteriosclerosis affects the blood vessels, narrowing their lumen and decreasing their ability to dilate.

Congenital heart disease occurs in approximately 1% of all live births. Death, however, from congenital heart disease has significantly decreased due to diagnostic advances and new surgical techniques. Nearly 1 million adults with congenital heart defects are living today in the United States (Ball et al., 2014, p. 804). Acquired heart diseases, though rare in childhood, include rheumatic fever, an inflammatory disorder that may occur following streptococcal infection (e.g., strep throat) and lead to heart valve damage. For most people, however, the heart continues to function effectively well into older adulthood unless the blood supply to the heart muscle is impaired by blood vessel disease. **Atherosclerosis**, the buildup of fatty plaques within the arteries, is the primary contributor to cardiovascular disease (CVD), which is the leading cause of death in North America.

Children are rarely affected by diseases of the blood vessels, although the increase in childhood obesity has increased the incidence in this age group. Hypertension or elevated BP may be associated with obesity, sedentary lifestyle, and stress in children and adolescents. During middle adulthood, the incidence of hypertension increases significantly. Hypertension, known as the silent killer because of its lack of symptoms, is a major risk factor for sudden cardiac death in middle adulthood.

FACTORS AFFECTING CARDIOVASCULAR FUNCTION

Many factors affect cardiovascular function. Some of these factors are called risk factors, because, if present, they increase the risk of CVD. Risk factors have been identified for CVD, hypertension, and

LIFESPAN CONSIDERATIONS Circulation**CHILDREN**

- Blood pressure should be taken routinely on children after age 3 years, but is not typically evaluated before that age.
- Heart murmurs, extra sounds detected when listening to the heart, are common in children, especially in the preschool years. The vast majority are not associated with a pathology, but are due to normal blood flow or transitional physiological processes that increase cardiac output (e.g., anemia, fever, exercise).

OLDER ADULTS

Normal changes of aging may contribute to problems of circulation in older adults, even when there is no actual pathology:

- Blood vessels become less elastic and have an increase in calcification. This results in restricted blood flow and a decrease of oxygen and nutrients delivered to tissues (heart, peripheral, and cerebral).
- Impaired valve function in the heart is often the result of increased stiffness and calcification and results in a decrease in cardiac output.
- A decrease of muscle tone in the heart results in a decrease in cardiac output.

- There is a decrease in baroreceptor response to blood pressure changes, making the heart and blood vessels less responsive to exercise and stress. This often results in dizziness, falls, orthostatic hypotension, and mental changes.
- A decrease in conduction ability in the heart also makes the heart less responsive to changes and stresses. This can also result in dizziness, falls, orthostatic hypotension, and mental changes.

All of these factors become important if the person is challenged by stressors, such as exercise, stress, fever, surgery, or other changes. If challenged, the circulatory system of older adults is not as effective or as quick to return to normal. Individuals living with normal changes of aging and/or pathologic conditions of the circulatory system need to learn to balance diet, medications, and exercise. Nurses have a large role in working with these clients to develop appropriate interventions and provide teaching to help them maintain optimal functioning. Teaching clients to recognize any changes or worsening of their condition is very important. They need to know when to contact their primary care provider to make any needed changes. Changing lifestyles and fine-tuning medications can be critical, and nurses can be a part of this in every phase of the nursing process.

peripheral vascular disease, and the majority of these factors are the same for all three disorders.

Risk Factors

Major traditional risk factors for CVD in general are classified as either *nonmodifiable* (cannot be reduced) or *modifiable* (can be reduced). Newer, nontraditional cardiovascular risk factors have also been identified (Box 51–1). It is important to remember that most CVD is preventable. Research has shown that individuals with low cardiovascular risk factors have a substantially reduced risk of developing CVD. Unfortunately, the processes that lead to CVD begin early in life. For example, epidemiologic studies provide evidence that “risk factors associated with CVD in adulthood have their origins in childhood and adolescence” (Berra, Fletcher, Hayman, & Miller, 2013, p. 505).

NONMODIFIABLE RISK FACTORS

The first nonmodifiable risk factor is *heredity*. There is a genetic influence on the development of CVD. That is, if a client has a parent

with heart disease, he or she is at higher risk. In addition, members of certain racial and ethnic groups, such as African Americans, have a higher risk of developing CVD. The second is *age*. Cardiovascular disorders used to primarily affect people over age 60. Research, however, has shown that the major lifestyle behaviors associated with CVD (e.g., patterns of diet, physical activity, and tobacco use) are established early in childhood and do influence the development of CVD risk factors in childhood, adolescence, and adulthood. Jaquith, Harris, and Penprase (2013) report that CVD risk is a growing reality for very young children based on their study, which determined that children often change from “no risk to being at risk for CVD before preschool” (p. 264). The third nonmodifiable risk factor is *gender*. Until menopause, estrogen has a protective effect in women, slowing the progression of atherosclerosis and reducing the risk of CVD. This effect is lost at menopause, and postmenopausal women have the same risk for CVD as men. Caboral (2013) and Kuznar (2010) note, however, that gender-specific trends in heart disease reveal that cardiovascular risk factors for women are increasing. One possible explanation for this narrowing gap is that young women may believe that they are more at risk for other diseases (e.g., cancer). Another reason for increasing CVD in American women is the increase in average body weight (Sherrod, Sherrod, Spitzer, & Cheek, 2013, p. 62). Nurses need to assess and teach both men and women about cardiovascular risk factors.

MODIFIABLE RISK FACTORS

Modifiable risk factors include elevated serum lipid levels, hypertension, cigarette smoking, diabetes, obesity, and sedentary lifestyle. Many of the *Healthy People 2020* objectives relate to these modifiable risk factors.

ELEVATED SERUM LIPID LEVELS A strong link exists between elevated serum lipid levels and the development of CVD. Lipid disorders, also called dyslipidemias, are abnormalities of lipoprotein metabolism and include elevations of total cholesterol, LDL cholesterol, or triglycerides; or deficiencies of HDL cholesterol. A high dietary intake of saturated fats *increases* the total LDL levels, and intake

BOX 51–1 Risk Factors for Cardiovascular Disease**TRADITIONAL RISK FACTORS**

- Nonmodifiable
 - Heredity
 - Age
 - Gender
- Modifiable
 - Elevated serum lipid level
 - Hypertension
 - Cigarette smoking
 - Diabetes
 - Obesity
 - Sedentary lifestyle

NONTRADITIONAL RISK FACTORS

- Metabolic syndrome (Met-S)
- C-reactive protein (CRP)
- Elevated homocysteine level

of polyunsaturated fatty acids *decreases* total LDL in most individuals. Studies have also shown that *trans*-fatty acids (e.g., stick margarine, deep-fried foods) raise LDL levels and lower HDL levels, resulting in an increase in total cholesterol. The American Heart Association (AHA) (2014) recommends that between 25% and 35% of total calories come from fats. The fats should come from polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils. The AHA also provides recommendations on its website for calories based on age, gender, and activity level.

Among adults 75 years and older, 31% of men and almost 58% of women have a total cholesterol level of 240 mg/dL or higher, which is considered high risk (Holm, 2010, p. 252). Older adults, just like all other age groups, have become more obese, which leads to high cholesterol levels. It is this kind of data that accounts for *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2013b) promoting the following objectives: Increase the proportion of adults who have had their blood cholesterol checked within the preceding 5 years; reduce the proportion of adults with high total blood cholesterol levels; reduce the mean total blood cholesterol levels among adults; and increase the proportion of adults with elevated LDL cholesterol who adhere to the prescribed cholesterol-lowering diet, physical activity, weight control, and drug therapy.

HYPERTENSION Hypertension increases the risk of CVD in several ways. First, it increases the workload of the heart, increasing oxygen demand and coronary blood flow. The increased workload also causes hypertrophy of the ventricles. Over time this can contribute to heart failure. Secondly, hypertension causes endothelial damage to the blood vessels, which stimulates the development of atherosclerosis. Atherosclerotic plaques in turn cause a worsening of hypertension by narrowing the vessel lumens and decreasing vessel elasticity. Therefore, there is a cyclical relationship between these two conditions that magnifies an affected person's risk for CVD.

High sodium intake can affect blood pressure and contribute to the development of hypertension. First, it may increase the release of natriuretic hormone, which indirectly contributes to hypertension. Additionally, sodium stimulates vasopressor mechanisms, which cause vasoconstriction. There is also evidence that other factors such as low potassium, calcium, and magnesium intake may contribute to vasoconstriction and the development of hypertension.

Healthy People 2020 (USDHHS, 2013b) includes the following objectives relating to hypertension: Reduce the proportion of adults, children, and adolescents with hypertension; increase the proportion of adults with prehypertension and hypertension who meet the recommended guidelines for body mass index (BMI), saturated fat consumption, sodium intake, physical activity, and moderate alcohol consumption; increase the proportion of adults with hypertension who are taking the prescribed medications to lower their blood pressure; and increase the proportion of adults with hypertension whose blood pressure is under control.

CIGARETTE SMOKING The cardiovascular system is affected by cigarette smoking. Nicotine increases heart rate, blood pressure, and peripheral vascular resistance, increasing the heart's workload. Smoking causes vasoconstriction, and in areas where vessels already are narrowed by atherosclerosis, tissue oxygenation can be impaired.

Healthy People 2020 (USDHHS, 2013e) includes many objectives relating to tobacco use, including these: Reduce tobacco use by adolescents and adults; reduce the initiation of tobacco use among

children, adolescents, and young adults; reduce the proportion of nonsmokers exposed to secondhand smoke; increase tobacco-free environments in schools, including all school facilities, property, vehicles, and school events; and increase tobacco screening in health care settings.

DIABETES Diabetes mellitus increases the risk of CVD and myocardial infarction (MI). High blood glucose levels are associated with accelerated development of atherosclerosis as well as high levels of serum lipids and triglycerides. Closely monitoring blood glucose levels in clients with diabetes and checking blood glucose levels in all clients for the development of increased levels are important nursing functions. Control of blood glucose levels can greatly reduce risk and slow development of atherosclerosis. Examples of objectives in *Healthy People 2020* (USDHHS, 2013a) that pertain to diabetes include the following: Reduce the annual number of new cases of diagnosed diabetes in the population; reduce the diabetes death rate; reduce the rate of lower extremity amputations in individuals with diagnosed diabetes; improve glycemic control among individuals with diabetes; and increase prevention behaviors in individuals with prediabetes who are at high risk for diabetes.

OBESITY Nearly two thirds of the adult population of the United States is overweight or obese (Burke & Wang, 2011). Obesity and diabetes are major health problems that are rapidly getting worse in the United States. In addition, people with obesity have an increased risk for the development of CVD because obesity is often accompanied by elevated serum lipid levels and is associated with hypertension. Thus, adults who are obese are at risk for diabetes and hypertension. Additionally, obesity places an increased workload on the heart, which increases oxygen demand. Research has shown that obese individuals have an increased risk for heart failure and death, and that risk increases in proportion to the degree of obesity.

Examples of objectives in *Healthy People 2020* (USDHHS, 2013c) that pertain to weight include the following: Increase the proportion of adults who are at a healthy weight; reduce the proportion of children and adolescents who are obese; increase the contribution of fruits and whole grains to the diets of the population ages 2 years and older; reduce consumption of calories from solid fats and added sugars in the population ages 2 years and older; and increase the percentage of schools that offer nutritious foods and beverages outside of school meals.

SEDENTARY LIFESTYLE Regular physical activity is associated with a reduction in the risk of death due to CVD, whereas a sedentary lifestyle is associated with increased risk. Physical exercise or activity increases the heart rate and, hence, the supply of oxygen in the body. With regular vigorous exercise, the heart muscle becomes more powerful and efficient. Aerobic exercise slows the atherosclerotic process, directly reducing the risk of CVD, and decreases risk of obesity and diabetes mellitus, therefore indirectly reducing risk as well.

A healthy lifestyle that includes a heart-healthy diet and physical activity promotes cardiovascular health. This is true throughout the life span. Physical activity recommendations for children and adolescents emphasize 60 minutes/day of moderate-to-vigorous physical activity (Berra et al., 2013). Because children and adolescents spend a great deal of time in school, one of the *Healthy People 2020* (USDHHS, 2013d) objectives is to increase the proportion of the nation's public and private schools that require daily physical education for all

Evidence-Based Practice How Do Racial, Ethnic, and Socioeconomic Disparities Affect Knowledge of Cardiovascular Disease Among Women with Metabolic Syndrome?

EVIDENCE-BASED PRACTICE

It is well known that racial, ethnic, and socioeconomic disparities are risks for many health conditions. The literature reflects that the metabolic syndrome (Met-S) is a recognizable cluster of risk factors associated with an increased risk for cardiovascular disease (CVD). Current public health strategies focus on educating the public about the traditional factors of hypertension, smoking, and elevated LDL cholesterol. The researchers (Giardina et al., 2011) focused on documenting the extent of CVD knowledge and awareness among women with Met-S and if such women were aware of options for managing an acute CVD emergency. Their data were derived from the baseline information of a cross-sectional, interviewer-assisted, face-to-face questionnaire of study participants recruited in four women's heart centers. This was part of the Improving, Enhancing and Evaluating Outcomes of Comprehensive Heart Care in High-Risk Women program, sponsored by the Office on Women's Health, USDHHS. A total of 698 women were enrolled in the study. A number of measures were collected: clinical characteristics (age, current/ever diagnosis of diabetes mellitus, hypertension, hyperlipidemia, smoking, overweight, and obesity), physical measures (BP, waist circumference, height, weight, laboratory data), race and ethnicity, education, residence (suburban or urban), type of insurance, Framingham Risk Score (FRS), and questions to assess awareness and knowledge of the leading cause of death among women, the early symptoms and signs of heart attack and stroke, and the action to take if experiencing a heart attack or stroke (i.e., to call 911). Sixty-four percent of the participants were classified for the presence or absence of metabolic risk. They ranged in age from 20 to 86 years with the mean being 55 years of age. Almost 44% were minority women. Thirty-three percent had less than high school or were high

school graduates and 36% had some college. Participants were primarily urban (77%); 32% had Medicaid or Medicare; and 44% had HMO, private pay, or other commercial insurance. Thirty percent of the participants had an income of ≤\$19,999, and 39% of the group had three or more components of Met-S with the frequency of Met-S greatest in Hispanics. The results showed the following: Education was significantly related to the Met-S and greater occurrence of Met-S occurred in those with less than a high school education (70%); the frequency of a high FRS was greater in both Hispanics (79%) and non-Hispanic Blacks (48%); and fewer women with high FRS or with the Met-S knew that the leading cause of death among women is heart disease or knew the signs and symptoms of a heart attack or the need to call 911. Other studies have documented an increase in overall knowledge of the leading cause of death among White women; however, this study demonstrates that Hispanic and African American women remain significantly less aware than White women about the leading cause of death.

IMPLICATIONS

This study showed that Met-S occurred with greater frequency among women who were Hispanic and those with less than or high school education. The researchers stress that women who are at high risk for CVD (racial, ethnic, socioeconomic, and educational disparities and Met-S) need to be targeted to learn important CVD facts and recognize how to manage steps in a cardiac emergency in order to reduce the potential for morbidity and mortality. Nurses working with women who have these characteristics should be aware of these clients' increased need for education about CVD and what to do if they experience signs and symptoms of an acute cardiac emergency.

students. The AHA (2013a) recommends at least 150 minutes per week of moderate exercise or 75 minutes per week of vigorous exercise for adults. The AHA (2013b) also states that nearly 40% of people over the age of 55 report no leisure-time physical activity when in fact the older an individual becomes, the more they need regular exercise. The *Healthy People 2020* objectives also include increasing the proportion of adults who meet current federal physical activity guidelines for aerobic physical activity and for muscle strength training.

NONTRADITIONAL RISK FACTORS

Other emerging modifiable risk factors that may influence cardiovascular function include the presence of metabolic syndrome or C-reactive protein or an elevated homocysteine level.

METABOLIC SYNDROME Metabolic syndrome (Met-S)

is a cluster of cardiovascular risk factors that increase the incidence of CVD. Five risk factors are included in Met-S: central obesity (e.g., increased waist circumference), increased triglycerides, hypercholesterolemia, hypertension, and elevated fasting glucose (Harris & Smith, 2014). A person is considered to have metabolic syndrome when at least three of the five risk factors are present. Each risk factor is usually treated individually. Overall, lifestyle activities and behaviors, such as nutrition and physical activity, are the best preventions for the development of Met-S risk factors.

C-REACTIVE PROTEIN Many studies have shown that acute myocardial infarction (AMI) involves an inflammatory process. A useful screening test for this inflammatory process is the **C-reactive protein (CRP)** assay. Recent research has focused on the use of

this inflammatory marker as an independent risk factor for CVD (Butcher & Beckstrand, 2010). Evidence does not suggest that lowering CRP reduces cardiovascular risk. Instead, CRP is used more as an assessment or predictor of who may be at risk. Usually, CRP screening is completed along with cholesterol screening to determine cardiovascular risk assessment. If the results are high, smoking cessation, diet, and exercise are recommended guidelines to reduce the CRP and cholesterol levels.

ELEVATED HOMOCYSTEINE LEVEL **Homocysteine** is an amino acid that has been shown to be increased in many people with atherosclerosis. Clients with elevated homocysteine levels may have an increased risk of MI, CVD, cerebrovascular accidents (stroke), and peripheral vascular disease. It is thought that individuals can reduce their homocysteine level by taking a multivitamin that provides folate, vitamin B₆, vitamin B₁₂, and riboflavin. However, clinical trials that attempted to lower homocysteine levels through B-vitamin treatment have varied in their results (Martí-Carvajal, Solà, Lathyris, Karakitsiou, & Simancas-Racines, 2013).

ALTERATIONS IN CARDIOVASCULAR FUNCTION

Cardiovascular function can be altered by conditions that affect:

1. The function of the heart as a pump
2. Blood flow to organs and peripheral tissues
3. The composition of the blood and its ability to transport oxygen and carbon dioxide.

Culturally Responsive Care

PATIENT-CENTERED CARE

Gender and Race Disparities in Clients with Cardiovascular Disease**ACUTE MYOCARDIAL INFARCTION**

Coronary heart disease is the leading cause of death in American females, yet women are underrepresented in the majority of cardiovascular research studies.

Women tend to have an acute myocardial infarction (AMI) at an older age than men and are more likely to have complications. The presence of chest pain varies between men and women. More women have pain-free AMIs than men. They also tend to have more mid-back, shoulder blade, and upper-back pain than men. Research reflects that women who have an AMI experience longer delays in treatment and less aggressive treatment than men. This results in increased mortality rates.

HEART FAILURE

Symptoms of heart failure (HF) occur earlier in African Americans, possibly because of the higher rate of uncontrolled hypertension. The rate of hypertension for both African Americans and Caucasians is greatest in the southeastern United States.

Studies reveal the following information about other risk factors for HF and other CVD:

- African Americans have a higher average BMI than Caucasians. African Americans do not hold the same body image values as Caucasians; a larger body size may be valued more positively.
- African Americans have a higher incidence of diabetes than other populations.
- The incidence of HF is increasing in African American women. However, few research studies include African American women.

CEREBROVASCULAR ACCIDENT (STROKE)

African Americans have a greater incidence, greater mortality, and greater severity of strokes than Caucasians.

IMPLICATIONS

Research on gender differences is gradually increasing. However, research focusing on differences by race and ethnicity remains limited and needs to be more thoroughly investigated. In the meantime, two important areas for client education include informing women that AMI does not occur only in men, and teaching the public about how to prevent risk factors that contribute to HF and cerebrovascular accidents.

Three major alterations in cardiovascular function are decreased cardiac output, impaired tissue perfusion, and disorders that affect the composition or amount of blood available for transport of gases.

Decreased Cardiac Output

Although the heart is normally able to increase its rate and force of contraction to increase cardiac output during exercise, fever, or other times of need, some conditions interfere with these mechanisms.

The vessels that supply blood to the heart muscle may become occluded by atherosclerosis or a blood clot, shutting off the blood supply to a portion of the myocardium. When this happens, the tissue becomes necrotic and dies, a condition known as a **myocardial infarction (MI)** or *heart attack*. If a large portion of the heart muscle is affected, particularly in the left ventricle, cardiac output falls

because the affected muscle no longer contracts. Signs and symptoms of MI are variable and may include the following:

- Chest pain; substernal and/or radiating to the left arm, jaw
- Nausea
- Shortness of breath
- Diaphoresis.

Heart failure may develop if the heart is unable to keep up with the body's need for oxygen and nutrients to the tissues. Heart failure usually occurs because of MI, but it may also result from chronic overwork of the heart, such as in clients with uncontrolled hypertension or extensive arteriosclerosis. In left-sided heart failure, the vessels of the pulmonary system become congested or engorged with blood. This may cause fluid to escape into the alveoli and interfere with gas exchange, a condition known as *pulmonary edema*. Signs of heart failure may include the following:

- Pulmonary congestion; adventitious lung sounds
- Shortness of breath
- Dyspnea on exertion (DOE)
- Increased heart rate
- S₃ heart sound
- Increased respiratory rate
- Nocturia
- Orthopnea
- Distended neck veins.

Other diseases such as myocarditis and cardiomyopathy also can affect the heart muscle, impairing its ability to contract and pump. Box 51–2 gives examples of conditions that may precipitate heart failure.

Very irregular or excessively rapid or slow heart rates can also decrease cardiac output. With irregular or very rapid heart rates, the ventricles may not fill adequately between beats, so stroke volume (amount pumped with each beat) falls. If the heart rate is too slow, the heart may not be able to increase its stroke volume enough to maintain the cardiac output. Abnormalities of heart rate and rhythm are known as dysrhythmias and can be identified on an electrocardiogram (ECG).

Alterations in the structure of the heart can affect cardiac output. Congenital heart defects result in abnormal blood flow and may even allow venous and arterial blood to mix. Oxygen supply to body tissues is affected in this case. Acquired heart diseases such as bacterial endocarditis and rheumatic fever may damage the heart valves,

BOX 51–2 Examples of Conditions That May Precipitate Heart Failure**CONDITIONS THAT INCREASE PRELOAD**

- Hypervolemia
- Valvular disorders such as mitral regurgitation
- Congenital defects such as patent ductus arteriosus

CONDITIONS THAT INCREASE AFTERLOAD

- Hypertension
- Atherosclerosis

CONDITIONS THAT AFFECT MYOCARDIAL FUNCTION

- Myocardial infarction
- Cardiomyopathy
- Coronary artery disease

affecting the flow of blood within the heart and to the great vessels. For example, if the mitral (bicuspid) valve becomes scarred and stenotic (constricted), it may not open fully, impairing filling of the left ventricle. Or, if the mitral valve does not fully close (mitral insufficiency), blood may escape back or regurgitate into the left atrium instead of entering the aorta each time the ventricle contracts.

Impaired Tissue Perfusion

Atherosclerosis is by far the most common cause of impaired blood flow to organs and tissues. As vessels narrow and become obstructed, distal tissues receive less blood, oxygen, and nutrients. **Ischemia** is a lack of blood supply due to obstructed circulation. Any artery in the body may be affected by atherosclerosis, although the effects are most often associated with coronary arteries, vessels supplying blood to the brain, and arteries in peripheral tissues. Partial obstruction of coronary arteries causes myocardial ischemia, often resulting in angina pectoris; if the obstruction is complete a heart attack (MI) occurs. Partial obstruction of cerebral vessels may cause a transient ischemic attack (TIA); if the obstruction is complete, a stroke (cerebrovascular accident) occurs. Peripheral vascular disease leads to ischemia of distal tissues such as the legs and feet. Gangrene and amputation may result. Signs of impaired peripheral arterial circulation in the legs and feet may include the following:

- Decreased peripheral pulses
- Pain or paresthesias
- Pale skin color
- Cool extremities
- Decreased hair distribution.

The risk factors for peripheral atherosclerosis are similar to those for CVD and include cigarette smoking, high fat intake, obesity, and a sedentary lifestyle. Hypertension and diabetes also increase the risk for atherosclerosis, particularly if the blood pressure or blood glucose levels are not maintained at near-normal levels.

Although much less common, other disorders such as vessel inflammation, arterial spasm, and blood clots also can occlude blood vessels, leading to ischemia. Tissue edema can impair flow through vessels and can increase the distance oxygen and nutrients must diffuse across to reach cells.

On the venous side, incompetent valves may allow blood to pool in veins, causing edema and decreasing venous return to the heart (Figure 51-7 ■). Veins also can become inflamed, reducing blood flow and increasing the risk of thrombus (clot) formation. Thrombi may then break loose, becoming emboli. These emboli tend to travel as far as the pulmonary circulation where they become trapped in small vessels (pulmonary emboli), occluding blood supply to the capillary side of the alveolar-capillary membrane. Although alveolar ventilation to the affected area often remains adequate, no gas exchange occurs there because of impaired blood flow. Signs of acute pulmonary embolism (PE) can be nonspecific and variable but may include the following:

- Sudden onset of shortness of breath
- Pleuritic chest pain.

Blood Alterations

Because most oxygen is transported to the tissues in combination with hemoglobin, the problems of inadequate RBCs, low hemoglobin levels, or abnormal hemoglobin structure can affect tissue

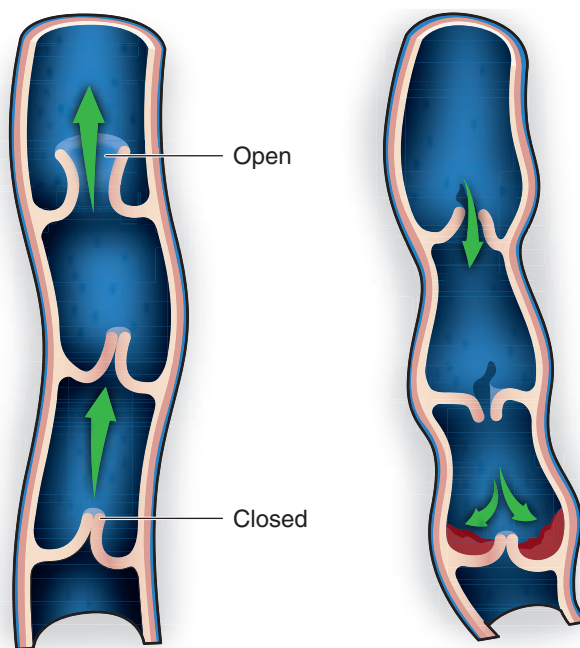

Figure 51-7 ■ *Left:* Vein with competent valve; *right:* vein with incompetent valve that allows blood to pool in the veins.

From *Medical Terminology: A Word-Building Approach*, 7th ed. (p. 298), by J. Rice, 2012. Reproduced by permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

oxygenation. Anemia has several different causes: RBCs are lost along with other components because of acute or chronic bleeding; if diet is deficient in iron or folic acid, hemoglobin and RBCs are not formed adequately; and some disorders cause RBCs to break down excessively. People with sickle cell disease produce an abnormal form of hemoglobin and may experience tissue ischemia during exacerbations of the disease. Signs of anemia may include the following:

- Chronic fatigue
- Pallor
- Shortness of breath
- Hypotension.

Blood volume also affects tissue oxygenation. If the blood volume is inadequate, as in hemorrhage or severe dehydration, blood pressure and cardiac output fall, and tissues may become ischemic. Conversely, clients with hypervolemia (excess blood volume), which can result from fluid retention or kidney failure, may develop heart failure and peripheral edema, also leading to tissue ischemia.

●●● NURSING MANAGEMENT

Assessing

Nursing assessment of the cardiovascular system status includes a history, physical examination, and a review of relevant diagnostic data, including cardiac monitoring.

Nursing History

A comprehensive nursing history should include data regarding:

- Current and past cardiovascular problems
- Family history of cardiovascular problems such as high blood pressure, increased cholesterol level, heart attack, and stroke

ASSESSMENT INTERVIEW Circulation

CURRENT OR PAST CARDIOVASCULAR PROBLEMS

- Do you have high blood pressure?
- Do you have any history of heart disease such as angina, heart attack, or heart failure? Have you ever had a cardiac catheterization, angiogram, or angioplasty? Have you ever been diagnosed with rheumatic fever, endocarditis, pericarditis, or other diseases of the heart? If so, when? Have you had cardiac surgery or stent placement?
- Have you ever been told that you have peripheral vascular disease? Do you ever develop pain in the calves of your legs when walking? How far can you walk before it occurs? What do you do to relieve it? Have you had surgery on your blood vessels?
- Do your feet and ankles ever swell or feel very cold, numb, or tingling? Do you experience pain in your feet? Is the pain changed by position?

- Do you become extremely fatigued with activity? Have you ever been told that you are anemic?

MEDICATION HISTORY

- Have you taken or do you take any over-the-counter or prescription medications for your heart or blood pressure or to increase blood flow?
- Do you take any anticoagulants or other medications to “thin” your blood?

LIFESTYLE

- Do you use tobacco? If so, what kind?
- Do you exercise? What kind of exercise and how often?
- How often do you drink alcoholic beverages such as beer, wine, or liquor? How much do you usually drink at a time?

- Other medical history including diabetes and respiratory disorders
- Exercise and activity level
- History of tobacco use
- Diet, including fat and salt intake, alcohol intake, caffeine intake including soft drinks and chocolate
- Presence of any symptoms such as pain, shortness of breath, dizziness, fatigue, palpitations, cough, and fainting
- Medications for heart, blood pressure, circulation, and cholesterol
- Lifestyle, including social support, stressors, and methods of coping.

Physical Assessment

To examine the cardiovascular system, a nurse first evaluates blood pressure in both arms (the results should be within 10 mmHg of each other) and palpates peripheral pulses for their strength and equality. The apical pulse is auscultated for rate, rhythm, and the quality of heart sounds. Apical pulse rate and peripheral pulse rates should not vary more than a few beats per minute from one another. Carotid arteries are auscultated for bruits (a sound of turbulence), which may indicate atherosclerosis and narrowing (see Chapter 30 ∞). Also important as an indicator of cardiac function is lung sounds. By auscultating the lungs for adventitious sounds, the nurse assesses for increased pulmonary vessel pressure secondary to decreased cardiac output.

Much information about the cardiovascular system is obtained by assessing the skin for color, temperature, hair distribution, lesions, and edema. Clients with extensive peripheral vascular disease may have cool feet with weak pulses and shiny, nearly hairless shins and feet. Pitting edema of the feet and ankles may be noted in clients with heart failure. See Chapter 30 ∞ for specific techniques for assessing the respiratory and cardiovascular systems.

One noninvasive measure used to assess for peripheral vascular disease is the ankle brachial index (ABI). This is the ratio of arterial pressure in the ankle compared with that in the arm. The ABI is a simple, reliable means for diagnosing peripheral arterial disease (PAD) (Vascular Disease Foundation, 2014). The ABI has been traditionally determined using a conventional sphygmomanometer and a Doppler instrument. Aneroid BP cuffs, however, are being replaced by automated blood pressure equipment. To perform an ABI, the client has to be supine for 5 to 10 minutes while the nurse gathers BP cuffs, a handheld Doppler instrument, and ultrasound gel. Place a BP cuff on the client's right arm and right ankle. After applying the gel, use the Doppler to determine the client's systolic pressure in the right

BOX 51-3 Measurement of an Ankle Brachial Index (ABI)

The ABI measurement compares the systolic blood pressure of the lower extremity with the systolic blood pressure of the brachial artery. A ratio is calculated based on the results.

$$\text{ABI} = \frac{\text{systolic pressure of the ankle}}{\text{systolic pressure of the arm}}$$

EXAMPLE

$$\text{ABI} = \frac{132 \text{ systolic pressure of ankle}}{124 \text{ systolic pressure of arm}} = 1.06$$

Interpretation of ABI:

- 1.00–1.29: normal
- 0.91–0.99: borderline
- 0.41–0.90: mild to moderate disease
- ≤0.40: severe disease.

From “Understanding the Ankle-Brachial Index,” by M. Moye, 2011, *Nursing*, 41(1), p. 68.

arm and right ankle using the right dorsalis pedis and posterior tibial arteries. Repeat this procedure for the client's left arm and ankle. Use the higher ankle pressure (dorsalis pedis or posterior tibial) for each lower extremity and the higher arm pressure. Box 51-3 explains how to measure the ABI.

Diagnostic Studies

Many diagnostic studies are available that can help to identify the presence of CVD. Diagnostic studies may also be used as screening tools to identify increased risk so that modifications can be made to reduce the risk of development of CVD. An example of this is the serum lipid level. If a client has an elevated serum lipid level, he or she should be educated about the effects of diet and the importance of reducing lipids to reduce the risk of CVD.

Cardiac Monitoring

Cardiac monitoring allows for continuous observation of the client's cardiac rhythm. Cardiac monitoring is a recording of the heart's electrical activity. It is used in many instances: for clients who have known or suspected CVD, during and after surgery, to monitor responses to drug therapy, and to monitor clients at risk for serious complications such as shock. Electrodes placed on the client's chest are attached to

Figure 51–8 ■ A client with cardiac monitoring.

a monitor cable and bedside monitor (Figure 51–8 ■). The monitor is equipped with alarms used to warn of potential problems such as very fast, very slow, or irregular heart rates. The alarm limits are usually set for 20 beats higher and lower than the client's baseline rate, often at 100 to 110 and 50 to 55, respectively, for adults. For ambulatory clients (in the hospital or at home), the electrodes connect to a transmitter unit (also called telemetry). This unit electronically sends the signal to a central monitor for display or may store the information to be retrieved later in the primary care provider's office. Another name for this type of ambulatory monitoring is a Holter monitor. Electrodes are attached and the client wears the monitor for 24 hours. A continuous ECG is recorded and later analyzed for irregularities.

Electrocardiography most commonly uses 12 “leads” or 12 different views of the heart. In contrast, cardiac monitoring uses 2 or 3 leads at any given time. See Chapter 34 ∞ for more information about ECGs.

CLINICAL ALERT!

It is important to remember that ECG monitoring is a recording of the electrical activity of the heart; it does not reflect mechanical contraction and cardiac output. *Always* remember to check the client to assess for cardiac function. Just looking at the ECG does not give an assessment of the client's status.

Blood Tests

Specimens of venous blood can be used for several tests that may reflect some aspect of cardiovascular functioning.

Because hemoglobin is the molecule to which oxygen attaches, a person's hemoglobin level gives an indication of the oxygen-carrying capacity of the blood. A decreased hemoglobin level increases the risk of oxygen deficit in body tissues, especially when CVD is present.

Measurement of serum electrolytes is important for clients with cardiovascular problems because electrolyte abnormalities such as hyperkalemia (higher than normal potassium) and hypokalemia (lower than normal potassium) can have a critical effect on the heart. Serum levels of magnesium, calcium, sodium, and phosphorus are also important to assess.

Measurement of certain enzyme levels in the blood is an important part of the diagnostic evaluation of clients with chest pain. Enzymes such as **creatinine kinase (CK)** and **troponin** are released

into the blood during an MI, as a result of cell membrane damage. Elevated levels of these enzymes can help differentiate between an MI (when myocardial cells actually die) and chest pain from a different cause such as angina or pleuritic pain.

Hemodynamic Studies

Hemodynamics is the study of the forces or pressures involved in blood circulation. Hemodynamic studies or monitoring procedures may be performed to evaluate fluid status and cardiovascular function. Parameters evaluated in hemodynamic studies include heart rate, arterial blood pressure, central venous pressure, pressures in the pulmonary vascular system, and CO. Some of these parameters—for example, heart rate, arterial blood pressure, and venous pressure—are measured directly using an arterial, central venous, or pulmonary artery catheter; others, such as stroke volume and cardiac output, are calculated. Hemodynamic studies are performed in a diagnostic cardiac laboratory and require informed consent. Clients in intensive and cardiac care units may undergo continuous hemodynamic monitoring to evaluate cardiovascular status and the effect of interventions. Nurses in these units are responsible for obtaining accurate readings and maintaining the integrity of the system.

Diagnosing

NANDA International (Herdman & Kamitsuru, 2014) includes the following diagnostic labels for clients with circulation problems:

- **Decreased Cardiac Output:** inadequate blood pumped by the heart to meet metabolic (demands) of the body
- **Risk for Peripheral Neurovascular Dysfunction:** vulnerable to disruption in the circulation, sensation, and motion of an extremity, which may compromise health
- **Activity Intolerance:** insufficient physiological or psychological energy to endure or complete required or desired daily activities.

Planning

When planning care the nurse identifies nursing interventions that will assist the client to achieve these broad goals:

- Maintain or improve tissue perfusion.
- Maintain or restore an adequate cardiac output.

Obviously, goals will vary according to the diagnosis and defining characteristics for each individual. Appropriate preventive and corrective nursing interventions that relate to these must be identified. Specific nursing activities can be selected to meet the client's individual needs. Examples of NIC interventions related to decreased cardiac output and tissue perfusion include the following:

- Circulatory Care: Arterial Insufficiency
- Cardiac Care
- Hemodynamic Regulation.

To promote the transport of oxygen and carbon dioxide, the nurse can optimize CO by reducing stress, planning appropriate activities, and positioning the client for improved vascular blood flow.

Implementing

Promoting Circulation

Most people in good health give little thought to their cardiovascular function. Changing position frequently, ambulating, and exercising

CLIENT TEACHING**Home Care and Circulation****MAINTAINING CARDIAC OUTPUT AND TISSUE PERFUSION**

Teach the symptoms of heart failure to the client and family and emphasize when to contact the primary care provider.

- Teach the client about the importance of maintaining regular physical activity to promote circulation and vascular health. Emphasize the need to increase activity levels gradually with the goal of exercising (walking, swimming, weight training, or aerobic exercise as recommended by the care provider) for at least 30 minutes five times per week.
- Instruct the client to avoid exposure to cold, wearing warm clothing as needed.
- Teach cardiopulmonary resuscitation or refer for instruction.

DIETARY ALTERATIONS

Instruct the client and family about prescribed dietary restrictions such as a low-sodium diet. Refer to a dietitian as needed for further instruction.

- Discuss dietary measures to reduce the risk of atherosclerosis, including reducing total and saturated fats in the diet, reducing weight if obese, and increasing the intake of dietary fiber.

MEDICATIONS

Instruct the client and family about prescribed medications, including effects, side effects, and administration instructions.

CLIENT TEACHING**Promoting a Healthy Heart**

Exercise regularly, participating in at least 30 minutes of moderate-intensity aerobic exercise five times a week.

- Do not smoke.
- Maintain your ideal weight.
- Eat a diet low in total fat, saturated fats, and cholesterol.
- Drink alcohol in moderation, if at all, consuming no more than 1 cocktail or 1 to 1 1/2 glasses of wine or beer daily.
- Reduce stress and manage anger.
- Effectively manage diabetes and hypertension, maintaining blood glucose and blood pressure levels within normal limits.
- If female, discuss with your health care provider the advantages and risks of hormone replacement therapy after menopause (or after a total hysterectomy).
- Consult your primary care provider about the advisability of low-dose aspirin therapy to further reduce the risk of CVD.

usually maintain adequate cardiovascular functioning. See Client Teaching for other ways to promote a healthy heart.

Immobility is harmful to cardiovascular function. Without activity of the calf and leg muscles, blood pools in the veins of the lower extremities. This stagnant (sluggish) blood flow may allow clots to develop (venous thrombosis). With time, these clots can break loose and become emboli, eventually lodging in the small vessels of the pulmonary vascular system. Blood flow and gas exchange in the lungs are then impaired.

Many nursing interventions can help clients maintain cardiac and vascular function. They may be classified as vascular and cardiac.

Vascular

- Position with the legs elevated to promote venous return to the heart. This is particularly important for clients with venous

dysfunction. Care should be taken, however, to avoid this position in clients with cardiac dysfunction because it will increase preload and may increase stress on the heart.

- Avoid pillows under the knees or more than 15 degrees of knee flexion to improve blood flow to the lower extremities and reduce venous stagnation.
- Encourage leg exercises (such as flexion and extension of the feet, active contraction and relaxation of calf muscles) for a client on bed rest, and promote ambulation as soon as possible.
- Encourage or provide frequent position changes.

Cardiac

- Position the client in a high-Fowler's position to decrease preload and reduce pulmonary congestion.
- Monitor intake and output. Fluid restriction is usually not required for clients with mild to moderate cardiac dysfunction. With severe heart failure, a fluid restriction may be ordered.

Medications

Many classes of medications are administered to clients with cardiovascular disorders. Drugs such as nitrates, calcium channel blockers, and angiotensin-converting enzyme (ACE) inhibitors reduce the workload of the heart and prevent vasoconstriction. Various drugs are used to treat cardiac dysrhythmias. Positive inotropic drugs such as digoxin are used to increase the contractile strength of the heart. (See the Drug Capsule feature on digoxin in Chapter 29 ∞.) Beta-adrenergic blocking agents such as propranolol or metoprolol may be given to block the sympathetic nervous system action on the heart and decrease oxygen consumption. Direct vasodilators may be used for clients with peripheral vascular disease and sometimes hypertension. Often clients are on numerous medications, and it is an important role of the nurse to help the client understand the purposes, effects, and side effects of the different medications.

Administering medications is an important nursing function. Nurses are responsible for assessing for the effects of medications and also for potential complications. Examples include:

- When diuretics are administered, the nurse assesses intake, output, and serum potassium level (because many diuretics can lower potassium level).
- When positive inotropic medications are administered, the nurse should assess blood pressure, heart rate, peripheral pulses, and lung sounds as indicators of cardiac output.
- When antihypertensive medications are administered, it is critical for the nurse to monitor blood pressure. Additionally, many antihypertensive medications can cause postural hypotension.

Preventing Venous Stasis

When clients have limited mobility or are confined to bed, venous return to the heart is impaired and the risk of venous stasis increases. Immobility is a problem not only for ill or debilitated clients but also for some travelers who sit with legs dependent for long periods in a motor vehicle or an airplane. Venous stasis may allow clots (venous thrombosis) to develop in a deep vein, often in the thigh or calf. This is called deep venous thrombosis or deep vein thrombosis (DVT). If the thrombus breaks free, it can travel and become a PE where it blocks a pulmonary artery or one of its branches. Blood flow and gas exchange in the lungs are then impaired. If the clot is large enough,

sudden death can occur. DVT is associated with the development of about 90% of all PEs (Larkin, Mitchell, & Petrie, 2012). The term *venous thromboembolism* (VTE) incorporates both DVT and PE. VTE is one of the most common preventable causes of hospital-related death, especially among older adults because advancing age is a major risk for VTE (McNamara, 2014; Pollak & McBane, 2014).

Preventing venous stasis is an important nursing intervention to reduce the risk of complications following surgery, trauma, or major medical problems. Positioning and leg exercises are discussed in Chapter 50 ∞ and antiemboli stockings in Chapter 37 ∞. Sequential compression devices are an additional mechanical measure to help prevent venous stasis.

Sequential Compression Devices

Clients who are undergoing surgery or who are immobilized because of illness or injury or are in a critical care unit may benefit from sequential compression devices (SCDs) to promote venous return from the legs. Another term used in the literature is intermittent pneumatic compression devices (IPCDs) and because there are different types of IPCDs, they are often collectively referred to as SCDs. SCDs are useful in preventing thrombi and edema, which may result from venous stasis, but they are not used for clients who have arterial insufficiency, cellulitis, infection of the extremity, active DVT, or preexisting venous thrombosis. SCDs inflate and deflate plastic sleeves to promote venous flow. The plastic sleeves are attached by tubing to an air pump that alternately inflates and deflates portions of the sleeve to a specified pressure.

SCDs are available in foot (sometimes called a foot pump), knee-length, or thigh-length sleeves. The foot pump artificially stimulates the venous plantar plexus (a large vein located in the foot) to increase blood circulation in the foot. The inflation and deflation of the pump simulate the blood flow that results from walking. For the knee-length or thigh-length SCDs, the ankle area inflates first, followed by the calf region, and then the thigh area. This sequential inflation and deflation process assists the leg muscles in moving blood toward the heart (Figure 51–9 ■). Larkin, Mitchell, and Petrie (2012) indicate that “another benefit of mechanical compression devices is that they contribute to increasing the fibrinolytic activity within the vasculature and thus to preventing fibrin clot formation” (p. 517).

Figure 51–9 ■ Sequential venous compression devices enhance venous return. They are available in knee-high or thigh-length versions.

Both knee-high and thigh-high SCDs are equally effective against VTEs if they are worn 90% of the day or for more than 21 of each 24 hours (Stone & Chamberlin, 2011). Clients may not wear them because of discomfort, warmth, or soiling, particularly for the thigh-high SCDs. Stone and Chamberlin conducted a study and found that using only the knee-high SCDs as the standard for the intensive care units in their hospital resulted in increased client compliance with wearing SCDs and no newly diagnosed DVTs in the ICU a year after the change was implemented.

The SCD is removed for ambulation and is usually discontinued when the client resumes normal activity. To avoid falls, remind the client that the SCD needs to be removed before ambulating, particularly when the client needs to use the bathroom during the night.

Sequential compression therapy often complements other preventive measures. The client's risk level for DVT or PE often determines the preventive measures used. For example, clients at low risk may require only antiemboli stockings. Clients at moderate risk may have both antiemboli stockings and sequential therapy as part of their treatment. The primary care provider may order antiemboli stockings, sequential therapy, and anticoagulation therapy for the high-risk client.

Skill 51–1 outlines how to apply a sequential compression device.

Applying Sequential Compression Devices

PURPOSES

- To promote venous return from the legs
- To decrease risk of deep venous thrombosis and/or PE

ASSESSMENT

Assess for baseline data:

- Cardiovascular status, including heart rate and rhythm, peripheral pulses, and capillary refill

- Color and temperature of extremities
- Movement and sensation of feet and lower extremities and Homans' sign

Applying Sequential Compression Devices—continued

PLANNING

Check the primary care provider's order for type of SCD sleeve.

Rationale: Foot, knee- and thigh-length sleeves are available.

- Read the manufacturer's directions for connecting and operating the compression controller.

DELEGATION

Unlicensed assistive personnel (UAP) often remove and reapply the SCD when performing hygiene care. The nurse should check that the UAP knows the correct application process for the SCD. Remind the UAP that the client should not have the SCD removed for long periods of time because the purpose of the SCD is to promote circulation. Remind UAP to inspect the SCD sleeve and tubing each time prior to applying the sleeves.

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and the procedure for applying the sequential compression device. **Rationale:** *The client's participation and comfort will be increased by understanding the rationale for applying the SCD.*
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Provide for client privacy and drape the client appropriately.
4. Prepare the client.
 - Place the client in a dorsal recumbent or semi-Fowler's position.
 - Measure the client's legs as recommended by the manufacturer if a thigh-length sleeve is required. **Rationale:** *Foot- and knee-length sleeves come in just one size; the thigh circumference determines the size needed for a thigh-length sleeve.*
5. Apply the sequential compression sleeves.
 - Place a sleeve under each leg with the opening at the knee.
 - Wrap the sleeve securely around the leg, securing the Velcro tabs. ① Allow two fingers to fit between the leg and the sleeve. **Rationale:** *This amount of space ensures that the sleeve does not impair circulation when inflated.*
6. Connect the sleeves to the control unit and adjust the pressure as needed.
 - Connect the tubing to the sleeves and control unit, ensuring that arrows on the plug and the connector are in alignment and that the tubing is not kinked or twisted. **Rationale:** *Improper alignment or obstruction of the tubing by kinks or twists will interfere with operation of the SCD.*
 - Turn on the control unit and adjust the alarms and pressures as needed. The sleeve cooling control and alarm should be on; ankle pressure is usually set at 35 to 55 mmHg.

Equipment

- Measuring tape
- SCD, including disposable sleeves, air pump, and tubing

① Applying a sequential compression device to the leg.

Rationale: *It is important to have the sleeve cooling control on for comfort and to reduce the risk of skin irritation from moisture under the sleeve. Proper pressure settings prevent injury to the client. Alarms warn of possible control unit malfunctions.*

7. Document the procedure.
 - Record baseline assessment data and application of the SCD. Note control unit settings.
 - Assess and document skin integrity and neurovascular and peripheral vascular status per agency policy while the SCD is in place. Remove the unit and notify the primary care provider if the client complains of numbness and tingling or leg pain. These may be symptoms of nerve compression.

EVALUATION

- Perform appropriate follow-up assessments, such as peripheral vascular status including pedal pulses, skin color and temperature, skin integrity, and neurovascular status, including movement and sensation.
- Compare to the baseline data, if available.
- Report significant deviations from normal to the primary care provider.

LIFESPAN CONSIDERATIONS Sequential Compression Devices**CHILDREN**

- Because young children tend to be more active, the SCD is rarely necessary unless the child is immobile (e.g., comatose).

OLDER ADULTS

- SCD sleeves may become loose as clients move around in bed. Check that the sleeves are secure and properly positioned.

Home Care Considerations Sequential Compression Devices**PATIENT-CENTERED CARE**

A sequential compression device may be used in the home. Inform the client or caregiver how to apply the device correctly

and how to operate the system, including how to respond to the alarm.

DRUG CAPSULE**Low Molecular Weight Heparin enoxaparin (Lovenox)****PREVENTION OF DEEP VENOUS THROMBOSIS**

The low molecular weight heparins are anticoagulants used to prevent deep venous thrombosis after hip, knee, or abdominal surgery. They are also used for clients at risk for thromboembolus secondary to prolonged bed rest due to acute illness. These heparins are given subcutaneously either once a day or every 12 hours. They have a predictable dose response and do not require daily lab test monitoring.

NURSING RESPONSIBILITIES

- Administration:
 - Administer deep subcutaneous. Do not give IM.
 - Client should be lying down during administration.
 - Do not expel the air bubble from the prefilled syringe. This avoids loss of the drug.
 - The manufacturer recommends injection into the right or left anterior lateral or posterior lateral aspect of the abdominal wall for best absorption.

- Alternate between right and left abdomen sites.
- Insert the entire length of the needle into a skinfold created by the thumb and forefinger; hold the skinfold until the needle is withdrawn.
- Do not massage the injection site to minimize bruising.
- Do not mix with other injections.
- Lovenox and regular heparin cannot be used interchangeably.
- Assess baseline lab data (e.g., CBC, liver function, coagulation) and monitor periodically.
- Observe for early signs/symptoms of bleeding.

CLIENT AND FAMILY TEACHING

- Review how to administer (see above).
- Administer at the same time each day.
- Report any unusual bleeding or bruising.
- Avoid aspirin or NSAIDs.

Note: Prior to administering any medications, review all aspects with a current drug handbook or other reliable source.

Cardiopulmonary Resuscitation

Cardiopulmonary resuscitation (CPR) is a combination of oral resuscitation (mouth-to-mouth breathing or use of a mask), which supplies oxygen to the lungs, and external cardiac massage (chest compression), which is intended to reestablish cardiac function and blood circulation. CPR is also referred to as *basic life support (BLS)*.

The AHA issues revised standards for CPR every five years (e.g., 2010, 2015). It covers all aspects of emergency cardiac care and simplifies CPR procedures so more health care professionals and lay rescuers might learn them and perform them correctly. The complete guidelines are available online.

A cardiac arrest is the cessation of cardiac function; the heart stops beating. Often a cardiac arrest is unexpected and sudden. When it occurs, the heart no longer pumps blood to any of the organs of the body. Breathing then stops, and the person becomes unconscious and limp. Within 20 to 40 seconds of a cardiac arrest, the victim is clinically dead. After 4 to 6 minutes, the lack of oxygen supply to the brain causes permanent and extensive damage.

The three cardinal signs of a cardiac arrest are apnea, absence of a carotid or femoral pulse, and dilated pupils. The person's skin appears pale or grayish and feels cool. Cyanosis is evident when respiratory function fails before heart failure.

A respiratory arrest (pulmonary arrest) is the cessation of breathing. It often occurs because of a blocked airway, but it can occur following a cardiac arrest and for other reasons. A respiratory

arrest may occur abruptly or be preceded by short, shallow breathing that becomes increasingly labored.

It is vital that all nurses be trained to perform CPR so resuscitation measures can be initiated immediately when a cardiac or respiratory arrest occurs. Nurses also can be instrumental in increasing community awareness of the need for CPR training and ensuring its availability.

Each health care facility has policies and procedures for announcing cardiac/respiratory arrest and initiating interventions, as well as a name by which this emergency is referred; such emergencies are often referred to as a "code." There may be a button at the head of each bed for calling a code, an extension dialed on the phone, or it may be a special phone used to announce the emergency. It is critical that each member of the client care team know the procedure for announcing this emergency. Calling the code summons the code team to the location of the emergency. The code team is made up of specially trained staff who can handle the emergency. Individuals are needed to perform rescue breathing, deliver chest compressions, administer medications, and make a record of the code activities. One person must be designated as the code leader—the person who directs the activities of the other team members.

Some clients have requested via an advance directive that, should they arrest, they not be resuscitated. It is every person's right to make an advance directive of their wishes, and a client's code status should always be documented, per agency policy, in the medical

record (e.g., do not resuscitate [DNR]). Under most circumstances, if there is no DNR order in the record, all clients who arrest will have resuscitation efforts begun. Both legally and ethically, there is no such thing as a “partial code,” “slow code,” or “mini code.”

Throughout any emergency situation, the nurse must remember the person behind all of the technology. There is a client with spiritual and emotional needs who requires a personal connection. Holding a hand, making eye contact, talking directly to them—brief, seemingly small things make a huge difference to clients. To humanize health care is always a goal. Nursing *therapeutic presence* is the key. This should be extended to family members as well.

Evaluating

Using the overall goals identified in the planning stage, the nurse collects data to evaluate the effectiveness of interventions.

Critical Thinking Checkpoint

Mrs. Gloria Papadopolis reports that she is having increasing difficulty because she experiences severe pain in her calf muscles after walking for more than a city block. The pain subsides if she rests for a few minutes, but returns with activity. Her feet are cool and pale; pedal and posterior tibial pulses are not palpable, and femoral pulses are difficult to palpate. She lives in a downtown apartment and uses public transportation to travel across town to visit her husband’s grave weekly.

1. What are the circulatory causes of her leg pain? Which risk factors would you expect to find in her history to support this conclusion?

If desired outcomes are not achieved, the nurse, client, and support people if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome “cardiac pump effectiveness” is not achieved, questions to be considered might include the following:

- Have other outcome measures for the goal of maintaining adequate cardiac output been met?
- Are prescribed medications being administered and/or taken as ordered?
- Are any additional factors placing stress on the heart?
- Is there a balance between factors that affect cardiac output, such as preload and afterload?
- Are there signs of fluid overload such as weight gain?

2. Name two nursing diagnoses appropriate for Mrs. Papadopolis. Which would have the highest priority and why?
3. The primary care provider suggests that Mrs. Papadopolis cease her visits to the cemetery since she has to walk a long way there to reach the grave site. Would you agree with this plan? Why or why not? What considerations or viewpoints influence your choice?
4. Mrs. Papadopolis says that she wears support stockings because her friend told her they help the circulation in her legs. How would you respond to this information?

See Critical Thinking Possibilities on student resource website.

Chapter 51 Review

CHAPTER HIGHLIGHTS

- The cardiovascular system transports gases in the blood to and from the tissues and facilitates the diffusion of gases between the capillaries and body tissues.
- The heart and the blood vessels make up the cardiovascular system. Together with blood, it is the major system for transporting oxygen and nutrients to the cells and removing wastes for disposal.
- The right side of the heart receives deoxygenated blood from the body and pumps it to the lungs via the pulmonary arteries; the left side receives oxygenated blood from the lungs and pumps it out to the body via the aorta.
- Coronary arteries supply oxygen and nutrients to the heart muscle.
- The cardiac cycle is made up of systolic and diastolic periods.
- The cardiac conduction system controls the electrical activity of the heart and the cardiac cycle: systole, contraction of the heart muscle and ejection of blood, and diastole, the relaxation period during which the heart fills with blood.
- Cardiac output depends on stroke volume, or the amount of blood ejected during systole, and heart rate.
- Systemic blood vessels carry blood to the tissues through a system of arteries, arterioles, and capillaries and return it to the heart through the venules, veins, and the venae cavae.
- Blood pressure rises gradually from birth to reach the adult range during adolescence.
- Atherosclerosis causes fatty plaque to develop within arteries.
- Decreased cardiac output, impaired tissue perfusion, and disorders affecting the blood are the major cardiovascular problems that affect oxygenation.
- Cardiac output may fall with a myocardial infarction (MI), heart failure, dysrhythmias, and structural alterations of the heart (e.g., valve deformities).
- The most common cause of impaired blood flow to organs and tissues is atherosclerosis; this can lead to tissue ischemia and pain.
- Cardiac monitoring is used for continuous observation of the heart rate and rhythm.
- Nursing interventions to promote circulation include using sequential compression devices to promote venous return from the legs, which prevents venous stasis.
- Cardiopulmonary resuscitation (CPR) is used during cardiopulmonary arrest. Each nurse needs to be aware of the hospital’s policies and procedures regarding emergencies.

TEST YOUR KNOWLEDGE

- The home health nurse has developed a teaching guide for a client with cardiovascular risk factors that focuses on the importance of regular physical activity with gradually increasing activity levels. This teaching guide specifically promotes which topic?
 - Cardiac output and tissue perfusion
 - Renal perfusion and formation of urine
 - Oxygen-carrying capacity of white blood cells
 - Effective breathing and airway clearance
- The client's electrocardiogram (ECG) monitor reflects normal electrical activity through the heart's conduction system. The nurse knows that the electrical impulse travels in which sequence?
 - Atrioventricular node
 - Bundle branches
 - Sinoatrial node
 - Bundle of His
 - Purkinje fibers
 Place the numbers in the correct sequence: _____
- Which would most likely be included in the evaluation of the client goal of "Demonstrate adequate tissue perfusion"?
 - Symmetrical chest expansion
 - Use of pursed-lip breathing
 - Brisk capillary refill
 - Activity intolerance
- A client is admitted with acute crushing chest pain that radiates down his left arm. The nurse expects which blood tests to be ordered for this client? Select all that apply.
 - Blood urea nitrogen (BUN)
 - Hemoglobin and hematocrit
 - Creatine kinase (CK)
 - Homocysteine level
 - Troponin
- Which client is most likely to experience poor cardiac output?
 - A client who has recently completed exercising and is talking easily with an exercise partner
 - A client who has a stroke volume of 70 mL per beat and a heart rate of 70 beats/min
 - A client with a sustained heart rate of 150 beats/min
 - A client who receives a positive inotropic medication
- The nurse is assigned to three clients with the following diagnoses: myocardial infarction (MI), heart failure (HF), and anemia. In planning for their nursing care, the nurse knows that all three clients will have which sign/symptom?
 - Pain
 - Distended neck veins
 - Shortness of breath
 - Nausea
- Which set of assessment data best validates that the nurse should initiate cardiopulmonary resuscitation on a comatose client?
 - Cool, pale skin; unconsciousness; absence of radial pulse
 - Cyanosis, slow pulse, dilated pupils
 - Absent pulses, flushed skin, pinpoint pupils
 - Apnea, absence of carotid or femoral pulses, dilated pupils
- Which diagnoses would be most appropriate for clients with cardiovascular disease? Select all that apply.
 - Ineffective Peripheral Tissue Perfusion*
 - Acute Confusion*
 - Decreased Cardiac Output*
 - Sleep Pattern Disturbance*
 - Activity Intolerance*
- The surgeon ordered sequential compression devices (SCDs) to be applied postoperatively. The client asks why the SCDs are needed. Which is the best response by the nurse when teaching the client about the purpose of SCDs?
 - They promote arterial circulation.
 - They promote venous return from the legs.
 - They decrease afterload.
 - They decrease postoperative pain.
- A client with severe mitral stenosis is having surgery tomorrow. While teaching the client, the nurse shows the client a diagram of the heart. Identify with an "X" which valve the client will have replaced.

See Answers to Test Your Knowledge in Appendix A.

READINGS AND REFERENCES

Suggested Readings

- Drumright, K., Julkenbeck, S., & Judd, C. (2013). The ABCs of acute PE. *Nursing made Incredibly Easy!*, 11(2), 45–49. *Pulmonary embolism (PE) is the most common preventable cause of death in the hospital setting. The most common risk factor for PE is DVT and VTE (which includes both PE and DVT). The authors review Virchow's triad, signs and symptoms, diagnosis, treatments, and prevention.*
- Elpern, E., Killeen, K., Patel, G., & Senecal, P. A. (2013). The application of intermittent pneumatic compression devices for thromboprophylaxis. *American Journal of Nursing*, 113(4), 30–36. doi:10.1097/01.NAJ.0000428736.48428.10
The authors note that "thromboprophylaxis, using either chemical or mechanical strategies or both, can reduce the incidence of VTE in the critically ill, and VTE prophylaxis is recommended for all critically ill patients" (p. 30). Mechanical prophylactic devices (i.e., SCDs) are widely used and are applied, maintained, and monitored exclusively by nursing personnel. The authors conducted an observational study, and this article reports the frequent errors found in the application of SCDs. This is important to know because applying SCDs incorrectly increases the client's risk of thrombosis.
- Herman, A. (2013). Coronary artery disease: The plaque plague. *Nursing made Incredibly Easy!*, 11(2), 34–43. doi:10.1097/01.NME.0000426303.65238.4e
The author provides a comprehensive overview of CAD including the pathophysiology of atherosclerotic plaque, the different types of plaque (along with pictures for the visual learner), information on MI, interventions for MI, treatment, teaching, and prevention strategies for CAD.

52 Fluid, Electrolyte, and Acid–Base Balance

LEARNING OUTCOMES

After completing this chapter, you will be able to:

1. Discuss the function, distribution, composition, movement, and regulation of fluids and electrolytes in the body.
2. Describe the regulation of acid–base balance in the body, including the roles of buffers, the lungs, and the kidneys.
3. Identify factors affecting normal body fluid, electrolyte, and acid–base balance.
4. Discuss risk factors for, and causes and effects of, fluid, electrolyte, and acid–base imbalances.
5. Collect assessment data related to clients' fluid, electrolyte, and acid–base balances.
6. Identify examples of nursing diagnoses, outcomes, and interventions for clients with altered fluid, electrolyte, or acid–base balance.
7. Teach clients measures to maintain fluid and electrolyte balance.
8. Implement measures to correct imbalances of fluids, electrolytes, acids, and bases, such as enteral or parenteral replacements and blood transfusions.
9. Evaluate the effect of nursing and collaborative interventions on clients' fluid, electrolyte, or acid–base balance.
10. Verbalize the steps used in:
 - a. Starting an intravenous infusion.
 - b. Monitoring an intravenous infusion.
 - c. Changing an intravenous container and tubing
 - d. Discontinuing an intravenous infusion.
 - e. Changing an intravenous catheter to an intermittent infusion lock.
 - f. Initiating, maintaining, and terminating a blood transfusion using a Y-set.
11. Recognize when it is appropriate to delegate aspects of fluid, electrolyte, and acid–base balance to unlicensed assistive personnel.
12. Demonstrate appropriate documentation and reporting of fluid, electrolyte, and acid–base balance activities.

INTRODUCTION

In good health, a delicate balance of fluids, electrolytes, acids, and bases maintains the body. This balance, or **homeostasis**, depends on multiple physiological processes that regulate fluid intake and output, as well as the movement of water and the substances dissolved in it between body compartments.

1308

Almost every illness has the potential to threaten this balance. Even in daily living, factors such as excessive temperatures or vigorous activity can disturb homeostasis if adequate water and salt intake are not maintained. Therapeutic measures, such as the use of diuretics or nasogastric suction, can also disturb the body's homeostasis unless water and electrolytes are replaced.

BODY FLUIDS AND ELECTROLYTES

The proportion of the human body composed of fluid is surprisingly large. Approximately 60% of the average healthy adult's weight is water, the primary body fluid. In good health this volume remains relatively constant, and a person's weight varies by less than 0.2 kg (0.5 lb) in 24 hours, regardless of the amount of fluid ingested.

Water is vital to health and normal cellular function, serving as:

- A medium for metabolic reactions within cells
- A transporter for nutrients, waste products, and other substances
- A lubricant
- An insulator and shock absorber
- A means of regulating and maintaining body temperature.

Age, sex, and body fat affect total body water. Infants have the highest proportion of water, accounting for 70% to 80% of their body weight. The proportion of body water decreases with age. In people older than 60 years of age, it represents only about 50% of total body weight. Women generally have a lower percentage of body water than men. In both women and older adults, this is due to lower levels of muscle mass and a greater percentage of fat tissue. Fat tissue is essentially free of water, whereas lean tissue contains a significant amount of water. Therefore, water makes up a greater percentage of a lean individual's body weight than of an individual who is obese.

Distribution of Body Fluids

The body's fluid is divided into two major compartments, intracellular and extracellular. **Intracellular fluid (ICF)** is found within the cells of the body. It constitutes approximately two thirds of the total body fluid in adults. **Extracellular fluid (ECF)** is found outside the cells and accounts for about one third of total body fluid. ECF is further subdivided into compartments. The two main compartments of ECF are intravascular and interstitial. **Intravascular fluid**, or **plasma**, accounts for approximately 20% of ECF and is found within the vascular system. **Interstitial fluid**, accounting for approximately 75% of ECF, surrounds the cells. The other compartments of ECF include the lymph and transcellular fluids. Examples of **transcellular fluid** include cerebrospinal, pericardial, pancreatic, pleural, intraocular, biliary, peritoneal, and synovial fluids (Figure 52–1 ■).

Intracellular fluid is vital to normal cell functioning. It contains solutes such as oxygen, electrolytes, and glucose, and it provides a medium in which metabolic processes of the cell take place.

Although ECF is in the smaller of the two compartments, it is the transport system that carries oxygen and nutrients to, and waste products from, body cells. For example, plasma carries oxygen from the lungs and glucose from the gastrointestinal tract to the capillaries of the vascular system. From there, the oxygen and glucose move across the capillary membranes into the interstitial spaces and then across the cellular membranes into the cells. The opposite route is taken for waste products, such as carbon dioxide going from the cells to the lungs, and metabolic waste going to the kidneys. Interstitial fluid transports wastes from cells by way of the lymph system, as well as directly into the blood plasma through capillaries.

Composition of Body Fluid

Extracellular and intracellular fluids contain oxygen from the lungs, dissolved nutrients from the gastrointestinal tract, excretory

Figure 52–1 ■ Total body fluid represents 40 L in an adult male weighing 70 kg (154 lb).

products of metabolism such as carbon dioxide, and charged particles called **ions**.

Many salts dissociate in water; that is, they break up into electrically charged ions. The salt called sodium chloride breaks up into one ion of sodium (Na^+) and one ion of chloride (Cl^-). These charged particles are called **electrolytes** because they are capable of conducting electricity. The number of ions that carry a positive charge, called **cations**, and ions that carry a negative charge, called **anions**, should be equal. Examples of cations are sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+}). Examples of anions include chloride (Cl^-), bicarbonate (HCO_3^-), phosphate (PO_4^{3-}), and sulfate (SO_4^{2-}).

Electrolytes generally are measured in milliequivalents per liter (mEq/L) or milligrams per 100 milliliters (mg/100 mL). The term **milliequivalent** refers to the chemical combining power of the ion, or the capacity of cations to combine with anions to form molecules, whereas the term *milligram* refers to the weight of the ion. Therefore, 1 mEq of any anion equals 1 mEq of any cation in terms of their capacity to combine into molecules. For example, sodium and chloride combine equally, so 1 mEq of Na^+ equals 1 mEq of Cl^- ; however, a molecule of sodium is not equal in weight to a molecule of chloride.

Clinically, the milliequivalent system is most often used. However, nurses need to be aware that different systems of measurement may be found when interpreting laboratory results. For example, calcium levels frequently are reported in milligrams per deciliter (1 dL = 100 mL) instead of milliequivalents per liter. It also is important to remember that laboratory tests are usually performed using blood plasma, an extracellular fluid. These results reflect what is happening in ECF, more specifically within intravascular fluid,

Figure 52-2 ■ Electrolyte composition (cations and anions) of body fluid compartments.

From *Fundamentals of Anatomy and Physiology*, 10th ed., by F. H. Martini, J. L. Nath, and E. F. Bartholomew, © 2015. Reproduced by permission of Pearson Education, Inc., Upper Saddle River, NJ.

but generally it is not possible to directly measure electrolyte concentrations within body cells.

The composition of fluids varies from one body compartment to another. In ECF, the principal electrolytes are sodium, chloride, and bicarbonate. Other electrolytes such as potassium, calcium, and magnesium are present, but in much smaller quantities. Plasma and interstitial fluid, the two primary components of ECF, contain essentially the same electrolytes and solutes, with the exception of protein. Plasma is a protein-rich fluid, containing large amounts of albumin, but interstitial fluid contains little or no protein.

The composition of ICF differs significantly from that of ECF. Potassium and magnesium are the primary cations present in ICF, and phosphate and sulfate are the major anions. As in ECF, other electrolytes are present within the cell, but in much smaller concentrations (Figure 52-2 ■).

Other body fluids such as gastric and intestinal secretions also contain electrolytes. This is of particular concern when these fluids are lost from the body (for example, in severe vomiting or diarrhea, or when gastric suction removes gastric secretions). Fluid and electrolyte imbalances can result from excessive losses through these routes.

Movement of Body Fluids and Electrolytes

The body fluid compartments are separated from one another by cell membranes and the capillary membrane. Although these membranes are completely permeable to water, they are considered to be **selectively permeable** to solutes, because substances other than

water move across them with varying degrees of ease. Small particles such as ions, oxygen, and carbon dioxide move easily across these membranes, but larger molecules such as glucose and proteins have more difficulty moving between fluid compartments.

Solutes are substances dissolved in a liquid. For example, when sugar is added to coffee, the sugar is the solute. Solutes may be **crystalloids** (salts that dissolve readily into true solutions) or **colloids** (substances such as large protein molecules that do not readily dissolve into true solutions). A **solvent** is the component of a solution that can dissolve a solute. In the previous example, coffee is the solvent for the sugar. In the body, water is the solvent; the solutes include electrolytes, gases such as oxygen and carbon dioxide, glucose, urea, amino acids, and proteins.

The concentration of solutes in body fluids is usually expressed as the **osmolality**. Osmolality is determined by the total solute concentration within a fluid compartment and is measured as parts of solute per kilogram of water.

Osmolality is reported as milliosmoles per kilogram (mOsm/kg). Sodium is by far the greatest determinant of the osmolality of plasma, or serum osmolality, although glucose and urea also contribute. Potassium, glucose, and urea are the primary determinants of the osmolality of intracellular fluid. The term **tonicity** may also be used to refer to the osmolality of one solution in relation to another solution. Solutions may be termed isotonic, hypertonic, or hypotonic. In relation to body fluids, an **isotonic** solution has the same osmolality as ECF. Normal saline, 0.9% sodium chloride, is an example of an isotonic solution. **Hypertonic** solutions, such as 3% sodium chloride, have a higher osmolality than ECF. **Hypotonic** solutions, such

as 0.45% sodium chloride, have a lower osmolality than ECF. See Table 52–10 later in this chapter for additional information about intravenous (IV) solutions.

Osmotic pressure is the power of a solution to pull water across a semipermeable membrane. When two solutions of different concentrations are separated by a semipermeable membrane, the solution with the higher solute concentration exerts a higher osmotic pressure, pulling water across the membrane to equalize the concentrations of the solutions. For example, infusing a hypertonic IV solution such as 3% sodium chloride will pull fluid out of red blood cells (RBCs) and into plasma, causing the cells to shrink. On the other hand, a hypotonic solution administered intravenously will cause the RBCs to swell as water is pulled into the cells by their higher osmotic pressure. In the body, plasma proteins also exert osmotic pressure called **colloid osmotic pressure** or **oncotic pressure**, holding water in plasma, and when necessary pulling water from the interstitial space into the vascular compartment. This is an important mechanism for maintaining vascular volume.

The methods by which water and solutes move in the body are called diffusion, osmosis, filtration, and active transport.

DIFFUSION

Diffusion occurs when two solutes of different concentrations are separated by a semipermeable membrane (Figure 52–3 ■). The rate of diffusion of a solute varies according to the size of the molecules, the concentration of the solution, and the temperature of the solution. Larger molecules move less quickly than smaller ones, molecules move from a solution of higher concentration to a solution of lower concentration, and increases in temperature increase the rate of motion of molecules and therefore the rate of diffusion.

OSMOSIS

Osmosis is a specific kind of diffusion in which *water* moves across cell membranes, from the less concentrated solution (the solution with less solute and more water) to the more concentrated solution (the solution with more solute and less water) (Figure 52–4 ■). In other words, water moves toward the higher concentration of solute in an attempt to equalize the concentrations of both water and solute. Osmosis occurs in the body when the concentration of solutes is higher on one side of a selectively permeable membrane, such as the capillary membrane, than on the other side. For example, a marathon runner loses a significant amount of body water through

Figure 52–3 ■ Diffusion: the movement of molecules through a semipermeable membrane from an area of higher concentration to an area of lower concentration.

Figure 52–4 ■ Osmosis: the movement of water molecules from a less concentrated area to a more concentrated area in an attempt to equalize the concentration of solutions on two sides of a membrane.

perspiration, increasing the concentration of solutes in the plasma. This higher solute concentration draws water from the interstitial space and cells into the vascular compartment to equalize the concentration of solutes in all fluid compartments. Osmosis is an important mechanism for maintaining homeostasis and fluid balance.

FILTRATION

Filtration is a process whereby fluid and solutes move together across a membrane from an area of higher pressure to an area of lower pressure. An example of filtration is the movement of fluid and nutrients from the capillaries of the arterioles to the interstitial fluid around the cells. The pressure that results in the movement of the fluid and solutes out of a compartment is called **filtration pressure**.

Hydrostatic pressure is the pressure exerted by a fluid within a closed system on the walls of the container in which it is contained. The hydrostatic pressure of blood is the force exerted by blood against blood vessel walls. Recall that the plasma proteins and other solutes in the blood exert osmotic pressure. Osmotic pressure opposes and balances the force of hydrostatic pressure, and holds fluid in the vascular compartment to maintain the vascular volume. However, when hydrostatic pressure is greater than osmotic pressure, fluid filters out of the blood vessels. Filtration pressure is the difference between the hydrostatic pressure and the osmotic pressure (Figure 52–5 ■).

ACTIVE TRANSPORT

Active transport is the movement of solutes across cell membranes from a less concentrated solution to a more concentrated one (Figure 52–6 ■). This process differs from diffusion and osmosis, which are passive processes, in that metabolic energy is expended. In active transport, a substance combines with a carrier on the outside surface of the cell membrane, and they move to the inside surface of the cell membrane. Once inside, they separate, and the substance is released to the inside of the cell. A specific carrier is required for each substance.

The process of active transport is of particular importance in maintaining the differences in sodium and potassium ion concentrations of ECF and ICF. Under normal conditions, sodium concentrations are higher in ECF, and potassium concentrations are higher in ICF. To maintain these proportions, an active transport mechanism (the sodium-potassium pump) is activated, moving sodium from cells into plasma and potassium from plasma into cells. Active

Figure 52-5 ■ Schematic of filtration pressure changes within a capillary bed. On the arterial side, arterial blood pressure exceeds colloid osmotic pressure, so that water and dissolved substances move out of the capillary into the interstitial space. On the venous side, venous blood pressure is less than colloid osmotic pressure, so that water and dissolved substances move into the capillary.

Figure 52-6 ■ An example of active transport. Energy (ATP) is used to move sodium and potassium molecules across a semipermeable membrane against sodium’s and potassium’s concentration gradients (i.e., from areas of lesser concentration to areas of greater concentration).

transport moves and holds sodium and potassium against their diffusion gradients.

Regulating Body Fluids

In a healthy person, the volumes and chemical composition of the fluid compartments stay within specific and narrow limits. Normally, fluid intake and fluid loss are balanced. Illness can upset this balance so that the body has too little or too much fluid.

FLUID INTAKE

During periods of normal activity at moderate temperature, the average adult drinks about 1,500 mL/day, despite the fact that they need 2,500 mL/day for normal functioning. The additional 1,000-mL volume is acquired from foods and from the oxidation of these foods during metabolic processes. The water content of food is relatively large, contributing about 750 mL/day. Water as a by-product of food metabolism accounts for most of the remaining fluid volume required. This quantity is approximately 200 mL/day for the average adult (Table 52-1).

The thirst mechanism is the primary regulator of fluid intake. The thirst center is located in the hypothalamus of the brain. A number of stimuli trigger the thirst center, including the osmotic pressure of body fluids, vascular volume, and angiotensin (a hormone released

TABLE 52-1 Average Daily Fluid Intake for an Adult

Source	Amount (mL)
Oral fluids	1,200–1,500
Water in foods	1,000
Water as by-product of food metabolism	200
Total	2,400–2,700

in response to decreased blood flow to the kidneys), causing the sensation of thirst and the desire to drink fluids.

Thirst is normally relieved immediately after drinking a small amount of fluid, when the ingested fluid distends the upper gastrointestinal tract, but before the fluid is actually absorbed from the gastrointestinal tract. However, this relief is only temporary, and thirst returns in about 15 minutes. The thirst is again temporarily relieved by drinking a small amount of fluid. This mechanism protects the individual from drinking too much, because it takes between 30 minutes and 1 hour for fluid to be absorbed and distributed throughout the body.

FLUID OUTPUT

Fluid losses from the body counterbalance the intake of fluid, as shown in Table 52-2. The routes of fluid output include:

- Urine
- Feces
- Insensible losses (through the skin as perspiration and through the lungs as water vapor in expired air).

TABLE 52-2 Average Daily Fluid Output for an Adult

Route	Amount (mL)
Urine	1,400–1,500
Insensible losses	
Lungs	350–400
Skin	350–400
Sweat	100
Feces	100–200
Total	2,300–2,600

URINE Urine is formed by the kidneys and excreted from the urinary bladder, and is the major route of fluid output. Normal urine output for an adult is 1,400 to 1,500 mL per 24 hours, or at least 0.5 mL per kilogram per hour. In healthy people, urine output may vary noticeably from day to day. Urine volume should automatically increase as fluid intake increases. If fluid losses through other routes are large, however, urine volume should decrease to maintain fluid balance.

FECES The chyme that passes from the small intestine into the large intestine contains both water and electrolytes. The volume of chyme entering the large intestine in an adult is normally about 1,500 mL/day. Of this amount, all but about 100 mL is reabsorbed in the proximal half of the large intestine. The reabsorbed volume contains primarily water and electrolytes.

INSENSIBLE LOSSES **Insensible fluid losses** occur through the skin and the lungs. They are called insensible because it is usually not noticeable and cannot be measured. Insensible fluid loss through the skin occurs in two ways, diffusion and perspiration. Water loss through diffusion is not noticeable but normally accounts for 300 to 400 mL/day. This loss can be significantly increased if the protective layer of the skin is damaged, as with burns or large abrasions. Perspiration, which may be noticeable but is not measurable, varies depending on factors such as environmental temperature, body temperature, and metabolic activity. Fever and exercise increase metabolic activity and heat production, thereby increasing fluid losses through the skin.

Another type of insensible loss is the water in exhaled air. In an adult, this is normally 300 to 400 mL/day. When respiratory rate accelerates, for example, due to exercise or an elevated body temperature, this loss can increase.

Certain fluid losses are required to maintain normal body function. These are known as **obligatory losses**. Approximately 500 mL of fluid must be excreted through the kidneys of an adult each day to eliminate metabolic waste products. Water lost through respirations, the skin, and in feces also are obligatory losses, necessary for temperature regulation and elimination of waste products. The total of all these losses is approximately 1,300 mL/day.

MAINTAINING HOMEOSTASIS

The volume and composition of body fluids are regulated through several homeostatic mechanisms. A number of organs and systems contribute to this regulation, including the kidneys, lungs, and the cardiovascular and gastrointestinal systems. Hormones such as antidiuretic hormone (ADH; also known as arginine vasopressin or AVP), the renin-angiotensin-aldosterone system, and atrial natriuretic factor are also involved, as are mechanisms to monitor and maintain vascular volume.

KIDNEYS The kidneys are the primary regulator of body fluids and electrolyte balance. They regulate the volume and osmolality of ECF by regulating water and electrolyte excretion. The kidneys control the reabsorption of water from plasma filtrate and ultimately the amount excreted as urine. Although 135 to 180 L of plasma per day is normally filtered in an adult, only about 1.5 L of urine is excreted. Electrolyte balance is maintained by selective retention and excretion by the kidneys. The kidneys also play a significant role in acid–base regulation, excreting hydrogen ion (H^+) and retaining bicarbonate.

HORMONES Several neuroendocrine control mechanisms help control fluid and electrolyte balance.

ANTIDIURETIC HORMONE ADH, which regulates water excretion from the kidney, is synthesized in the anterior portion of the hypothalamus and acts on the collecting ducts of the nephrons. When serum osmolality rises, ADH is produced, causing the collecting ducts to become more permeable to water. This increased permeability allows more water to be reabsorbed into the blood. As more water is reabsorbed, urine output falls and serum osmolality decreases because the water dilutes body fluids. Conversely, if serum osmolality decreases, ADH is suppressed, the collecting ducts become less permeable to water, and urine output increases. Excess water is excreted, and serum osmolality returns to normal. Other factors also affect the production and release of ADH, including blood volume, temperature, pain, stress, and some drugs such as opiates, barbiturates, and nicotine (Figure 52–7 ■).

RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM The renin-angiotensin-aldosterone system is another neuroendocrine control mechanism that contributes to maintaining fluid balance. Specialized receptors in the kidneys respond to changes in renal perfusion, stimulating the **renin-angiotensin-aldosterone system**. If blood flow or pressure to the kidney decreases, renin is released. Renin causes the conversion of angiotensinogen to angiotensin I, which is then converted to angiotensin II by angiotensin-converting enzyme. Angiotensin II acts directly on the nephrons to promote sodium and water retention. In addition, it stimulates the release of aldosterone from the adrenal cortex. Aldosterone also promotes sodium retention in the distal nephron. The net effect of the renin-angiotensin-aldosterone system is to increase blood volume (and renal perfusion) through sodium and water retention.

ATRIAL NATRIURETIC FACTOR Atrial natriuretic factor (ANF) is released from cells in the atrium of the heart in response to excess blood volume and stretching of the atrial walls. Acting on the nephrons, ANF promotes sodium wasting and acts as a potent diuretic, thus decreasing blood volume. ANF also inhibits thirst, reducing fluid intake.

Regulating Electrolytes

Electrolytes, charged ions capable of conducting electricity, are present in all body fluids and fluid compartments. Just as maintaining fluid balance is vital to normal body functioning, so is maintaining electrolyte balance. Although the concentration of specific electrolytes differs between fluid compartments, a balance of cations (positively charged ions) and anions (negatively charged ions) always exists. Electrolytes are important for:

- Maintaining fluid balance
- Contributing to acid–base regulation
- Facilitating enzyme reactions
- Transmitting neuromuscular reactions.

Most electrolytes enter the body through dietary intake and are excreted in the urine. Some electrolytes, such as sodium chloride and potassium, are not stored by the body and must be consumed daily to maintain normal levels. Other electrolytes, such as calcium, are stored in the body; when serum levels drop, ions can shift out of storage into the blood to maintain adequate serum levels for normal functioning,

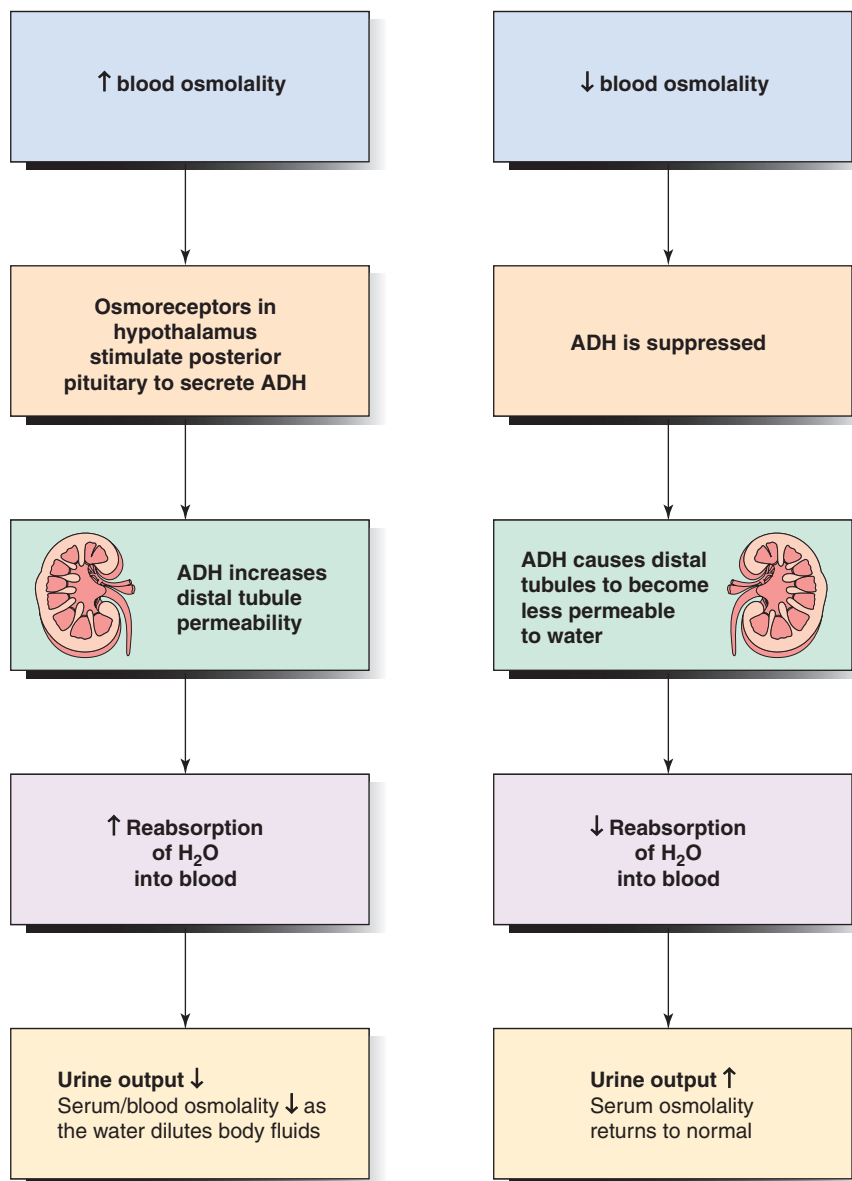

Figure 52–7 ■ Antidiuretic hormone (ADH) regulates water excretion from the kidneys.

at least in the short term. The regulatory mechanisms and functions of the major electrolytes are summarized in Table 52–3.

SODIUM

Sodium (Na^+) is the most abundant cation in ECF and a major contributor to serum osmolality. Normal serum sodium levels are 135 to 145 mEq/L. Sodium functions largely in controlling and regulating water balance. When sodium is reabsorbed from the kidney tubules, chloride and water are reabsorbed with it, thus maintaining ECF volume. Sodium is found in many foods, and found in high levels in foods such as bacon, ham, processed cheese, and table salt.

POTASSIUM

Potassium (K^+) is the major cation in ICF, with only a small amount found in the ECF. ICF levels of potassium are usually 125 to 140 mEq/L, while normal serum potassium levels are 3.5 to 5.0 mEq/L. The ratio of intracellular to extracellular potassium must be maintained for neuromuscular response to stimuli. Potassium is a

vital electrolyte for skeletal, cardiac, and smooth muscle activity. It is also involved in maintaining acid–base balance, and it contributes to intracellular enzyme reactions. Potassium must be ingested daily because the body cannot conserve it. Many fruits and vegetables, meat, fish, and other foods contain potassium (Box 52–1).

CALCIUM

The vast majority (99%) of calcium (Ca^{2+}) in the body is stored in the skeletal system, with a relatively small amount in extracellular fluid. Although the calcium outside the bones and teeth amounts to only about 1% of the total calcium in the body, it is vital in regulating neuromuscular function, including muscle contraction and relaxation, as well as cardiac function. ECF calcium is regulated by a complex interaction of parathyroid hormone, calcitonin (a hormone produced by the thyroid), and calcitriol (a metabolite of vitamin D). When calcium levels in the ECF fall, parathyroid hormone and calcitriol cause calcium to be released from bones into ECF and increase the absorption of calcium in the intestines, thus raising serum calcium levels.

Conversely, calcitonin stimulates the deposition of calcium in bone, reducing the concentration of calcium ions in the blood.

With increasing age, the intestines absorb calcium less effectively, and more calcium is excreted by the kidneys. Calcium shifts out of the bone to replace these ECF losses, increasing the risk of osteoporosis and fractures of the wrists, vertebrae, and hips. Lack of weight-bearing exercise (which helps keep calcium in the bones) and a vitamin D deficiency contribute to this risk, as do genetics and lifestyle factors. Milk and milk products are the richest sources

of calcium, with other foods such as dark green leafy vegetables and canned salmon containing smaller amounts. Many clients benefit from calcium supplements.

Serum calcium levels are often reported in two ways, based on the way it is circulating in the plasma. Approximately 50% of serum calcium circulates in a free, or unbound, form. The other 50% circulates bound to either plasma proteins or other nonprotein ions. The total serum calcium level (normal range: 8.5 to 10.5 mg/dL) represents both bound and unbound calcium. The ionized serum calcium level (normal range: 4.0 to 5.0 mg/dL) represents free, or unbound, calcium.

MAGNESIUM

Magnesium (Mg²⁺) is found primarily in the skeleton and ICF, where it is the second most abundant intracellular cation. It is important for intracellular metabolism, particularly in the production and use of ATP. Magnesium also is necessary for protein and DNA synthesis within the cells. Only about 1% of the body's magnesium is in ECF, and it has a normal serum level of 1.5 to 2.5 mEq/L. In ECF it is involved in regulating neuromuscular and cardiac function. Maintaining and ensuring adequate magnesium levels is an important part of the care of clients with cardiac disorders. Cereal grains, nuts, dried fruit, legumes, and green leafy vegetables are good sources of magnesium in the diet, as are dairy products, meat, and fish.

CHLORIDE

Chloride (Cl^-) is the major anion of ECF, and normal serum levels are 95 to 108 mEq/L. Chloride functions with sodium to regulate serum osmolality and blood volume. The concentration of chloride in ECF is regulated secondarily to sodium; when sodium is reabsorbed in the kidney, chloride usually follows. Chloride is a major component of gastric juice as hydrochloric acid (HCl) and is involved in regulating acid–base balance. It also acts as a buffer in the exchange of oxygen and carbon dioxide in RBCs. Chloride is found in the same foods as sodium.

PHOSPHATE

Phosphate (PO_4^{3-}) is the major anion of ICF. It also is found in ECF, bone, skeletal muscle, and nerve tissue. Normal serum levels of phosphate in adults range from 2.5 to 4.5 mg/dL. Children have much higher phosphate levels than adults, with that of a newborn nearly twice that of an adult. Higher levels of growth hormone and a faster rate of skeletal growth probably account for this difference. Phosphate is involved in many chemical actions of cells, and is essential for functioning of muscles, nerves, and red blood cells. It is also involved in the metabolism of protein, fat, and carbohydrate. Phosphate is absorbed from the intestine and is found in many foods such as meat, fish, poultry, milk products, and legumes.

BICARBONATE

Bicarbonate (HCO_3^-) is present in both ICF and ECF. Its primary function is regulating acid–base balance as an essential component of the body's buffering system. The kidneys regulate extracellular bicarbonate levels. Bicarbonate is excreted when too much is present; if more is needed, the kidneys both regenerate and reabsorb bicarbonate ions. Unlike electrolytes that must be consumed in the diet, adequate amounts of bicarbonate are produced through metabolic processes.

ACID–BASE BALANCE

An important part of regulating the homeostasis of body fluids is regulating their acidity and alkalinity. An **acid** is a substance that releases hydrogen ions (H^+) in solution. Strong acids such as hydrochloric acid release all or nearly all their hydrogen ions; weak acids like carbonic acid release some hydrogen ions. **Bases**, or alkalis, have a low hydrogen ion concentration and can accept hydrogen ions in solution. The relative acidity or alkalinity of a solution is measured by its **pH**, which is an inverse reflection of the hydrogen ion concentration of the solution. The higher the hydrogen ion concentration, the lower the pH; the lower the hydrogen ion concentration, the higher the pH. Water has a pH of 7 and is neutral. Solutions with a pH lower than 7 are acidic; those with a pH higher than 7 are alkaline. The pH scale is logarithmic; a solution with a pH of 5 is 10 times more acidic than one with a pH of 6.

Regulation of Acid–Base Balance

Body fluids are normally maintained within a narrow range that is slightly alkaline. The normal pH of arterial blood is between 7.35 and 7.45 (Figure 52–8 ■). Acids are continually produced during metabolism. Several body systems, including the respiratory and renal systems, and buffers are actively involved in maintaining the narrow pH range necessary for optimal functioning. Buffers help maintain acid–base balance by neutralizing excess acids or bases. The lungs and the kidneys help maintain a normal pH by either excreting or retaining acids and bases as needed.

Figure 52–8 ■ Body fluids are normally slightly alkaline, between a pH of 7.35 and 7.45.

BUFFERS

Buffers prevent excessive changes in pH by binding with or releasing hydrogen ions. If body fluids become too acidic, meaning excess hydrogen ions are present in body fluids, buffers bind with the hydrogen ions. If body fluids become too alkaline, meaning not enough hydrogen ions are present in body fluids, buffers can release hydrogen ions. The action of a buffer is immediate, but limited in its capacity to maintain or restore normal acid–base balance.

The major buffer in ECF is the bicarbonate (HCO_3^-) and carbonic acid (H_2CO_3) system. The amounts of bicarbonate and carbonic acid in the body vary; however, as long as a ratio of 20 parts of bicarbonate to 1 part of carbonic acid is maintained, the pH remains within its normal range of 7.35 to 7.45 (Figure 52–9 ■). However, adding a strong acid to ECF can change this ratio because bicarbonate is depleted in neutralizing the acid. When this happens, the pH drops, and the client has a condition called **acidosis**. The ratio can also be upset by adding a strong base to ECF, depleting carbonic acid as it combines with the base. In this case the pH rises and the client has **alkalosis**. In addition to the bicarbonate–carbonic acid buffer system, plasma proteins, hemoglobin, and phosphates also function as buffers in body fluids.

RESPIRATORY REGULATION

The lungs help regulate acid–base balance by eliminating or retaining carbon dioxide (CO_2). When combined with water, carbon dioxide forms carbonic acid ($\text{CO}_2 + \text{H}_2\text{O} = \text{H}_2\text{CO}_3$). This chemical reaction is reversible; carbonic acid breaks down into carbon dioxide and water. The lungs help regulate acid–base balance by altering the rate

Figure 52–9 ■ Carbonic acid–bicarbonate ratio and pH.

and depth of respirations. The response of the respiratory system to changes in pH is rapid, occurring within minutes.

Carbon dioxide is a powerful stimulator of the respiratory center in the brain. When blood levels of carbonic acid and carbon dioxide rise, the respiratory center is stimulated and the rate and depth of respiration increase. This causes an increased amount of carbon dioxide to be exhaled, and carbonic acid levels fall. By contrast, when blood levels of carbonic acid and carbon dioxide fall, the rate and depth of respiration decrease. This causes an increased level of carbon dioxide to be retained, and carbonic acid levels rise. Carbon dioxide levels in the blood are measured as PCO_2 , the partial pressure of the dissolved CO_2 in venous blood, and $PaCO_2$, the partial pressure of the dissolved CO_2 in arterial blood. Normal $PaCO_2$ is 35 to 45 mmHg.

RENAL REGULATION

Although buffers and the respiratory system can compensate for changes in pH, the kidneys are the ultimate long-term regulator of acid–base balance. They are slower to respond to changes, requiring hours to days to correct imbalances, but their response is more permanent and selective than that of the other systems. The kidneys maintain acid–base balance by selectively excreting or conserving bicarbonate and hydrogen ions. When excess hydrogen ions are present and pH falls (acidosis), the kidneys reabsorb and regenerate bicarbonate and excrete hydrogen ions. When insufficient hydrogen ions are present and pH rises (alkalosis), excess bicarbonate is excreted and hydrogen ions are retained. The normal serum bicarbonate level is 22 to 26 mEq/L.

The relationship between respiratory and renal regulation of acid–base balance is further explained in Box 52–2.

FACTORS AFFECTING BODY FLUID, ELECTROLYTES, AND ACID–BASE BALANCE

The ability of the body to adjust fluids, electrolytes, and acid–base balance is influenced by age, sex and body size, environmental temperature, and lifestyle.

BOX 52–2 Physiological Regulation of Acid–Base Balance

The lungs and kidneys are the two major systems that work on a continuous basis to help regulate the acid–base balance in the body. In the biochemical reactions above, the processes are all reversible and go back and forth as the body's needs change. The lungs can work very quickly and do their part by either retaining or getting rid of carbon dioxide by changing the rate and depth of respirations. The kidneys work much more slowly; they may take hours to days to regulate the balance by either excreting or conserving hydrogen and bicarbonate ions. Under normal conditions, the two systems work together to maintain homeostasis.

Age

Infants and growing children have much greater fluid turnover than adults because their higher metabolic rate increases fluid loss. Infants lose more fluid through the kidneys because immature kidneys are less able to conserve water than adult kidneys. In addition, infants' respiratory rate is much higher than that of adults, and their body surface area is proportionately greater than that of adults, both of which increase insensible fluid losses. This higher turnover of fluid, combined with the losses produced by disease, can create critical fluid imbalances in children much more rapidly than in adults.

In older people, the normal aging process may affect fluid balance. The thirst response is often diminished. Antidiuretic hormone levels remain normal or may even be elevated, but the nephrons become less able to conserve water in response to ADH. Higher levels of atrial natriuretic factor in older adults may also contribute to this impaired ability to conserve water. These normal changes of aging increase the risk of dehydration. When combined with the increased

LIFESPAN CONSIDERATIONS Fluid and Electrolyte Imbalance

INFANTS AND CHILDREN

Infants are at high risk for fluid and electrolyte imbalance because:

- Their immature kidneys cannot concentrate urine.
- They have a rapid respiratory rate and proportionately larger body surface area than adults, leading to greater insensible losses through the skin and respirations.
- They cannot express thirst, nor actively seek fluids.

Vomiting and/or diarrhea in infants and young children can lead quickly to electrolyte imbalance. Oral rehydration therapy (ORT) with electrolyte solutions such as Pedialyte should be used to restore fluid and electrolyte balance in mild to moderate dehydration. Prompt treatment with ORT can prevent the need for IV therapy and hospitalization. Even if the child is vomiting, small sips of an ORT solution can be helpful.

OLDER ADULTS

Older adults are at high risk for fluid and electrolyte imbalance because of decreases in:

- Thirst sensation
- Ability of the kidneys to concentrate urine
- Intracellular fluid and total body water

- Response to body hormones that help regulate fluid and electrolytes.

Other factors that may influence fluid and electrolyte balance in older adults are:

- Use of diuretics for hypertension and heart disease
- Decreased intake of food and water, especially in older adults with dementia or who are dependent on others to feed them and offer them fluids
- Preparations for diagnostic tests that include being NPO for long periods of time, laxatives, or contrast dyes
- Impaired renal function, for example, in older adults with diabetes.

All of these conditions increase older adults' risk for fluid and electrolyte imbalance, particularly under conditions that tax the normal compensatory mechanisms, such as a fever, influenza, surgery, or heat exposure. The change can happen quickly and become serious in a short time. Astute observations and quick actions by the nurse can help prevent serious consequences. A change in mental status may be the first symptom of impairment and must be further evaluated to determine the cause.

likelihood of heart diseases, impaired renal function, and multiple drug regimens, the older adult's risk for fluid and electrolyte imbalance is significant.

Sex and Body Size

Total body water also is affected by sex and body size. Fat cells contain little or no water, but lean muscle tissue has a high water content; therefore, people with a higher percentage of body fat have less body water than people with a higher percentage of lean muscle. Women generally have proportionately more body fat and, therefore, less body water than men. Water accounts for approximately 60% of an adult man's weight, but approximately 52% of an adult woman's weight. In someone who is obese this percentage may be even lower, with water accounting for only 30% to 40% of the person's weight.

Environmental Temperature

People with an illness and those participating in strenuous activity are at increased risk for fluid and electrolyte imbalances when the environmental temperature is high. Fluid losses through sweating are increased in hot environments as the body attempts to dissipate heat. These losses are even greater in people who are not accustomed to a hot environment.

Both electrolytes and water are lost through sweating. When only water is replaced, electrolyte depletion is a risk. A person who is electrolyte depleted may experience fatigue, weakness, headache, and gastrointestinal symptoms such as anorexia and nausea. The risk of adverse effects is even greater if lost water is not replaced. Body temperature rises, and the person is at risk for heat exhaustion or heatstroke; this happens when a person's heat production exceeds the body's ability to dissipate heat. Consuming adequate amounts of cool liquids, particularly during strenuous activity, reduces the risk of adverse effects from heat. Balanced electrolyte solutions and carbohydrate-electrolyte solutions such as sports drinks are recommended because they replace both water and electrolytes lost through perspiration.

Lifestyle

Lifestyle factors such as diet, exercise, stress, and alcohol consumption affect fluid, electrolyte, and acid–base balance.

Intake of fluids and electrolytes is affected by diet. People with anorexia nervosa or bulimia are at risk for severe fluid and electrolyte imbalances because of inadequate intake or purging regimens (e.g., induced vomiting, use of diuretics and laxatives). Seriously malnourished people have decreased serum protein levels, and may develop edema because serum osmotic pressure is reduced. When calorie intake is not adequate to meet the body's needs, fat stores are broken down and fatty acids are released, increasing the risk of acidosis.

Regular weight-bearing exercise such as walking or running has a beneficial effect on calcium balance. The rate of bone loss that occurs in postmenopausal women and older men is slowed with weight-bearing exercise, reducing the risk of osteoporosis.

Stress can increase cellular metabolism, blood glucose concentration, and catecholamine levels. In addition, stress can increase production of ADH and stimulate the renin-angiotensin-aldosterone system, both of which decrease urine production. The overall response of the body to stress is to increase blood volume.

Heavy alcohol consumption increases the risk of low calcium, magnesium, and phosphate levels. People who drink large amounts of alcohol are also at risk for acidosis associated with breakdown of fat tissue.

DISTURBANCES IN FLUID VOLUME, ELECTROLYTE, AND ACID–BASE BALANCES

A number of factors such as illness, trauma, surgery, and medications can affect the body's ability to maintain fluid, electrolyte, and acid–base balance. The kidneys play a major role in maintaining fluid, electrolyte, and acid–base balances, and renal disease is a significant cause of imbalances. In addition, decreased blood flow to the kidneys due to cardiovascular disease stimulates the renin-angiotensin-aldosterone system, causing sodium and water retention. Diseases such as diabetes mellitus, cancer, and chronic obstructive lung disease may affect acid–base balance. Clients who are confused or unable to communicate their needs are at risk for inadequate fluid intake. Vomiting, diarrhea, or nasogastric suction can cause significant fluid losses. Tissue trauma, such as burns, causes fluid and electrolytes to be lost from damaged cells. Medications such as diuretics or corticosteroids can result in abnormal losses of electrolytes and fluid loss or retention.

Fluid Imbalances

Fluid imbalances are of two basic types: isotonic and osmolar. Isotonic imbalances occur when water and electrolytes are lost or gained in equal proportions, so that the osmolality of body fluids remains constant. Osmolar imbalances involve the loss or gain of only water, so that the osmolality of the serum is altered. Thus, four categories of fluid imbalances may occur: (1) an isotonic loss of water and electrolytes, (2) an isotonic gain of water and electrolytes, (3) a hyperosmolar loss of only water, and (4) a hypo-osmolar gain of only water. These are referred to, respectively, as fluid volume deficit, fluid volume excess, dehydration (hyperosmolar imbalance), and overhydration (hypo-osmolar imbalance).

FLUID VOLUME DEFICIT

Isotonic **fluid volume deficit (FVD)** occurs when the body loses both water and electrolytes from the ECF in similar proportions. Thus, the decreased volume of fluid remains isotonic. In FVD, fluid is initially lost from the intravascular compartment, so it often is called **hypovolemia**.

FVD generally occurs as a result of (a) abnormal losses through the skin, gastrointestinal tract, or kidney; (b) decreased intake of fluid; (c) bleeding; or (d) movement of fluid into a third space. See the section on third space syndrome that follows.

For the risk factors and clinical signs related to fluid volume deficit, see Table 52–4.

THIRD SPACE SYNDROME In **third space syndrome**, fluid shifts from the vascular space into an area where it is not readily accessible as extracellular fluid. This fluid remains in the body but is essentially unavailable for use, causing an isotonic fluid volume deficit. Fluid may be isolated in the bowel, in injured tissue (e.g., severe burns), or in potential spaces such as the peritoneal or pleural cavities.

Third spacing has two distinct phases: loss and reabsorption. The client with third space syndrome during the loss phase has an isotonic fluid deficit. During the reabsorption phase, tissues begin to heal and fluid moves back into the intravascular space. Careful nursing assessment is vital to effectively identify and intervene for clients experiencing third spacing. Because fluid shifts from the vascular compartment (loss phase) and then back into the vascular compartment after time (reabsorption phase), assessment for manifestations of fluid volume deficit and excess is vital.

TABLE 52–4 Isotonic Fluid Volume Deficit

Risk Factors	Clinical Manifestations	Nursing Interventions
Loss of water and electrolytes from: <ul style="list-style-type: none"> • Vomiting • Diarrhea • Excessive sweating • Polyuria • Fever • Nasogastric suction • Abnormal drainage or wound losses Insufficient intake due to: <ul style="list-style-type: none"> • Anorexia • Nausea • Inability to access fluids • Impaired swallowing • Confusion, depression 	Complaints of weakness and thirst Weight loss: <ul style="list-style-type: none"> • 2% loss = mild FVD • 5% loss = moderate • 8% loss = severe Fluid intake less than output Decreased tissue turgor Dry mucous membranes, sunken eyeballs, decreased tearing Subnormal temperature Weak pulse; tachycardia Decreased blood pressure Postural (orthostatic) hypotension (significant drop in BP when moving from lying to sitting or standing position) Decreased capillary refill Decreased central venous pressure Decreased urine volume (<30 mL/hr) Increased specific gravity of urine (>1.030) Increased hematocrit Increased blood urea nitrogen (BUN)	Assess for clinical manifestations of FVD. Monitor weight and vital signs, including temperature. Assess tissue turgor. Monitor fluid intake and output. Monitor laboratory findings. Administer oral and IV fluids as indicated. Provide frequent mouth care. Implement measures to prevent skin breakdown. Provide for safety (e.g., provide assistance for a client rising from bed or chair).

FLUID VOLUME EXCESS

Fluid volume excess (FVE) occurs when the body retains both water and sodium in similar proportions to normal ECF. This is commonly referred to as **hypervolemia** (increased blood volume). FVE is always secondary to an increase in the total body sodium content, which leads to an increase in total body water. Because both water and sodium are retained, the serum sodium concentration remains essentially normal and the excess volume of fluid is isotonic. Specific causes of FVE include (a) excessive intake of sodium chloride; (b) administering sodium-containing infusions too rapidly, particularly to clients with impaired regulatory mechanisms; and (c) disease processes that alter regulatory mechanisms, such as heart failure, renal failure, cirrhosis of the liver, and Cushing's syndrome.

The risk factors and clinical manifestations for FVE are summarized in Table 52–5.

EDEMA In fluid volume excess, both intravascular and interstitial spaces have an increased water and sodium content. Excess interstitial fluid is known as edema. Edema typically is most apparent in areas

where the tissue pressure is low, such as around the eyes, and in dependent tissues (known as dependent edema), where hydrostatic capillary pressure is high.

Edema can be caused by several different mechanisms. The three main mechanisms are increased capillary hydrostatic pressure, decreased serum osmotic pressure, and increased capillary permeability. FVE increases capillary hydrostatic pressure, pushing fluid into the interstitial tissues. This type of edema is often seen in dependent tissues such as the feet, ankles, and sacrum because of the effects of gravity. Low levels of plasma proteins from malnutrition or liver or kidney diseases can reduce serum osmotic pressure, so that fluid cannot be held in the capillaries. This allows fluid to leak into interstitial spaces, causing edema. With tissue trauma and some disorders such as allergic reactions, capillaries become more permeable, allowing fluid to escape into interstitial tissues. Obstructed lymph flow also impairs the movement of fluid from interstitial tissues back into the vascular compartment, resulting in edema.

Pitting edema is edema that leaves a small depression or pit after finger pressure is applied to the swollen area. The pit is caused by

TABLE 52–5 Isotonic Fluid Volume Excess

Risk Factors	Clinical Manifestations	Nursing Interventions
Excess intake of sodium-containing IV fluids Excess ingestion of sodium in diet or medications (e.g., sodium bicarbonate antacids such as Alka-Seltzer or hypertonic enema solutions such as Fleet's) Impaired fluid balance regulation related to: <ul style="list-style-type: none"> • Heart failure • Renal failure • Cirrhosis of the liver 	Weight gain: <ul style="list-style-type: none"> • 2% gain = mild FVE • 5% gain = moderate • 8% gain = severe Fluid intake greater than output Full, bounding pulse; tachycardia Increased blood pressure and central venous pressure Distended neck veins Moist crackles (rales) in lungs; dyspnea, shortness of breath Mental confusion	Assess for clinical manifestations of FVE. Monitor weight and vital signs. Assess for edema. Assess breath sounds. Monitor fluid intake and output. Monitor laboratory findings. Place in Fowler's position. Administer diuretics as ordered. Restrict fluid intake as indicated. Restrict dietary sodium as ordered. Implement measures to prevent skin breakdown.

A

B

movement of fluid to adjacent tissue, away from the point of pressure (Figure 52-10 ■). Within 10 to 30 seconds the pit normally disappears as fluid returns to the area.

DEHYDRATION

Dehydration, or a hyperosmolar fluid imbalance, occurs when water is lost from the body, leaving the client with excess sodium. Because water is lost while electrolytes, particularly sodium, are retained, serum osmolality and serum sodium levels increase. Water is drawn into the vascular compartment from the interstitial space and cells, resulting in cellular dehydration. Older adults are at particular risk for dehydration because of decreased thirst sensation. Dehydration can also affect clients who are hyperventilating, have a prolonged fever, are in diabetic ketoacidosis, or are receiving enteral feedings with insufficient water intake.

OVERHYDRATION

Overhydration, or a hypo-osmolar fluid imbalance, occurs when water is gained in excess of electrolytes, resulting in low serum osmolality and low serum sodium levels. Water is drawn into the cells, causing them to swell. In the brain, this can lead to cerebral edema and impaired neurologic function. Overhydration, sometimes called water intoxication, often occurs when both fluid and electrolytes are lost, for example, through excessive sweating, but only water is replaced. It can also result from the syndrome of inappropriate antidiuretic hormone (SIADH), a disorder that can occur with some malignant tumors, AIDS, head injury, or administration of certain drugs such as barbiturates or anesthetics.

Electrolyte Imbalances

The most common and clinically significant electrolyte imbalances involve sodium, potassium, calcium, magnesium, chloride, and phosphate.

SODIUM

Sodium (Na^+), the most abundant cation in the extracellular fluid, not only moves into and out of the body but also moves in careful balance among the three fluid compartments. It is found in most body secretions, for example, saliva, gastric and intestinal secretions, bile, and pancreatic fluid. Therefore, continuous or excessive excretion of any of these fluids can result in a sodium deficit. Because of its role in regulating water balance, sodium imbalances usually are accompanied by water imbalances.

Hyponatremia is a sodium deficit, or serum sodium level of less than 135 mEq/L, and is, in acute care settings, a common electrolyte imbalance. Because of sodium's role in determining the osmolality of ECF, hyponatremia typically results in a low serum osmolality. Water is drawn out of the vascular compartment into interstitial tissues and the cells (Figure 52-11 A ■), causing the clinical manifestations associated with this disorder. As sodium levels decrease, the brain and nervous system are affected by cellular edema. Severe hyponatremia, serum levels below 115 mEq/L, is a medical emergency and can lead to increasing intracranial pressure and coma (Crawford & Harris, 2011).

Hypernatremia is excess sodium in ECF, or a serum sodium of greater than 145 mEq/L. Because the osmotic pressure of

Figure 52-11 ■ The extracellular sodium level affects cell size. A, In hyponatremia, cells swell; B, in hypernatremia, cells shrink in size.

DRUG CAPSULE

Diuretic Agent furosemide (Lasix)**THE CLIENT WITH FLUID VOLUME EXCESS**

Furosemide, which is a loop diuretic, inhibits sodium and chloride reabsorption in the loop of Henle and the distal renal tubule. This results in significant diuresis, with renal excretion of water, sodium chloride, potassium, magnesium, hydrogen, and calcium.

Furosemide is commonly used for the clinical management of edema secondary to heart failure, treatment of hypertension, and treatment of hepatic or renal disease. Therapeutic effects include diuresis and lowering of blood pressure.

NURSING RESPONSIBILITIES

- Assess the client's fluid status regularly. Assessment should include daily weight, close monitoring of intake and output, vital signs, skin turgor, edema, lung sounds, and mucous membranes.
- Monitor the client's potassium levels. Furosemide is a loop diuretic, which excretes potassium and may result in hypokalemia.
- Administer in the morning to avoid increased urination during hours of sleep.
- If the client is also taking digitalis glycosides, he or she should be assessed for anorexia, nausea, vomiting, muscle cramps,

paresthesia, and confusion. The potassium-depleting effect of furosemide places the client at increased risk for digitalis toxicity.

CLIENT AND FAMILY TEACHING

- Medication should be taken exactly as directed. If a dose is missed, take it as soon as possible; however, if a day has been missed, do not double the dose the next day.
- Weigh yourself daily, and report weight gain or loss of more than 3 pounds in 1 day to your primary care provider.
- Contact your primary care provider immediately if you begin to experience muscle weakness, cramps, nausea, dizziness, numbness, or tingling of the extremities.
- Some form of potassium supplementation may be needed. Your primary care provider may order oral potassium supplements for you; if not, you may need to consume a diet high in potassium.
- Make position changes from lying to sitting and sitting to standing slowly in order to minimize dizziness.

Note: Prior to administering any medication, review all aspects in a current drug handbook or other reliable source.

extracellular fluid is increased, fluid moves out of the cells into the ECF (Figure 52–11 B). As a result, the cells become dehydrated. Like hyponatremia, the primary manifestations of hypernatremia are neurologic in nature.

It is important to note that normally a person's thirst mechanism protects against hypernatremia. When an individual becomes thirsty, the body is stimulated to drink water, which helps correct the hypernatremia. Clients at highest risk for hypernatremia are those who are unable to access water, such as clients who are unconscious, clients who are unable to request fluids such as infants or older adults with dementia, or ill clients with an impaired thirst mechanism. Table 52–6 lists risk factors and clinical signs for hyponatremia and hypernatremia.

POTASSIUM

Although the amount of potassium (K^+) in extracellular fluid is small, it is vital to normal neuromuscular and cardiac function. Normal renal function is important for maintenance of potassium balance, because 80% of potassium is excreted by the kidneys. Potassium must be replaced daily to maintain its balance, which normally happens through food intake.

Hypokalemia is a potassium deficit, defined as a serum potassium level of less than 3.5 mEq/L. Gastrointestinal losses of potassium through vomiting and gastric suction are common causes of hypokalemia, as is the use of potassium-wasting diuretics, such as thiazide or loop diuretics. Symptoms of hypokalemia are usually mild until the level drops below 3 mEq/L, unless the decrease in potassium is rapid. When the decrease is gradual, the body compensates by shifting potassium from the intracellular environment into the serum.

Hyperkalemia is a potassium excess, defined as a serum potassium level greater than 5.0 mEq/L. Hyperkalemia is less common than hypokalemia, and rarely occurs in clients with normal renal function. It is, however, more dangerous than hypokalemia and can lead to cardiac arrest. As with hypokalemia, symptoms are more

severe and occur at lower levels when the increase in potassium is rapid. Table 52–6 lists risk factors and clinical signs for hypokalemia and hyperkalemia.

CLINICAL ALERT!

Potassium may be given intravenously for severe hypokalemia. It must **always** be diluted appropriately and **never** be given IV push. Potassium that is to be given IV should be mixed in the pharmacy and double-checked prior to administration by two nurses. The usual concentration of IV potassium is 20 to 40 mEq/L.

CALCIUM

Regulating the level of calcium (Ca^{2+}) in the body is more complex than the other major electrolytes, so calcium balance can be affected by many factors. Imbalances of this electrolyte are relatively common.

Hypocalcemia is a calcium deficit, defined as a total serum calcium level of less than 8.5 mg/dL or an ionized calcium level of less than 4.5 mEq/L. Severe depletion of calcium can cause tetany with muscle spasms and paresthesias (numbness and tingling around the mouth, hands, and feet), and can lead to seizures. Two signs indicate hypocalcemia: Chvostek's sign is a contraction of the facial muscles in response to tapping the facial nerve in front of the ear (Figure 52–12 A ■); Trousseau's sign is a carpal spasm in response to inflating a blood pressure cuff on the upper arm to 20 mmHg greater than the systolic pressure for 2 to 5 minutes (Figure 52–12 B). Clients at greatest risk for hypocalcemia are those whose parathyroid glands have been removed. This is frequently associated with thyroidectomy or other neck surgery, which can result in unintentional removal or damage to the parathyroid glands. Low serum magnesium levels (hypomagnesemia) and chronic alcoholism also increase the risk of hypocalcemia.

Hypercalcemia is a calcium excess, defined as a total serum calcium level greater than 10.5 mg/dL, or an ionized calcium level of greater than 5.5 mEq/L. It most often occurs when calcium is released

TABLE 52-6 Electrolyte Imbalances

Risk Factors	Clinical Manifestations	Nursing Interventions
HYPONATREMIA		
Loss of Sodium <ul style="list-style-type: none"> Gastrointestinal fluid loss Sweating Use of diuretics Gain of Water <ul style="list-style-type: none"> Hypotonic tube feedings Excessive drinking of water Excess IV D₅W (dextrose in water) administration Syndrome of Inappropriate ADH (SIADH) <ul style="list-style-type: none"> Head injury AIDS Malignant tumors 	Lethargy, confusion, apprehension Muscle twitching Abdominal cramps Anorexia, nausea, vomiting Headache Seizures, coma <i>Laboratory findings:</i> Serum sodium < 135 mEq/L Serum osmolality < 280 mOsm/kg	Assess clinical manifestations. Monitor fluid intake and output. Monitor laboratory data (e.g., serum sodium). Assess client closely if administering hypertonic saline solutions. Encourage food and fluid high in sodium if permitted (e.g., table salt, bacon, ham, processed cheese). Limit water intake as indicated.
HYPERNATREMIA		
Loss of Water <ul style="list-style-type: none"> Insensible water loss (hyperventilation or fever) Diarrhea Water deprivation Gain of Sodium <ul style="list-style-type: none"> Parenteral administration of saline solutions Hypertonic tube feedings without adequate water Excessive use of table salt (1 tsp contains 2,300 mg of sodium) Conditions such as: <ul style="list-style-type: none"> Diabetes insipidus Heat stroke 	Thirst Dry, sticky mucous membranes Tongue red, dry, swollen Weakness Severe hypernatremia: <ul style="list-style-type: none"> Fatigue, restlessness Decreasing level of consciousness Disorientation Convulsions <i>Laboratory findings:</i> Serum sodium > 145 mEq/L Serum osmolality > 300 mOsm/kg	Monitor fluid intake and output. Monitor behavior changes (e.g., restlessness, disorientation). Monitor laboratory findings (e.g., serum sodium). Encourage fluids as ordered. Monitor diet as ordered (e.g., restrict intake of salt and foods high in sodium).
HYPOKALEMIA		
Loss of Potassium <ul style="list-style-type: none"> Vomiting and gastric suction Diarrhea Heavy perspiration Use of potassium-wasting drugs (e.g., diuretics) Poor intake of potassium (as with debilitated clients, alcoholics, anorexia nervosa) Hyperaldosteronism 	Muscle weakness, leg cramps Fatigue, lethargy Anorexia, nausea, vomiting Decreased bowel sounds, decreased bowel motility Cardiac dysrhythmias Depressed deep-tendon reflexes Weak, irregular pulses <i>Laboratory findings:</i> Serum potassium < 3.5 mEq/L Arterial blood gases (ABGs) may show alkalosis T-wave flattening and ST-segment depression on ECG	Monitor heart rate and rhythm. Monitor clients receiving digitalis (e.g., digoxin) closely, because hypokalemia increases risk of digitalis toxicity. Administer oral potassium as ordered with food or fluid to prevent gastric irritation. Administer IV potassium solutions at a rate no faster than 10–20 mEq/h; never administer undiluted potassium intravenously. For clients receiving IV potassium, monitor for pain and inflammation at the injection site. Teach client about potassium-rich foods. Teach clients how to prevent excessive loss of potassium (e.g., through abuse of diuretics and laxatives).
HYPERKALEMIA		
Decreased Potassium Excretion <ul style="list-style-type: none"> Renal failure Hypoaldosteronism Potassium-conserving diuretics High Potassium Intake <ul style="list-style-type: none"> Excessive use of K⁺ containing salt substitutes Excessive or rapid IV infusion of potassium Potassium shift out of the tissue cells into the plasma (e.g., infections, burns, acidosis) 	Gastrointestinal hyperactivity, diarrhea Irritability, apathy, confusion Cardiac dysrhythmias or arrest Muscle weakness, areflexia (absence of reflexes) Decreased heart rate Irregular pulse Paresthesias and numbness in extremities <i>Laboratory findings:</i> Serum potassium > 5.0 mEq/L Peaked T wave, widened QRS on ECG	Closely monitor cardiac status and ECG. Administer diuretics and other medications such as glucose and insulin as ordered. Hold potassium supplements and K ⁺ conserving diuretics. Monitor serum K ⁺ levels carefully; a rapid drop may occur as potassium shifts into the cells. Teach clients to avoid foods high in potassium and salt substitutes.

TABLE 52–6 Electrolyte Imbalances—*continued*

Risk Factors	Clinical Manifestations	Nursing Interventions
HYPOCALCEMIA		
Surgical Removal of the Parathyroid Glands		
Conditions such as:	Numbness, tingling of the extremities and around the mouth	Closely monitor respiratory and cardiovascular status.
<ul style="list-style-type: none"> • Hypoparathyroidism • Acute pancreatitis • Hyperphosphatemia • Thyroid carcinoma 	Muscle tremors, cramps; if severe can progress to tetany and convulsions	Take precautions to protect a confused client.
Inadequate Vitamin D Intake		
<ul style="list-style-type: none"> • Malabsorption • Hypomagnesemia • Alkalosis • Sepsis • Alcohol abuse 	Cardiac dysrhythmias; decreased cardiac output	Administer oral or parenteral calcium supplements as ordered. When administering intravenously, closely monitor cardiac status and ECG during infusion.
	Positive Trousseau's and Chvostek's signs (see Table 52–8 and Figure 52–12)	Teach clients at high risk for osteoporosis about:
	Confusion, anxiety, possible psychoses	<ul style="list-style-type: none"> • Dietary sources rich in calcium. • Recommendation for 1,000–1,500 mg of calcium per day. • Calcium supplements. • Regular exercise. • Estrogen replacement therapy for postmenopausal women.
	Hyperactive deep-tendon reflexes	
	<i>Laboratory findings:</i>	
	Serum calcium < 8.5 mg/dL (total) or 4.5 mEq/L (ionized)	
	Lengthened QT intervals	
	Prolonged ST segments	
HYPERCALCEMIA		
<ul style="list-style-type: none"> • Prolonged immobilization 	Lethargy, weakness	Increase client movement and exercise.
Conditions such as	Depressed deep-tendon reflexes	Encourage oral fluids as permitted to maintain a dilute urine.
<ul style="list-style-type: none"> • Hyperparathyroidism • Malignancy of the bone • Paget's disease 	Bone pain	Teach clients to limit intake of food and fluid high in calcium.
	Anorexia, nausea, vomiting	Encourage ingestion of fiber to prevent constipation.
	Constipation	Protect a confused client; monitor for pathologic fractures in clients with long-term hypercalcemia.
	Polyuria, hypercalciuria	Encourage intake of acid-ash fluids (e.g., prune or cranberry juice) to counteract deposits of calcium salts in the urine.
	Flank pain secondary to urinary calculi	
	Dysrhythmias, possible heart block	
	<i>Laboratory findings:</i>	
	Serum calcium > 10.5 mg/dL (total) or 5.5 mEq/L (ionized)	
	Shortened QT intervals	
	Shortened ST segments	
HYPOMAGNESEMIA		
<ul style="list-style-type: none"> • Excessive loss from the gastrointestinal tract (e.g., from nasogastric suction, diarrhea, fistula drainage) • Long-term use of certain drugs (e.g., diuretics, aminoglycoside antibiotics) 	Neuromuscular irritability with tremors	Assess clients receiving digitalis for digitalis toxicity.
Conditions such as:	Increased reflexes, tremors, convulsions	Hypomagnesemia increases the risk of toxicity.
<ul style="list-style-type: none"> • Chronic alcoholism • Pancreatitis • Burns 	Positive Chvostek's and Trousseau's signs (see Table 52–8 and Figure 52–12)	Take protective measures when there is a possibility of seizures:
	Tachycardia, elevated blood pressure, dysrhythmias	<ul style="list-style-type: none"> • Assess the client's ability to swallow water prior to initiating oral feeding. • Initiate safety measures to prevent injury during seizure activity. • Carefully administer magnesium salts as ordered.
	Disorientation and confusion	Encourage clients to eat magnesium-rich foods if permitted (e.g., whole grains, meat, seafood, and green leafy vegetables).
	Vertigo	Refer clients to alcohol treatment programs as indicated.
	Anorexia, dysphagia	
	Respiratory difficulties	
	<i>Laboratory findings:</i>	
	Serum magnesium < 1.5 mEq/L	
	Prolonged PR intervals, widened QRS complexes, prolonged QT intervals, depressed ST segments, broad flattened T waves, prominent U waves	
HYPERMAGNESEMIA		
Abnormal retention of magnesium, as in:	Peripheral vasodilation, flushing	Monitor vital signs and level of consciousness when clients are at risk.
<ul style="list-style-type: none"> • Renal failure • Adrenal insufficiency • Treatment with magnesium salts 	Nausea, vomiting	If patellar reflexes are absent, notify the primary care provider.
	Muscle weakness, paralysis	Advise clients who have renal disease to contact their primary care provider before taking over-the-counter drugs.
	Hypotension, bradycardia	
	Depressed deep-tendon reflexes	
	Lethargy, drowsiness	
	Respiratory depression, coma	
	Respiratory and cardiac arrest if hypermagnesemia is severe	
	<i>Laboratory findings:</i>	
	Serum magnesium > 2.5 mEq/L	
	Electrocardiogram showing prolonged QT interval, prolonged PR interval, widened QRS complexes, tall T waves	

A. Positive Chvostek's Sign

B. Positive Trousseau's Sign

Figure 52-12 ■ A, Positive Chvostek's sign; B, positive Trousseau's sign.

From *Medical Surgical Nursing: Critical Thinking in Client Care*, 5th ed., by P. Lemone, K. Burke, and G. Bauldoff, 2011, Upper Saddle River, NJ: Pearson Education, Inc. Reproduced by permission.

in excess from the bony skeleton. This is usually due to malignancy or prolonged immobilization.

The risk factors and clinical manifestations related to calcium imbalances are found in Table 52-6.

MAGNESIUM

Magnesium (Mg^{2+}) imbalances are relatively common in hospitalized clients, although they may be unrecognized.

Hypomagnesemia is a magnesium deficiency, defined as a serum magnesium level of less than 1.5 mEq/L. It occurs more frequently than hypermagnesemia. Chronic alcoholism is the most common cause of hypomagnesemia. Magnesium deficiency also may aggravate the manifestations of alcohol withdrawal, such as delirium tremens (DTs).

Hypermagnesemia is a magnesium excess, defined as a serum magnesium level above 2.5 mEq/L, due to increased intake or decreased excretion. It is often iatrogenic, meaning caused by medical treatment; usually the cause is oversupplementation with magnesium.

Table 52-6 lists risk factors and manifestations for clients with altered magnesium balance.

CHLORIDE

Because of the relationship between sodium ions and chloride ions (Cl^-), imbalances of chloride commonly occur in conjunction with sodium imbalances.

Hypochloremia is a chloride deficit, defined as a serum chloride level below 95 mEq/L, and is usually related to excess loss of chloride through the GI tract, kidneys, or sweating. Hypochloremic clients are at risk for alkalosis, and may experience muscle twitching, tremors, or tetany.

Hyperchloremia is a chloride excess, defined as a serum chloride level above 108 mEq/L. Excess replacement of sodium chloride or potassium chloride is a risk factor for high serum chloride levels, as are conditions that lead to hypernatremia. The manifestations of hyperchloremia include acidosis, weakness, and lethargy, with the risk of dysrhythmias or coma.

PHOSPHATE

Phosphate (PO_4^{3-}) is found in both intracellular and extracellular fluid. Most of the phosphorus (P^+) in the body exists as PO_4^{3-} . Phosphate is critical for cellular metabolism because it is a major component of adenosine triphosphate (ATP). Phosphate imbalances frequently are related to therapeutic interventions for other disorders.

Hypophosphatemia is a phosphate deficit, defined as a serum phosphate level of less than 2.5 mg/dL. Glucose and insulin administration and total parenteral nutrition can cause phosphate to shift into the cells from extracellular fluid compartments, leading to hypophosphatemia. Alcohol withdrawal, acid-base imbalances, and the use of antacids that bind with phosphate in the GI tract are other possible causes. Manifestations of hypophosphatemia include paresthesias, muscle weakness and pain, mental changes, and possibly seizures.

Hyperphosphatemia is a phosphate excess, defined as a serum phosphate level greater than 4.5 mg/dL. It occurs when phosphate shifts out of the cells into extracellular fluids (e.g., due to tissue trauma or chemotherapy), in renal failure, or when excess phosphate is administered or ingested. Infants who are fed cow's milk are at risk for hyperphosphatemia, as are people who use phosphate-containing enemas or laxatives. Manifestations of hyperphosphatemia include numbness and tingling around the mouth and in the fingertips, muscle spasms, and tetany.

Acid-Base Imbalances

Acid-base imbalances are usually classified as respiratory or metabolic by the general or underlying cause of the disorder. Carbonic acid levels are normally regulated by the lungs through the retention or excretion of carbon dioxide, and problems lead to respiratory acidosis or alkalosis. Bicarbonate and hydrogen ion levels are regulated by the kidneys, and problems lead to metabolic acidosis or alkalosis. Healthy regulatory systems will attempt to correct acid-base imbalances, a process called **compensation**.

RESPIRATORY ACIDOSIS

Any condition that causes carbon dioxide retention, either due to hypoventilation or impaired lung function, causes carbonic acid levels to increase and pH to fall below 7.35, a condition known as **respiratory acidosis**. Serious lung diseases such as asthma and chronic obstructive pulmonary disease (COPD) are common causes of respiratory acidosis. Central nervous system depression due to anesthesia or a narcotic overdose can slow the respiratory rate enough to cause carbon dioxide retention. When respiratory acidosis occurs, the kidneys retain bicarbonate to restore the normal carbonic acid to bicarbonate ratio. The kidneys are relatively slow to respond to changes in acid–base balance, however, so this compensatory response may require hours to days to restore normal pH.

RESPIRATORY ALKALOSIS

When a person hyperventilates, more carbon dioxide than normal is exhaled, carbonic acid levels fall, and the pH rises to greater than 7.45. This condition is called **respiratory alkalosis**. Psychogenic

or anxiety-related hyperventilation is a common cause of respiratory alkalosis. Other causes include fever and respiratory infections. In respiratory alkalosis, the kidneys will excrete bicarbonate to return pH to within the normal range. Often, however, the cause of the hyperventilation is eliminated and pH returns to normal before renal compensation occurs.

METABOLIC ACIDOSIS

When bicarbonate levels are low in relation to the amount of carbonic acid in the body, pH falls and **metabolic acidosis** develops. This may occur because of renal failure and the inability of the kidneys to excrete hydrogen ions and produce bicarbonate. It also may occur when too much acid is produced in the body, for example, in diabetic ketoacidosis or starvation when fat tissue is broken down for energy. Metabolic acidosis stimulates the respiratory center, and the rate and depth of respirations increase. Carbon dioxide is eliminated and carbonic acid levels fall, minimizing the change in pH. This respiratory compensation occurs within minutes of the onset of the pH imbalance.

ANATOMY & PHYSIOLOGY REVIEW

Gas Exchange

Gas exchange. Oxygen from the alveoli moves into the blood, binds to red blood cells, and is carried to the body. Carbon dioxide dissolved in the blood or carried by red blood cells moves into the alveoli and is exhaled by the lungs.

From *Medical Language*, 2nd ed., by S. M. Turley, 2011, Upper Saddle River, NJ: Pearson Education, Inc. Reproduced with permission of Pearson Education, Inc., Upper Saddle River, New Jersey.

QUESTIONS

1. Hypoventilation can affect gas exchange. What are some causes of hypoventilation?
2. How does shallow breathing and hypoventilation cause PaCO₂ to increase and pH to decrease?
3. ABGs that indicate an increased PaCO₂ and a decreased pH reflect which acid–base imbalance?
4. Hyperventilation can also affect gas exchange. What are some causes of hyperventilation?
5. How does hyperventilation cause a decreased PaCO₂ and increased pH?
6. ABGs that indicate a decreased PaCO₂ and an increased pH reflect which acid–base imbalance?

See student resource website for answers.

METABOLIC ALKALOSIS

In **metabolic alkalosis**, the amount of bicarbonate in the body exceeds the normal 20-to-1 ratio. Ingestion of bicarbonate of soda as an antacid is one cause of metabolic alkalosis, as is prolonged vomiting with loss of hydrochloric acid from the stomach. The respiratory center is depressed in metabolic alkalosis, and respirations slow and become shallower. Carbon dioxide is retained and carbonic acid levels increase, helping balance the excess bicarbonate.

The risk factors and manifestations for acid–base imbalances are listed in Table 52–7.

●○○ NURSING MANAGEMENT

Assessing

Assessing clients for fluid, electrolyte, and acid–base balance and imbalances is an important nursing responsibility. Components of

TABLE 52–7 Acid–Base Imbalances

Risk Factors	Clinical Manifestations	Nursing Interventions
RESPIRATORY ACIDOSIS		
Acute lung conditions that impair alveolar gas exchange (e.g., pneumonia, acute pulmonary edema, aspiration of foreign body, near-drowning) Chronic lung disease (e.g., asthma, cystic fibrosis, or emphysema) Overdose of narcotics or sedatives that depress respiratory rate and depth Brain injury that affects the respiratory center Airway obstruction	Increased pulse and respiratory rates Headache, dizziness Confusion, decreased level of consciousness (LOC) Convulsions Warm, flushed skin Chronic: Weakness Headache <i>Laboratory findings:</i> Arterial blood pH < 7.35 PaCO ₂ > 45 mmHg HCO ₃ ⁻ normal or slightly elevated in acute; > 26 mEq/L in chronic	Frequently assess respiratory status and lung sounds. Monitor airway and ventilation; insert artificial airway and prepare for mechanical ventilation as necessary. Administer pulmonary therapy measures such as inhalation therapy, percussion and postural drainage, bronchodilators, and antibiotics as ordered. Monitor fluid intake and output, vital signs, and arterial blood gases. Administer narcotic antagonists as indicated. Maintain adequate hydration (2–3 L of fluid per day).
RESPIRATORY ALKALOSIS		
Hyperventilation due to: <ul style="list-style-type: none"> • Extreme anxiety • Elevated body temperature • Overventilation with a mechanical ventilator • Hypoxia • Salicylate overdose Brainstem injury Fever Increased basal metabolic rate	Complaints of shortness of breath, chest tightness Light-headedness with circumoral paresthesias and numbness and tingling of the extremities Difficulty concentrating Tremulousness, blurred vision <i>Laboratory findings (in uncompensated respiratory alkalosis):</i> Arterial blood pH > 7.45 PaCO ₂ < 35 mmHg	Monitor vital signs and ABGs. Assist client to breathe more slowly. Help client breathe in a paper bag or apply a rebreather mask (to inhale CO ₂).
METABOLIC ACIDOSIS		
Conditions that increase nonvolatile acids in the blood (e.g., renal impairment, diabetes mellitus, starvation) Conditions that decrease bicarbonate (e.g., prolonged diarrhea) Excessive infusion of chloride-containing IV fluids (e.g., NaCl) Excessive ingestion of acids such as salicylates Cardiac arrest	Kussmaul's respirations (deep, rapid respirations) Lethargy, confusion Headache Weakness Nausea and vomiting <i>Laboratory findings:</i> Arterial blood pH < 7.35 Serum bicarbonate less than 22 mEq/L PaCO ₂ < 38 mmHg with respiratory compensation	Monitor ABG values, intake and output, and LOC. Administer IV sodium bicarbonate carefully if ordered. Treat underlying problem as ordered.
METABOLIC ALKALOSIS		
Excessive acid losses due to: <ul style="list-style-type: none"> • Vomiting • Gastric suction Excessive use of potassium-losing diuretics Excessive adrenal corticoid hormones due to: <ul style="list-style-type: none"> • Cushing's syndrome • Hyperaldosteronism Excessive bicarbonate intake from: <ul style="list-style-type: none"> • Antacids • Parenteral NaHCO₃ 	Decreased respiratory rate and depth Dizziness Circumoral paresthesias, numbness and tingling of the extremities Hypertonic muscles, tetany <i>Laboratory findings:</i> Arterial blood pH > 7.45 Serum bicarbonate > 26 mEq/L PaCO ₂ > 45 mmHg with respiratory compensation	Monitor intake and output closely. Monitor vital signs, especially respirations, and LOC. Administer ordered IV fluids carefully. Treat underlying problem.

the assessment include (a) the nursing history, (b) physical assessment of the client, (c) clinical measurements, and (d) review of laboratory test results.

Nursing History

The nursing history is particularly important for identifying clients who are at risk for fluid, electrolyte, and acid–base imbalances. A client's current and past medical history reveals conditions such as chronic lung disease or diabetes mellitus that can disrupt normal balances. Medications prescribed to treat acute or chronic conditions (e.g., diuretic therapy for hypertension) also may place a client at risk for altered homeostasis. Functional, developmental, and socioeconomic factors must also be considered in assessing a client's risk. Older people and very young children, clients who must depend on others to meet their nutrition and hydration needs, and people who cannot afford or do not have the means to cook food for a balanced diet (e.g., homeless people) are at greater risk for fluid and electrolyte imbalances. Common risk factors are listed in Box 52–3.

When obtaining a nursing history, the nurse needs to not only recognize risk factors but also gather data about the client's food and fluid intake, fluid output, and the presence of signs or symptoms suggestive of altered fluid and electrolyte balance. The Assessment Interview provides examples of questions to elicit information regarding fluid, electrolyte, and acid–base balance.

Physical Assessment

Physical assessment to evaluate a client's fluid, electrolyte, and acid–base status focuses on the skin, the oral cavity and mucous membranes, the eyes, the cardiovascular and respiratory systems, and neurologic and muscular status. Data from this physical assessment are used to expand and verify information obtained in the nursing history. Refer to Tables 52–4 through 52–8 for possible abnormal findings related to specific imbalances.

BOX 52–3

Common Risk Factors for Fluid, Electrolyte, and Acid–Base Imbalances

CHRONIC DISEASES AND CONDITIONS

- Chronic lung disease (COPD, asthma, cystic fibrosis)
- Heart failure
- Kidney disease
- Diabetes mellitus
- Cushing's syndrome or Addison's disease
- Cancer
- Malnutrition, anorexia nervosa, bulimia
- Ileostomy

ACUTE CONDITIONS

- Acute gastroenteritis
- Bowel obstruction
- Head injury or decreased level of consciousness
- Trauma such as burns or crushing injuries
- Surgery
- Fever, draining wounds, fistulas

MEDICATIONS

- Diuretics
- Corticosteroids
- Nonsteroidal anti-inflammatory drugs

TREATMENTS

- Chemotherapy
- IV therapy and total parenteral nutrition
- Nasogastric suction
- Enteral feedings
- Mechanical ventilation

OTHER FACTORS

- Age: Very old or very young
- Inability to access food and fluids independently

Clinical Measurements

Three simple clinical measurements that the nurse can initiate without a primary care provider's order are daily weights, vital signs, and fluid intake and output.

ASSESSMENT INTERVIEW Fluid, Electrolyte, and Acid–Base Balance

CURRENT AND PAST MEDICAL HISTORY

- Are you currently seeing a health care provider for treatment of any chronic diseases such as kidney disease, heart disease, lung disease, high blood pressure, diabetes mellitus, diabetes insipidus, or thyroid, parathyroid, or adrenal disorders?
- Have you recently experienced any acute conditions such as gastroenteritis, severe trauma, head injury, or surgery?

MEDICATIONS AND TREATMENTS

- Are you currently taking any medications on a regular basis such as diuretics, steroids, potassium supplements, calcium supplements, hormones, salt substitutes, or antacids?
- Have you recently undergone any treatments such as dialysis, parenteral nutrition, tube feedings, or been on a ventilator?

FOOD AND FLUID INTAKE

- How much and what type of fluids do you drink each day?
- Describe your diet for a typical day. (Pay particular attention to the client's intake of foods high in sodium, and of protein, whole grains, fruits, and vegetables.)
- Have there been any recent changes in your food or fluid intake, for example, as a result of following a weight-loss program?
- Are you on any type of restricted diet?

- Has your food or fluid intake recently been affected by changes in appetite, nausea, or other factors such as pain or difficulty breathing?

FLUID OUTPUT

- Have you noticed any recent changes in the frequency or amount of urine output?
- Have you recently experienced any problems with vomiting, diarrhea, or constipation?
- Have you noticed any other unusual fluid losses such as excessive sweating?

FLUID, ELECTROLYTE, AND ACID–BASE IMBALANCES

- Have you gained or lost weight in recent weeks?
- Have you recently experienced any symptoms such as excessive thirst, dry skin or mucous membranes, dark or concentrated urine, or low urine output?
- Do you have problems with swelling of your hands, feet, or ankles? Do you ever have difficulty breathing, especially when lying down or at night? How many pillows do you use to sleep?
- Have you recently experienced any of the following symptoms: difficulty concentrating or confusion; dizziness or feeling faint; muscle weakness, twitching, cramping, or spasm; excessive fatigue; abnormal sensations such as numbness, tingling, burning, or prickling; abdominal cramping or distention; heart palpitations?

Daily Weights

Daily weights provide a relatively accurate assessment of a client’s fluid status. Significant changes in weight over a short time, for example, more than 2.3 kg (5 lb) in a week or more than 1 kg (2.2 lb) in 24 hours, are indicative of acute fluid changes. Each kilogram (2.2 lb) of weight gained or lost corresponds to 1 L of fluid gained or lost. Such fluid gains or losses indicate changes in total body fluid volume rather than in any specific compartment, such as the intravascular compartment. Rapid losses or gains of 5% to 8% of total body weight indicate moderate to severe fluid volume deficits or excesses.

To obtain accurate weight measurements, the scale should be balanced before each use, and the client should be weighed (a) at the same time each day (e.g., before breakfast and after the first void), (b) wearing the same or similar clothing, and (c) on the same scale. The type of scale (i.e., standing, bed, or chair) should be documented.

Regular assessment of weight is particularly important for clients in the community and extended care facilities who are at risk for

fluid imbalance. For these clients, measuring intake and output may be impractical because of lifestyle or problems with incontinence. Regular weight measurement, either daily, every other day, or weekly, provides valuable information about the client’s fluid status.

Vital Signs

Changes in vital signs may indicate, or in some cases precede, fluid, electrolyte, and acid–base imbalances. For example, elevated body temperature may be a result of dehydration or a cause of increased body fluid losses.

Tachycardia is an early sign of hypovolemia. Pulse *volume* will decrease in FVD and increase in FVE. Irregular pulse rhythms may occur with electrolyte imbalances. Changes in respiratory rate and depth may cause respiratory acid–base imbalances or indicate a compensatory mechanism in metabolic acidosis or alkalosis.

Blood pressure (BP), a sensitive measure for detecting blood volume changes, may fall significantly with FVD and hypovolemia or increase with FVE. Postural, or orthostatic, hypotension may also

TABLE 52–8 Focused Physical Assessment for Fluid, Electrolyte, or Acid–Base Imbalances

System	Assessment Focus	Technique	Possible Abnormal Findings
Skin	Color, temperature, moisture	Inspection, palpation	Flushed, warm, very dry Moist or diaphoretic Cool and pale
	Turgor	Gently pinch up a fold of skin over sternum for adults, on the abdomen or medial thigh for children	Poor turgor: Skin remains tented for several seconds instead of immediately returning to normal position
	Edema	Inspect for visible swelling around eyes, in fingers, and in lower extremities Compress the skin over the dorsum of the foot, around the ankles, over the tibia, in the sacral area	Skin around eyes is puffy, lids appear swollen; rings are tight; shoes leave impressions on feet Depression remains (pitting): See scale for describing edema in Figure 52–10.
Mucous membranes	Color, moisture	Inspection	Mucous membranes dry, dull in appearance; tongue dry and cracked
Eyes	Firmness	Gently palpate eyeball with lid closed	Eyeball feels soft to palpation
Fontanels (infant)	Firmness, level	Inspect and gently palpate anterior fontanel	Fontanel bulging, firm Fontanel sunken, soft
Cardiovascular system	Heart rate	Auscultation, cardiac monitor	Tachycardia, bradycardia; irregular; dysrhythmias
	Peripheral pulses	Palpation	Weak and thready; bounding
	Blood pressure	Auscultation of Korotkoff’s sounds BP assessment lying and standing	Hypotension Postural hypotension
	Capillary refill Venous filling	Palpation Inspection of jugular veins and hand veins	Slowed capillary refill Jugular venous distention; flat jugular veins, poor venous refill
Respiratory system	Respiratory rate and pattern	Inspection	Increased or decreased rate and depth of respirations
	Lung sounds	Auscultation	Crackles or moist rales
Neurologic	Level of consciousness (LOC)	Observation, stimulation	Decreased LOC, lethargy, stupor, or coma
	Orientation, cognition	Questioning	Disoriented, confused; difficulty concentrating
	Motor function	Strength testing	Weakness, decreased motor strength
	Reflexes	Deep-tendon reflex (DTR) testing	Hyperactive or depressed DTRs
	Abnormal reflexes	<i>Chvostek’s sign</i> : Tap over facial nerve about 2 cm anterior to tragus of ear <i>Trousseau’s sign</i> : Inflate a blood pressure cuff on the upper arm to 20 mmHg greater than the systolic pressure, leave in place for 2–5 min	Facial muscle twitching including eyelids and lips on side of stimulus Carpal spasm: contraction of hand and fingers on affected side

occur with FVD and hypovolemia. To assess for orthostatic hypotension, measure the client's BP and pulse in a supine position. Allow the client to remain in that position for 3 to 5 minutes, leaving the blood pressure cuff on the arm. Ask the client to stand up and immediately reassess the BP and pulse. A drop of 10 to 15 mmHg in the systolic BP with a corresponding drop in diastolic pressure and an increased pulse rate (by 10 or more beats per minute) is indicative of orthostatic or postural hypotension.

Fluid Intake and Output

Measurement and recording of all fluid intake and output (I&O) during a 24-hour period provides important data about a client's fluid and electrolyte balance. Generally, I&O are measured for hospitalized clients, particularly those at increased risk for fluid and electrolyte imbalance.

The unit used to measure I&O is the milliliter (mL). In household measures, 30 mL is roughly equivalent to 1 fluid ounce, 500 mL to 1 pint, and 1,000 mL to 1 quart. To measure fluid intake, nurses convert household measures such as a cup or soup bowl to metric units. Most agencies have a form for recording I&O, usually a bedside or computer record on which the nurse lists all items measured and the quantities per shift (Figure 52–13 ■).

Usually these forms provide conversion tables, since the sizes of dishes vary from agency to agency. Examples of equivalents are given in Box 52–4. Some agencies have a different form for recording the specifics of IV fluids, such as the type of solution, additives, time started, amount absorbed, and amount remaining per shift.

It is important to inform clients, family members, and all caregivers that accurate measurements of the client's fluid I&O are required, explaining why and emphasizing the need to use a bedpan, urinal, commode, or in-toilet collection device (unless a urinary drainage system is in place). Instruct the client not to put toilet tissue into the container with urine. Clients who wish to be involved in recording fluid intake measurements need to be taught how to compute the values and what foods are considered fluids.

To measure fluid intake, each item of fluid consumed or administered is recorded, specifying the time and type of fluid. All of the following fluids need to be recorded:

- **Oral fluids:** Water, milk, juice, soft drinks, coffee, tea, cream, soup, and any other beverages. Include water taken with medications. To measure the amount of water consumed from a water pitcher, measure how much water remains in the pitcher and subtract this amount from the volume of the full pitcher.

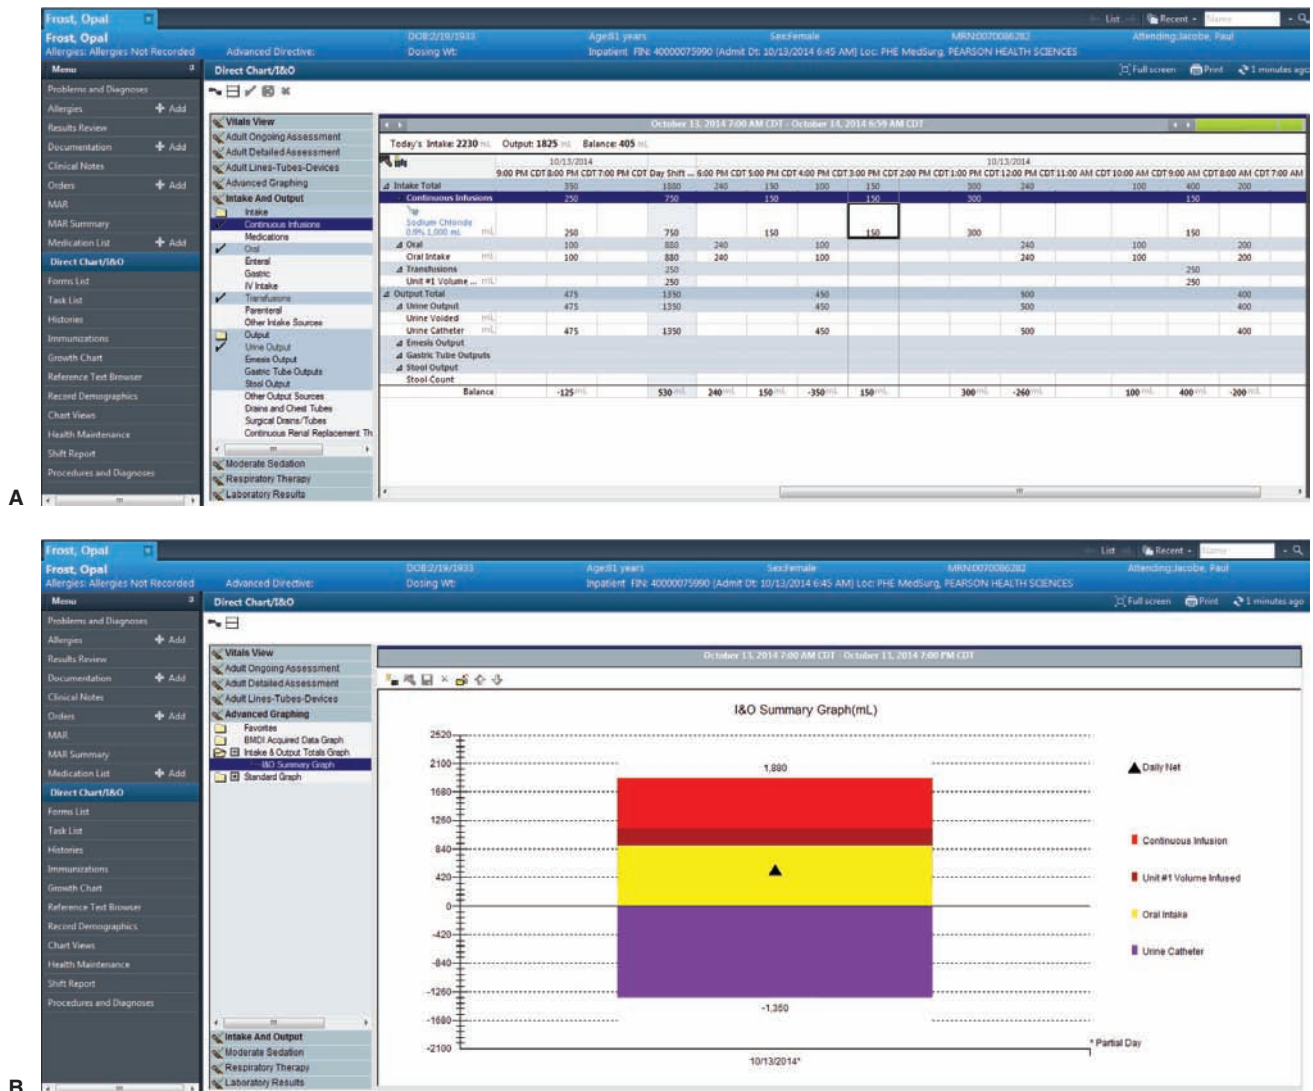

Figure 52–13 ■ A, A sample EHR fluid intake and output record; B, A sample 24-hour EHR summary graph. "A-B Fluid I/O Record" from Cerner Electronic Health Record. Copyright © by Cerner Corporation. Used by permission of Cerner Corporation.

BOX 52-4

Commonly Used Fluid Containers and Their Volumes

Water glass	200 mL
Juice glass	120 mL
Cup	180 mL
Soup bowl	
Adult	180 mL
Child	100 mL
Teapot	240 mL
Creamer	
Large	90 mL
Small	30 mL
Water pitcher	1,000 mL
Jell-O, custard dish	100 mL
Ice cream dish	120 mL
Paper cup	
Large	200 mL
Small	120 mL

- **Ice chips:** Record the fluid volume as approximately one half the volume of the ice chips. For example, if the ice chips fill a cup holding 200 mL and the client consumed all of the ice chips, the volume consumed would be recorded as 100 mL.
- **Foods that are or become liquid at room temperature:** These include ice cream, sherbert, custard, and gelatin. Do not measure foods that are pureed, because purees are simply solid foods prepared in a different form.
- **Tube feedings:** Remember to include the volume of water used for flushes before and after medication administration, intermittent feedings, residual checks, or any other water given via a feeding tube.
- **Parenteral fluids:** The exact amount of IV fluid administered must be recorded, since some fluid containers may be overfilled. Blood transfusions are included in the total.
- **IV medications:** IV medications that are administered as an intermittent or continuous infusion must also be included (e.g., ceftazidime 1 g in 50 mL of sterile water). Most IV medications are mixed in 50 to 100 mL of solution.
- **Catheter or tube irrigants:** Fluid used to irrigate urinary catheters, nasogastric tubes, and intestinal tubes must be recorded if not immediately withdrawn as part of the irrigation.

To measure fluid output, measure the following fluids (remember to observe appropriate infection control precautions):

- **Urinary output:** Following each voiding, pour the urine into a measuring container, note the amount, and record the amount and time on the I&O form. For clients with retention catheters, empty the drainage bag into a measuring container at the end of the shift (or at prescribed times if output is to be measured more often). Note and record the amount of urine output. In intensive care areas, urine output often is measured hourly. If a client is incontinent of urine, estimate and record these outputs. For example, for an incontinent client the nurse might record “Incontinent × 3” or “Drawsheet soaked in 12-in. diameter.” A more accurate estimate of the urine output of infants and incontinent clients may be obtained by first weighing diapers or incontinence pads that are dry, and then subtracting this weight from the weight of the soiled items. Each gram of weight left after subtracting is equal to 1 mL of urine. If urine is frequently soiled with feces, the number of voidings may be recorded rather than the volume of urine.

- **Vomitus and liquid feces:** The amount and type of fluid and the time need to be specified.
- **Tube drainage:** This includes gastric or intestinal drainage.
- **Wound and fistula drainage:** Drainage may be recorded by documenting the type and number of dressings or linen saturated with drainage, or by measuring the exact amount of drainage collected in a vacuum drainage (e.g., Hemovac) or gravity drainage system.

Fluid I&O measurements are totaled at the end of the shift (every 8 to 12 hours), and the totals are recorded in a client’s chart. In intensive care areas, nurses may record I&O hourly. Usually the staff on the night shift totals the amounts of I&O recorded for each shift and records the 24-hour total.

To determine whether fluid output is proportional to fluid intake, or whether there are any changes in a client’s fluid status, (a) compare the total 24-hour fluid output measurement with the total 24-hour fluid intake measurement and (b) compare both to previous measurements. Urinary output is normally equivalent to the amount of fluid intake; the usual range is 1,500 to 2,000 mL in 24 hours, or 40 to 80 mL in 1 hour (0.5 mL/kg per hour). Clients whose output substantially exceeds intake are at risk for fluid volume deficit, whereas clients whose intake substantially exceeds output are at risk for fluid volume excess. In assessing a client’s fluid balance it is important to consider additional factors that may affect I&O. For example, a client who is extremely diaphoretic or has rapid, deep respirations has fluid losses that cannot be measured but must still be considered in evaluating fluid status.

When there is a significant discrepancy between intake and output or when fluid intake or output is inadequate (for example, a urine output of less than 30 mL/h in an adult), this information should be reported to the primary care provider.

Laboratory Tests

Many laboratory studies are conducted to determine a client’s fluid, electrolyte, and acid–base status. Some of the more common tests are discussed here.

Serum Electrolytes

Serum electrolyte levels are often ordered for clients admitted to the hospital as a screening test for electrolyte and acid–base imbalances. Serum electrolytes also are routinely assessed for clients at risk in the community, for example, clients who are being treated with a diuretic for hypertension or heart failure. The most commonly ordered serum tests are for sodium, potassium, chloride, magnesium, and bicarbonate ions. Normal values of commonly measured electrolytes are shown in Box 52-5. Some primary care providers use a diagram

BOX 52-5 Normal Electrolyte Values for Adults*

Venous Blood

Sodium	135–145 mEq/L
Potassium	3.5–5.0 mEq/L
Chloride	95–108 mEq/L
Calcium, total	4.5–5.5 mEq/L or 8.5–10.5 mg/dL
Calcium, ionized	56% of total calcium (2.5 mEq/L or 4.0–5.0 mg/dL)
Magnesium	1.5–2.5 mEq/L or 1.6–2.5 mg/dL
Phosphate (phosphorus)	1.8–2.6 mEq/L or 2.5–4.5 mg/dL
Serum osmolality	280–300 mOsm/kg water

*Normal laboratory values vary from agency to agency.

Figure 52-14 ■ A, Format for a diagram of serum electrolyte results; B, example that may be seen in a primary care provider's documentation notes.

format for keeping track of the client's electrolytes when documenting in their progress notes (Figure 52-14 ■).

Complete Blood Count

A complete blood count (CBC), another basic screening test, includes information about **hematocrit (Hct)**, which measures the percentage of the volume of whole blood that is composed of RBCs. Hematocrit is a measure of the volume of cells in relation to plasma and is, therefore, affected by changes in plasma volume; hematocrit increases with dehydration and decreases with overhydration. Normal hematocrit values are 40% to 54% in men and 37% to 47% in women.

Osmolality

Serum osmolality is a measure of the solute concentration of blood. The particles included are sodium ions, glucose, and urea (blood urea nitrogen, or BUN). Serum osmolality can be estimated by doubling the serum sodium value, because sodium and its associated chloride ions are the major determinants of serum osmolality. Serum osmolality is used primarily to evaluate fluid balance. Normal values are 280 to 300 mOsm/kg. An increase in serum osmolality indicates a fluid volume deficit; a decrease reflects a fluid volume excess.

Urine osmolality is a measure of the solute concentration of urine. The particles included are nitrogenous wastes, such as creatinine, urea, and uric acid. Normal values are 500 to 800 mOsm/kg. An increased urine osmolality indicates a fluid volume deficit; a decreased urine osmolality reflects a fluid volume excess.

Urine Specific Gravity

Specific gravity is an indicator of urine concentration that correlates with urine osmolality and it can be measured quickly and easily by nursing personnel. Normal specific gravity ranges from 1.005 to 1.030 (usually 1.010 to 1.025). When urine osmolality is high, in fluid volume deficit, the specific gravity rises; when urine osmolality is low, in fluid volume excess, the specific gravity is low.

Urine pH

Measurement of urine pH may be obtained by laboratory analysis or by using a dipstick on a freshly voided specimen. Because the kidneys play a critical role in regulating acid–base balance, assessment of urine pH can be useful in determining whether the kidneys are responding appropriately to acid–base imbalances. Normally the pH

of the urine is relatively acidic, averaging about 6.0, but a range of 4.6 to 8.0 is considered normal. In metabolic acidosis, urine pH should decrease as the kidneys retain bicarbonate and excrete hydrogen ions; in metabolic alkalosis, the pH should increase as the kidneys retain hydrogen ions and excrete bicarbonate.

Arterial Blood Gases

Arterial blood gases (ABGs) are performed to evaluate a client's acid–base balance and oxygenation. Arterial blood is used because it provides a more accurate reflection of gas exchange in the pulmonary system than venous blood. Blood gases may be drawn by laboratory technicians, respiratory therapy personnel, or nurses with specialized skills. Because a high-pressure artery is used to obtain blood, it is important to apply pressure to the puncture site for at least 5 minutes after the procedure to reduce the risk of bleeding or bruising.

Six measurements are commonly used to interpret arterial blood gas tests:

- pH is a measure of the relative acidity or alkalinity of the blood, and is an inverse measure of the number of hydrogen ions in a solution. An acidic solution has more hydrogen ions, and this is reflected in a lower pH. An alkaline solution has fewer hydrogen ions, and this is reflected in a higher pH. The normal range for arterial pH is narrow, and death may ensue with pH values below 6.8 or above 7.8.
- PaO₂ is the partial pressure of oxygen dissolved in arterial plasma, and is an indirect measure of blood oxygen content. PaO₂ represents one of the two forms in which oxygen is transported in blood, and accounts for only about 3% of the oxygen content of the blood.
- PaCO₂ is the partial pressure of carbon dioxide in arterial plasma, and is the respiratory component of acid–base determination. Because carbon dioxide is regulated by the lungs, PaCO₂ is used to determine if an acid–base imbalance is respiratory in origin.
- HCO₃⁻ is a measure of the bicarbonate dissolved in arterial plasma, and represents the metabolic component of acid–base balance.
- Base excess (BE) is a calculated value of bicarbonate levels, also reflective of the metabolic component of acid–base balance. If the number is preceded by a plus sign, it represents a base excess; a BE above +2 indicates alkalosis. If the number is preceded by a minus sign, it represents a base deficit; a BE below -2 indicates acidosis.
- SpO₂ is oxygen saturation, which represents the percentage of hemoglobin that is combined (saturated) with oxygen. SpO₂ is the other form in which oxygen is transported in the blood and accounts for about 97% of the oxygen in the blood.

Normal ABG values are listed in Table 52-9 along with changes associated with common acid–base imbalances. Note that although the PaO₂ and SpO₂ are important for assessing respiratory status, they generally do not provide useful information for assessing acid–base balance and so are not included in this table.

When evaluating ABG results to determine acid–base balance, it is important to use a systematic approach such as the one outlined in Box 52-6. Nurses need to assess each measurement individually, and then look at the interrelationships to determine what type of acid–base imbalance may be present.

TABLE 52–9 Arterial Blood Gas Values**NORMAL VALUES OF ARTERIAL BLOOD GASES***

pH	7.35–7.45
PaO ₂	80–100 mmHg
PaCO ₂	35–45 mmHg
HCO ₃ ⁻	22–26 mEq/L
Base excess	-2 to +2 mEq/L
O ₂ saturation	95–98%

ARTERIAL BLOOD GAS VALUES IN COMMON ACID–BASE DISORDERS

Disorder	ABG Values	
Respiratory acidosis	pH	<7.35
	PaCO ₂	>45 mmHg (excess CO ₂ and carbonic acid)
	HCO ₃ ⁻	Normal (or >26 mEq/L with renal compensation)
Respiratory alkalosis	pH	>7.45
	PaCO ₂	<35 mmHg (inadequate CO ₂ and carbonic acid)
	HCO ₃ ⁻	Normal (or <22 mEq/L with renal compensation)
Metabolic acidosis	pH	<7.35
	PaCO ₂	Normal (or <35 mmHg with respiratory compensation)
	HCO ₃ ⁻	<22 mEq/L (inadequate bicarbonate)
Metabolic alkalosis	pH	>7.45
	PaCO ₂	Normal (or >45 mmHg with respiratory compensation)
	HCO ₃ ⁻	>26 mEq/L (excess bicarbonate)

*Some normal values will vary according to the kind of test carried out in the laboratory. Nurses are advised to use the normal values issued by the agency when interpreting laboratory results.

Diagnosing

NANDA International (Herdman & Kamitsuru, 2014) includes the following diagnostic labels that relate to fluid and acid–base imbalances:

- **Deficient Fluid Volume:** Decreased intravascular, interstitial, and/or intracellular fluid. This refers to dehydration, water loss alone without change in sodium.
- **Excess Fluid Volume:** Increased isotonic fluid retention.
- **Risk for Imbalanced Fluid Volume:** Vulnerable to a decrease, increase, or rapid shift from one to the other of intravascular, interstitial, and/or intracellular fluid, which may compromise health. This refers to body fluid loss, gain, or both.
- **Risk for Deficient Fluid Volume:** Vulnerable to experiencing decreased intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health.
- **Impaired Gas Exchange:** Excess or deficit in oxygenation and/or carbon dioxide elimination at the alveolar–capillary membrane.

BOX 52–6 Interpreting ABGs—Do You Have a Match?

1. Look at each number separately.
 - Label the pH:
 - If the pH is less than 7.35, the problem is acidosis.
 - If the pH is greater than 7.45, the problem is alkalosis.
 - Label the PaCO₂:
 - If the PaCO₂ is less than 35 mmHg, more carbon dioxide is being exhaled than normal and indicates respiratory alkalosis or compensation for a metabolic imbalance.
 - If the PaCO₂ is greater than 45 mmHg, less carbon dioxide is being exhaled than normal and indicates respiratory acidosis or compensation for a metabolic imbalance.
 - Label the bicarbonate:
 - If the HCO₃⁻ is less than 22 mEq/L, bicarbonate levels are lower than normal, indicating metabolic acidosis or compensation for a respiratory imbalance.
 - If the HCO₃⁻ is greater than 26 mEq/L, bicarbonate levels are higher than normal, indicating metabolic alkalosis or compensation for a respiratory imbalance.
2. Determine the cause of the acid–base imbalance.
 - Look at the pH—is it acidosis, alkalosis, or within the normal range?
3. Determine if the origin of the imbalance is respiratory or metabolic.
 - Check the PaCO₂ and HCO₃⁻. Which one corresponds with the same acid–base status as the pH?

EXAMPLE

pH = 7.33 (acidosis)
 PaCO₂ = 55 (acidosis)
 HCO₃⁻ = 29 (alkalosis)
 PaCO₂ (acidosis) MATCHES the pH (acidosis) = respiratory problem

Client has respiratory acidosis.

4. Look for evidence of compensation.

- Look at the value that does **not** match the pH:

EXAMPLES

- a. In respiratory acidosis (pH < 7.35, PaCO₂ > 45 mmHg), if the HCO₃⁻ is greater than 26 mEq/L, the kidneys are retaining bicarbonate to minimize the acidosis: renal compensation.
- b. In respiratory alkalosis (pH > 7.45, PaCO₂ < 35 mmHg), if the HCO₃⁻ is less than 22 mEq/L, the kidneys are excreting bicarbonate to minimize the alkalosis: renal compensation.
- c. In metabolic acidosis (pH < 7.35, HCO₃⁻ > 22 mEq/L), if the PaCO₂ is less than 35 mmHg, carbon dioxide is being eliminated to minimize the acidosis: respiratory compensation.
- d. In metabolic alkalosis (pH > 7.45, HCO₃⁻ > 26 mEq/L), if the PaCO₂ is greater than 45 mmHg, carbon dioxide is being retained to compensate for excess base: respiratory compensation.

Note: If the pH is within normal range, the body has completely compensated. Complete metabolic compensation takes time to develop and is the result of a chronic condition (e.g., chronic respiratory acidosis with COPD). If the pH is not within the normal range, compensation is partial.

Clinical applications of selected diagnoses are shown in the Nursing Care Plan and the Concept Map at the end of this chapter.

Fluid, electrolyte, and acid–base imbalances affect many other body areas and as a consequence may be the etiology of other nursing diagnoses, such as these:

- **Impaired Oral Mucous Membrane** related to fluid volume deficit
- **Impaired Skin Integrity** related to dehydration and/or edema

- *Decreased Cardiac Output* related to hypovolemia and/or cardiac dysrhythmias secondary to electrolyte imbalance (K^+ or Mg^{2+})
- *Ineffective Tissue Perfusion* related to decreased cardiac output secondary to fluid volume deficit or edema
- *Activity Intolerance* related to hypervolemia
- *Risk for Injury* related to calcium shift out of bones into extracellular fluids
- *Acute Confusion* related to electrolyte imbalance.

Planning

When planning care a nurse identifies nursing interventions that will assist the client to achieve these broad goals:

- Maintain or restore normal fluid balance.
- Maintain or restore normal balance of electrolytes in the intracellular and extracellular compartments.
- Maintain or restore gas exchange and oxygenation.
- Prevent associated risks (tissue breakdown, decreased cardiac output, confusion, other neurologic signs).

Obviously, goals will vary according to the diagnosis and defining characteristics for each individual. Appropriate preventive and corrective nursing interventions that relate to these must be identified. Specific nursing activities can be selected to meet a client's individual needs. Examples of application of these using NANDA, NIC, and NOC designations are shown in the Nursing Care Plan and the Concept Map at the end of this chapter. Examples of NIC interventions related to fluid, electrolyte, and acid–base balance include the following:

- Acid–base management
- Electrolyte management
- Fluid monitoring
- Hypovolemia management
- Intravenous (IV) therapy.

Specific nursing activities associated with each of these interventions can be selected to meet the individual needs of the client.

Nursing activities to meet goals and outcomes related to fluid, electrolyte, and acid–base imbalances are discussed in the next section. These include (a) monitoring fluid intake and output, cardiovascular and respiratory status, and results of laboratory tests; (b) assessing the

client's weight; location and extent of edema, if present; skin turgor and skin status; specific gravity of urine; and level of consciousness and mental status; (c) fluid intake modifications; (d) dietary changes; (e) parenteral fluid, electrolyte, and blood replacement; and (f) other appropriate measures such as administering prescribed medications and oxygen, providing skin care and oral hygiene, positioning the client appropriately, and scheduling rest periods.

Planning for Home Care

To provide for continuity of care, a client's needs for assistance with care in the home need to be considered. Home care planning includes assessment of a client's and family's resources and abilities for care, and the need for referrals and home health services. The accompanying Home Care Assessment describes the specific assessment data required to establish a home care plan. Based on the data gathered in assessment of the home situation, the nurse tailors the teaching plan for the client and family (see Client Teaching).

Implementing

Promoting Wellness

Most people rarely think about their fluid, electrolyte, or acid–base balance. They know it is important to drink adequate fluids and consume a balanced diet, but they may not understand the potential effects when this is not done. Nurses can promote clients' health by providing wellness teaching that will help them maintain fluid and electrolyte balance.

Enteral Fluid and Electrolyte Replacement

Fluids and electrolytes can be provided orally in the home or hospital if a client's health permits, meaning that the client is not vomiting, has not experienced an excessive fluid loss, and has an intact gastrointestinal tract and gag and swallow reflexes. Clients who are unable to ingest solid foods may be able to ingest fluids.

Fluid Intake Modifications

Increased fluids (ordered as “push fluids”) are often prescribed for clients with actual or potential fluid volume deficits arising, for example, from mild diarrhea or mild to moderate fevers. Guidelines for helping clients increase fluid intake are shown in Practice Guidelines.

Home Care Assessment Fluid, Electrolyte, and Acid–Base Balance

PATIENT-CENTERED CARE

CLIENT

- *Risk factors for imbalances:* the client's age, medications such as diuretic therapy or corticosteroids, and presence of chronic diseases such as diabetes mellitus, heart disease, lung disease, or dementia (see Box 52–3 on page 1327)
- *Self-care abilities for maintaining food and fluid intake:* mobility; ability to chew and swallow; ability to access fluids and respond to thirst, to purchase food, and prepare a balanced diet
- *Current level of knowledge (as appropriate):* prescribed diet, any fluid restrictions, activity restrictions, actions and side effects of prescribed medications, regular weight monitoring, gastric tube care and enteral feedings, central line or PICC catheter care, and parenteral fluids and nutrition

FAMILY

- *Caregiver availability, skills, and responses:* availability and willingness to assume responsibility for care, knowledge and

ability to provide assistance with preparing food and maintaining adequate intake of food and fluids, knowledge of risk factors and early warning signs of problems

- *Family role changes and coping:* effect on financial status, parenting and spousal roles, social roles
- *Alternate potential primary or respite caregivers:* other family members, friends, volunteers, church members, paid caregivers or housekeeping services; available community respite care (e.g., adult day care, senior centers)

COMMUNITY

- *Current knowledge of and experience with community resources:* home health agencies, organizations that offer financial assistance or assistance with food preparation, Meals-on-Wheels or meal services (e.g., at senior centers, homeless shelters), pharmacies, home IV services, and respiratory care services

CLIENT TEACHING**Promoting Fluid and Electrolyte Balance**

- Consume six to eight glasses of water daily.
- Avoid excess amounts of foods or fluids high in salt, sugar, and caffeine.
- Eat a well-balanced diet. Include adequate amounts of milk, milk products, or calcium-enriched alternatives to maintain bone calcium levels.
- Limit alcohol intake because it has a diuretic effect.
- Increase fluid intake before, during, and after strenuous exercise, particularly when the environmental temperature is high, and replace lost electrolytes from excessive perspiration as needed with commercial electrolyte solutions.
- Maintain normal body weight and body mass index for age and gender.
- Learn about and monitor side effects of medications that affect fluid and electrolyte balance (e.g., diuretics) and ways to handle side effects.
- Recognize possible risk factors for fluid and electrolyte imbalance such as prolonged or repeated vomiting, frequent watery stools, or inability to consume fluids because of illness.
- Seek prompt professional health care for notable signs of fluid imbalance such as sudden weight gain or loss, decreased urine volume, swollen ankles, shortness of breath, dizziness, or confusion.

CLIENT TEACHING**Home Care and Fluid, Electrolyte, and Acid–Base Balance****MONITORING FLUID INTAKE AND OUTPUT**

- Teach and provide the rationale for monitoring fluid intake and output to the client and family as appropriate, for example, how to use a commode or collection device (“hat”) in the toilet, how to empty and measure urinary catheter drainage, or how to count or weigh diapers.
- Instruct and provide the rationale for regular weight monitoring to the client and family, including weighing at the same time every day, using the same scale, and with the client wearing the same amount of clothing.
- Educate and provide the rationale to the client and family on when to contact a health care professional, such as in the cases of a significant change in urine output; any change of 5 pounds or more in a 1- to 2-week period or 2 pounds or more in 24 hours; prolonged episodes of vomiting, diarrhea, or inability to eat or drink; dry, sticky mucous membranes; extreme thirst; swollen fingers, feet, ankles, or legs; difficulty breathing, shortness of breath, need for an increased number of pillows to sleep on, or rapid heartbeat; and changes in behavior or mental status.

MAINTAINING FOOD AND FLUID INTAKE

- Instruct the client and family about any diet or fluid restrictions, such as a low-sodium diet.
- Teach family members the rationale for the importance of offering fluids regularly to clients who are unable to meet their own needs because of age, impaired mobility or cognition, or other conditions such as impaired swallowing due to a stroke.
- If the client is on enteral or IV fluids and feeding at home, teach and provide rationales to caregivers about proper administration and care. Contact a home health or home IV service to provide services and teaching.

SAFETY

- Instruct and provide the rationale to the client for changing positions slowly if appropriate, especially when moving from a supine to a sitting or standing position.
- Inform and provide the rationale to the client and family about the importance of good mouth and skin care. Teach the client to change positions frequently and to elevate the feet when sitting for a long period.

- Teach the client and family how to care for IV access sites or gastric tubes. Include what to do if tubes become dislodged.

MEDICATIONS

- Emphasize the importance of and rationale for taking medications as prescribed.
- Instruct clients taking diuretics to take the medication in the morning. If a second daily dose is prescribed, they should take it in the late afternoon to avoid disrupting sleep to urinate.
- Inform clients about any expected side effects of prescribed medications and how to handle them (e.g., if a potassium-depleting diuretic is prescribed, increase intake of potassium-rich foods; if taking a potassium-sparing diuretic, avoid excess potassium intake such as using a salt substitute).
- Teach clients when to contact their primary care provider, for example, if they are unable to take a prescribed medication or have signs of an allergic or toxic reaction to a medication.

MEASURES SPECIFIC TO CLIENT’S PROBLEM

- Provide instructions and rationales specific to the client’s fluid, electrolyte, or acid–base imbalance, such as:
 - a. Fluid volume deficit
 - b. Risk for fluid volume deficit
 - c. Fluid volume excess
 - d. Risk for fluid volume excess.

REFERRALS

- Make appropriate referrals to home health or community social services for assistance with resources such as meals, meal preparation and food delivery, IV infusions and access, enteral feedings, and homemaker or home health aide services to help with ADLs.

COMMUNITY AGENCIES AND OTHER SOURCES OF HELP

- Provide information about companies or agencies that can provide durable medical equipment such as commodes, lift chairs, or hospital beds for purchase, rental, or free of charge.
- Provide a list of sources for supplies such as catheters and drainage bags, measuring devices, tube feeding formulas, and electrolyte replacement drinks.
- Suggest additional sources of information and help such as the American Dietetic Association, the American Heart Association, and the American Lung Association.

PRACTICE GUIDELINES**Facilitating Fluid Intake**

- Explain to the client the reason for the required intake and the specific amount needed. This provides a rationale for the requirement and promotes compliance.
- Establish a 24-hour plan for ingesting the fluids. For a hospitalized or long-term care client, half of the total volume is given during the day shift, and the other half is divided between the evening and night shifts, with most of that ingested during the evening shift. For example, if 2,500 mL is to be ingested in 24 hours, the plan may specify 7–3 (1,500 mL); 3–11 (700 mL); and 11–7 (300 mL). Try to avoid the ingestion of large amounts of fluid immediately before bedtime to prevent the need to urinate during sleeping hours.
- Set short-term outcomes that the client can realistically meet. Examples include ingesting a glass of fluid every hour while awake or a pitcher of water by lunchtime.
- Identify fluids the client likes and make available a variety of those items, including fruit juices, noncaffeinated soft drinks, and milk (if allowed). Remember that beverages such as coffee, tea, and other caffeinated beverages have a diuretic effect, so their consumption should be limited.
- Help the client to select foods that tend to become liquid at room temperature (e.g., gelatin, ice cream, sherbet, custard), if these are allowed.
- For clients who are confined to bed, supply appropriate cups, glasses, and straws to facilitate adequate fluid intake, and keep fluids within easy reach.
- Make sure fluids are served at the appropriate temperature (i.e., hot fluids hot and cold fluids cold) and according to client preference.
- Encourage clients to participate in maintaining the fluid intake record if possible. This assists them to evaluate the achievement of desired outcomes.
- Be alert to any cultural implications of food and fluids. Some cultures may restrict certain foods and fluids, or temperatures of foods and fluids, and view others as having healing properties.

Restricted fluids may be necessary for clients who have fluid retention (fluid volume excess) as a result of renal failure, heart failure, SIADH, or other disease processes. Fluid restrictions vary from “nothing by mouth” to a precise amount ordered by a primary care provider. The restriction of fluids can be difficult for some clients, particularly if they are experiencing thirst. Guidelines for helping clients restrict fluid intake are shown in Practice Guidelines.

Dietary Changes

Specific fluid and electrolyte imbalances may require simple dietary changes. For example, clients receiving potassium-depleting diuretics need to be informed about foods with high potassium content (e.g., bananas, oranges, and leafy greens). Some clients with fluid retention need to avoid foods high in sodium. Most healthy clients can benefit from foods rich in calcium.

Oral Electrolyte Supplements

Some clients can benefit from oral electrolyte supplements, particularly when a medication is prescribed that affects electrolyte balance, when dietary intake is inadequate for a specific electrolyte, or when fluid and electrolyte losses are excessive, for example, as a result of excessive perspiration.

Corticosteroids and many diuretics can cause too much potassium to be eliminated through the kidneys. For clients taking these medications, potassium supplements may be prescribed. Instruct clients taking oral potassium supplements to take the medication with juice to mask the unpleasant taste and reduce the possibility of gastric distress. Emphasize the importance of taking the medication as prescribed and seeing their primary care provider on a regular basis. Because hyperkalemia can have serious cardiac effects, clients should never increase the amount of potassium being taken without

PRACTICE GUIDELINES**Helping Clients Restrict Fluid Intake**

- Explain the reason for the restricted intake and how much and what types of fluids are permitted orally. Many clients need to be informed that ice chips, gelatin, and ice cream, for example, are considered fluid.
- Help the client decide the amount of fluid to be taken with each meal, between meals, before bedtime, and with medications. For a hospitalized or long-term care client, half the total volume is usually scheduled during the day shift, when the client is most active, receives two meals, and most oral medications. A large part of the remainder is scheduled for the evening shift to permit fluids with meals and evening visitors.
- Identify fluids or fluid-like substances the client likes and make sure that these are provided, unless contraindicated. A client who is allowed only 200 mL of fluid for breakfast, for example, should receive the type of fluid he or she prefers.
- Set short-term goals that make the fluid restriction more tolerable. For example, schedule a specified amount of fluid at one or two hourly intervals between meals. Some clients may prefer fluids only between meals if the food provided at mealtime helps relieve thirst.
- Place allowed fluids in small containers such as a 4-ounce juice glass to allow the perception of a full container.
- Periodically offer the client ice chips as an alternative to water, because ice chips are approximately half of the frozen volume after they melt.
- Provide frequent mouth care and rinses to reduce the thirst sensation.
- Instruct the client to avoid ingesting or chewing salty or sweet foods (hard candy or gum), because these foods tend to produce thirst. Sugarless gum or candy may be an alternative for some clients.
- Encourage the client to participate in maintaining the fluid intake record if possible.

an order to do so. In addition, inform clients that most salt substitutes contain potassium, so it is important to consult with their primary care provider before using salt substitutes.

People who ingest insufficient milk and milk products benefit from calcium supplements. The recommended daily allowance for calcium is 1,000 to 1,500 mg. It is generally recommended that postmenopausal women take 1,500 mg of calcium per day to reduce the risk of osteoporosis. Long-term use of corticosteroid drugs can also cause calcium loss from the bone, and calcium supplements may help reduce this loss. Clients who take supplemental calcium need to maintain a fluid intake of at least 2,500 mL/day (unless contraindicated) to reduce the risk of kidney stones, which are commonly composed of calcium salts.

Although routine supplements for other electrolytes generally are not recommended, clients who have poor dietary habits, who are malnourished, or who have difficulty accessing or eating fresh fruits and vegetables may benefit from electrolyte supplements. A daily multiple vitamin with minerals may achieve the desired goal. People who engage in strenuous activity in a warm environment need to be encouraged to replace water and electrolytes lost through excessive perspiration by consuming a sports drink through available commercial fluid and electrolyte solutions.

Liquid nutritional supplements are often given to clients who are malnourished or have poor eating habits. They are used with frequency in older adults to bolster nutritional status and caloric intake. It is very important that clients read product labels accurately to be aware of the contents of the supplement. Some of them are very high in protein and high in potassium, which may be contraindicated in an individual with impaired renal function.

Parenteral Fluid and Electrolyte Replacement

IV fluid therapy is essential when clients are unable to take sufficient food and fluids orally. It is an efficient and effective method of supplying fluids directly into the intravascular fluid compartment and replacing electrolyte losses. The primary care provider usually orders the IV fluid therapy. The nurse is responsible for administering and maintaining the therapy and for teaching the client and significant others how to continue the therapy at home if necessary.

Intravenous Solutions

IV solutions can be classified as isotonic, hypotonic, or hypertonic. Most IV solutions are isotonic, having the same concentration of solutes as blood plasma. Isotonic solutions are often used to restore vascular volume. Hypertonic solutions have a greater concentration of solutes than plasma; hypotonic solutions have a lesser concentration of solutes. Table 52–10 provides examples of IV solutions and nursing implications.

IV solutions can also be categorized according to their purpose. Nutrient solutions contain some form of carbohydrate (e.g., dextrose, glucose, or levulose) and water. Water is supplied for fluid requirements and carbohydrate for calories and energy. For example, 1 L of 5% dextrose provides 170 calories. Nutrient solutions are useful in preventing dehydration and ketosis but do not provide sufficient calories to promote wound healing, weight gain, or normal growth in children. Common nutrient solutions are 5% dextrose in water (D₅W) and 5% dextrose in 0.45% sodium chloride (dextrose in half-normal saline).

Electrolyte solutions contain varying amounts of cations and anions. Commonly used solutions are normal saline (0.9% sodium chloride solution), Ringer’s solution (which contains sodium, chloride, potassium, and calcium), and lactated Ringer’s solution (which contains sodium, chloride, potassium, calcium, and lactate). Lactate is metabolized in the liver to form bicarbonate. Saline and balanced electrolyte solutions are commonly used to restore vascular volume, particularly after trauma or surgery. They also may be used to replace fluid and electrolytes for clients with continuing losses, for example, those experiencing gastric suction or wound drainage. Lactated Ringer’s solution is an alkalizing solution that may be given to treat metabolic acidosis. Acidifying solutions, in contrast, are administered to counteract metabolic alkalosis. Examples of acidifying solutions are 5% dextrose in 0.45% sodium chloride and 0.9% sodium chloride solution.

Volume expanders are used to increase the blood volume following severe loss of blood (e.g., from hemorrhage) or loss of plasma (e.g., from severe burns, which draw large amounts of plasma from the bloodstream to the burn site). Examples of volume expanders are dextran, plasma, albumin, and Hespan (a synthetic plasma expander).

TABLE 52–10 Selected Intravenous Solutions

Type/Examples	Comments/Nursing Implications
ISOTONIC SOLUTIONS 0.9% NaCl (normal saline) Lactated Ringer’s (a balanced electrolyte solution) 5% dextrose in water (D ₅ W)	Isotonic solutions such as normal saline (NS) and lactated Ringer’s initially remain in the vascular compartment, expanding vascular volume. Assess clients carefully for signs of hypervolemia such as bounding pulse and shortness of breath. D ₅ W is isotonic on initial administration but provides free water when dextrose is metabolized, expanding intracellular and extracellular fluid volumes. D ₅ W is avoided in clients at risk for increased intracranial pressure (IICP) because it can increase cerebral edema.
HYPOTONIC SOLUTIONS 0.45% NaCl (half normal saline) 0.33% NaCl (one-third normal saline)	Hypotonic solutions are used to provide free water and treat cellular dehydration. These solutions promote waste elimination by the kidneys. Do not administer to clients at risk for IICP or third-space fluid shift.
HYPERTONIC SOLUTIONS 5% dextrose in normal saline (D ₅ NS) 5% dextrose in 0.45% NaCl (D ₅ 1/2NS) 5% dextrose in lactated Ringer’s (D ₅ LR)	Hypertonic solutions draw fluid out of the intracellular and interstitial compartments into the vascular compartment, expanding vascular volume. Do not administer to clients with kidney or heart disease or clients who are dehydrated. Watch for signs of hypervolemia.

Peripheral Venipuncture Sites

The site chosen for venipuncture varies with the client's age, length of time an infusion is to run, the type of solution used, and the condition of veins. For adults, veins in the arm are commonly used; for infants, veins in the scalp and dorsal foot veins are often used. The larger veins of the adult's forearm are preferred over the metacarpal veins of the hand for infusions that need to be given rapidly and for solutions that are hypertonic, are highly acidic or alkaline, or contain irritating medications. The loss of subcutaneous tissue, thinning of the skin, and fragile veins in the older adult can be a challenge for the nurse when performing a venipuncture. It is common practice for the initial venipuncture to be in the most distal portion of the arm because this allows for subsequent venipunctures to move upward. The veins of the hands of the older adult, however, are not the best initial sites for venipuncture because of the loss of subcutaneous tissue and thinning of the skin (Phillips & Gorski, 2014).

The metacarpal, basilic, and cephalic veins are common venipuncture sites (Figure 52–15B). The ulna and radius act as natural splints at these sites, and the client has greater freedom of arm movement for activities such as eating. Although the antecubital basilic and median cubital veins are convenient, they are usually kept for

Figure 52–15 ■ Commonly used venipuncture sites: A, arm; B, hand. A also shows the site used for a peripherally inserted central catheter (PICC).

PRACTICE GUIDELINES

Vein Selection

- Use distal veins of the arm first; subsequent IV starts should be proximal to the previous site.
- Use the client's nondominant arm whenever possible.
- Select a vein that is:
 - a. Easily palpated and feels soft and full
 - b. Naturally splinted by bone
 - c. Large enough to allow adequate circulation around the catheter.
- Avoid using veins that are:
 - a. In areas of flexion (e.g., the antecubital fossa)
 - b. Highly visible, because they tend to roll away from the needle
 - c. Damaged by previous use, phlebitis, infiltration, or sclerosis
 - d. Continually distended with blood, or knotted or tortuous
 - e. In a surgically compromised or injured extremity (e.g., following a mastectomy), because of possible impaired circulation and discomfort for the client.

blood draws, bolus injections of medication, and insertion sites for a peripherally inserted central catheter (PICC) line (Figure 52–15A). See Practice Guidelines for vein selection and general tips for easier IV starts.

Historically, nurses used their eyes and hands to locate a suitable vein for a venipuncture. This could be especially challenging in some clients such as older adults, dark-skinned clients whose veins may not be visible, or clients who are obese, because their veins may not be visible or palpable. The Infusion Nursing Standards of Practice (Infusion Nurses Society [INS], 2011a) state that nurses should “consider using visualization technologies to aid in vein identification and selection” (p. S41). Currently transillumination devices are available that use light to allow for the location and identification of blood vessels. The client's skin color does not affect the ability to highlight veins. One type of device is applied to the client's skin. Focusing bright visible light onto and under the skin helps the nurse locate superficial veins. Another device is used by holding it about 18 cm (7 in.) above the skin. The veins are displayed on the surface of the skin.

Intravenous Infusion Equipment

Because equipment varies according to the manufacturer, nurses must become familiar with the equipment used in each particular agency. IV equipment consists of IV catheters, catheter stabilization devices, solution containers, infusion administration sets, IV filters, and IV poles.

Intravenous Catheters The Infusion Nurses Society *Standards of Practice* (2011a) state that the type of IV catheter to be used depends on the client's vascular access needs, which are based on the prescribed therapy, length of treatment, vascular integrity, client preference, and ability and resources available to care for the device (p. S37). All catheters must be radiopaque.

A *peripheral-short catheter* is used for usually less than 1 week. It comes in a variety of gauge sizes (i.e., 14 to 27) and types (e.g., winged or nonwinged, and over-the-needle) and the tip ends in a peripheral vein (INS, 2011a). Over-the-needle catheters (ONCs), also known as angi catheters, are commonly used for adult clients.

PRACTICE GUIDELINES

General Tips for Easier IV Starts

- Review the client's medical history. Avoid using an arm affected by hemiplegia or with a dialysis access, on the same side as a mastectomy, or near infections, below previous infiltrations or extravasations, and veins affected by phlebitis.
- Dilate the vein. Ways to do this include (a) dangle the client's arm over the side of the bed to encourage dependent vein filling, (b) ask the client to open and close his or her fist, (c) stroke the vein downward or lightly tap the vein, or (d) apply warm compresses to the site for 10 minutes.
- Make sure the client is positioned comfortably and has been medicated for pain if appropriate. Pain and anxiety stimulate the sympathetic nervous system and trigger vasoconstriction.
- Because of the risk of nerve injuries, as well as discomfort and restriction of movement, hand veins should be a last choice.
- If the ordered IV medication is irritating to veins and therapy is expected to last more than a few days, consult with the IV nurse or medical team to determine whether the client is a candidate for a midline catheter, a peripherally inserted central catheter, or another type of central venous access device.
- Use the smallest gauge catheter that will accommodate the therapy and allow good venous flow around the catheter tip. For routine hydration or intermittent therapy, use #22- to #27-gauge catheters; for transfusion therapy, use #20- to #24-gauge catheters; and for therapy for neonates or clients with very small, fragile veins, use #24- to #27-gauge catheters.
- Raise the bed or stretcher to a comfortable working height, and keep all equipment within reach. Stabilize the client's hand or arm with your nondominant arm, tucking it under your forearm if necessary to prevent movement.
- Limit your attempts to two. If you're not successful after two tries, ask another nurse to try.

Evidence-Based Practice Does Black Pepper Essential Oil Enhance IV Catheter Insertion?

EVIDENCE-BASED PRACTICE

Multiple attempts to insert an IV catheter are painful for the client and time consuming for the nurse. Nurses at a mid-Atlantic suburban community teaching hospital replicated a previous small, unpublished study that used black pepper essential oil to improve vein palpability and visualization. Black pepper (*Piper nigrum*) has a 4,000-year history of use as a spice. Hippocrates mentioned its medicinal uses and Kristiniak, Harpel, Breckenridge, and Buckle (2012) report that the antimicrobial activity of black pepper against *Staphylococcus aureus* in vitro is well documented.

The 3-month study used a pretest, post-test, quasi-experimental design. The study involved 120 hospitalized clients. A team of six vascular nurses (VRNs) selected the participants by determining, prior to venipuncture, that the clients had no vein visibility or palpability. The clients were assigned to treatment and control groups. Each of the six VRNs carried out standard care on 10 clients who met the inclusion criteria (i.e., no vein visibility or palpability). Standard care included the application of a hot pack and/or vigorous tactile stimulation of the vein. The next 10 clients (for each of the six VRNs) were assigned to the experimental (treatment) group. The experimental or black pepper group received 20% black pepper essential oil in a base of aloe vera gel applied topically to the site via roller ball 10 minutes prior to venipuncture. Each participant in the black pepper group was patch-tested for any skin reaction prior to

the intervention. If no reaction occurred, the VRN continued with the study. The maximum dose of the black pepper/aloe vera gel mixture was 3 mL. A tool was used to record vein visibility and palpability before and after the intervention. The scale for vein assessment was as follows: 0 = no vein visible or palpable; 1 = vein visible or palpable; and 2 = vein visible and palpable. Other data recorded included the number of attempts to access veins prior to the VRN's referral by the bedside nurse, and the number of attempts post-intervention by the VRN; demographic data, including age and gender; and the use of hot pack applications or tactile stimulation for the control group. The results showed that black pepper made a significant difference to vein visibility and palpation. A higher percentage of clients achieved a vein score of 2 or improved scoring (vein score of 1 or 2) to the black pepper intervention than standard nursing care. The number of IV catheter attempts following black pepper application was also half that of the control (standard nursing care) group.

IMPLICATIONS

The data provided statistical evidence that using black pepper essential oil improved vein visibility and palpability more than standard nursing care. Black pepper essential oil may improve vein access, thus reducing the number of IV catheter attempts, which improves client care by reducing client discomfort.

The plastic catheter fits over a needle (stylet) used to pierce the skin and vein wall (Figure 52–16 ■). Once inserted into the vein, the needle (stylet) is withdrawn and discarded, leaving the catheter in place. The nurse should use peripheral-short catheters equipped with a passive or active safety mechanism to prevent sharps injury. The active safety device requires activation by the nurse, and the passive safety device automatically activates after the stylet is removed from the catheter.

CLINICAL ALERT!

A peripheral-short catheter placed in an emergency situation where aseptic technique has been compromised shall be replaced as soon as possible and no later than 48 hours (INS, 2011b).

Butterfly, or wing-tipped, needles with plastic flaps attached to the shaft are sometimes used (Figure 52–17 ■). The flaps are held tightly together to hold the needle securely during insertion; after insertion, they are flattened against the skin and secured with tape. The butterfly needle is most frequently used for short-term therapy (e.g., less than 24 hours) such as with single-dose therapy, IV push medications, or blood sample retrieval (Phillips & Gorski, 2014).

A *peripheral-midline catheter* is 7.6 to 20.3 cm (3 to 8 in.) in length and inserted near the antecubital area into the basilic, cephalic, or brachial veins, with the preference being the basilic vein because of its larger diameter. The tip is advanced no farther than the distal axillary vein in the upper arm; the tip does not enter the central vasculature. Although the INS classifies the midline catheter as a peripheral catheter, the midline catheter is managed differently than the peripheral-short

Figure 52-16 ■ Schematic of an over-the-needle catheter.

Figure 52-17 ■ Schematic of a butterfly needle with adapter.

catheter. For example, an angiocatheter may stay in a vein for up to 72 hours maximum; a midline catheter can last from 1 to 4 weeks.

A **peripherally inserted central venous catheter (PICC)** is inserted in the basilic or cephalic vein just above or below the antecubital space of the right arm. The tip of the catheter rests in the superior vena cava. These catheters frequently are used for long-term IV access when the client will be managing IV therapy at home.

When long-term IV therapy or parenteral nutrition is anticipated, or a client is receiving IV medications that are damaging to vessels (e.g., chemotherapy), a **central venous access device (CVAD)** may be inserted. A CVAD is defined by the location of the catheter tip in a central vein. The CVAD catheter tip should reside in the lower one third of the superior vena cava, above the right atrium (Phillips & Gorski, 2014, p. 279) (Figure 52-18 ■). They may be inserted at a client's bedside or, for longer term access, surgically inserted. CVADs permit freedom of movement for ambulation; however, there is greater risk of complications, including hemothorax or pneumothorax, cardiac perforation, thrombosis, and infection. Assess the client closely for signs and symptoms such as shortness of breath, chest pain, cough, hypotension, tachycardia, and anxiety after the insertion procedure.

Implanted vascular access devices (IVADs) (Figures 52-19 ■ and 52-20 ■) are used for clients with chronic illness who require long-term IV therapy (e.g., intermittent medications such as chemotherapy, total parenteral nutrition, and frequent blood samples). This type of device is designed to provide repeated access to the central

Figure 52-18 ■ Central vascular access devices with A, subclavian vein insertion, and B, left jugular insertion.

venous system, avoiding the trauma and complications of multiple venipunctures. Using local anesthesia, implantable ports are surgically placed into a small subcutaneous pocket under the skin, usually on the anterior chest near the clavicle, and no part of the port is exposed. The distal end of the catheter is placed in the subclavian or jugular vein.

Special precautions need to be taken with all central lines and venous access ports to ensure asepsis and catheter patency. Nursing care of clients with these devices is outlined in Practice Guidelines.

SAFETY ALERT!

SAFETY

2014 THE JOINT COMMISSION NATIONAL PATIENT SAFETY GOALS (2013)

Goal 7: Reduce the Risk of Health Care–Associated Infections.
Goal 7.04.01: Implement Evidence-Based Practices to Prevent Central Line–Associated Bloodstream Infections.

- Perform hand hygiene prior to catheter manipulation.
- Use a standardized protocol to disinfect catheter hubs and injection ports before accessing the ports.

Figure 52-19 ■ An implanted vascular access device: A, components; B, the device in place.

Figure 52-20 ■ Left, An implanted vascular access device; Right, a Huber needle with extension tubing.

Catheter Stabilization Devices Securing or stabilizing an IV catheter helps decrease movement of the catheter at the insertion site, which helps prevent infection and the catheter from being dislodged (Gorski, 2010). Historically, nonsterile tape was used to

secure peripheral IV catheters. The INS standards (2011a) now recommends the use of manufactured catheter stabilization devices (Figure 52-21 ■) over other methods such as sterile tapes and surgical strips.

Solution Containers Solution containers are available in various sizes (50, 100, 250, 500, or 1,000 mL); the smaller containers are often used to administer medications. Most solutions are currently dispensed in plastic bags (Figure 52-22 ■). However, glass bottles may need to be used if the administered medications are incompatible with plastic. Glass bottles require an air vent so that air can enter the bottle and replace the fluid that enters the client's vein. Some bottles contain a tube that serves as a vent; other containers require a vent on the administration set. Air vents usually have filters to prevent contamination from the air that enters the container. Air vents are not required for plastic solution bags, because the bags collapse under atmospheric pressure when the solution enters the vein.

It is essential that the solution be sterile and in good condition, that is, clear. Cloudiness, evidence that the container has been opened previously, or leaks indicate possible contamination. Always check the expiration date on the label. Return any questionable or contaminated solutions to the pharmacy or IV therapy department.

CLINICAL ALERT!

Do not write directly on a plastic IV bag with a ballpoint pen (may puncture the bag) or indelible marker (may absorb through the bag into the solution).

Infusion Administration Sets Infusion administration sets (also called administration infusion sets) consist of an insertion spike, a drip chamber, a roller valve or screw clamp, tubing with secondary ports, and a protective cap over the connector to the IV catheter (Figure 52-23 ■). The insertion spike is kept sterile and inserted into the solution container when the equipment is set up and ready to start. The drip chamber permits a predictable amount of fluid to be delivered. A macrodrip drip chamber delivers between 10 and 20 drops (abbreviated gtt) per milliliter of solution. The specific amount is written on the package. Microdrip sets deliver 60 drops per milliliter of solution (Figure 52-24 ■). Many infusion sets include an in-line filter to trap air, particulate matter, and microbes. A special infusion set may be required if the IV flow rate will be regulated by an infusion pump.

Most infusion sets include one or more injection ports for administering IV medications or secondary infusions. Needleless systems are used because they reduce the risk of needlestick injury and contamination of the IV line. The needleless ports can be accessed with either a syringe that has a blunt cannula, or a Luer-Lok to administer medications, or an adapter can be added to the IV tubing for administration of secondary infusions (Figure 52-25 ■). When more than one solution needs to be infused at the same time, *secondary sets* such as the tandem and the piggyback IV setups are used. Another variation is a *volume-control set*, which is used if the volume of fluid or medication administered is to be carefully controlled (see Chapter 35 ∞).

Rather than using a continuous infusion, an intermittent infusion lock may be created by attaching a sterile injection cap or device (Figure 52-26 ■) to an existing IV catheter. This keeps the venous access available for the administration of intermittent or emergency

PRACTICE GUIDELINES

Caring for Clients with a Central Vascular Access Device

- After insertion, document the date; the insertion site; the brand, gauge, and catheter length; the location of the catheter tip (verified by x-ray); the length of the external segment; and client teaching. Do not use the access device until correct placement has been verified by x-ray.

SITE CARE

- Use strict aseptic technique (including the use of sterile gloves and mask) when caring for CVADs.
- The frequency of dressing changes is dependent on the dressing material. Transparent semipermeable membrane (TSM) dressings or tape and gauze are acceptable; however, gauze dressings do not allow for visualization of the insertion site and need to be changed every 48 hours or if the site requires visual inspection (Phillips & Gorski, 2014, p. 501). In contrast, TSM dressings allow for visualization and can be left in place for a maximum of 7 days if they remain clean, dry, and intact (INS, 2011a, p. S63). All dressings also should be changed when loose or soiled.
- Assess the site for any redness, swelling, tenderness, or drainage. Compare the length of the external portion of the catheter with its documented length to assess for possible displacement. Report and document any position changes or signs of infection.
- Follow agency protocol for cleaning solutions and types of dressings. Chlorhexidine gluconate is the preferred agent to clean the insertion site.
- Clean the skin around the site with chlorhexidine solution, using a back-and-forth motion for at least 30 seconds (INS, 2011b). Allow the site to air dry. A round dressing impregnated with chlorhexidine can also be applied to the insertion site to prevent catheter-related bloodstream infections (CRBSIs). See Figure 1.
- Apply a new stabilization device.
- Apply a sterile dressing.

CATHETER CARE AND FLUSHING

- Change the catheter cap as indicated by agency protocol. The catheter hub can be a source of infection. A 15-second scrub of the connection surface of the needleless connector has been shown to prohibit microorganism entry on the surface (Moureau & Dawson, 2010). Also available are commercial single-use Luer access valve disinfection caps. This cap contains isopropyl alcohol, which cleans the needleless connector before access and also protects it from contamination between uses. The cap is twisted onto the needleless connector and left in place until the next access to the connector is needed. The nurse removes and discards the old cap and the connector is ready for use without further wiping. See Figures 2 to 5. A study conducted by Wright et al. (2013) concluded that disinfecting caps filled with alcohol-soaked sponges reduced bacterial contamination in catheter hubs and the rate of CRBSIs.

- The solution used and frequency of flushing are determined by agency protocol for the specific type of port being used. Heparin-induced thrombocytopenia (HIT) has been reported with the use of heparin flush solutions. If heparin is used as part of the flushing protocol, the concentration should not be in amounts that cause systemic anticoagulation but in the lowest possible concentration to maintain patency (e.g., 10 units/mL). Many agencies are switching to needleless IV connectors that can be flushed with normal saline solution only.
- Flush the catheter before and after each dose of medication. The initial flush is to assess patency of the catheter, and the flush after administration of the medication is to ensure that the complete dose has entered the bloodstream and to prevent contact between incompatible medications.
- Use a 10-mL syringe to flush the catheter. Never apply force if you feel resistance.
- CVADs need to be locked after the final flush solution to decrease the risk of occlusion (INS, 2011a). Locking a catheter creates a column of fluid inside the lumen to maintain patency (Hadaway, 2012, p. 42). The process for locking a catheter varies depending on the manufacturer of the needleless connector.
- Blood reflux into the catheter lumen after flushing increases the risk of infection. Positive-pressure valve caps on central line catheters can help prevent blood reflux when used with negative-pressure needleless infusion caps (Mathers, 2011, p. 65). Thus, it is important for the nurse to know the type of needleless connector being used: positive-pressure, negative-pressure, or neutral-displacement needleless connector.

TEACHING

Provide clients with the following instructions:

- Do not allow anyone to take a blood pressure on the arm in which a PICC line is inserted.
- Wear a medical alert tag or bracelet if the device will be in place for a long period of time.
- For a PICC line, activity does not need to be restricted, except that the arm should not be immersed in water. Showering is allowed if the site and catheter are covered by a TSM dressing.
- For an implanted central venous access port, there are no activity restrictions, but the port or catheter tip can become dislodged. Signs of a dislodged catheter tip include pain in the neck or ear on the affected side, swishing or gurgling sounds, or palpitations; signs of a dislodged port include free movement of the port, swelling, or difficulty accessing the port. If any of these occur, or if symptoms of infection develop, notify the primary care provider immediately.

1 Protective disk with chlorhexidine gluconate (CHG) (BioPatch®).

2 Disinfecting cap (SwabCap™).

4 Twist cap onto needleless connector.

5 Remove outer packaging and leave cap in place.

3 Cap contains disinfecting solution.

medications. The device is commonly referred to as a saline lock because periodic injection with saline is used to keep blood from coagulating within the tubing.

Intravenous Filters IV filters are used to remove air and particulate matter from IV infusions and to reduce the risk of complications

Figure 52-23 ■ A standard IV administration set.

(e.g., infusion-related phlebitis) associated with routine IV therapies (Figure 52-27 ■). Most IV filters in current use consist of a membrane (pore size of 0.22 micron, although sizes vary). Some problems associated with filters include (a) clogging of the filter surface, which may stop

Figure 52-27 ■ Two types of IV filters.

or slow the flow rate when debris accumulates; and (b) binding of some drugs (e.g., insulin and amphotericin B) to the surface of the filter. When using filters, the nurse must remember that the filter should never be considered a substitute for quality care and meticulous technique.

Intravenous Poles IV poles (rods) are used to hang the solution container. Some poles are attached to hospital beds; others stand on the floor or hang from the ceiling. Still others are floor models with casters that can be pushed along when a client is up and walking. In the home, plant hangers or robe hooks (even kitchen cabinet knobs or an S-hook over the top of a door) may be used to hang solution containers. The height of most poles is adjustable. The higher the solution container, the greater the force of the solution as it enters the client and the faster the rate of flow.

Starting an Intravenous Infusion

Although the primary care provider is responsible for ordering IV therapy for clients, nurses initiate, monitor, and maintain the prescribed IV infusion. This is true not only in hospitals and long-term care facilities but increasingly in community-based settings such as clinics and clients' homes.

Before starting an infusion, the nurse determines the following:

- The type and amount of solution to be infused
- The exact amount (dose) of any medications to be added to a compatible solution
- The rate of flow or the time over which the infusion is to be completed.

If solutions are prepared by the pharmacy or another department, the nurse must verify that the solution supplied exactly matches that which the primary care provider ordered.

Understanding the purpose for the infusion is as important as assessing the client. For example, a nurse should question an order for 5% dextrose in water at 150 mL/h if the client has peripheral edema and other signs of fluid overload.

To perform venipuncture and start an IV infusion, see Skill 52-1.

Starting an Intravenous Infusion

Before preparing the infusion, the nurse first verifies the primary care provider's order indicating the type of solution, the amount to be

administered, the rate of flow or time over which the infusion is to be completed, and any client allergies (e.g., to tape or povidone-iodine).

PURPOSES

- To supply fluid when clients are unable to take in an adequate volume of fluids by mouth
- To provide salts and other electrolytes needed to maintain electrolyte balance
- To provide glucose (dextrose), the main fuel for metabolism
- To provide water-soluble vitamins and medications
- To establish a lifeline for rapidly needed medications

ASSESSMENT

Assess

- Vital signs (pulse, respiratory rate, and BP) for baseline data.
- Allergy to latex (e.g., tourniquet), tape, or iodine.
- Bleeding tendencies.
- Disease or injury to extremities.
- Status of veins to determine appropriate venipuncture site. Avoid sites that have been used recently. **Rationale:** *Recently*

used sites will be more prone to complications and discomfort. Determine if the client is right- or left-handed. **Rationale:** *Do not use the dominant hand if possible.*

- The agency policy about clipping hair in the area before a venipuncture. Shaving is not recommended because of the possibility of nicking the skin and subsequent infection.

PLANNING

Prior to initiating the IV infusion, consider how long the client is likely to have the IV, what kinds of fluids will be infused, and what medications the client will be receiving or is likely to receive. These factors may affect the choice of vein and catheter size. Review the client record regarding previous infusions. Note any complications and how they were managed.

DELEGATION

Due to the need for knowledge of anatomy and use of sterile technique, IV infusion therapy is not delegated to UAP. UAP may care for clients receiving IV therapy, and the nurse must ensure that the UAP knows how to perform routine tasks such as bathing and positioning without disturbing the IV. The UAP should also know what complications or adverse signs, such as leakage, should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may start IV infusions. Check the state's nurse practice act.

Equipment

Substitute appropriate supplies if the client has tape, antiseptic, or latex allergies

- Infusion set
- Sterile parenteral solution
- IV pole
- Nonallergenic tape
- Clean gloves
- Tourniquet
- Antiseptic swabs such as 10% povidone-iodine or 2% chlorhexidine gluconate with alcohol or 70% isopropyl alcohol. Chlorhexidine is becoming the standard of practice and is the antiseptic preferred by the INS (Phillips & Gorski, 2014, p. 338).
- IV catheter (Choose an IV catheter of the appropriate type and size based on the size of the vein and the purpose of the IV. A #20- to #22-gauge catheter is indicated for most adults. Always have an extra catheter and ones of different sizes available.)
- Sterile gauze dressing or transparent semipermeable membrane (TSM) dressing (preferred)
- Stabilization device
- Splint, if required
- Towel or bed protector
- Local anesthetic (optional and per agency policy)
- Electronic infusion device or pump (The nurse decides what device is needed as appropriate to the client's condition.)

IMPLEMENTATION

Preparation

- If possible, select a time to perform the venipuncture that is convenient for the client. Unless initiating IV therapy is urgent, provide any scheduled care before establishing the infusion to minimize excessive movement of the affected limb. **Rationale:** *Moving the limb after the infusion has been established could dislodge the catheter.*
- Make sure that the client's clothing or gown can be removed over the IV apparatus if necessary. Many agencies provide special gowns that open over the shoulder and down the sleeve for easy removal.
- Visitors or family members may be asked to leave the room if desired by the nurse or the client.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Venipuncture can cause discomfort for a few

seconds, but there should be no ongoing pain after insertion. If possible, explain how long the IV will need to remain in place and how it will be used.

2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Position the client appropriately.
 - Assist the client to a comfortable position, either sitting or lying. Expose the limb to be used but provide for client privacy.

(Note: Steps 4 through 10 may be performed outside of the client's room and then the system transported to the client's bedside.)
4. Apply a medication label to the solution container if a medication is added.
 - In many agencies, medications are added and labels are applied to IV containers in the pharmacy; if they are not, apply the label upside down on the container. **Rationale:** *The label is applied upside down so it can be read easily when the container is hanging up.*

Starting an Intravenous Infusion—continued

5. Open and prepare the infusion set.
 - Remove tubing from the package and straighten it out.
 - Slide the tubing clamp along the tubing until it is just below the drip chamber to facilitate its access.
 - Close the clamp.
 - Leave the ends of the tubing covered with the plastic caps until the infusion is started. **Rationale:** *This will maintain the sterility of the ends of the tubing.*
6. Spike the solution container.
 - Expose the insertion site of the bag or bottle by removing the protective cover.
 - Remove the cap from the spike and insert the spike into the insertion site of the bag or bottle. ①
7. Hang the solution container on the pole.
 - Adjust the pole so that the container is suspended about 1 m (3 ft) above the client's head. **Rationale:** *This height is needed to enable gravity to overcome venous pressure and facilitate flow of the solution into the vein.*
8. Partially fill the drip chamber with solution.
 - Squeeze the chamber gently until it is half full of solution. ②
Rationale: *The drip chamber is partially filled with solution to prevent air from moving down the tubing.*

① Inserting the spike.

② Squeezing the drip chamber.

9. Prime the tubing as described below. The term *prime* means “to make ready” but in common use refers to flushing the tubing to remove air.
 - Remove the protective cap and hold the tubing over a container. Maintain the sterility of the end of the tubing and the cap.
 - Release the clamp and let the fluid run through the tubing until all bubbles are removed. Tap the tubing if necessary with your fingers to help the bubbles move. **Rationale:** *The tubing is primed to prevent the introduction of air into the client. Air bubbles smaller than 0.5 mL usually do not cause problems in peripheral lines.*
 - Reclamp the tubing and replace the tubing cap, maintaining sterile technique.
 - If an infusion control pump, electronic device, or controller is being used, follow the manufacturer's directions for inserting the tubing and setting the infusion rate.
10. Perform hand hygiene again just prior to client contact.
11. Select the venipuncture site.
 - Use the client's nondominant arm, unless contraindicated (e.g., mastectomy, fistula for dialysis). Identify possible venipuncture sites by looking for veins that are relatively straight. The vein should be palpable, but may not be visible, especially in clients with dark skin. Consider the catheter length; look for a site sufficiently distal to the wrist or elbow such that the tip of the catheter will not be at a point of flexion. **Rationale:** *Sclerotic veins may make initiating and maintaining the IV difficult. Joint flexion increases the risk of irritation of vein walls by the catheter.*
 - Check agency protocol about shaving if the site is very hairy. Shaving is not recommended. **Rationale:** *Shaving can cause microabrasions that can increase the risk of infection.*
 - Place a towel or bed protector under the extremity to protect linens (or furniture if in the home).
12. Dilate the vein.
 - Place the extremity in a dependent position (lower than the client's heart). **Rationale:** *Gravity slows venous return and distends the veins. Distending the veins makes it easier to insert the needle properly.*
 - Apply a tourniquet firmly 15 to 20 cm (6 to 8 in.) above the venipuncture site. ③ Explain that the tourniquet will feel tight. **Rationale:** *The tourniquet must be tight enough to obstruct venous flow but not so tight that it occludes arterial flow. Obstructing arterial flow inhibits venous filling.* If a radial pulse can be palpated, the arterial flow is not obstructed.
 - Use the tourniquet on only one client. This avoids cross contamination to other clients. Be sure to ask if the client has a latex allergy.
 - For older adults with fragile skin, instead of applying a tourniquet, place the arm in a dependent position to allow the veins to engorge. **Rationale:** *The tourniquet can cause tissue damage and may not be needed to allow the vein to dilate.*
 - If the vein is not sufficiently dilated:
 - a. Massage or stroke the vein distal to the site and in the direction of venous flow toward the heart. **Rationale:** *This action helps fill the vein.*
 - b. Encourage the client to clench and unclench the fist. **Rationale:** *Contracting the muscles compresses the distal veins, forcing blood along the veins and distending them.*
 - c. Lightly tap the vein with your fingertips. **Rationale:** *Tapping may distend the vein.*
 - If the preceding steps fail to distend the vein so that it is palpable, remove the tourniquet and wrap the extremity in a warm towel for 10 to 15 minutes. **Rationale:** *Heat dilates superficial blood vessels, causing them to fill.* Then repeat steps to dilate the vein.

Starting an Intravenous Infusion—continued

3 Two types of tourniquets.

13. Minimize insertion pain as much as possible.

- Although the pain of insertion should be brief, prevention can and should be offered. Transdermal analgesic creams (e.g., EMLA, Synera) may be used, depending on policy. Allow at least 30 to 60 minutes for the topical analgesic to take effect (Phillips & Gorski, 2014).
- If desired and permitted by policy, inject 0.3 mL of 1% lidocaine (without epinephrine) intradermally over the site where you plan to insert the IV catheter. (Be sure to first apply gloves and clean the skin site as described in step 14.) Allow 5 to 10 seconds for the anesthetic to take effect (Phillips & Gorski, 2014).

14. Apply clean gloves and clean the venipuncture site. **Rationale:** Gloves protect the nurse from contamination by the client's blood.

- Clean the skin at the site of entry with a topical antiseptic swab (e.g., 2% chlorhexidine, or alcohol). Some institutions may use an anti-infective solution such as povidone-iodine (check agency protocol). Check for allergies to iodine or shellfish before cleansing skin with Betadine or iodine products.
- When using chlorhexidine solution (preferred), use a back-and-forth motion for a minimum of 30 seconds to scrub the insertion site and surrounding area (Phillips & Gorski, 2014). Allow the site to completely air dry before inserting the catheter. Do *not* fan, blow on, or wipe the skin.
- When using povidone-iodine, apply using swab sticks in a concentric circle beginning at the catheter insertion site and moving outward. The iodine should be in contact with the

skin for 2 minutes or longer to completely dry for adequate antisepsis (INS, 2011b, p. 66).

15. Insert the catheter and initiate the infusion.

- Remove the catheter assembly from its sterile packaging. Review instructions for using the catheter because a variety of needle safety devices are manufactured. Remove the cover of the needle (stylet).
- Use the nondominant hand to pull the skin taut below the entry site. **Rationale:** This stabilizes the vein and makes the skin taut for needle entry. It can also make initial tissue penetration less painful.
- Holding the over-the-needle catheter at a 15- to 30-degree angle with needle (stylet) bevel up, insert the catheter through the skin and into the vein. A sudden lack of resistance is felt as the needle (stylet) enters the vein. Use a slow steady insertion technique and avoid jabbing or stabbing motions.
- Once blood appears in the lumen or clear “flashback” chamber of the needle, lower the angle of the catheter until it is almost parallel with the skin, and advance the needle (stylet) and catheter approximately 0.5 to 1 cm (about 1/4 in.) farther. 4 Holding the needle assembly steady, advance the catheter until the hub is at the venipuncture site. The exact technique depends on the type of device used. **Rationale:** The catheter is advanced to ensure that it, and not just the stylet, is in the vein.
- If there is no blood return, try redirecting the catheter assembly again toward the vein. If the stylet has been withdrawn from the catheter even a small distance, or the catheter tip has been pulled out of the skin, the catheter must be discarded and a new one used. **Rationale:** Reinserting the stylet into the catheter can result in damage or slicing of the catheter. A catheter that has been removed from the skin is considered contaminated and cannot be reused.
- If blood begins to flow out of the vein into the tissues as the catheter is inserted, creating a hematoma, the insertion has not been successful. This is sometimes referred to as a blown vein. Immediately release the tourniquet and remove the catheter, applying pressure over the insertion site with dry gauze. Attempt the venipuncture in another site, in the opposite arm if possible. **Rationale:** Placing the tourniquet back on the same arm above the unsuccessful site may cause it to bleed. Placing the IV below the unsuccessful site could result in infusing fluid into the already punctured vein, causing it to leak.

4 Blood is noted in the flashback chamber once the stylet has entered the vein.

Starting an Intravenous Infusion—continued

- Release the tourniquet.
- Put pressure on the vein proximal to the catheter to eliminate or reduce blood oozing out of the catheter. Stabilize the hub with thumb and index finger of the nondominant hand.
- Remove the protective cap from the distal end of the tubing and hold it ready to attach to the catheter, maintaining the sterility of the end.
- Stabilize the catheter hub and apply pressure distal to the catheter with your finger. **5 Rationale:** *This prevents excessive blood flow through the catheter.*
- Carefully remove the stylet, engage the needle safety device if it does not engage automatically, and attach the end of the infusion tubing to the catheter hub. Place the stylet directly into a sharps container. If this is not within reach, place the stylet into its original package and dispose in a sharps container as soon as possible.
- Initiate the infusion or flush the catheter with sterile normal saline. **6 Rationale:** *Blood must be removed from the catheter lumen and tubing immediately. Otherwise, the blood will clot inside the lumen.* Watch closely for any signs that the catheter is infiltrated. Infiltration occurs when the tip of the IV is outside the vein and the fluid is entering the tissues instead. It is manifested by localized swelling, coolness, pallor, and discomfort at the IV site. **Rationale:** *Inflammation or infiltration necessitates removal of the IV needle or catheter to avoid further trauma to the tissue.*

16. Stabilize the catheter and apply a dressing.
 - Secure the catheter according to the manufacturer's instructions and agency policy. Several methods are used to stabilize the catheter including the use of a dressing and securement device. If tape is used, it must be sterile tape or surgical strips and they should be applied only to the catheter adapter and not placed directly on the catheter–skin junction site. Use of a manufactured stabilization device is preferred (INS, 2011a).
 - Apply a dressing. Two methods are used for applying a dressing: a sterile gauze dressing secured with tape and a TSM dressing. **7** Most common is the TSM because it allows for continuous assessment of the site and is more comfortable than gauze and tape (Phillips & Gorski, 2014, p. 345). Do not use ointment of any kind under a TSM dressing. Additional tape may be used to secure the IV catheter below the TSM, if necessary. Do not place tape on the TSM dressing.
 - Label the dressing with the date and time of insertion, gauge, and your initials. **8**
 - Apply an IV site protector, if available. Protective devices are available that help prevent dislodgement of the IV catheter and still provide easy assessment of the IV site. **9**
 - Loop the tubing and secure it with tape. **Rationale:** *Looping and securing the tubing prevent the weight of the tubing or any movement from pulling on the needle or catheter.*

5 Stabilize the catheter hub and occlude the vein with finger(s) while removing the stylet.

7 Applying a sterile one-piece IV stabilization and TSM dressing device.

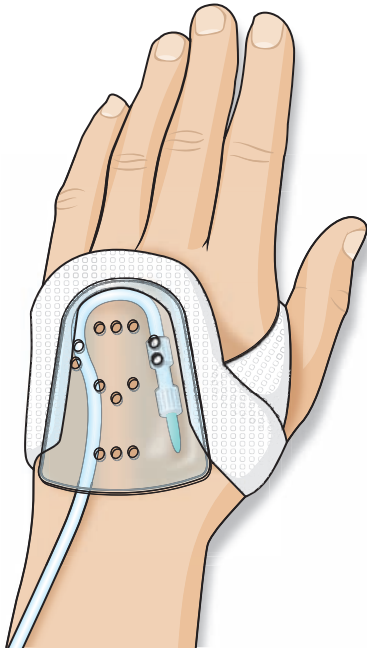

6 The catheter is stabilized while gently flushing it to determine patency.

8 IV site is labeled with date, time, size of catheter, and initials.

Starting an Intravenous Infusion—continued

9 IV site protective device.

17. Discard the tourniquet.
 - Remove and discard gloves.
 - Perform hand hygiene.
18. Ensure appropriate infusion flow.
 - Apply a padded arm board to splint the joint if needed.
 - Adjust the infusion rate of flow according to the order.
19. Label the IV tubing.
 - Label the tubing with the date and time of attachment and your initials. 10 This labeling may also be done when the infusion is started. **Rationale:** *The tubing is labeled to ensure that it is changed at regular intervals (i.e., according to agency policy).*
20. Document all assessments and interventions.
 - Record the venipuncture on the client's chart. Some agencies provide a special form for this purpose. Include the date

EVALUATION

- Regularly check the client for intended and adverse effects of the infusion.
- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- At least every 4 hours, check the skin status at IV site (warm temperature and absence of pain, redness, or swelling), status

10 Tubing labeled with date, time, and nurse's initials.

and time of the venipuncture; type, length, and gauge of the needle or catheter; venipuncture site, how many attempts were made, amount and type of solution used, including any additives (e.g., kind and amount of medications); flow rate; the type of dressing applied; and the client's general response.

SAMPLE DOCUMENTATION

1/15/2015 0600 Inserted 20-gauge, 1-inch angiocath in the right cephalic vein 4 inches above the (L) wrist on first attempt. StatLock used to stabilize catheter and Tegaderm dressing applied. IV infusing at 125 mL/h. Explained reason for IV. Verbalized understanding. _____ A. Luis, RN

- Report significant deviations from normal to the primary care provider.

Regulating and Monitoring Intravenous Infusions

Orders for IV infusions may take several forms, for example “3,000 mL over 24 hours,” “1,000 mL every 8 hours × 3 bags,” or “125 mL/h until oral intake is adequate.” The nurse initiating the IV calculates the correct flow rate, regulates the infusion, and monitors the client's responses. Unless an infusion control device is used, the nurse manually regulates the drops per minute of flow using the roller clamp to ensure that the prescribed amount of solution will be infused in the correct time span. Problems that can result from incorrectly regulated infusions include hypervolemia, hypovolemia, electrolyte imbalances, and medication complications.

The number of drops delivered per milliliter of solution varies with different brands and types of infusion sets. This rate,

called the **drop factor**, is printed on the package of the infusion set. Macrodrops commonly have drop factors of 10, 12, 15, or 20 drops/mL; the drop factor for microdrip sets is always 60 drops/mL (see Figure 52-24 earlier).

To calculate flow rates, the nurse must know the volume of fluid to be infused and the specific time for the infusion. Two commonly used methods of indicating flow rates are designating (1) the number of milliliters to be administered in 1 hour (mL/h) or (2) the number of drops to be given in 1 minute (gtt/min).

Occasionally, the IV rate order will read “keep vein open” (KVO) or “to keep open” (TKO). This order does not provide adequate direction for the nurse unless agency policy specifies the milliliters per hour equivalent for this order. Generally, the KVO rate is less than

50 mL/h. Some IV pumps have a keep-open rate choice built in. If the IV is not on this type of pump and no policy exists, contact the primary care provider for clarification.

Milliliters per Hour Hourly rates of infusion can be calculated by dividing the total infusion volume by the total infusion time in hours. For example, if 3,000 mL is infused in 24 hours, the number of milliliters per hour is

$$\frac{3,000 \text{ mL (total infusion volume)}}{24 \text{ h (total infusion time)}} = 125 \text{ mL/h}$$

Nurses need to check infusions at least every hour to ensure that the indicated milliliters per hour have infused and that IV patency is maintained.

Drops per Minute The nurse who begins an infusion must regulate the drops per minute to ensure that the prescribed amount of solution will infuse. Drops per minute are calculated by the following formula:

$$\text{Drops per minute} = \frac{\text{Total infusion volume} \times \text{drop factor}}{\text{Total time of infusion in minutes}}$$

If the requirements are 1,000 mL in 8 hours and the drip factor is 20 drops/mL, the drops per minute should be

$$\frac{1,000 \text{ mL} \times 20}{8 \times 60 \text{ min (480 min)}} = 41 \text{ drops/min}$$

The nurse regulates the drops per minute by tightening or releasing the IV tubing clamp and counting the drops for 15 seconds, then multiplying that number by 4.

A number of factors influence flow rate (Box 52–7).

Devices to Control Infusions

Historically, the nurse manually regulated the IV rate with the roller clamp on the administration set. Although a roller clamp can still be used, a number of other devices are currently available to control the rate of an infusion. The term *flow-control device* refers to any manual, mechanical, or electronic infusion device used to regulate the IV flow rate (INS, 2011a, p. S104). The INS *Standards of Practice* (2011a) state that the choice of a flow-control device (e.g., manual flow regulator, elastomeric balloon pump, electronic infusion pump) should consider the age and mobility of the client, severity of illness, type of therapy, and health care setting (p. S34).

BOX 52–7 Factors Influencing Flow Rates

- *The position of the forearm.* Sometimes a change in the position of the client's arm decreases flow. Slight pronation, supination, extension, or elevation of the forearm on a pillow can increase flow.
- *The position and patency of the tubing.* Tubing can be obstructed by the client's weight, a kink, or a clamp closed too tightly. The flow rate also diminishes when part of the tubing dangles below the puncture site.
- *The height of the infusion bottle.* Elevating the height of the infusion bottle a few inches can speed the flow by creating more pressure.
- *Possible infiltration or fluid leakage.* Swelling, a feeling of coldness, and tenderness at the venipuncture site may indicate infiltration.
- *Relationship of the size of the angiocath to the vein.* A catheter that is too large may impede the infusion flow.

In the acute health care setting, electronic infusion devices (EIDs) are predominantly used to regulate the infusion rate at pre-set limits. EIDs are powered by electricity or battery and are programmed to regulate the IV flow rate in either drops per minute or milliliters per hour (Phillips & Gorski, 2014, p. 288). They use positive pressure to deliver the IV solution, provide an accurate flow rate, are easy to use, and have alarms that signal problems with the infusion (e.g., when the solution in the IV bag is low, when there is air in the tubing, or when flow is impeded by an occlusion). The alarms are helpful; however, the nurse must still conduct regular assessment and evaluation of the IV site to ensure safe infusion.

CLINICAL ALERT!

Many EIDs use low infusion pressures, often lower than the pressure of a gravity delivery. As a result, they do not detect infiltration. When an infiltration occurs, the inline pressure may even drop and not trigger an alarm. Thus, it is important for the nurse to assess for infiltration for clients with EIDs (Phillips & Gorski, 2014, p. 296).

Another type of flow-control device is the multichannel pump. This type of pump can deliver several medications and fluids at the same time, at multiple rates, from bags, bottles, or syringes (Phillips & Gorski, 2014, p. 292). The multichannel pump usually has two to four channels with each channel being programmed independently (Figure 52–28 ■). Newer systems, called smart pumps, are EIDs with a computer system. They are programmable and include drug libraries with dose rate calculators, automatic flushing between medications, dual or triple simultaneous line control, memory, multiple alarm settings, air in line, pressure/resistance, battery, schedule reminders, volume settings down to 0.1 mL, panel locks, and digital displays.

Mechanical flow-control devices are often used to regulate infusion rates in home care and/or ambulatory settings. Examples of these nonelectric methods include use of a Dial-A-Flo in-line gravity control device and the elastomeric pump. The Dial-A-Flo in-line device (Figure 52–29 ■) is a manual regulator that controls the amount

Figure 52–28 ■ Programmable multichannel infusion pumps.

A

B

Figure 52-29 ■ A, The Dial-A-Flo in-line gravity control device; B, the manual rate-flow regulator.

of fluid to be administered. The Dial-A-Flo may be used in situations where a pump is not available or required, but prevention of fluid overload is important. The nurse presets the volume to be infused by rotating the dial to the desired rate. It is important for the nurse to remember that flow rate needs to be verified by counting the drops.

The elastomeric infusion pump (Figure 52-30 ■), a nonelectric portable disposable pump, is prefilled with a medication and connects to the client's needleless connector. It is a lightweight, disposable pump that delivers medications at a controlled rate. The medication is held

Figure 52-30 ■ An elastomeric infusion pump showing medication in the reservoir and protected by an exterior shell.

in a reservoir (balloon) that is inside a rigid, transparent container. The balloon exerts positive pressure, which releases the solution into the tubing that is attached to the client's vascular access device (Broadhurst, 2012, p. 144). It has an integrated flow restrictor that controls the flow rate, which can be set from 0.5 to 500 mL/h (Phillips & Gorski, 2014, p. 287). The elastomeric infusion pump is portable and can be put in a loose pocket or bag while infusing, allowing the client to be mobile. When the infusion is finished, the entire device is discarded. The elastomeric pump provides ease of use in the home care setting.

CLINICAL ALERT!

A flow-rate-control device should be used when administering IV fluid to older adults or pediatric clients. Both of these age groups are especially at risk for complications of fluid overload, which can occur with rapid infusion of IV fluids.

Skill 52-2 outlines the steps involved in monitoring an IV infusion.

Monitoring an Intravenous Infusion

PURPOSES

- To maintain the prescribed flow rate
- To prevent complications associated with IV therapy

ASSESSMENT

Assess

- Appearance of infusion site; patency of system
- Type of fluid being infused and rate of flow
- Response of the client

PLANNING

Review the client record regarding previous infusions and use of infusion devices. Note any complications and how they were managed. Gather the pertinent data.

- From the order, determine the type and sequence of solutions to be infused.
- Determine the rate of flow and infusion schedule.

Monitoring an Intravenous Infusion—continued

DELEGATION

Due to the need for sterile technique and technical complexity, inspection of IV sites and regulation of IV rates is not delegated to UAP. UAP may care for clients with such devices, and the nurse must ensure that the UAP knows what complications or adverse signs should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may manage infusions. Check the state's nurse practice act.

Equipment

None

IMPLEMENTATION

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Position the client appropriately.

- Assist the client to a comfortable position, either sitting or lying.
- Expose the IV site but provide for client privacy.

4. Ensure that the correct solution is being infused.

- Compare the label on the container (including added medications) to the order. If the solution is incorrect, slow the rate of flow to a minimum to maintain the patency of the catheter. If the infusing solution is contraindicated for the client, stop the infusion and saline-lock the catheter.

Rationale: *Just stopping the infusion may allow a thrombus to form in the IV catheter. If this occurs, the catheter must be removed and another venipuncture performed before the infusion can be resumed. Because IV tubing contains approximately 12 to 15 mL, it may be desirable to prevent even this much additional incorrect solution to infuse when the correct IV solution container is hung on existing tubing. In this case, all tubing should be removed until new tubing, primed with the correct solution, can be started.*

- Change the solution to the correct one, using new tubing if indicated.
- Document and report the error according to agency protocol.

5. Observe the rate of flow every hour.

- Compare the rate of flow regularly, for example, every hour, against the infusion schedule. **Rationale:** *Infusions that are off schedule can be harmful to a client.* To read the volume in an IV bag, pull the edges of the bag apart at the level of the fluid and read the volume remaining. **Rationale:** *Stretching the bag allows the fluid meniscus to fall to the proper level.*
- Observe the position of the solution container. If it is less than 1 m (3 ft) above the IV site, readjust it to the correct height of the pole. **Rationale:** *If the container is too low with a gravity IV infusion, the solution may not flow into the vein because there is insufficient gravitational pressure to overcome the pressure of the blood within the vein.*
- If too much fluid has infused in the time interval, check agency policy. The primary care provider may need to be notified.
- In some agencies, you will slow the infusion to less than the ordered rate so that it will be completed at the planned time. **Rationale:** *Solution administered too quickly may cause a significant increase in circulating blood volume*

(which is about 6 L in an adult). Hypervolemia may result in pulmonary edema and cardiac failure. Assess the client for manifestations of hypervolemia and its complications, including dyspnea; rapid, labored breathing; cough; crackles; tachycardia; and bounding pulses.

- In other agencies, if the order is for a specified amount of fluid per hour, the IV may be adjusted to the correct rate and the client monitored for signs of fluid overload.
- If the rate is too slow, adjust the IV to the prescribed rate. Also, check agency policy. Some agencies permit nursing personnel to adjust an IV that is behind time by a specified percentage. Adjustments above this amount may require a primary care provider's order. **Rationale:** *Solution that is administered too slowly can supply insufficient fluid, electrolytes, or medication for a client's needs.*
- If the prescribed rate of flow is 150 mL/h or more, check the rate of flow more frequently, for example, every 15 to 30 minutes.

6. Inspect the patency of the IV tubing and catheter.

- Observe the drip chamber. If it is less than half full, squeeze the chamber to allow the correct amount of fluid to flow in.
- Inspect the tubing for kinks or obstructions to flow. Arrange the tubing so that it is lightly coiled and under no pressure. Sometimes the tubing becomes caught under the client's body and the weight blocks the flow.
- Observe the position of the tubing. If it is dangling below the venipuncture, coil it carefully on the surface of the bed. **Rationale:** *The solution may not flow upward into the vein against the force of gravity.*
- Determine catheter position. Some methods include:
 - a. Aspirate the catheter for a blood return. Do this slowly and gently.
 - b. Lower the solution container below the level of the infusion site and observe for a return flow of blood from the vein. **Rationale:** *A return flow of blood indicates that the needle is patent and in the vein. Blood returns in this instance because venous pressure is greater than the fluid pressure in the IV tubing. Absence of blood return may indicate that the needle is no longer in the vein or that the tip of the catheter is partially obstructed by a thrombus, the vein wall, or a valve in the vein. (Note: With some catheters, no blood may appear even with patency because the soft catheter walls collapse during siphoning.)*
 - c. If there is leakage, locate the source. If the leak is at the catheter connection, tighten the tubing into the catheter. If the leak is elsewhere in the tubing, slow the infusion and replace the tubing. Estimate the amount of solution lost, if it was substantial. If the IV insertion site is leaking, the catheter will have to be removed and IV access reestablished at a new site.

Monitoring an Intravenous Infusion—continued

7. Inspect the insertion site for fluid infiltration. **Infiltration** is the unintentional administration of a nonvesicant solution or medication into the tissue surrounding the IV catheter (Martin, 2013, p. 392).
- If an infiltration is present, stop the infusion and remove the catheter. Restart the infusion at another site.
 - Start supportive treatment (e.g., elevate extremity or apply heat to the site (INS, 2011b). **Rationale:** *Warmth promotes comfort and vasodilation, facilitating absorption of the fluid from interstitial tissues.*
 - If the infiltration involves a **vesicant**, a medication or fluid that causes blisters, severe tissue injury, or necrosis if it escapes from the vein (Vacca, 2013), it is called **extravasation** and other measures are indicated. The extravasation of a vesicant drug should be considered an emergency. Usually, vesicants are administered only through central venous infusions and by specially certified nurses. Most nurses relate vesicants to chemotherapy medications, such as paclitaxel; however, there are a number of nonchemotherapeutic medications (e.g., vancomycin, dopamine, diazepam, digoxin) (Martin, 2013; Vacca, 2013).
 - For an extravasation:
 - a. Stop the infusion immediately.
 - b. For a peripheral-short catheter, disconnect the tubing from the catheter hub and attach a 3- or 5-mL syringe. Aspirate any fluid remaining in the hub and catheter.
 - c. Remove the catheter. Use a dry gauze pad to control bleeding.
 - d. Apply a new dry dressing. Do not apply excessive pressure to the area.
 - e. For a CVAD, do not remove the catheter. Clamp and cap the catheter hub. Follow agency procedure for flushing when extravasation is suspected.
 - f. Assess motion, sensation, and capillary refill distal to the injury. Measure the circumference of the extremity and compare it with the opposite extremity.
 - g. Notify the primary care provider.
 - h. Photograph the site if that is agency policy.
 - i. The affected arm should be elevated and, depending on the drug, heat or cold therapy should be implemented.
 - j. Pharmacologic treatment may be instituted depending on the type of vesicant that has caused the damage. Two such medications are hyaluronidase and phentolamine, which are used to lessen tissue injury. The best results occur when administered immediately after an extravasation (Martin, 2013).
 - k. The lack of recommendations and guidelines for the treatment of extravasation requires health care facilities to develop their own policies and procedures.
8. Inspect the insertion site for phlebitis (inflammation of a vein).
- Inspect and palpate the site at least every 8 hours. Phlebitis can occur as a result of injury to a vein, for example, because of mechanical trauma or chemical irritation. Chemical injury to a vein can occur from IV electrolytes (especially potassium and magnesium) and medications. The clinical signs are redness, warmth, and swelling at the IV site and burning pain along the course of a vein.
 - If phlebitis is detected, discontinue the infusion, and apply warm or cold compresses to the venipuncture site. Do not use this injured vein for further infusions.
9. Inspect the IV site for bleeding.
- Oozing or bleeding into the surrounding tissues can occur while the infusion is freely flowing, but is more likely to occur after the catheter has been removed from the vein.
 - Observation of the venipuncture site is extremely important for clients who bleed readily, such as those receiving anticoagulants.
10. Teach the client ways to maintain the infusion system, for example:
- Inform of any limitations on movement or mobility.
 - Explain alarms if an electronic control device is used.
 - Instruct to notify a nurse if:
 - a. The flow rate suddenly changes or the solution stops dripping.
 - b. The solution container is nearly empty.
 - c. There is blood in the IV tubing.
 - d. Discomfort or swelling is experienced at the IV site.
 - Inform that the nurse will be checking the venipuncture site.
11. Document relevant information.
- Record the status of the IV insertion site and any adverse responses of the client.
 - Document the client's IV fluid intake at least every 8 hours according to agency policy. Include the date and time; amount and type of solution used; container number; flow rate; and the client's general response. In most agencies, the amount remaining in each IV container is also recorded at the end of the shift.

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Consider urinary output compared to intake, tissue turgor, specific gravity of urine, vital signs, and lung sounds compared to baseline data.
- Regularly check the client for intended and adverse effects of the infusion. Report significant deviations from normal to the primary care provider.

Changing Intravenous Containers and Tubing.

IV solution containers are changed when only a small amount of fluid remains in the neck of the container and fluid still remains in the drip chamber. However, all IV bags should be changed every 24 hours, regardless of how much solution remains, to minimize the risk of contamination. Change primary administration sets and secondary tubing that remains continuously attached to them “no more frequently than every 96 hours” (INS, 2011b, p. 84). Change

intermittent infusion sets without a primary infusion every 24 hours or whenever their sterility is in question (INS, 2011b). Add-on devices (e.g., extension sets, filters, stopcocks) should be changed at the same time the administration set is changed (INS, 2011b). The INS *Standards of Care* (2011a) state “routine site care and dressing changes are not performed on short peripheral catheters unless the dressing is soiled or no longer intact” (p. S63). Skill 52-3 provides guidelines for changing an IV solution container and tubing.

Changing an Intravenous Container and Tubing

PURPOSES

- To maintain the flow of required fluids
- To maintain sterility of the IV system and decrease the incidence of phlebitis and infection
- To maintain patency of the IV tubing

ASSESSMENT

Assess

- Presence of fluid infiltration, leakage, bleeding, or phlebitis at IV site
- Allergy to tape or iodine
- Infusion rate and amount absorbed
- Blockages in IV system
- Appearance of the dressing for integrity, moisture, and need for change

PLANNING

Review primary care provider's orders for changes in fluid administration.

Equipment

- Container with the correct kind and amount of sterile solution
- Administration set, including sterile tubing and drip chamber

DELEGATION

This procedure includes assessment of the IV site and should be completed by a registered nurse. In many states, licensed vocational nurses with IV certification may complete the procedure.

IMPLEMENTATION

Preparation

1. Obtain the correct solution container.
 - Read the label of the new container.
 - Verify that you have the correct solution, correct client, correct additives (if any), and correct dose (number of bags or total volume ordered).

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate.
2. Perform hand hygiene and observe other appropriate infection prevention procedures.
3. Set up the IV equipment with the new container and label. See Skill 52-1, steps 1 to 10.
 - Label the tubing as shown in Figure 10 in Skill 52-1.
4. Assess the IV site.
 - Inspect the IV site for the presence of infiltration or inflammation. **Rationale:** *Inflammation or infiltration necessitates removal of the IV catheter to avoid further trauma to the tissues.*
 - Go to step 5 or discontinue and relocate the IV site if indicated. See Skills 52-1 and 52-4.
5. Disconnect the used tubing or remove the cap on an intermittent device.
 - Apply clean gloves.
 - Place a sterile swab under the hub of the catheter. **Rationale:** *This absorbs any leakage that might occur when the tubing is disconnected.*

- Clamp the tubing. With the fourth or fifth finger of the non-dominant hand, apply pressure to the vein above the end of the catheter. **Rationale:** *This helps prevent blood from coming out of the needle during the change of tubing.*
 - Holding the hub of the catheter with the thumb and index finger of the nondominant hand, remove the tubing or cap with the dominant hand, using a twisting and pulling motion. **Rationale:** *Holding the catheter firmly but gently maintains its position in the vein.*
 - Remove the used IV tubing.
 - Place the end of the used tubing in the basin or other receptacle.
6. Connect the new tubing or cap and reestablish the infusion.
 - Continue to hold the catheter and grasp the new tubing with the dominant hand.
 - Remove the protective tubing cap and, maintaining sterility, insert the tubing end securely into the needle hub. Twist it to secure it.
 - Open the clamp to start the solution flowing.
 7. Secure IV tubing with additional tape as required.
 8. Regulate the rate of flow of the solution according to the order on the chart.
 9. Document all relevant information.
 - Record the change of the solution container and tubing in the appropriate place on the client's chart. Also record the fluid intake according to agency practice. Record the number of the container if the containers are numbered at the agency. Also record your assessments.

EVALUATION

Evaluate the following:

- Status of IV site
- Patency of IV system
- Accuracy of flow

When an IV infusion is no longer necessary to maintain the client's fluid intake or to provide a route for medication administration, the infusion is either discontinued and the catheter removed or the

catheter is left in place and converted to a saline lock. Guidelines for discontinuing an IV infusion or converting the catheter to a lock are outlined in Skills 52–4 and 52–5, respectively.

Discontinuing an Intravenous Infusion

PURPOSE

- To discontinue an IV infusion when the therapy is complete or when the IV site needs to be changed

ASSESSMENT

Assess

- Appearance of the venipuncture site
- Any bleeding from the infusion site
- Amount of fluid infused
- Appearance of IV catheter

PLANNING

Review the client record regarding the primary care provider's orders. Note if there were any previous infusions and if there were any complications and how they were managed.

Equipment

- Clean gloves
- Linen-saver pad
- Small sterile dressing and tape

DELEGATION

In some states and agencies, removal of a peripheral IV catheter may be delegated to UAP. In others, removal of IV infusions or devices is not delegated to UAP. In any case, the nurse must ensure that the UAP knows what complications or adverse signs following removal should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may discontinue IV infusions. Check the state's nurse practice act.

IMPLEMENTATION

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Explain the reason for discontinuing the IV and that the procedure should cause no discomfort other than that associated with removing the tape.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy. Place a linen-saver pad under the extremity that has the IV.
- Prepare the equipment.
 - Clamp the infusion tubing. **Rationale:** *Clamping the tubing prevents the fluid from flowing out of the needle onto the client or bed.*
 - Apply clean gloves.
 - Remove the dressing, stabilization device, and tape at the venipuncture site while holding the needle firmly and applying countertraction to the skin. **1 Rationale:** *Movement of the catheter can injure the vein and cause discomfort to the client. Countertraction prevents pulling the skin and causing discomfort.*
 - Assess the venipuncture site. **Rationale:** *Assess for signs of infection or phlebitis.*
 - Apply the sterile gauze above the venipuncture site. Only touch the upper portion of the gauze pad and maintain sterility of the lower portion that is in contact with the venipuncture site.
- Withdraw the catheter from the vein.
 - Withdraw the catheter by pulling it out along the line of the vein. **Rationale:** *Pulling it out in line with the vein avoids injury to the vein. Do not press down on the sterile gauze pad while removing the catheter.* **2**

1 Remove the dressing, stabilization device, and tape while holding the IV catheter firmly.

- Immediately apply firm pressure to the site, using sterile gauze, for 2 to 3 minutes. **Rationale:** *Pressure helps stop the bleeding and prevents hematoma formation.*
 - Hold the client's arm above heart level if any bleeding persists. **Rationale:** *Raising the limb decreases blood flow to the area.*
 - Teach the client to inform the nurse if the site begins to bleed at any time or the client notes any other abnormalities in the area.
- Examine the catheter removed from the client.
 - Check the catheter to make sure it is intact. **Rationale:** *If a piece of tubing remains in the client's vein it could move centrally (toward the heart or lungs).*
 - Report a broken catheter to the nurse in charge or primary care provider immediately.

Discontinuing an Intravenous Infusion—continued

2 Withdraw the IV catheter from the vein. Do not apply pressure on the sterile gauze pad until the catheter is completely removed.

3 Apply new sterile dressing to the site with tape.

- If a broken piece can be palpated, apply a tourniquet above the insertion site. **Rationale:** *Application of a tourniquet decreases the possibility of the piece moving until a primary care provider is notified.*

7. Cover the venipuncture site.

- Apply new sterile dressing to the site with tape. 3
- **Rationale:** *The dressing continues the pressure and covers the open area in the skin, preventing infection.*
- Discard used supplies appropriately.
- Remove and discard gloves.
- Perform hand hygiene.

8. Read the amount remaining in the IV solution container.

9. Apply a black-out label 4 over the existing IV solution label prior to discarding the IV solution into a biohazard container (2).
Rationale: *The existing IV label contains client information.*

A

B

4 A, An IV black-out label; B, discarding an IV bag into a biohazard container after applying a black-out label to ensure client confidentiality

The black-out label conceals client information and ensures client confidentiality. These labels are called IV HIPAA-compliant labels.

10. Document all relevant information.

- Record the amount of fluid infused on the intake and output record and in the record, according to agency policy. Include the container number, type of solution used, time of discontinuing the infusion, and the client's response.

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- Report significant deviations from normal to the primary care provider.

Changing an Intravenous Catheter to an Intermittent Infusion Lock

PURPOSE

- To permit IV administration of medications or fluids on an intermittent basis

ASSESSMENT

Assess

- Patency of the IV catheter
- Appearance of the site (evidence of inflammation or infiltration)

PLANNING

Review the primary care provider's order.

- A specific order may be written to convert an IV access to a saline lock. The order also may be implied; for example, IV fluids are to be discontinued but the client has orders for an IV antibiotic every 6 hours or is receiving analgesics intravenously.
- From the primary care provider's order, determine the type and sequence of intermittent infusions.
- Review the client record regarding previous infusions and use of infusion devices. Note any complications and how they were managed.

Equipment

- Intermittent infusion cap or device
- Clean gloves
- TSM dressing
- Sterile 2×2 or 4×4 gauze
- Sterile saline for injection (without preservative) in a prefilled syringe, a 3-mL syringe with a needleless infusion device
- Isopropyl alcohol wipes
- Tape
- Clean emesis basin

DELEGATION

Due to the need for sterile technique and technical complexity, this procedure is not delegated to UAP. UAP may care for clients with such devices, and the nurse must ensure that the UAP knows what complications or adverse signs should be reported to the nurse.

In many states, a licensed practical nurse or licensed vocational nurse with special IV therapy training may manage intermittent infusion devices. Check the state's nurse practice act.

IMPLEMENTATION

Preparation

- Obtain the needed equipment and take to the client's bedside.

Performance

- Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Explain the reason for the intermittent device and that changing an IV to a saline lock should cause no discomfort other than that associated with removing tape from the IV tubing.
- Perform hand hygiene and observe other appropriate infection prevention procedures.
- Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy.
- Assess the IV site and determine the patency of the catheter (see Skill 52-2). If the catheter is not fully patent or there is evidence of phlebitis or infiltration, discontinue the catheter and establish a new IV site.
 - Expose the IV catheter hub and loosen any tape or dressing that is holding the IV tubing in place or that will interfere with insertion of the intermittent infusion plug into the catheter.
 - Clamp the IV tubing to stop the flow of IV fluid.
 - Open the gauze pad and place it under the IV catheter hub.

Rationale: This absorbs any leakage that might occur when the tubing is disconnected.
 - Open the alcohol wipe and intermittent infusion plug, leaving the plug in its sterile package.
- Remove the IV tubing and insert the intermittent infusion plug into the IV catheter.
 - Apply clean gloves.
 - Stabilize the IV catheter with your nondominant hand and use the little finger to place slight pressure on the vein above the end of the catheter. Twist the IV tubing adapter to loosen it from the IV catheter and remove it, placing the end of the tubing in a clean emesis basin.
 - Pick up the intermittent infusion plug from its package and remove the protective sleeve from the male adapter (see Figure 52-26), maintaining its sterility. Insert the plug into the IV catheter, twisting it to engage the Luer-Lok.
- Instill saline per agency policy. **Rationale:** Saline is used to maintain patency of the IV catheter when fluids are not infusing through the catheter. The intermittent lock will need to be flushed with a prescribed solution after each use or every 8 to 12 hours if not in use, according to agency policy. Some recommend flushing the lock by injecting saline using the push-pause method (a rapid succession of push-pause-push-pause movements exerted on the plunger of the syringe barrel) with the rationale that this creates a turbulence within the catheter lumen that causes a swirling effect to remove any debris (e.g., blood or medication) attached to the catheter lumen. However, no research supports this method of flushing. There are differences of opinion and practice regarding this type of flushing versus a smooth injection of the flush solution. Research is needed to provide evidence of which is the most effective (Phillips & Gorski, 2014, p. 359).
- Cover the site with a TSM dressing. **Rationale:** The TSM dressing provides protection from infection, allows for ease of assessment of the venipuncture site, and also promotes comfort, preventing the plug from catching on clothing or bedding.
- Remove and discard gloves.
 - Perform hand hygiene.
- Teach the client how to maintain the lock.
 - Notify the nurse or primary care provider if the plug or catheter comes out; if the site becomes red, inflamed, or painful; or if any drainage or bleeding occurs at the site.
- Document all relevant information.
 - Record the date and time when the infusion device was converted, the status of the IV insertion site, and any adverse responses of the client.

Changing an Intravenous Catheter to an Intermittent Infusion Lock—continued

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- Examine the IV site at regular intervals. Note patency and ease of flushing.
- Report significant deviations from normal to the primary care provider.

Complications of Infusion Therapy

Local complications of infusion therapy occur as adverse reactions and/or trauma to the venipuncture site. Correct venipuncture technique is a primary factor in prevention along with frequent assessments and monitoring of the venipuncture site. Common local complications include infiltration, extravasation, and phlebitis.

Infiltration is the unintended administration of a *nonvesicant* drug or fluid into the subcutaneous tissue. Infiltration can be caused by puncture of the vein during venipuncture, dislodgement of the catheter, or a poorly secured infusion device (Phillips & Gorski, 2014).

Extravasation is similar to infiltration with the difference between the two being the solution. That is, extravasation is the unintended administration of *vesicant* drugs or fluids into the subcutaneous tissue. Five measures can help prevent infiltration and extravasation. The first measure is the selection of the venipuncture site. Areas of joint flexion such as the hand, wrist, and antecubital fossa should be avoided. The gauge of the catheter should be the smallest that can deliver the prescribed therapy in an appropriate size vein. Knowing the osmolality and pH of medications and fluids is also important. For example, hypertonic fluids and medications should not be infused through a peripheral vein. Using a manufactured catheter stabilization device prevents unnecessary movement of the catheter in the vein is the fourth measure. Finally, the last measure is assessing patency of the catheter and vein frequently.

Phlebitis is an inflammation of the vein of which there are three types. *Mechanical phlebitis* is caused by too large of a catheter in a small vein causing irritation of the vein. *Chemical phlebitis* occurs when a vein becomes inflamed by irritating or vesicant solutions or medications. *Bacterial phlebitis* is inflammation of the vein and a bacterial infection, which can be caused by poor aseptic technique during insertion of the IV catheter and/or breaks in the integrity of the IV equipment. See Box 52–8 for common signs and symptoms of infiltration, extravasation, and phlebitis.

It is important for the nurse to assess all clients with an IV access for signs of phlebitis. One of the INS Standards directs nurses to document symptoms of phlebitis using a standardized scale (INS, 2011a). Ray-Barruel, Polit, Murfield and Rickard (2014), however, conducted a systematic review of 71 different phlebitis assessment scales and found an “absence of a universally accepted scale with strong demonstrated reliability” (p. 8). While there is still a need for a phlebitis scale that has strong measurement properties for use in clinical practice, there are two commonly used assessment scales that are also recommended by the INS: the INS Phlebitis Scale and the Visual Infusion Phlebitis (VIP) Scale. The INS Phlebitis Scale progresses from 0 (no symptoms) to 4 (all symptoms: pain, erythema, streak formation, palpable venous cord, purulent drainage)

BOX 52-8 Signs and Symptoms of Common Local Complications of Infusion Therapy

INFILTRATION

- Coolness of skin around site
- Skin blanching, tautness (i.e., client states it feels “tight”)
- Edema at, above, or below the insertion site
- Leakage at insertion site
- Absence of or “pinkish” blood return
- Difference in size of opposite hand or arm

EXTRAVASATION

Same as infiltration and can also include:

- Burning, stinging pain
- Redness followed by blistering, tissue necrosis, and ulceration

PHLEBITIS

- Redness at the site
- Skin warm
- Swelling
- Palpable cord along the vein
- Increase in temperature

From “Intravenous Therapy: A Review of Complications and Economic Considerations of Peripheral Access,” by S. Dychter, D. Gold, D. Carson, & M. Haller, 2012, *Journal of Infusion Nursing*, 35(2), pp. 84–91; and *Manual of I.V. Therapeutics* (6th ed.), by L. D. Phillips & L. A. Gorski, 2014, Philadelphia, PA: F.A. Davis Company.

(INS, 2011a, p. S65). The VIP Scale progresses from 0 (no symptoms) to 5 (all symptoms). In addition, it includes an action (observe to relocate cannula and consider or initiate treatment) for each score (Higginson & Parry, 2011).

Prevention strategies for phlebitis include practicing good hand hygiene, assessing the length of time needed for the infusion therapy, and considering alternatives (e.g., midline catheter or PICC) for long-term therapy, choosing the smallest catheter, stabilizing the catheter, infusing solutions at the prescribed rate, avoiding insertion of a peripheral IV catheter in an area of flexion, and assessing the IV site at least every 4 hours (Phillips & Gorski, 2014, p. 549).

Blood Transfusions

IV fluids can be effective in restoring intravascular (blood) volume; however, they do not affect the oxygen-carrying capacity of the blood. When red or white blood cells, platelets, or blood proteins are lost because of hemorrhage or disease, it may be necessary to replace these components to restore the blood’s ability to transport oxygen and carbon dioxide, clot, fight infection, and keep extracellular fluid within the intravascular compartment. A blood transfusion is the introduction of whole blood or blood components into venous circulation.

TABLE 52–11 The Blood Groups with Their Constituent Agglutinogens and Agglutinins

Blood Types	RBC Antigens (Agglutinogens)	Plasma Antibodies (Agglutinins)
A	A	B
B	B	A
AB	A and B	—
O	—	A and B

Blood Groups

Human blood is commonly classified into four main groups: A, B, AB, and O. The surface of an individual's red blood cells contains a number of proteins known as **antigens** that are unique for each person. Many blood antigens have been identified, but the A, B, and Rh antigens are the most important in determining blood group or type. Because antigens promote agglutination or clumping of blood cells, they are also known as **agglutinogens**. The A antigen is present on the RBCs of people with blood group A, the B antigen is present on the RBCs of people with blood group B, and A and B antigens are both present on the RBCs in people with group AB blood. Neither antigen is present on the RBCs of people with group O blood.

Preformed **antibodies** to RBC antigens are present in the plasma; these antibodies are often called **agglutinins**. People with blood group A have B antibodies (agglutinins); A antibodies are present in people with blood group B; and people with blood group O have antibodies to both A and B antigens. People with group AB blood do not have antibodies to either A or B antigens (Table 52–11). These naturally occurring antibodies are responsible for the rapid and severe reaction that occurs when ABO-incompatible blood is administered (Phillips & Gorski, 2014).

Rhesus (Rh) Factor

The Rh factor antigen is present on the RBCs of approximately 85% of the people in the United States. Blood that contains the Rh factor is known as Rh positive (Rh⁺); blood that does not contain the Rh factor is known as Rh negative (Rh⁻). In contrast to the ABO blood groups, Rh⁻ blood does not naturally contain Rh antibodies. However, after exposure to blood containing Rh factor (e.g., an Rh⁻ mother carrying a fetus with Rh⁺ blood, or transfusion of Rh⁺ blood into a client who is Rh⁻), Rh antibodies develop. Subsequent exposure to Rh⁺ blood places the client at risk for an antigen–antibody reaction and hemolysis of RBCs.

Blood Typing and Crossmatching

To avoid transfusing incompatible red blood cells, both blood donor and recipient are typed and their blood crossmatched. Blood typing

is done to determine the ABO blood group and Rh factor status. This test is also performed on pregnant women and neonates to assess for incompatibility between their blood types (particularly Rh factor incompatibilities).

Because blood typing only determines the presence of the ABO and Rh antigens, crossmatching is also necessary prior to transfusion to identify possible interactions of minor antigens with their corresponding antibodies. RBCs from the donor blood are mixed with serum from the recipient; a reagent (Coombs' serum) is added, and the mixture is examined for visible agglutination. If no antibodies to the donated RBCs are present in the recipient's serum, agglutination does not occur and the risk of a transfusion reaction is small.

Selection of Blood Donors

Screening of blood donors is rigorous. Criteria have been established to protect the donor from possible ill effects of donation and to protect the recipient from exposure to diseases transmitted through the blood. Blood donors are unpaid volunteers. Potential donors are eliminated by a history of hepatitis, HIV infection (or risk factors for HIV infection), heart disease, most cancers, severe asthma, bleeding disorders, or seizures. Donation may be deferred for people who have malaria, have been exposed to malaria or hepatitis, are anemic, have high or low BP, have low body weight, or who are pregnant, have had recent surgery, or take certain medications.

Blood and Blood Products for Transfusion

Most clients do not require transfusion of whole blood. It is much more common for clients to receive a transfusion of a particular blood component specific to their individual needs. Table 52–12 lists some of the common blood products that may be transfused.

Transfusion Reactions

Transfusion of ABO- or Rh- incompatible blood can result in a **hemolytic transfusion reaction**, which causes destruction of the transfused RBCs and subsequent risk of kidney damage or failure. To avoid hemolytic transfusion reactions, blood from the donor and from the recipient is tested for compatibility. This is referred to as a *type and crossmatch*. Other forms of transfusion reactions may also occur, including febrile or allergic reactions, circulatory overload, and sepsis. Because the risk of an adverse reaction is high when blood is transfused, clients must be frequently and carefully assessed before and during transfusion. Many reactions become evident within 5 to 15 minutes of initiating the transfusion, but reactions can develop any time during a transfusion; for this reason clients are most closely monitored during the initial period of the transfusion. Stop the transfusion immediately if signs of a reaction develop. Keep the line open with normal saline. Do not use the saline attached to the Y-set tubing because the filter contains blood and you do not want to give the client who is experiencing an acute transfusion reaction another drop of blood. Instead, use new IV tubing. Disconnect the infusion tubing from the hub of the IV catheter and replace with the new IV tubing. Do not piggyback the new tubing into the access port of the transfusion tubing, because it is possible that some of the blood product could be administered to the client. Hydrate the client with normal saline and notify the primary care provider. Continue to monitor vital signs (Phillips & Gorski, 2014). Possible transfusion reactions, their clinical signs and symptoms, and nursing implications are listed in Table 52–13.

Culturally Responsive Care

PATIENT-CENTERED CARE

Blood and Blood Products

- Jehovah's Witnesses do not receive blood or blood products. Blood volume expanders are acceptable if they are not derivatives of blood.
- Christian Scientists do not ordinarily use blood or blood products.

From *Cultural Diversity in Health and Illness* (8th ed.), by R. Spector, 2013, Upper Saddle River, NJ: Pearson Education, Inc. Reprinted with permission.

TABLE 52–12 Blood Products for Transfusion

Product	Use
Whole blood	Not commonly used except for extreme cases of acute hemorrhage. Replaces blood volume and all blood products: RBCs, plasma, plasma proteins, fresh platelets, and other clotting factors.
Packed red blood cells (PRBCs)	Used to increase the oxygen-carrying capacity of blood in anemias, surgery, and disorders with slow bleeding. One unit of PRBCs has the same amount of oxygen-carrying RBCs as a unit of whole blood. One unit raises hematocrit by approximately 2% to 3%.
Autologous RBCs	Used for blood replacement following planned elective surgery. Client donates blood for autologous transfusion 4–5 weeks prior to surgery.
Platelets	Replaces platelets in clients with bleeding disorders or platelet deficiency. Fresh platelets are most effective. Each unit should increase the average adult client's platelet count by about 5,000 platelets/microliter.
Fresh frozen plasma	Provides clotting factors. Does not need to be typed and crossmatched (contains no RBCs).
Albumin and plasma protein fraction	Blood volume expander; provides plasma proteins.
Clotting factors and cryoprecipitate	Used for clients with clotting factor deficiencies. Each provides different factors involved in the clotting pathway; cryoprecipitate also contains fibrinogen.

TABLE 52–13 Transfusion Reactions

Reaction: Cause	Clinical Signs	Nursing Intervention*
Hemolytic reaction: incompatibility between client's blood and donor's blood	Fever or chills, flank pain, and reddish or brown urine, tachycardia, hypotension	<ol style="list-style-type: none"> 1. Discontinue the transfusion immediately. <i>Note:</i> When the transfusion is discontinued, the blood tubing must be removed as well. Use <i>new</i> tubing for the normal saline infusion. 2. Maintain vascular access with normal saline, or according to agency protocol. 3. Notify the primary care provider immediately. 4. Monitor vital signs. 5. Monitor fluid intake and output. 6. Send the remaining blood, bag, filter, tubing, a sample of the client's blood, and a urine sample to the laboratory.
Febrile reaction: sensitivity of the client's blood to white blood cells, platelets, or plasma proteins; does not cause hemolysis	Fever; chills; warm, flushed skin; headache; anxiety; nausea	<ol style="list-style-type: none"> 1. Discontinue the transfusion immediately. 2. Keep the vein open with a normal saline infusion. 3. Notify the primary care provider. 4. Give antipyretics as ordered.
Allergic reaction (mild): sensitivity to infused plasma proteins	Flushing, urticaria, with or without itching	<ol style="list-style-type: none"> 1. Stop the transfusion immediately. Keep vein open with normal saline. 2. Notify the primary care provider. 3. Administer medication (antihistamines, steroids) as ordered.
Allergic reaction (severe): antibody–antigen reaction	Dyspnea, stridor, decreased oxygen saturation, chest pain, flushing	<ol style="list-style-type: none"> 1. Stop the transfusion immediately. 2. Keep the vein open with a normal saline solution. 3. Notify the primary care provider immediately. 4. Monitor vital signs. Administer cardiopulmonary resuscitation if needed. 5. Administer medications and/or oxygen as ordered.
Circulatory overload: blood administered faster than the circulation can accommodate	Dyspnea, hypotension, orthopnea, crackles (rales), distended neck veins, tachycardia, hypertension	<ol style="list-style-type: none"> 1. Stop the transfusion immediately. 2. Place the client upright. 3. Notify the primary care provider. 4. Administer diuretics and oxygen as ordered.
Sepsis: contaminated blood administered	High fever, chills, vomiting, diarrhea, hypotension, oliguria	<ol style="list-style-type: none"> 1. Stop the transfusion. 2. Keep the vein open with a normal saline infusion. 3. Notify the primary care provider. 4. Administer IV fluids, antibiotics. 5. Obtain a blood specimen from the client for culture. 6. Send the remaining blood and tubing to the laboratory.

* Nurses should follow the agency's protocol regarding interventions. These may vary among agencies.

The hospital must have a protocol relating to transfusion reactions. Common measures include:

- Notify the blood bank.
- Examine the label on the blood container to check for errors in identifying the client, blood, or blood component.
- Obtain laboratory specimens (e.g., blood work, urine sample).
- Send blood container (whether or not it contains any blood), attached infusion set, and IV solution to the blood bank (American Association of Blood Banks [AABB], 2009, p. 79).

Administering Blood

Special precautions are necessary when administering blood. When a transfusion is ordered, the nurse or other personnel obtain blood in plastic bags from the blood bank just before starting the transfusion. One unit of whole blood is 500 mL; a unit of packed red blood cells (RBCs) is 200 to 250 mL. Do not store the blood in the refrigerator on the nursing unit; lack of temperature control may damage the blood. Once blood or a blood product is removed from the blood bank refrigerator, it must be administered within a limited amount of time (e.g., packed RBCs should not hang for more than 4 hours after being removed from the blood bank refrigerator). Follow agency policies for verifying that the unit is correct for the client. The U.S. Food and Drug Administration (2011) requires blood products to have bar codes to allow for scanning and machine-readable information on blood and blood component container labels to help reduce medication errors.

Traditionally, blood has usually been administered through an #18- to #20-gauge IV needle or catheter with the belief being that using smaller needles may slow the infusion and damage blood cells (hemolysis). However, studies have shown that blood infusions through smaller gauge catheters can be completed within 4 hours without hemolysis. Current practice guidelines established by the AABB and endorsed by the American Red Cross and the INS recommend that a #14- to #22 gauge IV catheter is acceptable for transfusion of cellular blood components in adults (Makic, Martin, Burns, Philbrick, & Rau, 2013, p. 36). Large-bore IV catheters are difficult to insert in older adults and oncology clients. Using a smaller gauge catheter (i.e., #22-gauge) is more comfortable for the client, may reduce the number of needlesticks, and avoid complications (e.g., infiltration, hematomas, and phlebitis). Blood administration sets (Y-sets) are used to keep the vein open while starting the transfusion and to flush the line with normal saline before the blood enters the tubing (Figure 52–31 ■).

The infusion tubing has a filter inside the drip chamber. A transfusion should be completed within 4 hours of initiation. The maximum time for use of a blood filter is 4 hours (Phillips & Gorski, 2014). The

SAFETY ALERT!

SAFETY

2014 THE JOINT COMMISSION NATIONAL PATIENT SAFETY GOALS (2013)

Goal 1: Improve the accuracy of patient identification.

Goal 01.03.01: Eliminate Transfusion Errors Related to Patient Misidentification.

- Before initiating a blood or blood component transfusion:
 - Match the blood or blood component to the order.
 - Match the patient to the blood or blood component.
 - Use a two-person verification process or a one-person verification process accompanied by automated identification technology, such as bar coding.

Figure 52–31 ■ Schematic of a Y-set for blood administration.

AABB (2009) states: “With the exception of 0.9% sodium chloride, no drug or medication should be added to blood or blood components unless they have been approved by the FDA or there is documentation that the addition is safe and does not adversely affect the blood or blood component” (p. 42). If an additional unit needs to be transfused, follow agency guidelines. A new blood administration set is to be used with each component (Phillips & Gorski, 2014). New IV tubing is used for administering other IV fluids following a transfusion.

CLINICAL ALERT!

Normal saline must always be used when giving a blood transfusion. If the client has an infusion of any other IV solution, stop that infusion and flush the line with saline prior to initiating the transfusion, or establish IV access through an additional site. Solutions other than saline can cause damage to the blood components.

To initiate, maintain, and terminate a blood transfusion, see Skill 52–6.

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set

PURPOSES

- To restore blood volume after severe hemorrhage
- To restore the oxygen-carrying capacity of the blood
- To provide plasma factors, such as antihemophilic factor (AHF) or factor VIII, or platelet concentrates, which prevent or treat bleeding

ASSESSMENT

Assess

- Vital signs
- Physical examination including fluid balance and heart and lung sounds as manifestations of hypo- or hypervolemia
- Status of infusion site
- Blood test results such as hemoglobin value or platelet count
- Any unusual symptoms

PLANNING

- Review the client record regarding previous transfusions. Note any complications and how they were managed (e.g., allergies or previous adverse reactions to blood).
- Confirm the primary care provider's order for the number and type of units and the desired speed of infusion.
- In some agencies, written consent for transfusion is required. Check policy and obtain as indicated.
- Know the purpose of the transfusion.
- Plan to begin the transfusion as soon as the component is ready. Typing and crossmatching can take several hours.
- Note any premedication ordered by the primary care provider (e.g., acetaminophen or diphenhydramine). Schedule their administration (usually 30 minutes prior to the transfusion).

DELEGATION

Due to the need for sterile technique and technical complexity, blood transfusion is not delegated to UAP. The nurse must ensure that the UAP knows what complications or adverse signs can occur and should be reported to the nurse. In some states only RNs can administer blood or blood products.

Equipment

- Unit of whole blood, packed RBCs, or other component
- Blood administration set
- IV pump, if needed
- 250 mL normal saline for infusion
- IV pole
- Venipuncture set containing a #14- to #22-gauge catheter (if one is not already in place)
- Alcohol swabs
- Tape
- Clean gloves

IMPLEMENTATION

Preparation

- If the client has an IV solution infusing, check whether the IV catheter and solution are appropriate to administer blood. The IV catheter size ranges between #14 and #22 gauge, and the solution *must* be normal saline. Dextrose (which causes lysis of RBCs), Ringer's solution, medications and other additives, and hyperalimentation solutions are incompatible. Refer to step 6 below if the infusing solution is not compatible.
- If the client does not have an IV solution infusing, check agency policies. In some agencies an infusion must be running before the blood is obtained from the blood bank. In this case, you will need to perform a venipuncture on a suitable vein (see Skill 52-1) and start an IV infusion of normal saline.

Performance

1. Prior to performing the procedure, introduce self and verify the client's identity using agency protocol. Explain to the client what you are going to do, why it is necessary, and how he or she can participate. Instruct the client to report promptly any sudden chills, nausea, itching, rash, dyspnea, back pain, or other unusual symptoms.
2. Provide for client privacy and prepare the client.
 - Assist the client to a comfortable position, either sitting or lying. Expose the IV site but provide for client privacy.
3. Perform hand hygiene and observe other appropriate infection prevention procedures.
4. Prepare the infusion equipment.
 - Ensure that the blood filter inside the drip chamber is suitable for the blood components to be transfused. Attach the blood tubing to the blood filter, if necessary. **Rationale:** Blood filters have a surface area large enough to allow the blood components through easily but are designed to trap clots.
5. Prime the tubing.
 - Apply gloves.
 - Close all the clamps on the Y-set: the main flow rate clamp and both Y-line clamps.
 - Insert the piercing pin (spike) into the saline solution.
 - Hang the container on the IV pole about 1 m (39 in.) above the venipuncture site.
6. Start the saline solution.
 - Open the upper clamp on the normal saline tubing, and squeeze the drip chamber until it covers the filter and one third of the drip chamber above the filter.
 - Tap the filter chamber to expel any residual air in the filter.
 - Open the main flow rate clamp, and prime the tubing with saline.
 - Close both clamps.

Rationale: Infusing normal saline before initiating the transfusion also clears the IV catheter of incompatible solutions or medications.

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set—continued

7. Obtain the correct blood component for the client.
 - Check the primary care provider's order with the requisition.
 - Check the requisition form and the blood bag label with a laboratory technician or according to agency policy. Specifically, check the client's name, identification number, blood type (A, B, AB, or O) and Rh group, the blood donor number, and the expiration date of the blood. Observe the blood for abnormal color, RBC clumping, gas bubbles, and extraneous material. Return outdated or abnormal blood to the blood bank.
 - With another nurse (most agencies require an RN), verify the following before initiating the transfusion (Phillips & Gorski, 2014, p. 731):
 - a. *Order*: Check the blood or component against the primary care provider's written order.
 - b. *Transfusion consent form*: Ensure the form is completed per facility policy.
 - c. *Client identification*: The name and identification number on the client's identification band must be identical to the name and number attached to the unit of blood.
 - d. *Unit identification*: The unit identification number on the blood container, the transfusion form, and the tag attached to the unit must agree.
 - e. *Blood type*: The ABO group and Rh type on the primary label of the donor unit must agree with those recorded on the transfusion form.
 - f. *Expiration*: The expiration date and time of the donor unit should be verified as acceptable.
 - g. *Compatibility*: The interpretation of compatibility testing must be recorded on the transfusion form and on the tag attached to the unit.
 - h. *Appearance*: There should be no discoloration, foaming, bubbles, cloudiness, clots or clumps, or loss of integrity of the container.
9. Establish the blood transfusion.
 - Close the upper clamp below the IV saline solution container.
 - Open the upper clamp below the blood bag. The blood will run into the saline-filled drip chamber. If necessary, squeeze the drip chamber to reestablish the liquid level with the drip chamber one third full. (Tap the filter to expel any residual air within the filter.)
 - Readjust the flow rate with the main clamp.
 - Remove and discard gloves.
 - Perform hand hygiene.
10. Observe the client closely for the first 15 minutes.
 - Phillips and Gorski (2014) report that the AABB recommends that "transfusions of RBCs be started at 1–2 mL/min for the first 15 minutes of the transfusion" (p. 732). **Rationale:** *This small amount is enough to produce a severe reaction but small enough that the reaction could be treated successfully.*
 - Note adverse reactions, such as chills, nausea, vomiting, skin rash, dyspnea, back pain, or tachycardia. **Rationale:** *The earlier a transfusion reaction occurs, the more severe it tends to be. Promptly identifying such reactions helps to minimize the consequences.*
 - Remind the client to call a nurse immediately if any unusual symptoms are felt during the transfusion such as chills, nausea, itching, rash, dyspnea, or back pain.
 - If any of these reactions occur, report these to the nurse in charge, and take appropriate nursing action. See Table 52–13 on page 1359.
11. Document relevant data.
 - Record starting the blood, including vital signs, type of blood, blood unit number, sequence number (e.g., #1 of three ordered units), site of the venipuncture, size of the catheter, and drip rate.

CLINICAL ALERT!

It is safer to have one nurse read the information for verification to the other nurse; this avoids errors that can be made if both nurses look at the tags together.

- If any of the information does not match *exactly*, notify the charge nurse and the blood bank. Do not administer blood until discrepancies are corrected or clarified.
 - Sign the appropriate form with the other nurse according to agency policy.
 - Make sure that the blood is left at room temperature for no more than 30 minutes before starting the transfusion. Agencies may designate different times at which the blood must be returned to the blood bank if it has not been started. **Rationale:** *As blood components warm, the risk of bacterial growth also increases.* If the start of the transfusion is unexpectedly delayed, return the blood to the blood bank after 30 minutes. Do *not* store blood in the unit refrigerator. **Rationale:** *The temperature of unit refrigerators is not precisely regulated and the blood may be damaged.*
8. Prepare the blood bag.
 - Invert the blood bag gently several times to mix the cells with the plasma. **Rationale:** *Rough handling can damage the cells.*
 - Expose the port on the blood bag by pulling back the tabs.
 - Insert the remaining Y-set spike into the blood bag.
 - Suspend the blood bag.
 12. Monitor the client.
 - Fifteen minutes after initiating the transfusion (or according to agency policy), check the vital signs. If there are no signs of a reaction, establish the required flow rate. Most adults can tolerate receiving one unit of blood in 1.5 to 2 hours. Do not transfuse a unit of blood for longer than 4 hours.
 - Assess the client, including vital signs, per agency policy. If the client has a reaction and the blood is discontinued, send the blood bag and tubing to the laboratory for investigation of the blood.
 13. Terminate the transfusion.
 - Apply clean gloves.
 - If no infusion is to follow, clamp the blood tubing. Check agency protocol to determine if the blood component bag needs to be returned or if the blood bag and tubing can be disposed of in a biohazard container. The IV line can be discontinued or capped with an adapter or a new infusion line and solution container may be added. If another transfusion is to follow, clamp the blood tubing and open the saline infusion arm. Check agency protocol. A new blood administration set is to be used with each component (Phillips & Gorski, 2014, p. 733).

SAMPLE DOCUMENTATION

1/21/2015 1400 1 unit of PRBCs (#65234) hung to be infused over 3 hours. IV site in (L) forearm with 20 G angiocath. VS taken (see transfusion record). Informed to contact nurse if begins to experience any discomfort during transfusion. Stated he would use the call light _____ C. Jones, RN

Initiating, Maintaining, and Terminating a Blood Transfusion Using a Y-Set—continued

SKILL 52-6

- If the primary IV is to be continued, flush the maintenance line with saline solution. Disconnect the blood tubing system and reestablish the IV infusion using new tubing. Adjust the drip to the desired rate. Often a normal saline or other solution is kept running in case of delayed reaction to the blood.
 - Measure vital signs.
14. Follow agency protocol for appropriate disposition of the used supplies.
- Discard the administration set according to agency practice.
 - Dispose of blood bags and administration sets.
 - a. On the requisition attached to the blood unit, fill in the time the transfusion was completed and the amount transfused.
 - b. Attach one copy of the requisition to the client's record and another to the empty blood bag if required by agency policy.
 - c. Agency policy generally involves returning the bag to the blood bank for reference in case of subsequent or delayed adverse reaction.

- Remove and discard gloves.
 - Perform hand hygiene.
15. Document relevant data.
- Record completion of the transfusion, the amount of blood absorbed, the blood unit number, and the vital signs. If the primary IV infusion was continued, record connecting it. Also record the transfusion on the IV flow sheet and intake and output record.

SAMPLE DOCUMENTATION

4/21/2015 1420 c/o feeling warm, headache, & backache. Skin flushed. T 102.6°F, BP 140/90, P 112, R 28. Approximately 50 mL PRBCs (#65234) infused over past 20 minutes. Infusion stopped. IV tubing changed, NS infusing at 15 mL/hr. Blood & attached tubing sent to blood bank. Dr. Riley notified. _____ C. Jones, RN

EVALUATION

- Perform follow-up based on findings or outcomes that deviated from expected or normal for the client. Relate findings to previous data if available.
- Report significant deviations from normal to the primary care provider.

Evaluating

Using the overall goals identified in the planning stage of maintaining or restoring fluid balance, maintaining or restoring pulmonary ventilation and oxygenation, maintaining or restoring normal balance of electrolytes, and preventing associated risks of fluid, electrolyte, and acid–base imbalances, the nurse collects data to evaluate the effectiveness of interventions.

If desired outcomes are not achieved, the nurse, client, and support person if appropriate need to explore the reasons before modifying the care plan. For example, if the outcome “Urine output is greater

than 1,300 mL per day and within 500 mL of intake” is not achieved, questions to be considered might include the following:

- Have other outcome measures for the goal of achieving fluid balance been met?
- Does the client understand and comply with planned fluid intake?
- Is all urinary output being measured?
- Are unusual or excessive amounts of fluid being lost by another route (e.g., gastric suction, excessive perspiration, fever, rapid respiratory rate, wound drainage)?
- Are prescribed medications being taken or administered as ordered?

NURSING CARE PLAN Deficient Fluid Volume

Assessment Data

Nursing Assessment

Merlyn Chapman, a 27-year-old sales clerk, reports weakness, malaise, and flu-like symptoms for 3–4 days. Although thirsty, she is unable to tolerate fluids because of nausea and vomiting, and she has liquid stools 2–4 times per day.

Physical Examination

Height: 160 cm (5'3")
 Weight: 66.2 kg (146 lb)
 Mild fever: 38.6°C (101.5°F)
 Pulse: 96 beats/min
 Respirations: 24/min
 Scant urine output
 BP: 102/84 mmHg
 Dry oral mucosa, furrowed tongue, cracked lips

Diagnostic Data

Urine specific gravity: 1.035
 Serum sodium 145 mEq/L
 Serum potassium 3.5 mEq/L
 Chest x-ray negative

Nursing Diagnosis

Deficient Fluid Volume related to nausea, vomiting, and diarrhea as evidenced by decreased urine output, increased urine concentration, weakness, fever, decreased skin/tongue turgor, dry mucous membranes, increased pulse rate, and decreased blood pressure

Desired Outcomes*

Fluid Balance [0601] as evidenced by not compromised:

- 24-hour intake and output balance
- Urine specific gravity
- Blood pressure
- Pulse rate
- Temperature
- Skin turgor
- Moist mucous membranes

NURSING CARE PLAN Deficient Fluid Volume—*continued*

Nursing Interventions*/Selected Activities	Rationale
Fluid Management [4120]	
Weigh daily and monitor trends.	<i>Weight helps to assess fluid balance.</i>
Maintain accurate I&O record.	<i>Accurate records are critical in assessing the client's fluid balance.</i>
Monitor vital signs as appropriate.	<i>Vital sign changes such as increased heart rate, decreased blood pressure, and increased temperature indicate hypovolemia.</i>
Give fluids as appropriate.	<i>As her nausea decreases encourage oral intake of fluids as tolerated, again to replace lost volume.</i>
Administer IV therapy as prescribed.	<i>Mrs. Chapman will probably require IV replacement of fluid. This is especially true because her oral intake is limited because of nausea and vomiting.</i>

Evaluation

Outcomes met. Mrs. Chapman remained hospitalized for 48 hours. She required fluid replacement of a total of 5 liters. Her blood pressure increased to 122/74 mmHg, pulse rate decreased to a resting level of 74 beats/min, and respirations decreased to 12/min. Her urine output increased as the fluid was replaced and was adequate at >0.5 mL/kg per hour by the time of discharge. The urine specific gravity was 1.015. Lab work on the day of discharge was K⁺: 3.8 and Na⁺: 140. She had elastic skin turgor and moist mucous membranes. She was taking oral fluids and was able to discuss symptoms of deficient fluid volume that would necessitate her calling her health care provider.

*The NOC # for desired outcomes and the NIC # for nursing interventions and selected activities are listed in brackets following the appropriate outcome or intervention. Outcomes, interventions, and activities selected are only a sample of those suggested by NOC and NIC and should be further individualized for each client.

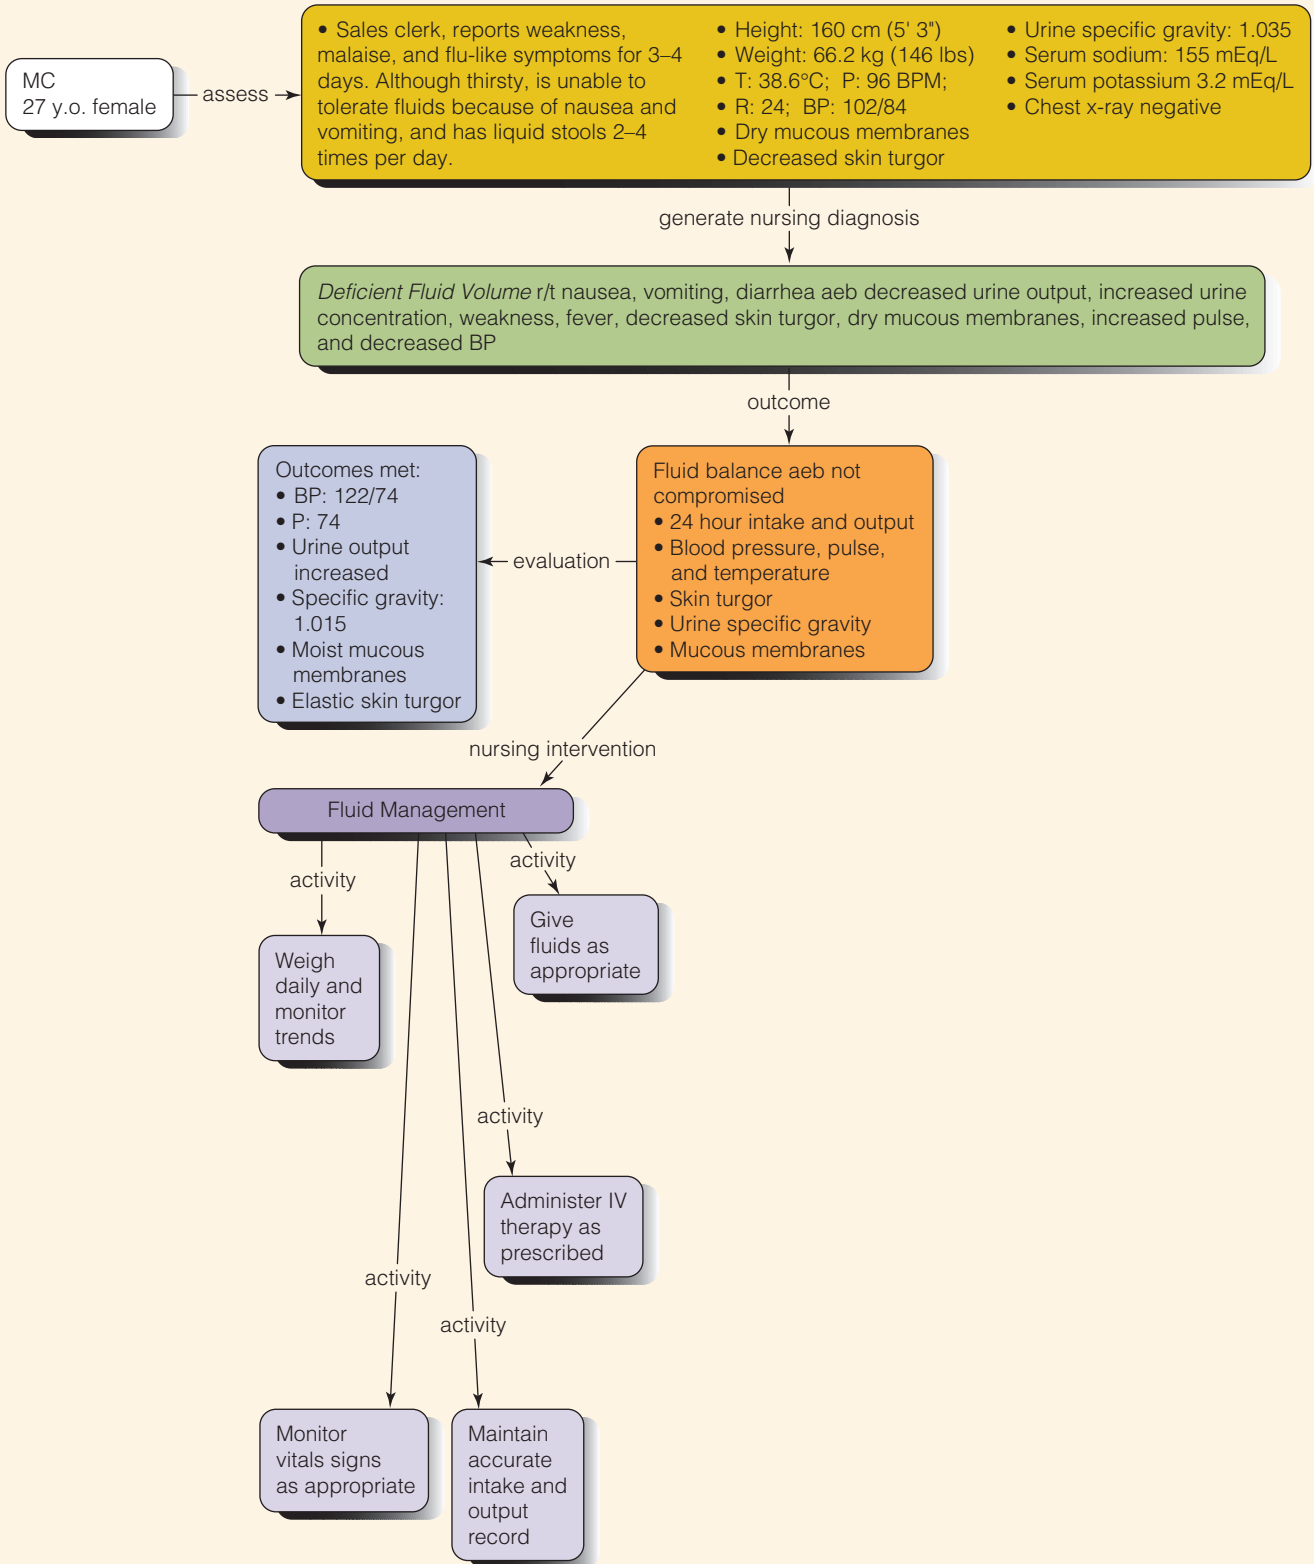

APPLYING CRITICAL THINKING

1. Offer suggestions for ways to help Mrs. Chapman increase her oral intake.
2. Mrs. Chapman asks why you weigh her every morning. How do you respond?

See Critical Thinking Possibilities on student resource website.

CONCEPT MAP

Deficient Fluid Volume

Chapter 52 Review

CHAPTER HIGHLIGHTS

- A balance of fluids, electrolytes, acids, and bases in the body is necessary for good health.
- Body fluid is divided into two major compartments: intracellular fluid (ICF) inside the cells and extracellular fluid (ECF) outside the cells.
- ECF is subdivided into two compartments: intravascular (plasma) and interstitial. It constitutes about one third of total body fluid.
- ECF is in constant motion throughout the body. It is the transport system that carries nutrients to and waste products from the cells.
- The percentage of total body fluid varies according to an individual's age, body fat, and gender. The younger a person is, and the less body fat present, the greater the proportion of body fluid; postadolescent females have a smaller percentage of fluid in relation to total body weight than men.
- There are two types of body electrolytes (ions): positively charged ions (cations) and negatively charged ions (anions).
- The principal ions of ECF are sodium (cation), chloride (anion), and bicarbonate (anion); the principal ions of ICF are potassium and magnesium (cations), and phosphate and sulfate (anions).
- Fluids and electrolytes move among the body compartments by osmosis, diffusion, filtration, and active transport.
- The major fluid pressures exerted as part of the movement of fluid and electrolytes from one compartment to another are osmotic pressure and hydrostatic pressure.
- The three sources of body fluid are liquids and food, which are ingested, and the oxidation of food. Fluid intake is regulated by the thirst mechanism.
- Fluid output occurs chiefly through excretion of urine, although body fluid is also lost through sweat, feces, and respiration.
- In healthy adults, measurable fluid intake and output should balance (about 1,500 mL per day). The output of urine normally approximates the oral intake of fluids. Water from food and oxidation is balanced by fluid loss through urine, feces, and insensible losses, such as losses through the skin as perspiration.
- A number of body systems and organs are involved in regulating the volume and composition of body fluids: the kidneys, lungs, the cardiovascular and gastrointestinal systems, and the endocrine system. The kidneys are the primary regulator of fluid and electrolyte balance.
- Substances such as antidiuretic hormone, the renin-angiotensin-aldosterone system, and atrial natriuretic factor are also involved in maintaining fluid balance.
- The acid–base balance (pH range) of body fluids is maintained within a precise range of 7.35 to 7.45.
- Acid–base balance is regulated by buffers, which neutralize excess acids or bases; the lungs, which eliminate or retain carbon dioxide, a potential acid; and the kidneys, which excrete or conserve bicarbonate and hydrogen ions.
- Factors that influence an individual's fluid, electrolyte, and acid–base balance include age, gender and body size, environmental temperature, and lifestyle. Illness, trauma, surgery, and certain medications can place individuals at risk for fluid, electrolyte, and acid–base imbalances.
- Fluid imbalances include fluid volume deficit (FVD), also referred to as hypovolemia; fluid volume excess (FVE), also referred to as hypervolemia; dehydration, a deficit in water and an increase in serum sodium level; and overhydration, an excess of water and decrease in serum sodium level.
- Acid–base imbalance occurs when the normal 20-to-1 ratio of bicarbonate to carbonic acid is upset. Imbalances may be either respiratory or metabolic in origin; either can result in acidosis or alkalosis.
- Fluid, electrolyte, and acid–base imbalances are most accurately determined through laboratory examination of blood plasma.
- Assessment relative to fluid, electrolyte, and acid–base balances includes (a) a nursing history; (b) physical examination of the skin, oral cavity, eyes, jugular vein, veins of the hand, and the neurologic system; (c) measurement of body weight, vital signs, and fluid intake and output; and (d) diagnostic studies of blood and urine.
- A nursing history includes data about the client's fluid and food intake; fluid output; signs of fluid, electrolyte, and acid–base imbalances; and medications, therapies, or disease processes that may disrupt these balances.
- NANDA-approved nursing diagnoses that relate specifically to fluid, electrolyte, and acid–base imbalances include *Deficient Fluid Volume*, *Excess Fluid Volume*, *Risk for Imbalanced Fluid Volume*, *Risk for Deficient Fluid Volume*, and *Impaired Gas Exchange*. Other diagnoses that may be relevant are *Impaired Oral Mucous Membrane*, *Impaired Skin Integrity*, *Decreased Cardiac Output*, *Ineffective Tissue Perfusion*, *Activity Intolerance*, *Risk for Injury*, and *Acute Confusion*.
- In many instances, fluids and electrolytes can be provided orally to clients who are experiencing or at risk of developing fluid deficits. The nurse needs to establish with the client a 24-hour plan for ingesting the necessary fluids and to respect the client's fluid preferences.
- For clients with fluid retention, fluids may need to be restricted; a schedule and short-term goals that make the fluid restriction more tolerable need to be developed.
- For clients experiencing excessive fluid losses, the administration of fluids and electrolytes intravenously is necessary. Meticulous aseptic technique is required when caring for clients with IV infusions.
- Preventing complications such as infiltration, extravasation, and phlebitis is an important aspect of IV therapy.
- The administration of blood transfusions involves accurately matching and identifying the blood for the individual, correctly identifying the recipient, and monitoring the client throughout the procedure for transfusion reactions.

TEST YOUR KNOWLEDGE

- An older nursing home resident has refused to eat or drink for several days and is admitted to the hospital. The nurse should expect which assessment finding?
 - Increased blood pressure
 - Weak, rapid pulse
 - Moist mucous membranes
 - Jugular vein distention
- A man brings his elderly wife to the emergency department. He states that she has been vomiting and has had diarrhea for the past 2 days. She appears lethargic and is complaining of leg cramps. What should the nurse do first?
 - Start an IV.
 - Review the results of serum electrolytes.
 - Offer the woman foods that are high in sodium and potassium content.
 - Administer an antiemetic.
- The nurse administers an IV solution of D₅ 1/2NS to a postoperative client. This is classified as what type of intravenous solution? _____
- An older client comes to the emergency department experiencing chest pain and shortness of breath. An arterial blood gas is ordered. Which of the following ABG results indicates respiratory acidosis?
 - pH 7.54; PaCO₂ 28 mmHg; HCO₃ 22 mEq/L
 - pH 7.32; PaCO₂ 46 mmHg; HCO₃ 24 mEq/L
 - pH 7.31; PaCO₂ 35 mmHg; HCO₃ 20 mEq/L
 - pH 7.50; PaCO₂ 37 mmHg; HCO₃ 28 mEq/L
- The intake and output (I&O) record of a client with a nasogastric tube who has been attached to suction for 2 days shows greater output than input. Which nursing diagnoses are most applicable? Select all that apply.
 - Deficient Fluid Volume
 - Risk for Deficient Fluid Volume
 - Impaired Oral Mucous Membranes
 - Impaired Gas Exchange
 - Decreased Cardiac Output
- Which client statement indicates a need for further teaching regarding treatment for hypokalemia?
 - “I will use avocado in my salads.”
 - “I will be sure to check my heart rate before I take my digoxin.”
 - “I will take my potassium in the morning after eating breakfast.”
 - “I will stop using my salt substitute.”
- An older man is admitted to the medical unit with a diagnosis of dehydration. Which sign or symptom is most representative of a sodium imbalance?
 - Hyperreflexia
 - Mental confusion
 - Irregular pulse
 - Muscle weakness
- The client’s arterial blood gas results are pH 7.32; PaCO₂ 58; HCO₃ 32. The nurse knows that the client is experiencing which acid–base imbalance?
 - Metabolic acidosis
 - Respiratory acidosis
 - Metabolic alkalosis
 - Respiratory alkalosis
- A client is admitted to the hospital for hypocalcemia. Nursing interventions relating to which system would have the highest priority?
 - Renal
 - Cardiac
 - Gastrointestinal
 - Neuromuscular
- The nurse would assess for signs of hypomagnesemia in which of the following clients? Select all that apply.
 - A client with renal failure
 - A client with pancreatitis
 - A client taking magnesium-containing antacids
 - A client with excessive nasogastric drainage
 - A client with chronic alcoholism

Meeting the Standards

This unit discusses the fundamentals of physiological health including activity and exercise, sleep, pain management, nutrition, urinary and fecal elimination, oxygenation, circulation, fluid and electrolyte balance, and acid–base balance. Most clients in the acute care setting will have one or more issues related to these physiological requirements and the nurse must be alert to the client's needs to prevent complications from developing.

CLIENT: Agnes AGE: 71 CURRENT MEDICAL DIAGNOSES: Fractured left hip

Medical History: Agnes is a healthy and active African American woman who lives alone. Agnes and her sisters decided it would be fun to go roller skating, and she fell and fractured her left hip. The fracture was diagnosed by x-ray in the emergency department. She underwent open reduction of the fracture and was admitted to the orthopedic unit of the hospital. She will be transferred to a rehabilitation facility once her condition has stabilized. Agnes has a 30-year history of hypertension that she controls with diet and atenolol 50 mg once daily and hydrochlorothiazide 25 mg once per day.

Personal and Social History: Agnes is single and has no children, but she has many friends as well as two sisters and a brother who live nearby. Even in the emergency department after hearing the diagnosis, she and her sisters have been laughing about what fun it will be telling people she broke her hip roller skating. She has a wonderful sense of humor and is often heard laughing. She retired 6 years ago after having worked for 45 years as a pediatric nurse.

Questions

American Nurses Association Standard of Professional

Performance #3 is Outcomes Identification: *The nurse identifies expected outcomes for a plan individualized to the client or situation by considering associated risks, benefits, costs, current scientific evidence, expected trajectory of the condition, and clinical expertise when formulating expected outcomes.*

1. Develop an expected outcome for this client related to chapters in this unit including activity and exercise, pain management, fecal elimination, and circulation.
2. What risks can you identify for this client related to activity and exercise, sleep, nutrition, and oxygenation?

American Nurses Association Standard of Professional

Performance #4 is Planning: *The registered nurse develops a plan that prescribes strategies and alternatives to attain expected outcomes by establishing the plan priorities with the health care consumer, family, and others as appropriate.*

3. When planning care with Agnes related to activity and exercise, pain management, nutrition, fecal elimination, oxygenation, and circulation, establish the priorities of care.

American Nurses Association Standard of Professional

Performance #5A is Coordination of Care: *The registered nurse coordinates the delivery of care with a focus on maximizing the client's independence and quality of life.*

4. Of activity and exercise, sleep, pain management, nutrition, urinary elimination, fecal elimination, oxygenation, circulation, and fluid, electrolyte, and acid–base balance, which one carries the greatest risk to Agnes's independence and quality of life?
5. What actions can the nurse take to promote and maximize Agnes's independence?

American Nurses Association. (2010). *Nursing: Scope and standards of practice* (2nd ed.). Silver Spring, MD: Author.

See Suggested Answers to End-of-Unit Meeting the Standards Questions on student resource website.

Appendix A Answers to Test Your Knowledge

Chapter 1: Historical and Contemporary Nursing Practice

- Answer:** 1, 4, and 5. **Rationale:** Option 2, Florence Nightingale, contributed to the nursing care of soldiers in the Crimean War. Option 3, Fabiola, used her wealth to provide houses of caring and healing during the Roman Empire. **Cognitive Level:** Knowledge. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-1.
- Answer:** 2, 3, and 5. **Rationale:** State boards of nursing set minimum educational requirements for licensure. Professional organizations establish educational criteria for program accreditation. The National Council of State Boards of Nursing conducts practice studies and creates the NCLEX-RN®. Neither physicians (option 1) nor hospital administrators (option 4) are involved in setting nursing curricula. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-3.
- Answer:** 2. **Rationale:** Continuing education refers to formalized experiences designed to enhance the knowledge or skill of practitioners. The other answers are examples of in-service education, which is designed to upgrade the knowledge or skills of current employees with regard to the specific setting, and is usually less formal in presentation. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 1-4.
- Answer:** 3. **Rationale:** Health promotion focuses on maintaining normal status without consideration of diseases. Option 1 is an example of illness prevention. Option 2 is aesthetic (i.e., not needed for health promotion or disease prevention). Option 4 focuses on disease detection. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-6.
- Answer:** 3. **Rationale:** All are noted nurses. Linda Richards was America's first trained nurse, and Mary Mahoney was America's first Black trained nurse. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-2.
- Answer:** 2. **Rationale:** Option 1, the advanced beginner, demonstrates marginally acceptable performance. Option 3, the proficient practitioner, has 3 to 5 years of experience and has developed a holistic understanding of the client. Option 4, the expert practitioner, demonstrates highly skilled intuitive and analytic ability in new situations. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-11.
- Answer:** 4. **Rationale:** The National Student Nurses Association developed the Code of Academic and Clinical Conduct for nursing students in 2001. Option 1, ANA, developed *Standards of Nursing Practices*. Option 2, NLN, focuses on nursing education. Option 3, the American Association of Colleges of Nursing (AACN), is the national organization that focuses on the advancement and maintenance of America's baccalaureate and higher degree nursing education programs. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-13.
- Answer:** 1. **Rationale:** All will impact nursing but not necessarily the supply and demand issue. The aging population contributes to more older adults needing specialized care (increasing the demand). Fewer nursing faculty to educate students and fewer nurses practicing because of retirement contribute to the decreasing supply. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-12.
- Answer:** 2. **Rationale:** All of the expanded roles function as health care advocates and all could work with individuals affected by violence.

However, the forensic nurse specifically integrates forensic skills into nursing practice. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-9.

- Answer:** Progression **Rationale:** The focus has changed to academic progression for all nurses. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 1-3.

Chapter 2: Evidence-Based Practice and Research in Nursing

- Answer:** 4. **Rationale:** Trial and error is not considered valid evidence, and may even be harmful to clients. Clinical experience (option 1), the opinions of experts (option 2), and client values and preferences (option 3) are all considered valid evidence in evidence-based practice. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-3.
- Answer:** 1. **Rationale:** Quantitative research collects numerical data. Sleep deprivation can be defined by numbers of hours without sleep and wound healing can be measured by the size of the wound in relation to a period of time. While some of the other options may be calculated using sophisticated numerical processes, they are not as easily measured and may be more appropriate for qualitative research methods. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-4.
- Answer:** 3. This study investigates the subjective experience of stress, through the collection of narrative data. Options 1, 2, and 4 are examples of quantitative research using numbers and values. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-4.
- Answer:** 2. **Rationale:** The key purpose of a study's methodology is to generate data that are reliable and valid, thus controlling extraneous variables is a major function. The hypotheses that are tested are formed during the problem identification phase of a study (option 1). Grants and funding sources are not related to methodology (option 3). Protecting subjects' rights (option 4) is an important consideration, but not the key purpose of a methodology. **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.
- Answer:** 2. **Rationale:** PICO stands for patient/client, population, or problem; intervention; comparison; and outcome. These are helpful components of a research question and help to identify key terms for a literature search. Options 1, 3, and 4 are incorrect. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.
- Answer:** 2. **Rationale:** Since the primary purpose of research is to improve the quality of client care, the nurse should determine if published research results are applicable to the specific client population. Published studies may have flawed designs, data collection, or analysis (option 1). Although more than one well-conducted study with similar findings supports usefulness of the results, applicability must still be determined for the specific client population (option 3). It is not realistic for the nurse to rerun the raw data to check the results of the study. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-6.
- Answer:** 1. **Rationale:** A research critique is the thoughtful consideration of a study's strengths and weaknesses, and how these affect the quality and usefulness of study results. Options 2 and 3 describe elements of a research critique. The summary of a study and its key findings

(option 4) comprise an abstract. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-5.

8. **Answer:** 4. **Rationale:** The right to self-determination means that subjects feel free of constraints, coercion, or any undue influence to participate in a study. There is not enough information given to indicate if any of the other rights in options 1, 2, and 3 have been violated. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-7.
9. **Answer:** 3, 2, 1, 5, 4, 6. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-2.
10. **Answer:** 3. **Rationale:** There may have been unique aspects to this research that would not be applicable in a different setting or with different clients. Not all research is flawed (option 1) and it may or may not have taken cost into consideration (option 2). Research is not limited to the study of physiological problems (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 2-1.

Chapter 3: Nursing Theories and Conceptual Frameworks

1. **Answer:** 3. **Rationale:** A supposition or system of ideas proposed to explain a given phenomenon is a theory. Concepts are mental images that are included within a theory (option 1); a conceptual framework is a group of related ideas, statements, or concepts (option 2); and a paradigm is a pattern of shared understandings and assumptions about reality and the world (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-1.
2. **Answer:** 2. **Rationale:** A group of related ideas or statements is a conceptual framework. A philosophy is a belief system (option 1); a supposition or system of ideas proposed to explain a given phenomenon is a theory (option 3); and a paradigm is a pattern of shared understandings and assumptions about reality and the world (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-1.
3. **Answer:** 4. **Rationale:** A set of shared understandings and assumptions about reality and the world is a paradigm. A concept is a mental image (option 1); a conceptual framework is a group of related ideas, statements, or concepts (option 2); and a practice discipline is a field of study in which the central focus is performance of a professional role (option 3). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-1.
4. **Answer:** 1. **Rationale:** Practice disciplines are fields of study in which the central focus is performance of a professional role. Time and experience are necessary for developing proficiency in any profession or career (option 2). Research and theory development do not have performance as their primary focus. The primary focus of nursing is providing quality service to humans (option 3). Team or group practice can be a part of a career in humanities, computer science, or rocket science (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-5.
5. **Answer:** 2. **Rationale:** Person/client, environment, health, and nursing are relevant when providing care for any client whether in the hospital, at home, in the community, or in elementary school systems. These elements can be used to understand diseases, conduct and apply research, and develop nursing theories, as well as implement the nursing process. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-3.
6. **Answer:** 1. **Rationale:** Practice theories assist the nurse to reflect on nursing care. Theories describing the interrelationships among a broad range of concepts within nursing are grand theories, not midlevel, and both require more testing through nursing research (option 2). Schools of nursing in the United States may or may not be organized around any theory or conceptual model (option 3). Nursing theory guides the direction of research and education and practice (option 4). **Cognitive**

Level: Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-4.

7. **Answer:** 3. **Rationale:** The purpose of any theory is to help interpret phenomena. Programs of research should have a theoretical framework but the theory is not the reason for the research (option 1). Theory is as applicable in science as it is in art (options 3 and 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 3-2.

Chapter 4: Legal Aspects of Nursing

1. **Answer:** 3. **Rationale:** This is the best answer because the nurse is assessing the client's level of knowledge as a result of the discussion with the primary care provider. Based on this assessment, the nurse may initiate other actions (e.g., call the primary care provider if the client has many questions). In option 1, the nurse is not assessing if the client received enough information to give consent. Option 2 is one way to assess the client's level of knowledge regarding the procedure. However, it is not the best approach because it is a closed-ended question, asking for only a "yes" or "no" response. Option 3 provides more information from the client in his or her own words. The statement in option 4 is true; however, the nurse should first verify if the client received enough information to give consent. After the assessment, this statement may be appropriate but the assessment needs to be done first. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 4-4.
2. **Answer:** 4. **Rationale:** Battery is the willful touching of a person without permission. Another name for an unintentional tort is professional negligence/malpractice. This situation is an *intentional* tort because the nurse executed the act on purpose. Assault is the attempt or threat to touch another person unjustifiably or without permission. Invasion of privacy injures the feelings of the person and does not take into consideration how revealing information or exposing the client will affect the client's feelings. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 4-10.
3. **Answer:** 2. **Rationale:** The nurse should call the person who wrote the order for clarification. Administering the medication is incorrect because knowing the dose is outside the normal range and not questioning the order could lead to client harm and liability for the nurse. Calling the pharmacist is not the best answer because it will not solve the problem, and the nurse needs to seek clarification from the person who wrote the order. The nurse should suspend administration but not refuse to administer the medication until the issue is resolved. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-7.
4. **Answer:** 1. **Rationale:** All elements such as duty, foreseeability, causation, harm/injury, and damages must be present for professional negligence to be proven. The nurse is a licensed professional responsible for individual actions. Notifying the primary care provider does not exempt the nurse from liability. Because it is apparent the standard of practice was not performed, a breach of duty does exist. Violation/omission of the standard of practice resulted in an excessive dosage. Therefore foreseeability is present; however, no harm occurred to the client. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 4-9.
5. **Answer:** 4. **Rationale:** A sterile, invasive procedure that places the client at significant risk for infection is generally outside the scope of practice of a UAP. Even though the UAP is a nursing student, the agency job description should be followed. The job description is the standard of care in this situation. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-13.

6. **Answer:** 3. **Rationale:** A DNR order only controls CPR and similar lifesaving treatments. All other care continues as previously ordered. Competent clients can still decide about their own care (including the DNR order). Nothing about the DNR order is related to when the client may die. Because clients' medical conditions and their views of their lives can change, a new DNR order is required for each admission to a health care agency. Once admitted, that order stands until changed or until it expires according to agency policy. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 4-7.
7. **Answer:** 3. **Rationale:** The only person entitled to information without written consent is the client and those providing direct care. The nurse has open access to information regarding assigned clients only. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-11.
8. **Answer:** 1, 2, and 5. **Rationale:** The nurse is subject to the limitation of the state law and should be familiar with the Good Samaritan laws in the specific state. Gross negligence would be described by the individual state law. Unless there is another equally or more qualified person present, the nurse needs to stay until the injured person leaves. The nurse should ask someone else to call or go for additional help. Since there was no prior agreement, the nurse cannot accept compensation. Also, the nurse is not employed by the accident victim. The same client rights apply at the scene of an accident as well as those in the workplace. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 4-12.
9. **Answer:** 1, 3, and 4. **Rationale:** Interacting with others (versus isolating self from others) and setting limits on the number of hours working are positive behaviors and not indicative of possible impairment. The other options are warning signs for impairment. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 4-6.
10. **Answer:** 2 and 3. **Rationale:** Standards of practice require a complete assessment. A nurse needs to be sure the client's needs have been met. They both can impact client safety and do not follow standards of care. The other options meet the standards of practice. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 4-7.

Chapter 5: Values, Ethics, and Advocacy

1. **Answer:** 1. **Rationale:** A nurse's actions in an ethical dilemma must be defensible according to moral and ethical standards. The nurse may have strong personal beliefs but distancing oneself from the situation does not serve the client (option 2). A team is not always required to reach decisions (option 3), and the nurse is not obligated to follow the client's wishes automatically when they may have negative consequences for self or others (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 5-2.
2. **Answer:** 2. **Rationale:** The nurse has an ethical responsibility to act only when actions are safe or risks minimized. This nurse is putting the client at unnecessary risk for a medication error. Many medical practices are controversial but not necessarily unethical (option 1). The nurse should follow agency policy. Although some may view nurses' strikes as unethical, supporting others who are striking is a personal decision (option 3). Although a client statement in confidence to a nurse may have ethical overtones, it does not automatically constitute an ethical dilemma. Since the assigned health care provider is a member of the team, principles of confidentiality do not include him or her (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 5-4.
3. **Answer:** 1. **Rationale:** Autonomy is the client's (or surrogate's) right to make his or her own decision. The nurse is obliged to respect a client's or significant other's informed decision. These parents may modify their decision as time goes on and the child's condition, or their feelings, change. This situation is not clearly one of nonmaleficence (do no harm) in option 2 or beneficence (do good) in option 3 since there are many aspects of both. If the child appeared to be suffering or an effective treatment was being denied, these principles might apply. Justice (fairness) generally applies when the rights of one client are being balanced against those of another client (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 5-3.
4. **Answer:** 3. **Rationale:** In values clarification, clients are assisted to think about the factors that influence their beliefs and decisions. Any judgmental statement that reflects the rightness or wrongness of the client's thoughts or actions will impede this process (options 1, 2, and 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 5-2.
5. **Answer:** 4. **Rationale:** A major role of the client advocate is to mediate between conflicting parties. The nurse needs to assess the situation before offering an intervention. Informing the family is an intervention without assessment (option 1). If the primary care provider sends the client home, the nurse has not acted to assist in resolving or reducing the conflict (option 2). If the nurse assists in resolving or reducing the conflict, the added expense of an attorney may not be needed. However, legal action should be a last resort (option 3). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 5-5.
6. **Answer:** 4. **Rationale:** The nurse is obliged to design care and to act according to the professional code of ethics even if the nurse holds different values. The client's need for value-based care takes precedence over the nurse's values; however, nurses can choose not to participate in care with which they have conflicting values (options 1 and 2). The client outcome can be the same even when different moral frameworks are used (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 5-1.

Chapter 6: Health Care Delivery Systems

1. **Answer:** 3. **Rationale:** Actions such as diet modification that help to prevent an illness or detect it in its early stages are primary preventions. Treatment of a disease such as with antibiotic therapy (option 1) or surgery (option 4) is secondary prevention, while rehabilitation efforts following an illness (option 2) are considered tertiary prevention. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 6-1.
2. **Answer:** 2. **Rationale:** City, county, state, or federal government funds pay for health department and agency activities aimed at the global health of the community. Hospitals may provide a variety of wellness and clinic programs in addition to inpatient services (option 1). Surgery may be performed in outpatient surgery centers and physicians' offices in addition to within hospitals (option 3). Skilled nursing, extended care, and long-term care facilities provide care to persons of all ages who require rehabilitation or subacute care. This is not necessarily related to insurance coverage for hospital stays (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 6-2.
3. **Answer:** 1. **Rationale:** Primary care providers are limited to generalist physicians and advanced practice nurses. In some cases a gynecologist may qualify as a primary care provider and in other cases not. Physical therapists (option 2) do not have a scope of practice broad enough to serve as primary care providers. Pharmacists (option 3) and case managers/discharge planners (option 4) are not responsible for providing direct client care. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 6-3.

4. **Answer:** 2. **Rationale:** When people have inadequate insurance for health costs, they tend to avoid early and preventive care. This results in eventual use of much more costly resources such as emergency departments. Methods to provide minimum levels of insurance coverage have been successful in other countries. The number of children is increasing, but in the United States and Canada, this is a nonmodifiable factor (option 1). Also, the majority of health care costs are incurred by adults and older adults who tend to have multiple and chronic health conditions. There is currently a significant shortage of nurses and maldistribution of physicians so reducing their numbers would only worsen the problem (option 3). Competition among manufacturers is more likely to cause costs to fall than to rise (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 6-4.
5. **Answer:** 4. **Rationale:** A health maintenance organization involves a set monthly membership fee and predictable visit or deductible costs. Medicare covers a minimal number of preventive and outpatient services so the cost cannot be anticipated (option 1). Individual fee-for-service insurance is perhaps the most costly to the client, with potentially large differences between the amount of coverage the insurance company pays and the provider's charges (option 2). PPOs are less costly than fee-for-service entities, but more expensive than HMOs (option 3). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Management. **Nursing Process:** Planning. **Learning Outcome:** 6-6.

Chapter 7: Community Nursing and Care Continuity

1. **Answer:** 3. **Rationale:** The *Health System Reform Agenda* (ANA, 2008) called for case management of those with ongoing health care needs. Options 1, 2, and 4 are incorrect because the agenda also proposed that primary care be community based but that essential services be paid for by a combination of public and private funding sources (not just public funds) and be phased in gradually. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 7-1.
2. **Answer:** 1. **Rationale:** The Pew Commission identified the need for modern health care providers to be proficient in the use of technology. Care should be emphasized in primary, rather than tertiary, settings (option 2). The commission also identified the need for contemporary (not traditional) clinical strategies (option 3) and for collaborative decision making with clients (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 7-5.
3. **Answer:** 2. **Rationale:** In community-based health care, clients are cared for according to their geographic locations such as where they live or work, rather than at a major medical center or similar provider setting, which facilitates access. The other options are incorrect because emphasis is more on client wellness and prevention than on illness and may be paid for through any of the usual forms of insurance or payment (including managed care, private pay, or welfare). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 7-4.
4. **Answer:** 2. **Rationale:** In collaboration, each member of the team, including the client, participates in sharing ideas and reaching consensus on the best plan of care. The team is generally led by the health care professional most skilled in the client's specific areas of need (option 1). Once the plan is established, it may be implemented by any member of the team or a designate at an appropriate time and place (option 3). It is not necessarily delegated by the nurse (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 7-6.
5. **Answer:** 4. **Rationale:** Effective discharge planning would have included an assessment of home care needs prior to the client leaving the hospital. The kind of care is determined before the client leaves the
- current setting. That is why it is called discharge "planning." Following a thorough assessment, the client would be taught self-care strategies and a basic plan of care for the coming days (option 3). Obtaining medications and a ride home does not indicate the client possesses the knowledge and skills needed to manage care after discharge (option 2). If the client will need care at home, those referrals would be made by the discharge planner and communicated to the client. Option 4 indicates the client knows and accepts these referrals. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 7-7.
6. **Answer:** 4. **Rationale:** The home health nurse more commonly works with one person or family at one time—addressing their particular needs that may be similar to or different from those of others. The community health nurse will focus on activities that influence the larger group of individuals affected. These include options 1 and 2—prevention and monitoring of infectious disease plus actions that will promote health for multiple affected individuals (e.g., food, water, and shelter). **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 7-5.

Chapter 8: Home Care

1. **Answer:** 3. **Rationale:** Although hospitals have recently become more welcoming to families, a major strength of home care is the involvement and proximity of loved ones. Curative and lifesaving approaches may be used both at home and in the hospital (option 1). An asset of home care nurses is their ability to manage complex symptoms (option 2). This includes expertise in pain management, but the same legal strategies are available in either in-home care or hospitals (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 8-2.
2. **Answer:** 1. **Rationale:** Assuming the client is medically stable, feeding and bathing are tasks within the aide's abilities. Options 2, 3, and 4 are incorrect because teaching the client about or adjusting medications (and oxygen is considered a medication) and performing assessments are duties restricted to the registered nurse. **Cognitive Level:** Applying. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 8-4.
3. **Answer:** 2. **Rationale:** The nurse needs to encourage the client to express feelings or thoughts that led to the refusal so that misunderstandings can be clarified and other possible solutions explored. The nurse should apply the principle that all behavior has meaning. Otherwise, the nurse is intervening before assessing the situation (option 1). The approach in option 3 did not work the first time. A reason for the refusal needs to be explored. Option 4 is almost a threat and has a paternalistic implication. Clients are entitled to make informed decisions to perform or not perform recommended activities. Notifying the primary care provider is implementing an intervention before the nurse has done an assessment. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 8-5.
4. **Answer:** 1. **Rationale:** If the caregiver's own health is becoming threatened, it may be a sign of overload. It would be appropriate for the caregiver to ask for assistance from others (option 2), or to ask for clarification of ways he or she can assist the client (option 3). Sadness related to a poor prognosis would be a normal and expected response as long as it does not evolve into depression (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 8-7.
5. **Answer:** 4. **Rationale:** A physician's authorization of the plan of care is needed before home health care by a nurse can be initiated. Insurance coverage is not required although the agency may need proof of the client's ability to pay if insurance is not available or adequate (option 1).

Many clients benefit from home health care even if there is no in-home caregiver present or needed (option 2). The health problem for which home care is needed may be chronic or acute and may necessitate preventive, curative, or palliative therapy (option 3). **Cognitive Level:** Applying. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 8-3.

6. **Answer:** 1, 3, and 6. **Rationale:** Nurses may work with hospice clients as a subset of home health. In home health, nurses care for both client and family and perform physical, psychosocial, and emotional interventions. Skilled nursing facilities are not considered locations for home health nursing (option 2). Home health can include high-tech equipment and procedures (option 4). Clients may have home care whether or not they can afford other health care. **Cognitive Level:** Remembering. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 8-4.
7. **Answer:** 4. **Rationale:** The emergency response necklace only works within the client's home in proximity to the base station. It will not activate away from home. The client needs to wear it at all times when home. It can be worn when away from home but the client must understand that activating it when away will not summon assistance. It is appropriate for the client to wear a medical alert bracelet at all times (option 1) and have a list of medications posted on the refrigerator (option 2). Area rugs should be removed if clients could trip on them (option 3). **Cognitive Level:** Applying. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 8-6.

Chapter 9: Electronic Health Records and Information Technology

1. **Answer:** 1, 2, 4, and 5. **Rationale:** Technology can facilitate almost every aspect of nursing administration. Both individual employee and overall institutional compliance with accreditation standards and criteria are tracked (option 1). Most common medical diagnoses and costs of all care can be retrieved from the electronic databases (option 2). Financial performance, as well as the results of client satisfaction surveys, are common computer applications (options 4 and 5). Option 3 is incorrect because, although the results of performance appraisals may be entered into a computer program for tracking purposes, it would be an overstatement to say that this indicates which employees are doing the best job since that is a very subjective determination. Computers do a better job in providing concrete, quantitative data. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 9-4.
2. **Answer:** 3. **Rationale:** Control over who has access to confidential computerized data is the greatest concern. Computer hackers can bypass codes and gain access to personal information, which could result in identity theft. The benefits often outweigh the cost (option 1). Computerized data can be much more accurate than paper-and-pencil data (option 2). Due to ease of making copies and backups, electronic data can last forever (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 9-2.
3. **Answer:** 4. **Rationale:** Since learners may do their online work at different times and do much of their work offline, it may be harder for them to feel and act like a class group. The courses are often self-paced and, thus, may take a longer or shorter time to complete than on-campus courses (option 1). Interpersonal communication is possible through e-mail and chat, plus audio and video file sharing allow learners to see and hear the faculty as well as each other (option 2). For most web-based courses, learners may log on at their convenience (option 3). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 9-1.
4. **Answer:** 3. **Rationale:** Although all steps of the research process can be accomplished with and without computers, electronic analysis of quantitative data helps ensure accuracy and speeds the process

immensely. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 9-5.

5. **Answer:** 1. **Rationale:** Each website is different and the practitioner is compelled to evaluate the site and the treatment to determine if it is evidence based, safe, and appropriate for the client. Website-described treatments often report results of extensive research (option 2). One of the most important advantages of posting treatment information and results on the Internet is that many different people can determine if the treatment is useful for their clients (option 3). Some websites are actually advertising, but many are sponsored by legitimate organizations such as the National Cancer Institute (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 9-3.

Chapter 10: Critical Thinking and Clinical Reasoning

1. **Answer:** 2. **Rationale:** The nurse has inferred and concluded something that is beyond the available information (and in this case may not be accurate). The prescription and the diarrhea are facts (option 1). It would be judgment and opinion if the nurse stated that the laxative would make the diarrhea worse and should not be given (options 3 and 4). (*Note:* Critical thinking will cause this nurse to examine the assumptions made and gather more data before acting.) **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 10-1.
2. **Answer:** 1. **Rationale:** The nurse recognizes that many assumptions (beliefs) could interfere with the client eating—such as that the food presented is not culturally appropriate. These assumptions must be clarified with the process of clinical reasoning. Options 2 and 3 reach conclusions not supported by the facts. In option 4, the nurse has made a judgment or has an opinion that may not be accurate. Also, the nurse is acting without assessment. Implementation should be preceded by assessment. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 10-2.
3. **Answer:** 2. **Rationale:** Reviewing evidence-based literature and identifying similarities in the clinical manifestations of symptoms is an act of clinical reasoning. Past experiences in care enhance the nurse's ability to recognize and respond in the delivery of client-centered care. Clinical judgment in nursing is a decision-making process to ascertain the right action to implement at the appropriate time during client care (option 1). Reflection is the nurse's review of the care provided to determine strategies to improve future care (option 3). Intuition is a problem-solving approach that relies on a nurse's inner sense (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 10-2.
4. **Answer:** 1. **Rationale:** The research method uses a research study-based approach to problem solving. Trial and error (option 2) and intuition (option 3) would involve unstructured approaches resulting in less predictable results. The nursing process generally uses application of known interventions, previously determined by the scientific (research) process (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 10-5.
5. **Answer:** 4. **Rationale:** It is important to project what problems might interfere with the plan and have appropriate responses prepared to prevent the interferences. The purpose for the decision should have been clear enough at the outset as to not require reexamination at this point (option 1). Clients and families should be consulted early—in the purpose-setting and criteria-setting steps. Criteria should not be set until all significant participants have an opportunity to present their point of view (option 2). Considering various means for reaching the outcomes is the same as examining alternatives (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 10-4.

6. **Answer: 2. Rationale:** The nurse's intuition is like a sixth sense that allows the nurse to recognize cues and patterns to reach correct conclusions. The nurse appropriately obtains vital signs and an oxygen saturation to assess the client's clinical picture more fully. Option 1 supports appropriate nursing actions, but the client's respiratory status should be assessed first. Usually, a physician must order a chest x-ray (option 2). The rapid response team (option 4) may be needed if the client's condition becomes more critical. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementing. **Learning Outcome:** 10-2.
7. **Answer: 1. Rationale:** By reconsidering the type of dressing used based on research, the nurse is using integrity. Options 2 and 3 are critical thinking attitudes characterized by an awareness of the limits of one's own knowledge, and being trustworthy. Option 4 indicates an attitude of not being easily swayed by the opinions of others. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 10-4.
8. **Answer: 1. Rationale:** Nurses must embrace exploration of the perspectives of individuals from different ages, cultures, religions, socioeconomic levels, and family structures to create environments that support critical thinking. Option 2 relates to nurses who should increase their tolerance for ideas that contradict previously held beliefs. Option 3 is conducted when a nurse benefits from a rigorous personal assessment to determine which attitudes he or she already possesses and which need to be cultivated. Option 4 occurs when nurses find it valuable to attend conferences in clinical or educational settings that support open examination of all sides of issues and respect for opposing viewpoints. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 10-1.
9. **Answer: 2. Rationale:** The nurse recognizes the need to obtain further information from the client in order to respond directly to the client's statement. Option 1 passes off the client's educational needs to another practitioner. Options 3 and 4 are nontherapeutic. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 10-5.
10. **Answer: 4. Rationale:** A nurse thinks critically, evaluates possible solutions, and uses problem solving. Intuition (option 1) is not a sufficient basis for implementing wound care when significant data on alternative care strategies are available. Research (option 2) is a more comprehensive rigorous process and not typically implemented while caring for an infected wound. Trial and error (option 3) is unsafe and inappropriate for care of an infected wound. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 10-5.

Chapter 11: Assessing

1. **Answer: 1. Rationale:** Identifying problems/needs is part of a nursing diagnosis. For example, a client with difficulty breathing would have *Impaired Gas Exchange* related to constricted airways as manifested by shortness of breath (dyspnea) as a nursing diagnosis. Organizing the family history is part of the assessment phase. Establishing goals is part of the planning phase. Administering an antibiotic is part of the implementation phase. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 11-1.
2. **Answer: 3. Rationale:** During assessment, data are collected, organized, validated, and documented. Hypotheses are generated during diagnosing; outcomes are set during planning; and documentation occurs throughout the nursing process. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-1.
3. **Answer: 2. Rationale:** Primary data come from the client (option 4), whereas secondary data come from any other source (chart, family). Subjective data are covert (reported or an opinion), whereas objective data can be measured or validated (weight—option 1, edema—option 3).

If the spouse had stated that the client had eaten only toast and tea, this would be secondary objective (measured) data. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-5.

4. **Answer: 3. Rationale:** Eliciting feelings requires an open-ended question that does more than seek factual information (option 1) and cannot be answered with a single word (option 2). The family can provide indirect information about the client, but is not most likely to provide the most accurate information (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-8.
5. **Answer: 4. Rationale:** Frameworks help the nurse be systematic in data collection. Other members of the health care team may use very different conceptual organizing frameworks so data may not correlate (option 1). Cost-effective care (option 2) is more likely to occur with systematic application of the nursing process, but use of a framework for assessment alone may not accomplish this goal. Because the framework is structured and because of the nature of client needs/problems, creativity and intuition in care planning are not assured (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-10.
6. **Answer: 1. Rationale:** Assessing provides a database of the client's physiological and psychosocial responses to his or her health status. Client strengths and problems (option 2) are identified in the diagnosing phase of the nursing process, a care plan is established (option 3) in the planning phase, and care, prevention, and wellness promotion (option 4) are part of the implementing phase. **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-3.
7. **Answer: 3. Rationale:** In validating, the nurse confirms that data is complete and accurate. Subjective data is collected in the collecting activity (option 1), a framework is applied to the data in the organizing activity (option 2), and data is recorded in the documenting activity (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-4.
8. **Answer: 1. Rationale:** The nursing process focuses on client needs. It is dynamic rather than static (option 2), emphasizes client responses rather than physiology and illness (option 3), and is collaborative rather than used exclusively by nurses (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-4.
9. **Answer: 4. Rationale:** Interpreting collected data is necessary to help validate its accuracy. Observing includes the senses of smell, hearing, and touch in addition to vision (option 1). Using priority setting, observing must often be performed simultaneously with other activities (option 2). A systematic approach to observing data helps ensure nothing is missed and the nurse pays attention to the most important data first (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Assessment. **Learning Outcome:** 11-6.
10. **Answer: 2, 4, and 5. Rationale:** The nurse plans the interview so that privacy is observed. A comfortable distance between nurse and client to respect the client's personal space is about 3 feet. Using a standard form will help ensure the nurse doesn't omit gathering any vital information. Lighting should be at a normal level—neither bright nor dim (option 1). The nurse should be at the same height as the client, usually sitting, at approximately a 45° angle facing the client. The nurse standing over the client creates an uncomfortable atmosphere for an interview (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 11-9.

Chapter 12: Diagnosing

1. **Answer: 2. Rationale:** In diagnosing, data from assessment (option 1) are analyzed and problems, risks, and strengths are identified before diagnostic statements can be established. Interventions (option 3) are more commonly part of the planning and implementing phases of the nursing

- process. Cost (option 4) is an important consideration but would be estimated in the planning phase. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-4.
- Answer: 2. Rationale:** Because the venous return is impaired, fluid is static, resulting in swelling. Therefore, decreased venous return is the cause (etiology) of the problem. *Excess Fluid Volume* is the nursing diagnosis, and edema of the lower extremity is the sign/symptom or critical attribute. The cause is known. **Cognitive Level:** Application. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-6.
 - Answer: 1. Rationale:** States the relationship between the stem (caregiver role strain) and the cause of the problem. Option 2: The diagnostic statement says the same thing as the related factor (falls and collapse). Option 3: It is inappropriate to use medical diagnoses such as stroke within a nursing diagnosis statement. Option 4 is vague. The statement must be specific and guide the plan of care (fatigue may be a result of sleep deprivation and does not direct intervention). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-2.
 - Answer: 4. Rationale:** The PES format assists with comprehensive and accurate organization of client data. More efficient planning may or may not reduce health care costs. Nursing diagnostic statements should be confirmed with the client but using PES does not ensure this. PES statements can be wellness or illness focused. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-5.
 - Answer: 1. Rationale:** A collaborative (multidisciplinary) problem is indicated when both medical and nursing interventions are needed to prevent or treat the problem. If nursing care alone (whether that care involves independent or dependent nursing actions) can treat the problem, a nursing diagnosis is indicated. If medical care alone can treat the problem, a medical diagnosis is indicated. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-3.
 - Answer: 1. Rationale:** A risk nursing diagnosis is appropriate when the evidence for the problem indicates that a condition exists that makes the client vulnerable to a problem. A syndrome diagnosis is assigned by a nurse's clinical judgment to describe a cluster of nursing diagnoses that have similar interventions (option 2). Health promotion diagnoses are used when the client seeks to increase well-being but need not currently be well (option 3). An actual diagnosis is used when the client already exhibits the problem (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-1.
 - Answer: 3. Rationale:** Diagnostic labels are continuously reviewed and revised as indicated by research—much more of which is needed. The original taxonomy has been replaced by Taxonomy II and is no longer based on a nurse theorist (options 1 and 2). New diagnoses are approved by NANDA International's Diagnostic Review Committee, not by a vote of nurses (option 4). **Cognitive Level:** Remembering. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-7.
 - Answer: 1, 4, and 5. Rationale:** A client's movement toward a goal (option 1) or whose behavior is inconsistent with population norms (options 4 and 5) represents a cue that further analysis toward creating a nursing diagnosis is required. Corrected vision (option 2) and bladder and bowel control at age 18 months (option 3) are consistent with population norms. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Diagnosis. **Learning Outcome:** 12-4.
- time (option 1). Of the three types of planning that need to be done at this time, initial is the highest priority since he has just had surgery. The client also requires the ongoing type of planning necessary to determine the care appropriate for this shift (option 2). Discharge planning needs to start on admission to ensure adequate client preparation for management of health needs outside the health agency (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 13-2.
- Answer: 1. Rationale:** Policy and procedure documents provide data about how certain situations are handled. Standardized care plans (option 2) and standards of care (option 4) are written for groups of clients with similar medical or nursing diagnoses. They generally do not address questions such as hospital routines and nonmedical client needs. *Note:* Even hospital policies are not absolute. Each situation must be analyzed and responded to individually. Orthopedic protocols (option 3) would address elements specifically associated with the surgery, not whether the family slept in the room. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 13-5.
 - Answer: 2. Rationale:** More detailed assessment data and consultation with the client would be needed to absolutely confirm the priority. Postoperative nausea to the level of inhibiting oral intake has the greatest likelihood of leading to complications and requires nursing intervention now. The client's pain level is not extreme considering the recency of the surgery, and pain intervention can be assumed to be effective (option 1). Although the constipation is probably bordering on abnormal, a nursing intervention would most likely begin with oral treatment, which is not possible due to the nausea. More invasive interventions such as an enema or suppository would not be commonly administered the first day postoperative (option 3). Wound infection can occur, but there are no data to indicate that this requires a change in the current plan (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 13-5.
 - Answer: 3. Rationale:** The goal or outcome should state the opposite of the nursing diagnosis stem, and thus healthy intact skin is the reverse condition of impaired skin integrity. Turning in bed, applying lotion, and using a special mattress are all interventions that may result in achieving the goal (options 1, 2, and 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 13-8.
 - Answer: 3. Rationale:** Although there may be standard policies or routines for measuring intake and output, the nursing intervention should specify if this is to be done "routinely" or at specific intervals (e.g., q4h). The nurse is also aware, however, that critical thinking indicates that the intake and output should be monitored more frequently than ordered if assessment reveals abnormal findings. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 13-9.
 - Answer: 3, 1, 4, and 2. Rationale:** In planning, first the nurse sets priorities and then writes goals/outcomes, selects interventions, and then writes the nursing care plan. **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 13-1.
 - Answer: 2. Rationale:** Standardized care plans provide a list of interventions from which the nurse can choose. The plan must still be individualized (option 1). Standardized plans could be longer or shorter than nurse-authored ones (option 3), but have not been approved by any outside accreditor (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 13-3.
 - Answer: 1. Rationale:** Goal statements provide the standard against which outcomes are measured. Nursing diagnoses are prioritized before goals are written (option 2). Both independent and dependent interventions may be appropriate for any goal (option 3). Clarity of

Chapter 13: Planning

- Answer: 4. Rationale:** Strategic planning is an ongoing process focused on organizational change rather than individual clients so it is least useful and not relevant in this case. The client requires initial planning because he has just arrived on the orthopedic unit for the first

the goal does not influence delegation of the intervention (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 13-6.

9. **Answer:** 4. **Rationale:** NOC outcomes should reflect both the nurse's and the client's values of what is trying to be achieved. The outcomes still must be customized (option 1), but address only one nursing diagnosis at a time (option 2). Outcomes are narrow/specific end points, not broad (option 3). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 13-7.
10. **Answer:** 1. **Rationale:** Interventions should address the etiology of the nursing diagnosis. Both independent and dependent interventions should be selected if appropriate (option 2) and several interventions may be needed for a single outcome (option 3). Both action and assessment-type interventions can be used (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Planning. **Learning Outcome:** 13-10.

Chapter 14: Implementing and Evaluating

1. **Answer:** 3. **Rationale:** The first step of implementing is reassessing the client to determine that the activity is still indicated and safe. The next action would be to determine if assistance is required (option 2), then implement the intervention (delegating if appropriate) (option 1), and last document the intervention (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Implementation. **Learning Outcome:** 14-3.
2. **Answer:** 4. **Rationale:** It is never acceptable practice for the nurse to document a nursing activity before it is carried out. This would be very unsafe because many things can cause an activity to be postponed or canceled and prior charting would be inaccurate, misleading, and potentially dangerous. In a few situations, it may be permissible to chart frequent or routine activities some time following the activities such as at the end of a shift or after a particular interval (e.g., every 4 hours) rather than immediately following the activity. **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Implementation. **Learning Outcome:** 14-4.
3. **Answer:** 1. **Rationale:** The desired outcomes and indicator statements reflect the parameters by which success will be measured. The goal can be met even if the nursing activities were not carried out or were ineffective (options 2 and 3). Although the desired outcome, by definition, indicates a change in the client's condition (behavior, knowledge, or attitude), only specific changes (desired outcomes) reflect the success of the care plan (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-5.
4. **Answer:** 2. **Rationale:** There is no reason to delete (option 1) or modify (option 3) the nursing diagnosis or demote its priority (option 4) because the risk factors that prompted it are still present. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 14-7.
5. **Answer:** 2. **Rationale:** Because this assessment focuses on how care is provided, it is a process evaluation. A structure evaluation (option 1) would focus on the setting (e.g., how well equipment functions), and outcome evaluations (option 3) focus on changes in client status (e.g., whether reported satisfaction levels vary with type of person who answers the call light). An audit (option 4) would be a chart or document review. **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-8.
6. **Answer:** 1. **Rationale:** During implementing, the nurse also assesses and compares with the initial assessment. Evaluating follows implementing (option 2), mobilization of other health care teams is a part of implementing (option 3), and evaluating occurs during or immediately after each intervention, not waiting for all interventions to be completed (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-1.

7. **Answer:** 3. **Rationale:** This client needs psychosocial support rather than skills related to knowledge (options 1 and 2) or hands-on activity (option 4). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-2.
8. **Answer:** 1, 4, and 5. **Rationale:** Nurses should always have clear rationales for their actions, clients should be given options whenever possible, and client teaching is a constant, integral part of implementing. Primary care provider orders must be critically evaluated and modified to meet individual client needs (option 2). Clients may have nurses provide needed care but should take care of themselves whenever possible since dependency has its own complications (option 3). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-4.
9. **Answer:** 2. **Rationale:** Evaluating requires that client behavior be compared to expected outcomes. Goals may be partially met in addition to completely met or unmet (option 1). An outcome may be achieved but not be a direct result of the plan or interventions (option 3). A care plan should be continued, modified, or terminated based on achievement of outcomes (option 4). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-6.
10. **Answer:** 4. **Rationale:** Quality improvement (QI) plans corrective actions for problems. QI focuses on process rather than outcomes (option 1), client care rather than structure (option 2), and aims for improvement rather than confirmation of quality (option 3). **Cognitive Level:** Understanding. **Client Need:** N/A. **Nursing Process:** Evaluation. **Learning Outcome:** 14-9.

Chapter 15: Documenting and Reporting

1. **Answer:** 3. **Rationale:** All of the other answers endanger the client's confidentiality. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-1.
2. **Answer:** 1. **Rationale:** Critical pathways work best for clients with one diagnosis. Option 2 is a possibility; however, there may be many individualized needs. Because that information is not available, the best answer is 1. Options 3 and 4 have too many diagnoses to work well with a critical pathway. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 15-3.
3. **Answer:** 4. **Rationale:** It is the most complete answer. The client's record is a legal record and should not be altered with correcting liquid. You may see "error" written above a mistake even though many authors suggest not writing it. It is important to also put your name or initials next to the words of the mistaken entry. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-6.
4. **Answer:** 4. **Rationale:** Option 4 is the "best" answer although it could be more complete by adding the response of the primary care provider. Option 1 is too vague because it is not clear if the nurse found the client or was present when the client fell. Also, there is no need to write the word *client* because it is the client's chart. Option 2 is judgmental, revealing a negative attitude toward the person. It would be better to describe specific signs and symptoms such as staggering, slurred speech, and smell of alcohol on breath. Option 3 is too general and can be more specific by charting "2 cm × 3 cm purplish bruise on mid-inner thigh along with color." **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 15-6.
5. **Answer:** 1. No known allergies; 2. Bathroom privileges; 3. When necessary; 4. Diet as tolerated. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-6.

6. **Answer:** 2. **Rationale:** The graphic record provides the trend of the vital signs. Option 1, verbal information, is not appropriate for validation assessment that is measurable. This is more appropriate for pain or dizziness. The medication record would not include documentation of blood pressure ranges (option 3). The progress notes (option 4) provide information about how the client is progressing. It may have information about the client's BP if it was a problem. The best answer is option 2. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 15-4.
7. **Answer:** 1, 2, and 4. **Rationale:** Option 3 is incorrect because it could be a HIPAA violation if others hear protected health information. Option 5 is not needed unless it is a concern and it would not be done for every client. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-8.
8. **Answer:** 2, 3, and 5. **Rationale:** Option 1: "MS" is on the "Do Not Use" list—the nurse needs to write out morphine sulfate. Option 4 has three errors—should not have a trailing zero after the decimal point; "u" and "SQ" are on the "Do Not Use" list. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-7.
9. **Answer:** 1. **Rationale:** Option 1 is the most specific, nonassuming, and nonjudgmental charting. Option 2 could be more specific by describing the lesions and not calling them "burns." Option 3 is making a judgment of elder abuse, and option 4 is also making an assumption that the lesions are from cigarette burns. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 15-6.
10. **Answer:** 1, 2, and 4. **Rationale:** Military time is commonly used; documenting worries or concerns provides clues to other nurses; gossip, unprofessional comments or thoughts, or personnel issues should not be recorded in the client's chart. Option 3 is incorrect because charting should be done as events occur. Waiting until the end of the shift increases the chance of forgetting something. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 15-6.

Chapter 16: Health Promotion

1. **Answer:** 3. **Rationale:** Holism implies consideration of all aspects of the client's life. Although arranging for home care (option 1), facilitating spirituality (option 2), and offering coping resources (option 4) may be appropriate, the nurse begins a holistic approach to care by examining, with the client, in what ways the illness influences the various segments of her life. The client is the best source of information regarding personal needs. Assessment should always precede intervention. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 16-1.
2. **Answer:** 3. **Rationale:** Learning about sleep will increase the older adult's well-being, which is the focus of health promotion. Prevention of falls (option 1) is health protection because the focus is avoiding injury. Learning about cardiovascular risk factors (option 2) relates to health protection/disease prevention. How to stop smoking (option 4) focuses on health protection and avoiding illness. **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 16-5.
3. **Answer:** 2. **Rationale:** Choices are often related to learned experiences, lifestyle, and values. The client obviously values the business more than physical health. When a person feels strongly enough, a lower level need (rest) can be postponed until a higher level need (success, safety) is met. It is very likely that no one else can meet that need for him and the lower need must still be met eventually. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 16-3.
4. **Answer:** 3. **Rationale:** A person in this stage recognizes there is a problem, is seriously considering changing, actively gathers information, and verbalizes plans to change in the near future. Option 1 reflects the precontemplation stage in which the person denies there is a problem. Option 2 reflects the planning stage in which the person makes final plans to accomplish the change, and option 4 is the maintenance stage in which the person made the change and demonstrates the appropriate behavioral change. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 16-8.
5. **Answer:** 2. **Rationale:** Perceived self-efficacy is the confidence the person has for achieving the desired outcome. Option 1 is a person's perceptions about available time, inconvenience, expense, and difficulty performing the activity. Option 3 is the person's perceptions concerning the behaviors, beliefs, or attitudes of others. Option 4 refers to the person's perception of the environment and how it assists or detracts from the healthy behavior. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 16-7.
6. **Answer:** 2, 3, and 5. **Rationale:** The *Healthy People 2020* goals are broad based. Options 1 and 4 are specific methods to promote healthy behaviors and would be seen in the objectives for a *Healthy People 2020* topic area. **Cognitive Level:** Comprehending. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 16-4.
7. **Answer:** 1. **Rationale:** Option 2 is a strategy for the contemplation stage, option 3 is a strategy for the preparation stage, and option 4 is a strategy for the maintenance stage. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 16-9.
8. **Answer:** 4. **Rationale:** Change is a complex process and a nurse should not give up or assume that the client does not want to change (option 1). People often resist a tough approach because it can make them feel cornered. This approach may work for some people but not for everyone (option 2). The goal of teaching is to try to help the client become the expert as well (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 16-11.
9. **Answer:** 1. **Rationale:** The compensatory mechanism of increasing the heart rate is the body's way of trying to balance an ineffective cardiac output since the BP has decreased. Decompensation (option 2) occurs when the compensatory mechanism is ineffective. Self-regulation (option 3) refers to the homeostatic mechanisms that come into play automatically in the healthy person. Equilibrium (option 4) is balance through adaptation to the environment. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 16-2.
10. **Answer:** 3. **Rationale:** Option 1 is a physiological need. Option 2 is a love and belonging need, and option 4 is a safety and security need. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 16-3.

Chapter 17: Health, Wellness, and Illness

1. **Answer:** 3. **Rationale:** Frustration is an example of an emotion. The client who chooses healthy foods (option 1) represents the physical component, taking parenting classes enhances the intellectual component (option 2), and the bowling league (option 4) enhances both the physical and social components. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 17-2.
2. **Answer:** 2. **Rationale:** The mother has taken on the sick role by expecting to be excused from her usual role responsibilities. The sick role states that individuals are not answerable for their illness, contrary to

the obese client's perspective (option 1). In the sick role, the client tries to get better as opposed to the man who misses his physical therapy appointments (option 3). The older adult is not following the sick role expectation to rely on competent help (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Physiological Adaptation. **Nursing Process:** Assessment. **Learning Outcome:** 17-7.

3. **Answer:** 1. **Rationale:** The behavior is most representative of health promotion, which is the central focus of the health belief model. The clinical model focuses on relieving signs and symptoms of illness (option 2). The role performance model emphasizes social activities such as fulfilling a particular role (option 3). The agent–host–environment model focuses on predicting illness (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Analysis. **Learning Outcome:** 17-3.
4. **Answer:** 2, 3, and 4. **Rationale:** Significant evidence exists that a trusting relationship with the provider, effectiveness of the medication, and simple dosing regimen are important predictors of adherence to a medical regimen. Neither education nor sex has been shown to be a predictive factor (options 1 and 5). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 17-5.
5. **Answer:** 1. **Rationale:** Although not always practical, direct observation is the best method to measure adherence (for example, watching heroin addicts actually take their methadone dose). Because lack of adherence may be life threatening or damaging to the client as well as others, waiting until the client displays illness and waiting until laboratory values reflect a lack of adherence are not the best methods (options 2 and 3). Client report or recall is not always accurate, even if the client believes he or she is telling the truth (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 17-5.
6. **Answer:** 4. **Rationale:** The actual term used to describe the diagnosis is less important because the client may have no frame of reference for it. That is not to say that the diagnosis is unimportant because clients may be familiar with common diagnoses such as heart disease or cancer and ascribe historical meaning to them. Ability to perform usual activities, culture, and availability of health care will all be strong influences on the client's definition of health or wellness (options 1, 2, and 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 17-1.
7. **Answer:** 4. **Rationale:** Genetics is an internal variable affecting health. Options 1, 2, and 3 are all external variables. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 17-4.
8. **Answer:** 2. **Rationale:** By definition, a chronic illness has no known cure, the person will always have it to some degree. Although acute illnesses may have severe symptoms, many chronic illnesses also have severe symptoms (option 1). Although signs and symptoms of chronic illnesses may never go completely away, they can get better and worse at different times (option 3). Chronic illnesses can be treated, just not cured (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 17-6.
9. **Answer:** 3, 5, 1, 4, and 2. **Rationale:** The proper sequence of Suchman's stages of illness are signs and symptoms appear, the client takes on the sick role, the client makes contact with medical care, the client takes on a dependent role, and the client goes into rehabilitation/recovery. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 17-8.
10. **Answer:** 1, 2, 3, and 5. **Rationale:** In the sick role, she would likely feel guilt and some anger but give up usual roles and accept help from others, and decrease social interactions. The only reaction that would be unlikely is that the woman would take on a job to pay expenses. This

would be inconsistent with the sick role. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 17-9.

Chapter 18: Culturally Responsive Nursing Care

1. **Answer:** 3. **Rationale:** There is an ongoing shift in the U.S. population that includes a decreasing number of White Americans (formerly the majority population) and an increasing number of other cultural groups. The birth rate is actually decreasing (option 1); limited access to health care is a complex issue that is not the major factor here (option 2); and immigration has increased (option 4). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 18-3.
2. **Answer:** 2. **Rationale:** Cultural differences may result in various interpretations of a medical regime. Cultural competence results in recognition of the right "not to fit." This is a standard of practice and should be initiated with all clients (option 1). Teaching or explaining the effects of lack of adherence would be more appropriate than warning (option 3). Asking a person of the same culture to assist may be helpful after the nurse discusses the matter with the client (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 18-10.
3. **Answer:** 3. **Rationale:** The nurse should indicate that he or she is open to diverse views and practices. Option 1 assumes the client follows this particular cultural practice, which may not be the case. The nurse should assess before intervening. It may be good to learn more about the culture (option 2), but that is not the best starting place to care for the client. Subcultures exist among all cultures. Reading books is helpful, but assessment of individual situations is the best approach. Option 4 reflects an incorrect approach to culturally appropriate care. The nurse needs to assess which customs and practices the individual client performs before drawing conclusions. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 18-10.
4. **Answer:** 3. **Rationale:** Culturally competent implies that, within the delivered care, the nurse understands and attends to the total context of the client's situation, including awareness of immigration, stress factors, and cultural differences. Options 1 and 2 do not show that the nurse needs to respect the choices made by the clients. Option 4 shows bias or stereotyping. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** N/A. **Learning Outcome:** 18-4.
5. **Answer:** 3. **Rationale:** National cultural health goals include providing equal access to quality health care for everyone. It would be inappropriate for all cultures to receive the same care; care should be customized (option 1). The same life expectancy for all U.S. citizens is not realistic (option 2). Assimilation (option 4) is not an appropriate health goal because assimilation is a conscious effect. Therefore, it is not always possible and this may cause severe stress and anxiety. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 18-3.
6. **Answer:** 1. **Rationale:** Herbal teas are an example of a restoring health action. Prayer (option 2) and exercise (option 4) would be examples of maintaining actions, whereas wearing symbolic objects (option 3) is a protective action. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 18-6.
7. **Answer:** 2. **Rationale:** Steam is a natural substance and would be compatible with folk healing preferences. Hospitalization and medications are typical Western medical strategies (options 1 and 3). A watch-and-wait approach (option 4) is not particularly associated with a folk healing perspective. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 18-5.
8. **Answer:** 1, 2, 3, and 6. **Rationale:** Technology skills (option 4) and intelligence (option 5) are individual, personal characteristics and less

influenced by one's culture than valuing of elders (option 1), gender roles (option 2), nonverbal communication (option 3), or diet (option 6). Culture may, however, influence how technologic skills (option 4) and intelligence (option 5) are viewed and valued. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 18-5.

9. **Answer:** 4. **Rationale:** To gather assessment data regarding the client's heritage, nurses must explore clients' beliefs and practices. A good beginning would be to ask clients to indicate from the checklist which apply to them. Physical exam (option 1) and medical history (option 2) may suggest some cultural affiliation but the nurse cannot assume that these findings show significant affiliation from the client's perspective. Blood analysis generally provides little data for a heritage assessment although blood type and some immunologic or genetic data can be relevant (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 18-9.
10. **Answer:** 2. **Rationale:** If an interpreter is not available at your agency, you must still meet the expectations of providing information in a way the client can comprehend it. Providing written instructions, whether in English or the client's language, is insufficient since the client may not be able to read and remains unable to have questions answered (option 1). Family members should not be relied on to interpret medical information (option 3). Option 4 is not an appropriate action. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 18-7.

Chapter 19: Complementary and Alternative Healing Modalities

1. **Answer:** 3. **Rationale:** Although the effectiveness of alternative therapies is sometimes not scientifically established, many people report significant benefit from them for a wide variety of conditions. Alternative therapies often cost less, but this is not a primary consideration (option 1). Clients often seek alternative therapies because traditional therapies are ineffective, but this is not the primary difference (option 2). Both traditional and alternative therapies utilize products from nature (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 19-1.
2. **Answer:** 1. **Rationale:** Spirituality gives us purpose and meaning in life; involves a relationship with oneself, others, and a higher power; and involves finding significant meaning in the entirety of life. Spirituality is a much broader concept than religion and religious services. Responsibility to life patterns is a concept of humanism. **Cognitive Level:** Applying. **Client Need:** Psychological Integrity. **Nursing Process:** N/A. **Learning Outcome:** 19-9.
3. **Answer:** 2. **Rationale:** Healing environments are created when nurses empower clients to make healthy decisions. They are not dependent on technology (option 1) or primary care providers' orders (option 4). A safe physical environment is neither necessary nor sufficient for there to be a healing environment (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 19-2.
4. **Answer:** 4. **Rationale:** Naturopathy focuses on the total person. The primary focus is disease prevention. Naturopathy may be the best choice in decreasing disease rates by empowering and educating people about ways to stay healthy. Belief in a higher being is not a core principle. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 19-5.
5. **Answer:** 2. **Rationale:** Qi is the flow of energy in the body that must be uninterrupted for a person to be in a healthy state. All other imbalances may result from an imbalance in the flow of qi or flow of vital energy through specific anatomic points along the surface of the body (options 1, 3, and 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** N/A. **Learning Outcome:** 19-7.

6. **Answer:** 2. **Rationale:** Thirty percent of current prescription drugs are derived from plants. Herbs and medications are similar in structure and therapeutic value (option 1). Some medications may be more powerful than herbs but not all are (option 3), and herbs tend to be less dangerous than medications (option 4). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 19-4.
7. **Answer:** 1. **Rationale:** Serious interactions can occur between herbs and medications. It is acceptable that people choose herbs as a way to maintain health and treat minor disorders (option 2). Although the knowledge the nurse gains may be helpful, contributing to research is not the primary reason for assessing herb use (option 3). While we hope clients share important information with us, they also have free will about what they choose to share (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 19-10.
8. **Answer:** 4. **Rationale:** The oils in options 1, 2, and 3 will burn the skin if they are not diluted in a carrier oil. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 19-10.
9. **Answer:** 1, 2, 4, and 5. **Rationale:** Massage is a way of communicating without words, including the caring intent of the provider. It provides mental and physical relaxation. Massage speeds the removal of metabolic waste products, allowing more oxygen and nutrients to reach the cells and tissues. It lowers blood pressure and slows the heart rate. Passive exercise from massage cannot strengthen muscles (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 19-6.
10. **Answer:** 1. **Rationale:** There is no evidence that massage (option 2), herbs (option 3), or yoga (option 4) improves pregnancy rates, although relaxation and good physical conditioning are generally encouraged. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 19-10.

Chapter 20: Concepts of Growth and Development

1. **Answer:** 3. **Rationale:** The sequence of each stage of development is predictable, although the time of onset, the length of the stage, and the effects of each stage vary with the person. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 20-2.
2. **Answer:** 4. **Rationale:** The study of growth (physical) and development (function and skills) is correct because the answer needs to have both components to be complete. Option 1 addresses only the growth aspects. Option 2 addresses only developmental aspects, and option 3 addresses only the environmental factors that might influence growth and development. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 20-1.
3. **Answer:** 3. **Rationale:** Toddlers typically demonstrate negative behavior and are hesitant around strangers, resisting close contact with people they do not know well. They do not have sophisticated language skills and often use crying or fussing to communicate. Older school-age children and adolescents are likely to cooperate without complaint in many health procedures (option 1). School-age children, engaged in the task of industry versus inferiority, display curiosity about how things work, asking many questions of nurses (option 2). Preschool-age children, who are in the fantasy, curiosity, and exploration stage, like to manipulate objects and play "pretend" (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 20-7.
4. **Answer:** 4. **Rationale:** Adolescents need to establish identity, which involves developing a more mature sense of independence and responsibility. Providing her with schoolwork keeps her connected to her

- peer group and gives a sense of accomplishment. Also, it prevents the client from “worrying” about getting behind in school assignments. Interaction with peers is very important during this stage, but they are likely to be attending school during the day (option 1); an infant’s sense of trust is reinforced if parents room-in, and older infants and toddlers experience less separation anxiety if parents are nearby (option 2); and preschool and school-age children would benefit from the distraction and social interaction of others in the recreation room (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 20-5.
5. **Answer:** 2. **Rationale:** The client is in Erikson’s stage of integrity versus despair. Finding meaning and purpose in his life after retirement is a sign of achievement. His comments regarding visits to his family and being asked by friends to help with their projects indicate that he is actively involved and purposeful (options 1 and 4). His comment regarding needing medication for knee pain can be expected in many older people, especially those who have been laborers or suffered injury when younger (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 20-5.
6. **Answer:** 2. **Rationale:** This stage includes the preadolescent period. The peer group increasingly influences behavior. Physical, cognitive, and social development increases and communication skills improve. One needs to allow time and energy for the school-age child to pursue hobbies and school activities and to recognize and support the child’s achievement. Option 1 is a judgmental statement as this is not unusual and not indicative of problems in the home. It is good to be supportive of the school-age child; however, making her stay home with her family might cause anger and resentment (option 3). Option 4 is also a judgmental statement. Even though this is normal development, calling the father “silly” is not therapeutic communication. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 20-8.
7. **Answer:** 2. **Rationale:** Erikson’s late childhood stage focuses on initiative versus guilt. During this stage, the children are beginning to have the ability to evaluate their own behavior and are learning the degree to which assertiveness and purpose influence the environment. Option 1 is incorrect because Fowler’s focus is spiritual development. Both options 3 and 4 are names of adult theorists. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 20-7.
8. **Answer:** 1. **Rationale:** Piaget identifies this phase as the intuitive thought phase with significant behaviors as follows: egocentric thinking diminishes, thinks of one idea at a time, includes others in the environment, words express thoughts. Erikson identifies this developmental stage as industry versus inferiority, and the children are learning the degree to which assertiveness and purpose influence the environment. They begin to have the ability to evaluate their own behavior. Fowler identifies this stage as intuitive-projective, a combination of images and beliefs given by trusted others, mixed with the child’s own experience and imagination. Therefore, the nurse knows that this child has a normal imagination and needs to explore and learn about this new piece of equipment in language appropriate to his age. For option 2, imagination is normal for this age group, and stating that he needs to be “a big boy” is counterproductive. Option 3 is incorrect because his language skills are developing and he needs to understand the world around him. Option 4 is incorrect because adding to his fears will only increase his anxiety level and decrease his trust in you as a nurse. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 20-11.
9. **Answer:** 1. **Rationale:** All of the nursing actions listed here are appropriate, but attachment theory emphasizes the importance of parents being available to their child when the child is experiencing stress. The best action would be to encourage the mother to stay with her child as much as possible. Putting a picture of the mother in the crib (option 2) may provide some comfort, since by 15 months of age, children demonstrate object permanence and people permanence, so the child “knows” the mother will return. Holding and cuddling the child (option 3) may also provide comfort, but the child must trust the caregiver, and the nurse’s other responsibilities may restrict the amount of time and when he or she can be with the child. Distraction (option 4) can temporarily refocus the child’s attention, but it does not address the need for emotional and physical contact with the parent. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 20-10.
10. **Answer:** 2. **Rationale:** Although many young adults are choosing to live with their parents, often for economic reasons, option 2 raises concern, because it implies a degree of selfishness and lack of effort to establish independence. This may not be the case, however, and the nurse would need to gather more information before making any judgments. Twenty-five-year-olds, according to psychosocial development theory, have established a sense of self-identity, made a commitment to their community through work and the social group, and are engaged in intimate relationships. According to Erikson, they are in the stage of intimacy versus isolation, moving into the adult stage of generativity versus stagnation. From Havighurst’s perspective, early adults are starting families of their own, managing a home, and taking on the responsibility of work and civic life. Avoiding a relationship and neglecting a career or lifestyle commitment are red flags for failure to achieve developmental milestones at this age. Engaging in healthy exercise (option 1) reflects a quality of self-identity for this individual. Option 3 suggests the client actively cooperates in his recovery and is able to focus on the future (wanting to recover from surgery). Option 4 indicates the client is part of a “congenial social group” (Havighurst). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 20-8.

Chapter 21: Promoting Health from Conception Through Adolescence

1. **Answer:** 4. **Rationale:** Providing opportunities for the parent to express worries and discuss facts about SIDS gives more control over the situation. The nurse can also provide her with information about the Back to Sleep campaign. Option 1: The highest incidence of SIDS occurs between 2 and 4 months of age, but it does occur in older infants. It is not the best response because it provides facts but does not address the parent’s immediate concerns. Option 2: SIDS affects boys more than girls. However, this information is likely to increase anxiety and does not address the concerns of the parent. Option 3: There is no known cause of SIDS, although respiratory problems may be present in some infants. This response is insensitive to the needs of the mother. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 21-8.
2. **Answer:** 3. **Rationale:** Preschool-age children use fantasy and make-believe to learn about, understand, and master their environment, including their concepts of death. The child’s conceptualization of death is consistent with her cognitive development. The response in option 1 negates the child’s understanding and limits her ability to develop fuller understanding and adapt to the loss. Option 2 negates the child’s attempts to understand and deal with the loss. Option 4 is incorrect because at 4 years of age, children can hear explanations such as “when people get old they will die,” but these children do not have a firm grasp of the meaning of time and age, and probably will not understand. **Cognitive Level:** Applying. **Client Need:** Health Promotion/Maintenance and Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 21-6.

3. **Answer:** 1. **Rationale:** It is the responsibility of adults to supervise children constantly and closely when around water. Option 2, learning water safety and how to swim, is important and should be encouraged at an early age, but that still does not ensure a child's safety. Option 3 is incorrect because young children are at risk near any amount of water that can cover the nose and mouth. Option 4: Infants and toddlers can drown in a very small amount of water, even several inches in a bathtub or "kiddie pool." **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment and Health Promotion/Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 21-8.
4. **Answer:** 2. **Rationale:** School-age children acquire stereognosis, the ability to identify an unseen object simply by touch. Option 1: Birth weight triples by about 12 months. Children enter school age weighing about 45 pounds and gain about 5 to 7 pounds per year. Option 3: Significant physical change occurs during the school-age years. Option 4: Fat deposits do not normally appear until puberty. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 21-1.
5. **Answer:** 1. **Rationale:** Increased fat deposits are normal as girls begin hormonal changes of puberty. During this stage of development, females become very sensitive about their appearance and need reassurance. Option 2: Puberty is a period when children become more self-conscious of their appearance. They need to be reassured that normal weight gain and body changes with fat deposits are to be expected. The nurse would need to perform further individual assessments before determining if a weight problem existed. Option 3: Regular strenuous exercise should be a part of the healthy adolescent's lifestyle, but its goal should be to provide energy and strength, not to control weight. Option 4: Dieting and efforts to lose weight can threaten the health of adolescents. This intervention lacks scientific evidence. Unless an actual or potential disease process exists, a balanced diet is most appropriate. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 21-1.
6. **Answer:** 2. **Rationale:** Many newborn babies have a misshapen head because of the molding made possible by fontanelles in the bone structure of the skull and overriding of the sutures. This asymmetry is usually corrected within the first 7 to 10 days. Option 1: The client is crying and upset; the nurse's response needs to be more sensitive and caring. Option 3: Educational materials are not appropriate for a client who is crying and emotionally upset. Option 4: The client is concerned about the misshapen head right now. The most appropriate intervention should focus on relieving the current emotional state. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 21-1.
7. **Answer:** 1. **Rationale:** Although toddlers like to explore the environment, they always need to have a significant person nearby. Parents need to know that young children experience acute separation anxiety and that abandonment is their greatest fear. Option 2: This is normal toddler development. Option 3: Child is probably not old enough to perform manipulative-type strategies. Option 4: This is normal behavior for this age group. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 21-3.
8. **Answer:** 3. **Rationale:** The child can perform regular activities as long as the injured arm and the cast are not placed in jeopardy. Option 1: A competent nurse could answer this question. Option 2: A 5-year-old needs to be physically active. This would be more appropriate for health problems in which moving about could prevent healing or cause injury. Limiting a preschooler to only sitting activities is unrealistic. Option 4: Riding a bike and jumping rope could place the client at risk for injury. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 21-2.
9. **Answer:** 1. **Rationale:** During the phase of concrete operations, children change from egocentric interactions to cooperative interactions. They also develop an increased understanding of concepts that are associated with specific objects. They learn to add and subtract and understand cause-and-effect relationships. Option 2 action is indicative of the pre-conceptual phase—an egocentric approach that uses magical thinking. Option 3 action is indicative of the formal operations phase—reasoning is deductive and futuristic. Option 4 is indicative of physical growth. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 21-4.
10. **Answer:** 1. **Rationale:** Often the first noticeable sign of puberty in females is the appearance of the breast bud, although the appearance of hair along the labia may precede this. Option 2: The growth spurt in girls is between ages 10 and 14, but is too vague to be noticeable. Option 3: The eccrine glands are found over most of the body and produce sweat. The apocrine glands develop in the axillae, anal and genital areas, external auditory canals, and around the umbilicus and the areola of the breasts. Option 4: Mood swings are not as definitive as physical changes. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 21-2.

Chapter 22: Promoting Health in Young and Middle-Aged Adults

1. **Answer:** 3. **Rationale:** The average age for the onset of menopause in American women is 47 years. Therefore, there is nothing abnormal about ongoing menses in a 45-year-old woman, and gynecologic care is not warranted (option 1). As a woman nears menopause, ovulation may become irregular and difficult to predict. Conception remains a possibility, and the lack of predictable ovulation may actually increase the likelihood of unintended pregnancy (option 2). Many women have no negative symptoms of menopause, and the experience of menopause is highly culturally determined (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 22-2.
2. **Answer:** 2. **Rationale:** Generation X is characterized by both skepticism and resentment of people in authority (such as a nurse). Baby boomers tend to be interested in improving themselves, and health teaching may be viewed as self-improvement (option 1). Generation Y and Millennials are the same cohort, and are most likely to receive their health information from technologic sources, such as the Internet (options 3 and 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 22-1.
3. **Answer:** 3. **Rationale:** Lung cancer is the most common cause of cancer death in women age 24 to 65 years. Breast cancer is common, but deaths related to breast cancer have declined. Lymphoma and colon cancer are significant diseases for both men and women (options 2, 3, and 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 22-7.
4. **Answer:** 4. **Rationale:** Although HIV and syphilis may have more disastrous health effects, chlamydia is the most prevalent infectious disease in the United States. Gonorrhea is still common, and its prevalence may vary geographically, but chlamydia is more common and therefore the most likely contracted STI (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 22-9.
5. **Answer:** 2. **Rationale:** Kohlberg's initial work indicated that moral development was completed by adulthood, but more recent research has demonstrated that moral development continues throughout adulthood. Moral development refers to a decision-making process of right and wrong, and proceeds in a series of predictable stages (option 3). Moral development and spirituality are unrelated, and represent very

- different spheres of human thought and behavior (option 4). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 22-5.
6. **Answer:** 2. **Rationale:** The middle-aged person is generally attempting to relate to adult children and grandchildren as well as assisting aging parents. Hence, continuous efforts to meet the needs of others occur. Selecting a life partner is the developmental task for young adults. Reviewing one's life course is the task for older adulthood (option 3). Establishing a sense of self is usually achieved during adolescence (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 22-3.
 7. **Answer:** 3. **Rationale:** Because individuals over 50 years of age tend to have multiple chronic illnesses as well as an aging immune system, the influenza vaccine is highly recommended. Influenza can lead to serious complications in older adults. The pneumococcal vaccine protects against the most common pathogens that cause pneumonia. The vaccine must be given every 10 years. Immunization for pertussis is only appropriate in children, and meningococcal vaccine is appropriate in adolescents and young adults living in congregate housing. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 22-9.
 8. **Answer:** 1, 2, 3, and 5. **Rationale:** Hypertension (elevated blood pressure) forces the heart to work harder, resulting in decreased function of the heart; the electrocardiogram assesses cardiac rhythm and rate; high cholesterol levels are directly related to a decrease in arterial size, which decreases circulation blood to the cardiac tissue; activity level (e.g., dyspnea on exertion) can indicate cardiovascular disease. While cardiac impairment may decrease sexual performance, which is important to assess, the others would have priority given the limitations for the screening program (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 22-9.
 9. **Answer:** 1. **Rationale:** Asking the individual if she or he is afraid of someone at home, or if someone hurt her or him, is a critical step in a comprehensive assessment. Intimate partner violence is a serious problem for women and men of all ages, cultures, and socioeconomic levels. The nurse should suspect it in people whose injuries are not consistent with the history they give. Referring the individual to a shelter without completing a thorough assessment may lead to inappropriate care (option 2); the nursing process requires assessment before intervention. Collaboration with other health care professionals may be very helpful but an assessment needs to be done first (option 3). Documentation of the assessment does not directly address, reduce, nor solve the concern (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 22-7.
 10. **Answer:** 3. **Rationale:** Each of these activities indicates achievement of a developmental task, but the nurse must know which task is appropriate for the client's chronological age. Obtaining and decorating a place to live is an activity that establishes independence from parents, a task for young adults. Creating a scrapbook is an important strategy to enhance ego integrity, a developmental task for older adults (option 1). Working with philanthropic groups is a hallmark of generativity, a developmental task for those in midlife (option 2). Considering career paths is more appropriate to the identity task of adolescence (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 22-3.
- ineffective coping may be a problem. The nurse needs to be attentive to the problem and be prepared to call on appropriate resources, if needed. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 23-11.
2. **Answer:** 3. **Rationale:** Because the hearing loss occurs in the ability to distinguish high-pitched tones, speaking in a low and distinctive voice tone is the most appropriate method of communicating with the clients. Hearing loss in the older adult includes a loss of the ability to discern higher frequencies, and speaking slowly at a particular volume is not the best way to communicate with the clients (option 1). The stem indicates the clients have noticeable hearing loss, but does not indicate the clients are deaf; large lettering is appropriate if the client has a visual problem (option 2); hearing aids are not usually effective when the problem is related to neural damage (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 23-8.
 3. **Answer:** 2. **Rationale:** Reminiscence about past life events, doing a "life review" of past experiences, especially if they were positive, is considered to be a normal psychosocial activity of older adults. It helps them focus on past accomplishments and contributions to society, thus increasing their self-concept. If behavioral or significant memory problems had been noted, then a geriatric psychiatric consult would be appropriate, but not in this situation (option 1). Other social activities and conversations should certainly be encouraged, but not to the point of demeaning the importance of his life stories (options 3 and 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 23-12.
 4. **Answer:** 4. **Rationale:** It is a myth regarding the aging process that most old people are depressed. By relating that depression is not a normal part of aging, the nurse can further dialogue with the daughter. The older client's number of losses is less important than how she copes (option 1). A depressed affect may be the older adult's usual look (option 2). It is yet to be determined if in fact she is depressed (option 3). **Cognitive Level:** Remembering. **Client Need:** Safe and Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 23-15.
 5. **Answer:** 3. **Rationale:** This option will provide the nurse with the most information for potential intervention. Options 1, 2, and 4 are incorrect because urinary incontinence is not normal and it is something the nurse should investigate. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 23-15.
 6. **Answer:** 1. **Rationale:** The client has lost muscle strength. Strengthening exercises will improve his mobility and lessen the possibility of a fall. Option 2: Information indicates the client has difficulty rising from a seating position, not standing after he reaches the position; further assessment is needed before implementing this intervention. Option 3: Praise should come after the proper intervention is implemented and a plan is in place so that the praise is focused toward a goal to resolve the problem. Option 4 resolves the problem immediately but does nothing to resolve the underlying problem. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 23-8.
 7. **Answer:** 4. **Rationale:** Sexual activity is possible for older adults although the responses are slower. The clients would need a health history and physical assessment of the cardiovascular system before drawing this conclusion (option 1). With the introduction of Viagra, older men are more able to perform than in the past (option 2). Older men's interest tends to decline, but it is not known whether it is related to impotence; apparently this older client is interested in sexual activity (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 23-16.

Chapter 23: Promoting Health in Older Adults

1. **Answer:** 1, 3, and 4. **Rationale:** Grieving is a normal behavior after the death of a loved one, and the behaviors listed in options 1, 3, and 4 indicate signs of normal grieving. When grieving becomes extreme, and signs of self-neglect or alcohol or substance abuse are obvious,

8. **Answer:** 3. **Rationale:** Presbyopia is loss of near vision related to aging. Option 1 is loss of hearing ability related to aging. Option 2 is dry mouth related to a decrease in saliva, and option 4 is a decrease in the motility of the esophagus related to aging. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 23-8.
9. **Answer:** 4. **Rationale:** This response reflects an understanding of the different stages of independence and control an older adult experiences when admitted to the hospital and the need for the nurse to assess the client's need for control and autonomy. After admission, the client willingly gives up autonomy to the hospital routine because the client wants to get better (option 4). As the client's health improves and progresses, he or she wants to increase autonomy (option 1). Before discharge the client is thinking about if he or she can go home (option 2). Option 3 is not realistic given the usual hospital routine. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 23-6.
10. **Answer:** 3. **Rationale:** The nurse treats the older woman with empathy. Saying the sister is dead may trigger agitation or an argument. It may start the grieving process all over again and be distressing for the woman (option 1). These responses should be avoided. It is more compassionate to focus on the woman's feelings, and encourage her to talk about her sister and remembered events. Long-term memory remains functional in many clients with dementia compared to short-term memory. By having her reminisce, the nurse can stimulate the woman's recall of events from a long time ago (option 3). It is deceptive to say the sister won't visit today or that the woman should wait to see if she does visit today (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 23-12.

Chapter 24: Promoting Family Health

1. **Answer:** 1. **Rationale:** Grandparents, aunts, and uncles are considered extended family members. Parents and spouse are considered immediate family members. Children who no longer live at home are considered immediate family members. Roommates and close family friends may be considered extended family members if grandparents, aunts, and uncles do not exist. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-2.
2. **Answer:** 4. **Rationale:** The data indicate that Mary is at the greatest risk of developing a health problem due to her stress of repeating a year of high school, many colds, drug use, and no support indicated beyond her family. Although Alice has a heart problem, she also has strong support medically and spiritually. Bill has asthma but no other risk factors are identified. Kim has back problems, is the mother of four children, and is married for the second time to an alcoholic and is also at risk, but not as great a risk as Mary. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosis. **Learning Outcome:** 24-5.
3. **Answer:** 1. **Rationale:** The health history of the client's current living partners is critical information since many illnesses are communicable or environmental. Giving this advice, the nurse also validates that family are whoever the client says they are. History of illness data of blood relatives is also extremely valuable and should always be included, whether or not the client lives with them. Neither the history nor the physical exam is more important than the other—both are necessary for a complete plan of care. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-4.
4. **Answer:** A visual representation of family members by gender, age, health status, and lines of relationships through the generations is referred to as a genogram. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 24-4.
5. **Answer:** 1, 2, and 4. **Rationale:** It is essential for the nurse to determine the duration of the illness, the meaning of the illness to the family and its significance to family systems, and the financial impact of the illness in order to completely assess the impact of the illness on the family as a whole. Duration of the illness will determine the degree of disruption and adaptation required. These factors affect the members of the family in addition to the ill client. Option 3: Coping mechanisms used by other families with similar illnesses may not be relevant because families vary greatly in their makeup and function patterns. Option 5: Knowing the incidence of the illness in the community at large is an important factor for the community health nurse in exploring epidemiologic issues such as prevention strategies and public health policies but is not as relevant for assisting the particular family. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 24-6.
6. **Answer:** 1. **Rationale:** Presenting to the clinic indicates the family is probably ready to face the health challenges caused by the previous activities. There is no evidence that the adult child or parent is experiencing disabling coping (option 2). *Impaired Parenting* applies when the parent is unable to care for a child rather than the reverse. Although some strain must be experienced by the child, evidence does not indicate that *Caregiver Role Strain* is the most important aspect of the situation. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosis. **Learning Outcome:** 24-6.
7. **Answer:** 3. **Rationale:** Establishing trust allows for effective communication and confirms that there is mutual commitment to the goals. Meetings with the family as a group should be goal oriented. A trusting relationship is important for communication as well as accepting and implementing a plan. While considering the cost of health care is important, it does not take priority over a trusting relationship with the nurse. A detailed history and examination of each family member is relevant but family members or the family as a whole will need to trust the nurse before providing the information. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 24-6.
8. **Answer:** 4. **Rationale:** The focus of activity on personal purposes does not promote effective family functioning. A family system that functions efficiently focuses primarily on purposes involving the total system, allows input from the outside, has personal boundaries that are well defined, and interdependent family members. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 24-3.
9. **Answer:** 2. **Rationale:** A family should provide an environment that supports the growth of the individual members. It is neither possible nor appropriate for the family to try to provide everything each member wants (option 1), nor that members are accepted into society (option 3). Although the family protects its members, a healthy family will share and use appropriate resources with the broader community (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 24-1.
10. **Answer:** 3. **Rationale:** A family with sudden loss of income and health insurance is at the greatest risk for developing a health problem because it may no longer be able to afford preventive or therapeutic care. Having family members in many different developmental stages may cause stressors but this is not of high priority (option 1). The history of adult-onset diabetes on the 42-year-old father's side and the sedentary lifestyle should be addressed but will not likely cause immediate health problems (options 2 and 4). **Cognitive Level:** Analyzing. **Client Need:** Health promotion and maintenance. **Nursing Process:** Planning. **Learning Outcome:** 24-5.

Chapter 25: Caring

- Answer:** 2. **Rationale:** This assessment activity gathers more information to help the nurse know the client's usual self-care practices. Option 1 aims to provide comfort. Option 3 is a therapeutic, not an assessment, activity. Option 4 does not meet the aim of knowing the client. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 25-4.
- Answer:** 1. **Rationale:** Teaching the client to make self-care decisions at home empowers him to care for his illness. Empowerment is not the primary goal for options 2, 3, and 4. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-4.
- Answer:** 3. **Rationale:** Mayeroff defines patience as "allowing the other to grow in his own way and time." Options 1, 2, and 4 are not clearly the goal. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 25-3.
- Answer:** 1. **Rationale:** In this situation, culture care diversity addresses the differences between Indonesian medical practices and traditional American practices. Universality addresses the similarities among the cultures. Since Leininger's theory addresses cultural elements relevant to nursing, options 2, 3, and 4 are incorrect. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 25-2.
- Answer:** 3. **Rationale:** This represents an ethical dilemma. Options 1, 2, and 4 are ways of knowing less clearly related to the situation. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 25-6.
- Answer:** 1. **Rationale:** The nurse's presence is most significant in this situation. Assessment (option 2), knowing the client (option 3), and empowering the client (option 4) are not the focus of the nurse's action. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 25-6.
- Answer:** 2. **Rationale:** As depicted in Figure 25-1, this is the model for the theory of bureaucratic caring. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 25-2.
- Answer:** 1. **Rationale:** Empirical knowing is gained from studying scientific models and theories. Aesthetic knowing arises from application in practice (option 2). Personal knowing arises from self-examination (option 3). Ethical knowing arises from confronting conflicting values (option 4). **Cognitive Level:** Applying. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 25-3.
- Answer:** 4. **Rationale:** Meditation involves the described behaviors. Storytelling involves communication with others (option 1). Yoga combines various postures with breathing practices (option 2). Music therapy involves listening to music (option 3). **Cognitive Level:** Analyzing. **Client Need:** N/A. **Nursing Process:** N/A. **Learning Outcome:** 25-5.
- Answer:** 3. **Rationale:** Twenty-five minutes of vigorous activity 3 days a week is the recommendation for a healthy lifestyle. Ten minutes is an insufficient amount of time for moderate exercise (option 1), as is 20 minutes (option 2). Daily vigorous activity for 30 minutes may be too strenuous (option 4), depending on the client's level of conditioning. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 25-6.

Chapter 26: Communicating

- Answer:** 3. **Rationale:** Nonverbal, gentle touch is an important tool; overstimulation may affect the client in a negative way. Option 1: Written communication requires a higher level of consciousness than verbal. Option 2: The client does not have a hearing problem but lacks the ability to interpret and understand communication. Option 4: Lack of facial expression may increase fear. **Cognitive Level:** Applying. **Client**

Need: Psychosocial Integrity. **Nursing Process:** Implementation.

Learning Outcome: 26-9.

- Answer:** 3, 1, 2, 4. **Rationale:** During the preinteraction phase (option 3), the nurse gathers information about the client before meeting the client. During the introductory phase (option 1), the nurse usually engages in some social interaction to put the client at ease. During the working phase (option 2), the nurse helps the client to explore feelings and helps the client plan a program. During the termination phase (option 4), the nurse summarizes or reviews the process that took place. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 26-6.
- Answer:** 1 and 3. **Rationale:** Options 1 and 3 are listening behaviors; options 2, 4, and 5 are barriers to listening. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-4.
- Answer:** 1. **Rationale:** Respect is correct because the nurse is validating the client's feeling. It is not genuineness (option 2) because the nurse is giving information versus being genuine. Concreteness (option 3) is giving a specific example. The nurse is not confronting (option 4) but supporting through respect for the client's feelings. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-6.
- Answer:** 2. **Rationale:** Because anxiety and low self-esteem precede powerlessness, which results in indecisiveness, it is the most correct answer; nursing management always deals with the client's current display of needs. Options 1 (anxiety) and 3 (low self-esteem) may cause a sense of powerlessness that results in indecisiveness. Option 4: There is no evidence that the client's social interactions are less than adequate. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 26-9.
- Answer:** 2 and 3. **Rationale:** Assessing possible visual or hearing problems allows the nurse to provide appropriate interventions (e.g., inserting hearing aid). Communicating what will be occurring at a stressful time helps the client feel more secure and can reduce anxiety. Option 1 is not the best answer as the client could say yes/no or nod the head and the nurse will not know if the client fully understands. It would be better to ask the client to tell you where he or she is. Option 4 is important to do; however, immediately after surgery is not the best time as the client may be in pain and/or groggy from the anesthesia. Option 5 is false reassurance because the nurse does not know if the client is going to feel better. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-4.
- Answer:** 3. **Rationale:** All of the other options are forms of elderspeak. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-3.
- Answer:** 4. **Rationale:** Option 4 is a therapeutic technique using an open-ended question that allows the client to elaborate. The other options are barriers to communication. Option 1 is incorrect because the client did not ask about the abilities of the surgeon and the response does not focus on the client. Option 2 is changing the subject, and option 3 is giving advice. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 26-9.
- Answer:** 2. **Rationale:** Option 2 uses an "I" statement, which is assertive communication and is clear and direct. The message includes only the necessary information. Option 1 contains inflammatory language ("ineffective" and "you prescribed"). Options 3 and 4 do not provide the health care provider with specific information and could stimulate defensive behaviors. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 26-12.
- Answer:** 1. **Rationale:** It encourages the client to verbalize and choose the topic of the conversation. Option 2 is used when the nurse is

unsure of the message and asks the client to repeat or restate the message. Option 3 is used to help a client differentiate the real from the unreal, and there is no information available to indicate this is a concern in this situation. Option 4 is used at the end of an interview or teaching session. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 26-4.

Chapter 27: Teaching

- Answer:** 2. **Rationale:** Options 1 and 3 are psychomotor, and 4 is under the cognitive domain. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 27-3.
- Answer:** 3. **Rationale:** Options 1 and 2 are passive learning strategies. Learning is faster and retention better when the learner is actively involved. Option 4 promotes affective learning about adapting to a chronic health condition and is important. However, the question asks about learning diet information. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 27-9.
- Answer:** 2. **Rationale:** The client most ready to learn is experiencing or has recently experienced the least amount of stress or is the least preoccupied with other concerns. There will be no separation anxiety because the parents are present. The storybook may allow the child to learn information about the hospital and ask questions. The client in option 1 will be preoccupied by his illness. The client in option 3 is most likely still in pain. It would be better to wait until the pain is resolved. It would also be important to check if the client is too sleepy because pain medication can have that effect also. The client in option 4 may be too tired after his physical therapy treatment. This would need to be assessed. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 27-5.
- Answer:** 1. **Rationale:** Individuals learn in various ways, such as visually, group learning, auditory, and participatory. The individual knows how learning has occurred in the past. Option 2 is a component of the implementation phase of teaching, and the question is asking how to assess a client's style of learning. Options 3 and 4 involve others and it is best to ask the client. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 27-7.
- Answer:** 3. **Rationale:** Option 1 is an old diagnosis, which has been changed. Option 2 is a wellness nursing diagnosis; the data would need to address that the client is seeking health information and why in order to be the correct answer. The diagnosis of *Noncompliance* is associated with the intent to comply, but situational factors make it difficult. The data in the question do not support option 4. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 27-9.
- Answer:** 2, 3, and 5. **Rationale:** Options 2, 3 and 5 are open-ended questions that will give the client the opportunity to provide information that will help the nurse assess level of knowledge and subsequently provide/discuss needed information with the client. Options 1 and 4 are closed-ended (yes/no) questions. A "no" answer may cause a discussion but it will be difficult for the nurse to assess if it is the information the client really wants to know. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 27-7.
- Answer:** 1, 2, 3, and 4. **Rationale:** All of these statements could indicate a low literacy skill. The nurse will need to assess which teaching strategies will be most appropriate and will also need to carefully evaluate if the client has learned the skill and necessary information. Option 5 reflects an ability to read the material with a request for additional clarification. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 27-8.

- Answer:** 3. **Rationale:** All are important factors to assess. The priority, however, would be the potential economic factor because the medications can be very expensive and the client may not take them if he or she cannot afford them. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 27-7.
- Answer:** 3. **Rationale:** This option is the easiest for the nurse to evaluate. Option 1 is difficult to evaluate because "understand" is too vague. Option 2 refers more to an affective outcome and the question is asking about a cognitive outcome. Option 4 is telling more about the husband than the client. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 27-13.
- Answer:** 2. **Rationale:** This is the only option that clearly reflects the teaching process, evaluation method, and the response of the client indicating evidence of learning. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 27-14.

Chapter 28: Leading, Managing, and Delegating

- Answer:** 1. **Rationale:** This is a situation in which urgent decisions are needed, and one person provides instructions without input from others (autocratic). This is especially appropriate if the rest of the group is not functioning at an appropriate level. Option 2 would be found in shared governance structures when the risks are low and there is time for collaboration. Option 3 is most effective in groups with high levels of professional and personal maturity and where cooperation and coordination are not significant. Option 4 involves the rigid use of rules. Because managing casualties is a highly unpredictable activity, enforcement of rules is not appropriate. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** N/A. **Learning Outcome:** 28-2.
- Answer:** 1. **Rationale:** In this situation, the manager needs to verify and clarify the client's statement with the assigned nurse before taking any direct action. Assigning another nurse to administer the client's medications (option 2) could be dangerous because it assumes the client is accurate in his statement. It is premature to review proper medication procedures with the nurse before knowing for certain that the procedure has not been followed (option 3). If the manager determines that there is disagreement about whether or not the medications have been given, it might be appropriate for the manager, nurse, and client to discuss the situation together (option 4) but certainly not before the manager has a private conversation about the situation with the nurse. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 28-7.
- Answer:** 2. **Rationale:** The manager is responsible for evaluating the staff (accountable) but has no authority to terminate staff who do not meet the standards nor promote staff with outstanding performance. In option 1 the manager has authority to carry out the reduction, but is not accountable because the actions were delegated and not initiated independently. In option 3, the manager has only responsibility; in option 4, both authority and accountability. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 28-6.
- Answer:** 3. **Rationale:** A fresh postoperative client is, by definition, in a somewhat unstable condition and the nurse must assess and supervise this initial transfer. A UAP should be able to perform the transfer safely with a new wheelchair; the scenario does not indicate that the wheelchair had special features (option 1) or that the client is an older adult. Age does not determine need for assistance and the UAP should be able to transfer the older adult client (option 2). The task is simple and can be easily recalled safely after an absence (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 28-8.

5. **Answer:** 4. **Rationale:** Interaction between the two groups may lead to a compromise. Option 1: Although explaining the reasons for the desired change is useful, overemphasis on the rationale may not be useful since resistance is often more emotional than rational. Option 2: This situation does not meet the criteria for an autocratic leadership style. There is no urgency and the task primarily involves the staff. Option 3: If the manager were not solidly committed to the new proposal, it should not be introduced, because it will result in unnecessary disturbance. Option 4: The manager should be open to modification of the proposal if justified. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Implementation. **Learning Outcome:** 28-10.
6. **Answer:** 2. **Rationale:** Managers are employees and have been given authority by the institution for which they work. The other options are characteristic of leaders more than managers. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** N/A. **Learning Outcome:** 28-1.
7. **Answer:** 2, 3, and 5. **Rationale:** An effective leader is open to members' views on both sides of issues, orchestrates group activities, and is open to and solicits feedback on their style. They use the style most natural to them rather than adopt another (option 1) and use a style appropriate to the situation and the groups as a whole, not varying for each member (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 28-3.
8. **Answer:** 3. **Rationale:** Middle managers supervise first-level managers and serve as liaison between first- and upper-level managers. First-level managers supervise nonmanagerial staff (option 1) and report institutional changes to direct-care staff (option 2). Creating institutional goals and strategic plans is the responsibility of upper-level managers (option 4). **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 28-4.
9. **Answer:** 4. **Rationale:** Evaluating outcomes and effectiveness is part of the coordinating function of management. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** N/A. **Learning Outcome:** 28-5.
10. **Answer:** 3. **Rationale:** In this situation, the UAP was not given the right direction and communication—that the client was not permitted to be out of bed. UAPs commonly weigh clients so it was the right task and right person (options 1 and 2). Although supervision might have prevented the error, it was the nurse's responsibility to tell the UAP of the client's mobility status and, if necessary, the proper way to weigh such a client (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Planning. **Nursing Process:** Evaluation. **Learning Outcome:** 28-9.

Chapter 29: Vital Signs

1. **Answer:** 2. **Rationale:** Although the temperature is slightly lower than expected for the morning, it would be best to determine the client's previous temperature range next. This may be a normal range for this client. Depending on that finding, the nurse might want to retake it in a few minutes—no need to wait 15 minutes (option 3) or with another thermometer to see if the initial thermometer was functioning properly. Chart after determining that the temperature has been measured properly (option 4). **Cognitive Level:** Applying. **Client Need:** Health Maintenance and Promotion. **Nursing Process:** Assessment. **Learning Outcome:** 29-4.
2. **Answer:** 3. **Rationale:** The apical rate would confirm the rate and determine the actual cardiac rhythm for a client with an abnormal rhythm; a radial pulse would only reveal the heart rate and suggest an arrhythmia. For clients in shock, use the carotid or femoral pulse (option 1). The radial pulse is adequate for determining a change in the orthostatic heart rate (option 2). The radial pulse is appropriate for routine postoperative vital sign checks for clients with regular pulses (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 29-5.
3. **Answer:** 4. **Rationale:** Since the client's needs are always considered first, the measurement should be delayed unless the client is in distress or there are other urgent reasons. Option 1: Respirations should be measured for 30 seconds to 1 minute and are affected by talking. Option 2: There needs to be an important reason for interrupting the client. Option 3: It is inappropriate to wait and listen to the client's conversation. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 29-3d.
4. **Answer:** 2. **Rationale:** If the cuff is inflated to about 30 mmHg over previous systolic pressure, that would be 168. To ensure that the diastolic has been determined, the cuff should be released slowly until the mid-60s mmHg (and then completely) for someone with a previous reading of 74. The cuff should be deflated at a rate of 2 to 3 mm per second. Thus, a range of 90 mmHg will require 30 to 45 seconds. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 29-3e.
5. **Answer:** 1. **Rationale:** Vital signs measurement may be delegated to UAP if the client is in stable condition, the findings are expected to be predictable, and the technique requires no modification. Only the preoperative client meets these requirements. In addition, UAP are not delegated to take apical pulse measurements for the client with an irregular pulse as would be the case with the client newly started on antiarrhythmic medication (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 29-8.
6. **Answer:** 3, 4, and 5. **Rationale:** For this client, the nurse could take an axillary, tympanic, or temporal artery temperature. Due to the facial drooping and difficulty swallowing, the oral route is not recommended (option 1). Although the rectal route could be used, it would require unnecessary moving and positioning of a client who cannot assist, and it would not provide a significant advantage over the other routes (option 2). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 29-1.
7. **Answer:** 4. **Rationale:** The posterior tibial and pedal pulses in the foot are considered peripheral and at least one of them should be palpable in normal individuals. Option 1: A bounding radial pulse is more indicative that perfusion exists. Options 2 and 3: Apical and carotid pulses are central and not peripheral. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcome:** 29-9.
8. **Answer:** 3. **Rationale:** Dyspnea, difficult or labored breathing, is commonly related to inadequate oxygenation. Therefore, the client is likely to experience shortness of breath, that is, a sense that none of the breaths provide enough oxygen and an immediate second breath is needed. Option 1: Shallow respirations are seen in tachypnea (rapid breathing). Option 2: Wheezing is a high-pitched breathing sound that may or may not occur with dyspnea. Option 4: The medical term for coughing up blood is hemoptysis and is unrelated to dyspnea. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 29-7.
9. **Answer:** 3. This blood pressure should be recorded as 180/105/95 mmHg using the systolic/1st diastolic/2nd diastolic convention. **Rationale:** Phase 1 first sound is a clear tapping when deflation of the cuff begins. Phase 2 has a muffled, swishing sound. In phase 3, blood is flowing freely via an increasingly open artery; sounds are more crisp and more intense but softer than phase 1. Phase 4 sounds become muffled and have a soft blowing quality. In phase 5 the last sound is heard followed by silence. **Cognitive Level:** Analyzing.

Client Need: Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 29-9.

10. **Answer:** 4. **Rationale:** The SpO₂ in this case is 97%. Option 1 indicates the systolic blood pressure of 121 mmHg, option 2 the mean arterial pressure of 95 mmHg, option 3 the pulse of 87 beats/min, and option 5 the diastolic blood pressure of 84 mmHg. In addition, the client's temperature is shown. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 29-3f.

Chapter 30: Health Assessment

- Answer:** 2. **Rationale:** Resonance is a normal sound over the lung. Tympany would be heard over the stomach (air filled) (option 1), hyperresonance is never a normal finding (option 3), and dullness would be heard below (not above) the 10th intercostal space (option 4). **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 30-3; 30-4k.
- Answer:** 4. **Rationale:** The client should sit for examination of the head and neck. For palpation of the abdomen (option 1), genitals (option 2), and breast (option 3), the client should be supine. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 30-2.
- Answer:** 1. **Rationale:** A bruit suggests abnormal turbulence in the aorta, and the primary care provider must be notified. For absence of bowel sounds to be considered abnormal, they must be silent for 3 to 5 minutes (option 2). Continuous bowel sounds are normally heard over the ileocecal valve following meals (option 3). Bowel sounds are more commonly irregular than they are regular (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 30-3; 30-4o; 30-8.
- Answer:** 1. **Rationale:** If a pedal pulse, which is more distal than the popliteal, is present, then adequate arterial circulation to the leg is present even though the popliteal artery has not been located. Presence of a femoral pulse would not provide confirmation that arterial flow exists below that point (option 2). Taking a thigh BP requires locating the popliteal pulse (option 3). Because the purpose of finding the popliteal pulse is to provide information about arterial circulation to the leg, checking the distal pulse before requesting assistance from another nurse is appropriate (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcomes:** 30-3; 30-4m.
- Answer:** 2. **Rationale:** Visual acuity often lessens with age. Facial hair is likely to become coarser, not finer (option 1). The sense of smell becomes less, rather than more acute (option 3). The respiratory rate and rhythm is regular at rest (option 4). However, both may change quickly with activity and be slow to return to the resting level. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluating. **Learning Outcome:** 30-3.
- Answers include color, turgor, temperature, moisture, lesions, odor, and edema. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 30-4b.
- Answer:** 3. **Rationale:** Recent memory includes events of the current day. Recalling a series of numbers tests immediate recall (option 1). Recalling childhood events tests remote (long-term) memory (option 2), and subtracting backwards from 100 tests attention span and calculation skills (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcomes:** 30-3; 30-4q.
- Answer:** 4. **Rationale:** If the client can only read the first three lines, vision is impaired and could lead to falls or other injuries. This impaired vision is not related to deficient knowledge (option 1) or memory

(option 2) and may or may not be related to circulation (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcomes:** 30-3; 30-8.

- Answer:** 3. **Rationale:** Use the pads of two fingers and a gentle rotating motion over the nodes. None of the other options is proper palpation of lymph nodes. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 30-2.
- Answer:** Of the terms listed, only equal, symmetrical, and firm are normal findings. Atrophied, flaccid, contractured, hypertrophied, crepitation, spastic, and tremor are abnormal findings. Review the terms in the glossary to go over their meanings. **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcomes:** 30-4p; 30-8.

Chapter 31: Asepsis

- Answer:** 2. **Rationale:** Blocking the movement of the organism from the reservoir will succeed in preventing the infection of any other individuals. Since the carrier individual is the reservoir and the condition is chronic, it is not possible to eliminate the reservoir (option 1). Blocking the entry into a host (option 3) or decreasing the susceptibility of the host (option 4) will be effective for only that one single individual and, thus, is not as effective as blocking exit from the reservoir. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 31-9.
- Answer:** 1. **Rationale:** Since the hands are frequently in contact with clients and equipment, they are the most obvious source of transmission. Regular and routine hand hygiene is the most effective way to prevent movement of potentially infective materials. PPE (gloves and masks) is indicated for situations requiring standard precautions (option 2). Isolation precautions are used for clients with known communicable diseases (option 3). Routine use of antibiotics is not effective and can be harmful due to the incidence of superinfection and development of resistant organisms (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-8.
- Answer:** 3. **Rationale:** Standard precautions include all aspects of contact precautions with the exception of placing the client in a private room. A mask is indicated when working over a sterile wound rather than an infected one (option 1). Disposable food trays are not necessary for clients with infected wounds unlikely to contaminate the client's hands (option 2). Sterile technique (surgical asepsis) is not indicated for all contact with the client (option 4). The nurse would utilize clean technique when dressing the wound to prevent introduction of additional microbes. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-10.
- Answer:** 1. **Rationale:** Unless overly contaminated by material that has splashed in the nurse's face and cannot be effectively rinsed off, goggles may be worn repeatedly (option 1). Since gowns are at high risk for contamination, they should be used only once and then discarded or washed (option 2). Surgical masks (option 3) and gloves (option 4) are never washed or reused. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-11b.
- Answer:** 4. **Rationale:** It should not be necessary to unroll this small edge of the cuff. The most important consideration is the sterility of the fingers and hand that will be used to perform the sterile procedure. The rolled-under portion is now contaminated and should not be unrolled by the nurse or colleague since it would then touch the remaining sterile portion of the glove (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 31-11d.

6. **Answer:** 2, 3, and 4. **Rationale:** Flu shots are recommended for all adults over age 50. Only adults at risk need to receive hepatitis B and A vaccine (note that this is different than for children). Options 1 and 5 are incorrect because all adults should receive a tetanus booster every 10 years (or sooner if injured) and adults over age 60 should receive the herpes zoster vaccination. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcomes:** 31-8; 31-6.
7. **Answer:** Because a malnourished client with a wound is less able to resist an infection, *Risk for Infection* is the most likely nursing diagnosis. Others may include *Pain* or *Imbalanced Nutrition* but they are less focused on the immediate health risk. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Diagnosing. **Learning Outcome:** 31-7.
8. **Answer:** 2. **Rationale:** Raw foods touched by human hands can carry significant infectious organisms and must be washed or peeled. Antimicrobial soap is not indicated for regular use and may lead to resistant organisms. Hand hygiene should occur as needed. Hot water can dry and harm skin, increasing the risk of infection (option 1). Clients should learn all the signs of inflammation and infection (e.g., redness, swelling, pain, heat) and not rely on the presence of pus to indicate this (option 3). People should not share washcloths or towels (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcomes:** 31-8; 31-5.
9. **Answer:** 1. **Rationale:** Sterile objects are considered unsterile if placed lower than the waist. Only area 1 in this situation would be considered sterile. Above the neck, higher than 2 inches above the elbow, below the waist/table, and the back are all considered unsterile. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 31-1; 31-11c.
10. **Answer:** 3. **Rationale:** All items within 1 inch of the edge of the sterile field are considered contaminated because the edge of the field is in contact with unsterile areas. When hands are ungloved, forceps tips are to be held downward to prevent fluid from becoming contaminated by the hands and then returned to the sterile field (option 1). Fields should be established immediately before use to prevent accidental contamination when not observed closely (option 2). Reaching over a sterile field increases the chances of dropping an unsterile item onto or touching the sterile field (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 31-11c.
- Chapter 32: Safety**
1. **Answer:** 3. **Rationale:** In the event of a fire, the nurse's priority responsibility is to rescue or protect the clients under his or her care. The next priorities are to report or alert the fire department, contain or confine, and extinguish the fire. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-6.
2. **Answer:** 1. **Rationale:** When educating a group of young to middle-aged adults on safety, it is important to instruct them on the leading cause of injuries in this group. The leading cause of injuries in this group is related to automobile use. Option 2 is the leading cause for school-age children. Option 3 is the leading cause for older adults, and option 4 relates to adolescents. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-4.
3. **Answer:** 3. **Rationale:** The placement of the bedside commode next to his bed will assist in decreasing the number of steps he is required to ambulate. This will assist in protecting him from injury due to falls. Option 1: Leaving the light on would assist the client in locating the bathroom, but would not reduce the risk of fall when rushing to the bathroom. Option 2: The nurse cannot withhold a client's medication without consulting with the primary care provider. Option 4: If the client has orders to be up with assistance and the side rails are up, he is at risk for falls as well as falling from a greater distance. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-7.
4. **Answer:** 3. **Rationale:** A home that was built prior to 1978 has lead-based paint. The ingestion of lead-based paint chips places that child at risk for elevated serum lead levels and neurologic deficits. The most appropriate nursing diagnosis for this child is *Risk for Poisoning*. Option 1: The risk for suffocation is greater in infants and is not related to a home with lead-based paint. Options 2 and 4 are not related to lead-based paint. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Nursing Diagnosis. **Learning Outcome:** 32-5.
5. **Answer:** 4. **Rationale:** Option 4 is an intervention that can allow the client to feel independent and also alert the nursing and nursing staff when the client needs assistance. It is the most realistic answer that promotes client safety. Option 1 can increase agitation and confusion and removes the client's independence. Option 2 would help but transfers the responsibility to the family member. Option 3 is inappropriate since the client could fall during the unobserved interval and it is not a realistic answer for the nurse. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcomes:** 32-6; 32-12a.
6. **Answer:** 2 and 5. **Rationale:** Options 2 and 5 are measures needed to keep the client safe in the event of another seizure. Option 1 is incorrect because the current nursing literature states to not put anything in the client's mouth during a seizure. Options 3 and 4 are more relevant after the cause of the seizure is known. Seizures are not all classified as epilepsy. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcomes:** 32-8; 32-12b.
7. **Answer:** 4. **Rationale:** Placing the bed in the lowest position results in a client falling the shortest distance. The client is least likely to fall when getting out of a bed that is at an appropriate height. Option 1 can cause a fall with injury because the client may fall from a higher distance when trying to get over the rail. Option 2 is important to do as certain medications can increase the risk of falling; however, this is not the best answer because it is not applicable to all clients. Option 3 would help the nurse to assess a client's risk for falling but would not prevent injury. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 32-7.
8. **Answer:** 3, 4, and 5. **Rationale:** Reviewing near misses could identify flaws in the system or practices that placed the client at risk. Communication among staff and with clients will increase the efficiency and create an atmosphere where nurses are willing to discuss errors openly so that the flaws in the system can be corrected. Options 1 and 2 are inappropriate answers. A competent nurse may make medication errors. Also, evidence is needed to support these conclusions. **Cognitive Level:** Understanding. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcomes:** 32-1; 32-3.
9. **Answer:** 3. **Rationale:** Suicide and homicide are two leading causes of death among teenagers. Adolescent males commit suicide at a higher rate than adolescent females. Options 1 and 2 are true; however, neither would be as high a priority as preventing suicide. Option 4 is not true. A driver's education course does not ensure safe practice. **Cognitive Level:** Analysis. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 32-4.
10. **Answer:** 1, 3, 4, and 5. **Rationale:** Standards require documentation of the necessity for restraints. The implementation of range-of-motion exercises prevents joint stiffness and pain from disuse. Orienting the client helps the nurse determine the necessity of the restraint. Option 2 is inappropriate because it may cause injury if the side rail is lowered

without untying the restraint. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcomes:** 32-9; 32-12c.

Chapter 33: Hygiene

- Answer:** 3. **Rationale:** The client fits the descriptors for a semidependent functional level (see Table 33–2). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 33-3.
- Answer:** 3. **Rationale:** The client will be positioned in a side-lying position with the head of the bed lowered because the client is at risk for aspiration. The absence of the gag reflex lets the nurse know that the client has no natural defense (cough) and is at a higher risk for aspiration. All other answers are assessments more appropriate prior to bathing the client. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 33-4.
- Answer:** 2. **Rationale:** A lotion will help moisten the skin. Perfumed lotions contain alcohol, which is drying to the skin. Soaking the feet for a long time or frequently also causes dry skin (option 1). Applying foot powder is appropriate to prevent or control unpleasant foot odor (option 3). Elastic stockings may decrease circulation (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-15c.
- Answer:** 1. **Rationale:** Turn off the hearing aid. Option 2 is incorrect because an in-the-ear hearing aid is cleaned with a damp cloth. Option 3 is incorrect; make sure the volume is turned all the way down because a too loud volume is distressing. Check that the battery is in the hearing aid; do not remove the batteries (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-15h.
- Answer:** 4. **Rationale:** Both the placement of the linens for a surgical bed and placing the bed in a high position facilitate the client's transfer from a stretcher into the bed. The linens for a closed bed are drawn up to the top of the bed and under the pillows (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-14.
- Answer:** 1, 2, and 4. **Rationale:** Moving quickly may agitate the client (option 3). Protesting, screaming, and crying are not normal. Stop the bath and approach again later (option 5). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 33-8.
- Answer:** 4. **Rationale:** It is important to retract the foreskin to remove the smegma that collects under the foreskin and can cause bacterial growth. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 33-1.
- Answer:** 1, 3, and 5. **Rationale:** The developmental level warrants supervision. If the bottle is given during naps or bedtime, the solution has continuous contact with the toddler's teeth. The first visit to the dentist should occur between the ages of 2 and 3 (option 2). More than 50% of older adults have their own teeth (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 33-4.
- Answer:** 2. **Rationale:** The client needs to avoid walking barefoot because that could cause injury that may result in an infection. Also, neurologic impairment is likely as a result of the diabetes, which may result in decreased sensation. The client would be unaware of an injury. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 33-4.
- Answer:** 1. **Rationale:** Fowler's is a semisitting position that should ease the client's breathing. The head of the bed (HOB) in semi-Fowler's is lower (option 2). The HOB is lowered in the Trendelenburg position (option 3). Although the HOB is raised in the reverse Trendelenburg

position, it is a straight tilt and may not be as comfortable as Fowler's (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 33-13.

Chapter 34: Diagnostic Testing

- Answer:** 2. **Rationale:** Option 2 is very low and can lead to death. The client's red blood cells participate in oxygenation. Options 1, 3, and 4 are within normal range and should not be reported to the primary care provider. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-3.
- Answer:** 3. **Rationale:** Option 3 is the most important nursing measure. This will inform the staff that the client is on a 24-hour urine collection. Option 1 is not appropriate since the first voided specimen is to be discarded. Option 2 is not an appropriate nursing measure since the specimen container is clean not sterile, and one container is needed—not individual containers. Option 4 is inappropriate because some 24-hour urine collections do not require refrigeration. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-6.
- Answer:** 2. **Rationale:** A KUB is an x-ray of the kidneys, ureters, and bladder. This does not require direct visualization. Option 1 is an IVP, an intravenous pyelogram, which requires the injection of a contrast media. Option 3 is a retrograde pyelography, which requires the injection of a contrast media. Option 4 is a cystoscopy, which uses a lighted instrument (cystoscope) inserted through the urethra, resulting in direct visualization. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-8.
- Answer:** 4. **Rationale:** This type of nuclear scan demonstrates the ability of tissues to absorb the chemical to indicate the physiology and function of an organ. Option 1 is an invasive procedure that focuses on blood flow through an organ. Options 2 and 3 provide information about density of tissue to help distinguish between normal and abnormal tissue of an organ. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-9.
- Answer:** 3. **Rationale:** Bone marrow aspiration includes deep penetration into soft tissue and large bones such as the sternum and iliac crest. This penetration can result in bleeding. The client should be observed for bleeding in the days following the procedure. Option 1 is a nursing action during a liver biopsy. Option 2 is a nursing action for a thoracentesis, and Option 4 is a nursing action for a lumbar puncture. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-10.
- Answer:** 1 and 4. **Rationale:** ALT is an enzyme that contributes to protein and carbohydrate metabolism. An increase in the enzyme indicates damage to the liver. The liver contributes to the metabolism of protein, which results in the production of ammonia. If the liver is damaged, the ammonia level is increased. Options 2, 3, and 5 (myoglobin, cholesterol, and BNP) are relevant for heart disease. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 34-2.
- Answer:** 3. **Rationale:** A glycosylated hemoglobin will indicate the glucose levels for a period of time, which is indicated by the nurse practitioner. Options 1 and 2 will provide information about the current blood glucose, not the past history. Option 4 is used to assess for liver disease. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-2.
- Answer:** 2, 3, and 5. **Rationale:** The nurse should obtain the stool specimen from two different areas of the stool. The nurse should observe for a blue color change, which is indicative of a positive result. The nurse should assess for the ingestion of vitamin C by the client

because it is contraindicated for 3 days prior to taking the specimen. Option 1 is incorrect since the reagent is placed on the specimen after it is applied to the testing card. Option 4 is incorrect because a pink color would be considered negative and does not require verification.

Cognitive Level: Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-5.

9. **Answer:** 2. **Rationale:** The puncture site is usually on the posterior chest. The client should be positioned leaning forward. This will allow the ribs to separate for exposure of the site. Option 1 is incorrect. The client should not be placed in the Trendelenburg position because the site would not be exposed. Option 3 is incorrect since changes in vital signs do not routinely occur with this procedure. Option 4 is incorrect. The client does not need to be medicated for pain with this procedure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 34-10.
10. **Answer:** 2, 4, and 5. **Rationale:** The sputum specimen should be sent immediately to the laboratory. The client should be provided mouth care before and after the specimen is collected. The sputum specimen should be collected for three consecutive days. Option 1 is incorrect because the sputum specimen is collected in the morning not in the evening. Option 3 is incorrect because the term *spit* indicates that saliva is being examined. The client needs to cough up or expectorate mucus or sputum. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 34-7.

Chapter 35: Medications

1. **Answer:** 2. **Rationale:** If there is any doubt, the medication administration process should be interrupted until the question is clarified. Listen to the client. Find out any other information the client may have about that certain medication. For example, does he know the dosage of the medication taken at home? Do not administer the medication (option 1). Inform the client that you will check the chart first. Review the chart to make sure there is no discrepancy between the physician's order and the MAR. Review the physician's progress notes because the medication may have been increased or reduced as part of the treatment plan (option 3). Check with the pharmacist because sometimes a pill may be a different color or shape based on the pharmaceutical company. Do not leave medications at the bedside. Medications should never be left unattended (option 4). Inform the client of your findings. The client will appreciate that you took the time to make sure that he received the correct medication. While it takes time to check out the client's statement, you will be glad that you avoided a potential medication error. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-11.
2. **Answer:** 4. **Rationale:** Options 1, 2, and 3 are written appropriately. Option 4 is incorrect because the dosage is missing from this order. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 35-6.
3. **Answer:** 1, 3, and 5. **Rationale:** Five milliliters is too large an amount to inject into one site. The nurse needs to divide the amount into two 2.5-mL injections. A 3-mL syringe could be used (option 1). The length of the needle will depend on the muscle development of the client. The nurse needs to assess the client. The presumption, based on the information provided, is that this client's muscle mass is within normal limits. The needle length would need to be 1 1/2 inches because the medication is ordered to be given "deep IM" (option 5). This also suggests that the medication should be given in the preferred site for IM injections—the ventrogluteal site—because it provides the greatest thickness of gluteal muscle. The gauge of the needle for an IM injection into the ventrogluteal muscle can range between #20 and #23 (option 3). The nurse needs to assess the viscosity of the medication. Smaller gauges (e.g., #23) produce less tissue trauma; however, viscous solutions may require a larger gauge (e.g., #20–#21). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-5.
4. **Answer:** 3. **Rationale:** The type of syringe for subcutaneous injections depends on the medication to be given. This situation does not indicate that the medication is insulin and, thus, another syringe is needed. Generally a 2-mL syringe is used for most subcutaneous injections. Generally, a #20- to #23-gauge needle is used for IM injections. Needle size and length are based on the client's body mass, the intended angle of insertion, and the site of the injection. Generally, a #25-gauge, 5/8-inch needle is used for adults of normal weight and the needle is inserted at a 45° angle. Because 2 inches of tissue can be grasped or pinched at the site of the injection, the nurse should administer the medication at a 90° angle to ensure the medication reaches subcutaneous tissue. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18b.
5. **Answer:** 1. **Rationale:** A tuberculin test is given by intradermal injection. A tuberculin syringe is used because the dosage will most likely be 0.1 mL. A short, fine needle is needed to avoid entering the subcutaneous tissue. The needle should have a short bevel and usually be between #25 and #27 gauge. The needle should be between 1/4 to 5/8 inch long. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18a.
6. **Answer:** 4. **Rationale:** If the nurse goes by the amount of the medication (0.5 mL) only, the deltoid muscle would be the site. However, knowing and assessing the client is critical. The muscles of an older, emaciated client will most likely be diminished or atrophied. The nurse should consider the ventrogluteal site because that site will have the most muscle mass. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 35-17c; 35-12.
7. **Answer:** 1. **Rationale:** Due to renal insufficiency, the dose of the medication would need to be decreased in order to avoid accumulation of the medication and the risk of toxicity. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 35-12.
8. **Answer:** 2. **Rationale:** To straighten the ear canal in children less than 3 years of age, the ear must be pulled down and back. In individuals over 3 years of age, the ear is pulled up and back. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-20c.
9. **Answer:** 0.375 or rounded to 0.38 mL. **Rationale:** After converting to like numbers, the formula would be set up as follows:
 400 micrograms = 1 mL
 150 micrograms = X mL
 Cross multiply (400 X = 150)
 Divide by 400
 X = 0.375
Cognitive Level: Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-9.
10. **Answer:** 3, 4, 1, 5, 2, 6, 7, and 8. **Rationale:** This is the correct order for this skill—first the nurse mixes the insulin, assesses the skin, and cleanses the skin. The nurse would then pinch the skin, insert the needle, inject the medication, count to five, and remove the syringe. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 35-18b.

Chapter 36: Skin Integrity and Wound Care

1. **Answer:** 2. **Rationale:** A score ranging from 15 to 18 is considered at risk and a turning schedule is appropriate. Option 1 requires a score above 18 (normal and ongoing assessment is indicated). Option 3, moderate risk, for which a transparent barrier would be appropriate, is applied to persons with scores of 13 to 14. Option 4, very high risk,

- is assigned for those with a score of 9 or less. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Management. **Nursing Process:** Implementation. **Learning Outcome:** 36-2.
2. **Answer:** 1. **Rationale:** Wound culture specimens should be obtained from a cleaned area of the wound. Microbes responsible for the infection are more likely to be found in viable tissue. Collected drainage contains old and mixed organisms. An appropriate specimen can be obtained without causing the client the discomfort of debriding. The nurse does not generally debride the wound to obtain a specimen. Once systemic antibiotics have been begun, the interval following a dose will not significantly affect the concentration of wound organisms. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 36-10.
 3. **Answer:** 3. **Rationale:** Hydrocolloid dressings protect shallow ulcers and maintain an appropriate healing environment. Alginates (option 1) are used for wounds with significant drainage; dry gauze (option 2) will stick to new granulation tissue, causing more damage. A dressing is needed to protect the wound and enhance healing. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 36-11.
 4. **Answer:** 1. **Rationale:** The heating pad needs to be removed. After 30 minutes of heat application, the blood vessels in the area will begin to exhibit the rebound effect, resulting in vasoconstriction. Lowering the temperature, but still delivering heat—dry or moist—will not prevent the rebound effect. The visual appearance of the site on inspection (option 3) does not indicate if rebound is occurring. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 36-14.
 5. **Answer:** 3. **Rationale:** Immobile and dependent persons should be repositioned at least every 2 hours, not every 4, so this client or family member requires further teaching. Warm water and moisturizing damp skin are correct techniques for skin care. Red areas that do not return to normal skin color should be reported. It would also be correct to use a foam pad to help relieve pressure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 36-10.
 6. **Answer:** Potential pressure ulcer sites for side-lying clients include ankles, knees, trochanters, ilia, shoulders, and ears. These are important areas to assess. Other answers may also be correct. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 36-8.
 7. **Answer:** 2. **Rationale:** This client has an actual impairment of the integrity of the skin due to the rash and the scratching so is no longer “at risk.” Because the damage is at the skin level, it is not impaired tissue integrity (option 3) since that would involve deeper tissues. Surface excoriation is also not prone to becoming infected. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 36-9.
 8. **Answer:** 1, 3, and 4. **Rationale:** Risk factors for pressure ulcers include low-protein diet, lengthy surgical procedures, and fever. Protein is needed for adequate skin health and healing. During surgery, the client is on a hard surface and may not be well protected from pressure on bony prominences. Fever increases skin moisture, which can lead to skin breakdown, plus the stress on the body from the cause of the fever could impair circulation and skin integrity. Insomnia (option 5) would generally involve restless sleeping, which transfers pressure to different parts of the body and would reduce the chances of skin breakdown. A waterbed (option 5) distributes pressure more evenly than a regular mattress and, thus, actually reduces the chances of skin breakdown. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 36-1.
 9. **Answer:** 1, 2, and 4. **Rationale:** To irrigate a wound, the nurse uses clean gloves to remove the old dressing and to hold the basin collecting the irrigating fluid plus sterile gloves to apply the new dressing. A 60-mL syringe is the correct size to hold the volume of irrigating solution plus deliver safe irrigating pressure. The irrigation fluid should be room or body temperature—certainly not refrigerated. Forceps may be used to remove or apply a dressing but are not required for irrigation. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 36-13b.
 10. **Answer:** 2. **Rationale:** The knot of the triangle sling must be kept off the spinal processes because this would be uncomfortable and put unnecessary pressure on the vertebrae. The elbow should be flexed slightly less than 80° (not >90° as in option 1) so the hand is above the elbow to prevent dependent swelling. The sling must extend past the wrist in order to support the hand. Although the sling must be removed to check for circulation and skin integrity, every 2 hours (option 4) is unnecessarily frequent and impractical. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 36-13c.

Chapter 37: Perioperative Nursing

1. **Answer:** 3. **Rationale:** These tests are specific to liver function. Option 1 evaluates fluid and electrolyte status. Option 2 evaluates renal status; option 4 evaluates nutritional status. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-3.
2. **Answer:** 2. **Rationale:** Grieving is the state in which an individual experiences reactions in response to an expected significant loss. The definition for option 1 is “confusion in mental picture of one’s self” and is often characterized by negative responses such as shame, embarrassment, guilt, or revulsion. Option 3, fear, is usually characterized by feelings of dread, fright, apprehension, or alarm. Ineffective coping, option 4, is usually characterized by verbalization of inability to cope or ask for help, inappropriate use of defense mechanisms, or inability to meet role expectations. **Cognitive Level:** Applying. **Client Need:** Psychological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 37-4.
3. **Answer:** 4. **Rationale:** Option 1 is incorrect because of the ASA guidelines for preoperative fasting. Option 2 is incorrect because clients are taught how to cough and also how to splint their incision to prevent complications. Option 3 is incorrect because anticoagulants are discontinued a few days before surgery to avoid excessive bleeding post-operatively. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 37-6.
4. **Answer:** 2. **Rationale:** The symptoms describe decreased cardiac output and not any of the other listed complications. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-10.
5. **Answer:** 3. **Rationale:** Options 1 and 2 are incorrect because the client is still recovering from the anesthesia used during surgery. Option 4 is incorrect because pain usually decreases after the second or third post-operative day. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 37-10.
6. **Answer:** Splinting. **Rationale:** If the incision is painful when the client coughs, splinting the abdomen may reduce the pain. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 37-6.
7. **Answer:** 4. **Rationale:** The tongue can obstruct the airway in a semi-conscious client. Repositioning in the side-lying position with the face slightly down will help prevent occlusion of the pharynx and also allow drainage of mucus out of the mouth. Option 1 is incorrect because a pillow under the head increases the risk of aspiration or airway obstruction. Because the problem is airway obstruction, actions to promote an open airway are most appropriate. The nurse would want to keep the airway in place (option 2). The problem is obstruction, not

percentage of available oxygen (option 3). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 37-9.

8. **Answer:** 1 and 3. **Rationale:** Anesthetics, narcotics, fasting, and inactivity all inhibit peristalsis. Oral fluids and food are started after the return of peristalsis. The client may feel hungry but peristalsis may not be present. The other options are important but not related specifically to advancing the client's diet. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 37-9.
9. **Answer:** Safety. **Rationale:** The client's protective reflexes are compromised, especially with general anesthesia. Thus, the perioperative nurse needs to maintain the client's safety during surgery. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 37-5.
10. **Answer:** 2, 3, and 5. **Rationale:** Option 1 is incorrect because sterile technique is used. The suture material that is visible is in contact with bacteria and must not be pulled beneath the skin during removal (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Learning Outcome:** 37-12e.

Chapter 38: Sensory Perception

1. **Answer:** 4. **Rationale:** A sudden, unexpected admission for surgery may involve many experiences (e.g., lab work, x-rays, signing of forms) while the client is in pain or some form of discomfort. The time for orientation will thus be lessened. After surgery, the client may be in pain and possibly in a critical care setting. Options 1 and 2 reflect a greater risk for sensory deprivation, and option 3 is a normal activity for a teenager. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 38-3.
2. **Answer:** 3. **Rationale:** The transfer to a different setting can change the amount or patterning of incoming stimuli accompanied by a diminished, exaggerated, distorted, or impaired response to such stimuli. The onset of restlessness and agitation is a characteristic of acute confusion. Options 1 and 2: There is no evidence of longstanding or progressive deterioration of intellect and personality. Option 4: *Disturbed Thought Processes* is applied when cognitive abilities (e.g., dementia) interfere with the ability to accurately interpret stimuli. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 38-6.
3. **Answer:** 2. **Rationale:** Because of the paraplegia (paralysis of lower body), the client is unable to feel discomfort. The client will be taught to lift self using chair arms every 10 minutes if possible. Option 1 is an actual problem versus a potential problem. In option 3, the client wears glasses that help correct the poor vision. Option 4 is more of a *Risk for Injury* diagnosis. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 38-6.
4. **Answer:** 2. **Rationale:** This client could use an assistive device that flashes a light when the doorbell rings. Option 1 relates to safety of the environment rather than sensory alteration. Options 3 and 4 reflect how the client adapts to the sensory alteration. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Evaluation. **Learning Outcome:** 38-7.
5. **Answer:** 4. **Rationale:** Option 4 is the only response that helps orient the client and treats the client with respect. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 38-7.
6. **Answer:** 1, 3, and 4. **Rationale:** Options 2 and 5 relate to interventions for a client with a hearing impairment. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 38-7.
7. **Answer:** 3. **Rationale:** A disorganized, cluttered environment increases confusion. Option 1: Keeping the room well lit during waking

hours promotes adequate sleep at night. It is important to eliminate unnecessary noise (option 2). Client does not meet the standard criteria for restraint application (option 4). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 38-8.

8. **Answer:** 2, 4, and 5. **Rationale:** Options 1 and 3 are clinical signs of sensory overload. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 38-3.
9. **Answer:** Identifying taste: 5; Stereognosis: 3; Snellen chart: 1; Identifying aromas: 4; Tuning fork: 2. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 38-4.
10. **Answer:** 1. **Rationale:** The amplified telephone helps with hearing and provides a means for communicating with others. Option 2 refers to a tactile impairment. Option 3 relates to a visual impairment, and option 4 an olfactory impairment. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 38-7.

Chapter 39: Self-Concept

1. **Answer:** 1. **Rationale:** Sally has an inappropriate view of her physical self, which is body image. Personal identity is a sense of uniqueness (option 2); self-expectation consists of those things one believes the self should be able to do (option 3); and core self-concept includes the most vital central beliefs about one's identity (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-2.
2. **Answer:** 3. **Rationale:** This is role conflict—several different roles are competing for the person's time, energy, and abilities. Role ambiguity results when there are unclear expectations of the role (option 1). Role strain exists when there are feelings of inadequacy in performing a role (option 2). Role enhancement is a nursing intervention (option 4). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-2.
3. **Answer:** 2. **Rationale:** This is a realistic and measurable outcome. Restored self-esteem is vague and not measurable (option 1). Teaching is an intervention, not an outcome (option 3). Decreased preoccupation with altered self relates to body image rather than self-esteem (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 39-6.
4. **Answer:** 1. **Rationale:** This response encourages the client to say more and focuses on the positive. Option 2 is condescending and closes the discussion. Both options 3 and 4 ignore the emotional component of the client's statement and do not address the person's feelings of worthlessness. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 39-6; 39-7.
5. **Answer:** 4. **Rationale:** A person who follows the crowd is demonstrating unsuccessful resolution of this task. Successful resolution would result in assertion of independence (option 1). Inability to express desires is symptomatic of unresolved toddlerhood autonomy versus shame and doubt (option 2), while difficulty being a team player suggests unresolved early school-age industry versus inferiority (option 3). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 39-1.
6. **Answer:** 3. **Rationale:** Self-awareness consists of the relationship between own and others' perceptions of the person. The other options reflect only how the nurse sees himself or herself. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 39-2.
7. **Answer:** 1. **Rationale:** A person who perceives herself primarily in terms of relationships with others must have the ability to perform those roles considered in planning care. Although it may seem

important for her to develop outside interests, she may not be able to do this, especially with a new diagnosis of a chronic condition. It is not mandatory for the family to be present during care planning, although items impacting their lives should be validated with them before the plan is finalized. Psychological counseling is not automatically indicated unless her role performance is unhealthy. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 39-4; 39-6.

8. **Answer:** 2 and 5. **Rationale:** A person with chronic low self-esteem often is able to only make negative statements about self. The client would have difficulty confronting authority (option 1). Option 3 relates to role performance. Option 4 is incorrect because the client would have difficulty achieving even common/realistic goals and is not likely to set extremely high goals. Option 6, sleeping, is generally not impaired with low self-esteem. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 39-5.
9. **Answer:** 2 and 3. **Rationale:** The client with poor self-concept should be encouraged to say positive self-statements and minimize negative ones. Such clients should not be encouraged to compare themselves with others (option 1). Having them care for others can be a very therapeutic intervention for such individuals (option 4). They should be given realistic and normal levels of expectations for their behavior. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 39-6.
10. **Answer:** 4. **Rationale:** The social self is how one is perceived by others and is difficult, if not impossible, to influence since the client does not control the viewpoints of other persons. With planning, the number of the client's resources can be increased, self-knowledge improved, and core self-concept broadened since these are within the client's control. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 39-3.

Chapter 40: Sexuality

1. **Answer:** 4. **Rationale:** Clients still may feel shame and discomfort regarding sexuality. Most people assume that providers have a great deal of information (option 1). Many clients have questions and concerns (option 2). Although talking with someone of the same gender may make it easier for some women, it is not a requirement for assessment and intervention (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 40-1.
2. **Answer:** 2. **Rationale:** Transgender persons' anatomic gender is not the same gender as they feel themselves to be. Option 1 is the definition of intersex. Option 3 is the definition of bisexuality. Gender identity is a lifelong belief and not altered by an acute condition (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-3.
3. **Answer:** 4. **Rationale:** Masturbation is a normal activity for most people and assists with self-exploration of sexuality. There is no evidence that masturbation interferes with academic achievement (option 2). Individuals masturbate at all ages of life (option 3). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-5.
4. **Answer:** 2. **Rationale:** Orgasmic response and sex drive are often inhibited by antidepressants. If the depression lifts, there may be an improvement but the focus in option 1 is on the partner rather than where it should be—on the client. Retrograde ejaculation is associated with removal of the prostate gland (option 3). Skin hypersensitivity is not a side effect of antidepressant medications (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 40-8.
5. **Answer:** 4. **Rationale:** More information is needed before intervening. Also, the client needs the opportunity to express her feelings. Option 1 is an unprofessional response and false reassurance. The ANA Code of Ethics indicates that clients are entitled to a timely and appropriate response to their needs. Option 2 suggests postponing the discussion and that the primary care provider is the better person to deal with her concerns, which is untrue. Option 3 represents feeding into her negative self-concept and inappropriate self-disclosure. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 40-4.
6. **Answer:** 1. **Rationale:** Dyspareunia is painful intercourse. Knowledge of the partner's awareness will contribute to resolution. Involuntary vaginal spasms are called vaginismus (option 2). Painful menstruation is called dysmenorrhea (option 3). Breast swelling can occur during portions of the menstrual cycle but is unrelated to painful intercourse (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcomes:** 40-6; 40-7.
7. **Answer:** 3. **Rationale:** Antihypertensive medications are known to affect sexual functioning in several different ways, so some focused history questions would be indicated. There is no evidence of a relationship between sexual functioning and anti-inflammatories, hypnotics, or antihistamines (options 1, 2, and 4). However, the underlying condition that leads the client to take other medications could be important. Side effects of any medication could impact sexual interest or energy level, which reinforces the importance of including taking a sexual health history for all clients. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcomes:** 40-6; 40-7; 40-8.
8. **Answer:** 2. **Rationale:** LI includes instructing clients regarding when sexual activity is safe or unsafe. P involves giving permission to be sexual beings and to discuss issues (option 1). SS includes specific suggestions that help clients promote optimal functioning (option 3). Intensive therapy (IT) requires special skills offered by a nurse specialist or sex therapist (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcomes:** 40-1; 40-9.
9. **Answer:** 4. **Rationale:** A change in sexual frequency is not abnormal but may suggest an opportunity for enhanced knowledge if he desires. It does not suggest pathology or disturbed body image (options 1 and 2). It would be incorrect to assume his lifestyle is sedentary merely because the frequency of his sexual activity has decreased (option 3). Further assessment of the reason for the decrease in sexual activity is indicated. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcomes:** 40-1; 40-2; 40-4; 40-8.
10. **Answer:** 3. **Rationale:** The key term is *ineffective*. If the suggestions given by the nurse are ineffective in reaching the desired goals, the client may require intervention from someone with more specialized skills. Verbalizing constructive methods of modifying sexual activity are healthy responses and do not require a more skilled therapist (option 1). The generalist nurse can refer the client to education and support groups (option 2). Experimenting with new sexual activities is probably a healthy direction and does not suggest the need for referral (option 4). **Cognitive Level:** Understanding. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 40-8.

Chapter 41: Spirituality

1. **Answer:** 4. **Rationale:** Options 1 and 2 involve assessment and diagnosis, not planning. Option 3, simply keeping the client busy, does not necessarily contribute to feeling fulfilled or purposeful. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcomes:** 41-1; 41-3; 41-6.

2. **Answer:** 3. **Rationale:** The best initial response is to assess. Option 1 may be interpreted as distancing by the client. Option 2 inserts the nurse's experience, which is generally inappropriate. Option 4 is not appropriate for someone in spiritual distress. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 41-5; 41-6.
 3. **Answer:** 3. **Rationale:** The key term is *full*. Option 1 would be inadequate; option 2 is only partial presencing; and option 4 is transcendent presencing. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 41-6.
 4. **Answer:** 3. **Rationale:** This client portrays no distress (option 1) or risk for distress (option 2), but rather the potential for enhanced spiritual health as a result of the transformative illness experience. Option 4 is not a valid diagnosis. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-1; 41-2.
 5. **Answer:** 4. **Rationale:** Assessment is always the first step of the process of spiritual caregiving or any nursing activity. Options 1, 2, and 3 may not respect the spiritual beliefs of either the nurse or the client. While an assessment may lead the nurse to share personal beliefs, these are never urged on the client. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 41-1; 41-4; 41-7.
 6. **Answer:** 3. **Rationale:** Many older adults are religious and spiritually aware. Options 1, 2, and 4 are disputed by recent research evidence. **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcomes:** 41-1; 41-3.
 7. **Answer:** 3. **Rationale:** Options 1, 2, and 4 are potentially uncaring or unethical. Jehovah's Witnesses have a well-developed network of representatives who can be called to explain and explore medical options with their fellow believers and medical staff. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 41-1; 41-4; 41-6.
 8. **Answer:** 2. **Rationale:** Residing in the SNF likely will curb the client's participation in her church. Options 1, 3, and 4 are incorrect because it is not known if the relocation or an alteration in religious practice will affect her spiritual well-being in either a negative or positive way. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-1; 41-2; 41-5.
 9. **Answer:** 4. **Rationale:** Recognizing personal emotional responses to events that parallel those experienced by a client, allows a nurse to identify an empathic response to a client's spiritual or emotional need. Options 1, 2, and 3 fail to show a nurse drawing deep to recognize inner experience that can inform empathy. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 41-8.
 10. **Answer:** 1. **Rationale:** Although the mother is arguably angry, it is unknown whether this anger is impairing her religiosity or her coping. More data are needed before determining that either option 2 or 3 is the best diagnosis. The mother is experiencing distress versus being at risk for it (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosis. **Learning Outcomes:** 41-2; 41-5.
2. **Answer:** 4. **Rationale:** Wearing glasses is another example of beginning a new strategy to assist with what will be a lifelong health need even though it is not necessarily a desired change. Interviewing for a job (option 1) is a very short-lived situational stressor. Coping strategies effective while a teenager may not be relevant at age 50 (option 2). Experiencing the stress of a divorce is a social/role stressor quite unlike that of a health problem (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-9.
 3. **Answer:** 1. **Rationale:** In the transaction model, stress is a very personal experience and varies widely among individuals. Option 2 represents the stimulus model, and option 3 represents the response model of stress. In option 4, external resources and support are a factor in determining stress levels but omit the key aspects of internal/personal influences. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-1.
 4. **Answer:** 3. **Rationale:** With stress, respirations increase, pupils dilate, peripheral blood vessels constrict, and the heart rate increases. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-3.
 5. **Answer:** 2. **Rationale:** It is too soon for *Caregiver Role Strain* to be an appropriate nursing diagnosis—especially since the child is not at home. *Ineffective Denial* and *Fear* are common reactions to this type of threat (options 1 and 3). The father demonstrates *Compromised Family Coping* by his difficulty in being supportive (option 4). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 42-8.
 6. **Answer:** 1, 3, and 4. **Rationale:** Common stressors among young adults include marriage, starting a new job, and leaving the parental home. Stressors from aging parents are more common among middle-aged adults (option 2); decreased physical abilities is a stressor in older adults (option 5); and changing body structure serves as a stressor in both children and older adults (option 6). **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 42-7.
 7. **Answer:** 2. **Rationale:** All four areas of health promotion strategies may be important, but for this client sleep is likely to be the most adversely affected by travel in which changing time zones and unfamiliar sleeping quarters are common. It is easier for clients to adapt to modifying exercise (option 1), nutrition (option 3), and time management (option 4) during travel than it is to control sleep. Thus, it becomes the most important area requiring intervention to avoid worsening the existing stress. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 42-9.
 8. **Answer:** 4. **Rationale:** Unless the nurse feels in physical danger, it is important to remain with the client, allow the anger to dissipate, and then begin assessing the cause. Leaving the room provides no therapeutic action (option 1). Option 2 may be considered setting limits, which can be helpful, but cannot occur until the client is calmer. All behavior is meaningful; it is inappropriate to ignore the client's behavior (option 3). **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 42-9.
 9. **Answer:** 1. **Rationale:** This client is exhibiting severe anxiety and, therefore, learning is impaired but not impossible (see Table 42-2). Therefore, it is most appropriate for the nurse to teach only those things that are critical for the client to learn at this time. The nurse also recognizes that learning may not be retained at this level of anxiety and plans to reinforce the teaching when the client is less anxious. **Cognitive Level:** Applying. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 42-4.
 10. **Answer:** 1, 2, and 4. **Rationale:** Compensation (option 1) may allow the client to overcome a weakness. Displacement (option 2) allows the client to express feelings safely. Repression (option 4) protects the

Chapter 42: Stress and Coping

1. **Answer:** 3. **Rationale:** Taking on additional work would only serve as an additional stressor. In addition, a nurse who has not begun resolution of feelings is unlikely to be able to meet clients' emotional needs. Effective coping may include verbalizing feelings (one-on-one or in groups) or initiating distractions (options 1, 2, and 4). Of course, the nurse may not disclose confidential information to her partner or others who would not already have this information. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 42-6.

client from further emotional trauma until able to cope. Minimization (option 3) prevents the client from accepting responsibility for actions. Regression (option 5) returns the client to a lower/previous developmental level. *Note:* Each of these may be more or less effective defenses depending on the exact context of the situation. **Cognitive Level:** Understanding. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 42-5.

Chapter 43: Loss, Grieving, and Death

- Answer:** 1, 2, and 3. **Rationale:** Correct answers include abbreviated (normal grief that is briefly experienced), anticipatory grief (experienced before the loss/death but appropriate), and disenfranchised grief (the emotions are felt privately, just not expressed in public). Unhealthy/abnormal types of grief include complicated grief (option 4) in several different forms: Unresolved grief is extended in length and severity (option 5). With inhibited grief, symptoms are suppressed, and other effects, including somatic, are experienced instead (option 6). **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 43-2.
- Answer:** 2. **Rationale:** When possible, modifications of policy that demonstrate respect for individual differences should be explored. The primary care provider is in no position to modify the implementation of hospital policy (option 3). Utilizing an empty room and a staff member for a deceased client is an inappropriate use of resources (option 4). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Planning. **Learning Outcome:** 43-8.
- Answer:** 1. **Rationale:** This statement acknowledges the family's grief simply. Avoid statements that may be interpreted as overly impersonal (option 2), false support (option 3), or harsh (option 4). **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 43-8.
- Answer:** 3. **Rationale:** Until children are about 5 years old, they believe that death is reversible. Between ages 5 and 9, the child knows death is irreversible but believes it can be avoided (option 2). Between 9 and 12 years of age, the child recognizes that he, too, will someday die (option 3). At 12 to 18 years old, the child builds on previous beliefs and may fear death, but often pretends not to care about it (option 4). **Cognitive Level:** Remembering. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 43-4.
- Answer:** 4. **Rationale:** Adaptive responses indicate the client can put the loss into perspective and begin to develop strategies for coping with the loss. Although the other options are responses the client might likely give and feel, and are not pathologic, they do not demonstrate movement toward a goal of adaptation nor problem solving. **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 40-3.
- Answer:** 1. **Rationale:** The nurse needs to assess and explore the meaning of the client's crying. Options 2 and 4 leap to assumptions about the meaning of the tears and ignore the possibility of the client's distress. Option 3 suggests that the client has the same feelings as the nurse, which may not be correct. **Cognitive Level:** Application. **Client Need:** Psychosocial Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 43-3.
- Answer:** 4. **Rationale:** Quality of life is determined by the client and expressed in terms of his or her satisfaction with a variety of aspects of life. Although being able to pay for care (option 1), having apparent spiritual peace (option 2), and absence of physiological complications (option 3) may appear to contribute to good quality of life, only the client's expression of satisfaction can provide the data the nurse requires to evaluate the goal. **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 43-5.
- Answer:** 4. **Rationale:** To plan with and assist the family, the nurse needs more data regarding the family's reactions to their loss.

Information on issues such as insurance coverage (option 1) can wait until later and may be more appropriately the responsibility of social services rather than the nurse. It is important for the nurse to determine their understanding of their injuries but they are stated as minor (option 2). Once the nurse has assessed the family's responses it will be important to determine availability of outside resources to assist them (option 3). **Cognitive Level:** Analyzing. **Client Need:** Psychosocial Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 43-1.

- Answer:** 3. **Rationale:** If there is no heartbeat, the client has died. Before death, the blood pressure may not be able to be heard on auscultation because it is very low (option 1). Loss of the gag reflex (option 2) occurs with loss of muscle tone but can exist in many circumstances unrelated to dying. Vasodilation and pooling of fluids at the end of life may cause cool and darkened extremities but these are not reliable signs of death (option 4). **Cognitive Level:** Comprehension. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 43-6.
- Answer:** 1. **Rationale:** Assisting the client to die with dignity involves allowing the client to participate in and choose the direction of the remainder of his or her life. Sharing the nurse's own views about life after death (option 2) does not enhance client dignity. The nurse should not assume that avoiding talking about dying and emphasizing the present (option 3) is therapeutic for the client. Only if the client wishes to have someone else perform care is doing so supporting death with dignity (option 4). Otherwise, it may have the opposite effect. **Cognitive Level:** Application. **Client Need:** Psychological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 43-7.

Chapter 44: Activity and Exercise

- Answer:** 2. **Rationale:** A key word in the question is *base*, and the feet provide this foundation. Leaning backward actually decreases balance (option 1), and tensing abdominal muscles alone (option 3) or bending the knees (option 4) does not affect the base of support. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 44-7.
- Answer:** 1, 3, and 5. **Rationale:** Isotonic exercise increases muscle tone, mass, and strength, maintains joint flexibility, and improves circulation. During isotonic exercise, both heart rate and cardiac output quicken to increase blood flow to all parts of the body (option 4). Little or no change in blood pressure occurs (option 2). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 44-2.
- Answer:** 1. **Rationale:** Vital signs that do not return to baseline 5 minutes after exercising indicate intolerance of exercise at that time. This is a real problem, not "at risk for," as in option 2. There is no evidence that the client requires assistance (impaired mobility, option 3), or is immobile (disuse syndrome, option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 44-6.
- Answer:** 3. **Rationale:** Although the crutches (or cane) are always used along with the weaker leg, the weaker leg should go down the stairs first. The stronger leg can support the body as the weaker leg moves forward. All of the other statements are correct. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 44-9.
- Answer:** 4. **Rationale:** When the client performs the movements systematically, using the same sequence during each session, the nurse can evaluate that the teaching was understood and is successful. When performing active ROM the client should exercise to the point of slight resistance, but never past that point of resistance in order to prevent further injury (option 1). The client should perform each exercise at least three times, not just once (option 2). The client should perform each series of exercises twice daily, not just once per day (option 3).

- Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 44-8.
- Answer:** 1. **Rationale:** Normal gait involves a level gaze, an initial rotation beginning in the spine, heel strike with follow-through to the toes, and opposite arm and leg swinging forward. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 44-5.
 - Answer:** 1, 4, and 5. **Rationale:** Eating and bathing will flex the elbow joint, and grasping and manipulating utensils to eat and write will take the thumb through its normal ROM. Walking flexes the hip. Shaving and eating require elbow flexion, not extension (option 2). Writing brings the fingers toward the inner aspect of the forearm, thus flexing the wrist joint (option 3). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 44-1.
 - Answer:** 3. **Rationale:** It is prudent for nurses to understand and use proper body mechanics at all times to decrease risk, while keeping in mind the importance of assistive devices and help from other staff. While it is generally accepted that proper body mechanics alone will not prevent injury, many work settings do not yet have “no manual lift” and “no solo lift” policies and resources in place. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 44-7.
 - Answer:** 4. **Rationale:** Placing the client in a safe position is the best maneuver. Leaving the client creates unsafe conditions because the client may faint before being able to return to her room (options 1 and 2). Rapid, shallow breathing (hyperventilation) may increase the dizziness (option 3). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 44-10g.
 - Answer:** 2. **Rationale:** The reddened area of the skin can lead to skin breakdown. The other options are within normal limits. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 44-3g.

Chapter 45: Sleep

- Answer:** 2. **Rationale:** This is the brainstem where the reticular formation (and RAS) is located and which integrates sensory information from the peripheral nervous system and relays the information to the cerebral cortex. An intact cerebral cortex and reticular formation are necessary for the regulation of sleep and waking states. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 45-1.
- Answer:** 4. **Rationale:** Most clients with sleep apnea report excessive daytime sleepiness. If they don't volunteer this, clients should be asked if they fall asleep or struggle to stay awake at work. Although cardiac arrhythmias may occur, they are usually only detectable during a sleep study, and thus the client would not be aware of them (option 1). Nasal obstruction is rarely the cause of sleep apnea or a complaint of clients with sleep apnea (option 2). There are many causes of chest pain, and this is unlikely to be something reported by clients with sleep apnea unless they have underlying cardiac disease (option 3). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 45-6.
- Answer:** 2. **Rationale:** Falling asleep within 20 to 30 minutes is normal for adults and would represent substantial improvement in the client's difficulties. Most adults do not need to sleep 8 to 10 hours per day (option 1). Although it would be ideal to remove the source of the client's stress, he is unlikely to have a plan to pay all his bills within 5 days (option 3). Distraction or keeping busy until bedtime will not prevent the client from worrying about his bills at bedtime (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 45-7.
- Answer:** 4. **Rationale:** Suddenly stopping barbiturate sleeping pills can precipitate a dangerous withdrawal. Doses should be tapered gradually and the tapering process supervised by the client's primary care provider. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-4.
- Answer:** 1. **Rationale:** Preschool children require 10 to 12 hours of sleep per night. Young children often rise early, so it is more appropriate to put the child to bed earlier in the evening. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-3.
- Answer:** 1, 3, and 5. **Rationale:** It is important to find out if he is obtaining sufficient sleep. If he gets more sleep on weekends than weekdays, insufficient sleep may be the cause of his difficulties staying awake in class. It is important to determine if his symptoms are chronic (e.g., longer than 3 months) or if they are of recent onset. Some prescribed and over-the-counter medications and herbal remedies can cause sleep disturbances. Although alcohol abuse or binge drinking can cause health problems, neither is likely to cause excessive daytime sleepiness (option 2). Unless the person is sleep deprived, boring classes will not induce sleep (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 45-6.
- Answer:** 4. **Rationale:** The client's symptoms, combined with his weight, suggest that he has obstructive sleep apnea and should be referred to a sleep disorders specialist for further evaluation. It would not be wrong to refer him to a dietitian for weight loss counseling (option 2), but being evaluated by a sleep disorders specialist is more critical. Drinking alcohol or taking sleeping pills is not advised in clients with sleep apnea because they disrupt the client's sleep patterns (option 3). **Cognitive Level:** Analyzing. **Client Needs:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-5.
- Answer:** 1. **Rationale:** Reducing exposure to bright light in the morning, when driving home, and when going to sleep will make it easier to fall asleep after work. Exercising before going to bed will increase arousal (option 2). Caffeine consumed at the beginning of a 12-hour shift will not assist the nurse in remaining awake during the latter part of the shift (option 3). Although working in a brightly lit area will reduce drowsiness, this strategy is rarely available to nurses working the night shift; lights are often dimmed in hospital corridors and client rooms (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-7.
- Answer:** 3. **Rationale:** Napping frequently reappears in older adults. Unless the person has difficulty falling asleep at night, there is no reason an individual should not be allowed to take a 15- to 20-minute nap in the early afternoon. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 45-3.
- Answer:** 1, 3, and 4. **Rationale:** Reducing environmental noise, as well as the number of times she is disturbed for medications and vital signs, will reduce the likelihood that she will awaken during the night. Delivering necessary care at 1.5- or 3-hour intervals is consistent with multiples of the 90-minute sleep cycle. Since it is unlikely that all of the noise in the environment can be eliminated, using a fan to generate a steady background noise may help mask sounds of people talking, carts being moved through the halls, and other noise. Music is not usually recommended because it can be interesting to listen to, thus encouraging wakefulness (option 2). The room temperature needs to be satisfactory for the client. A room that is too warm is not usually conducive for sleep (option 5). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 45-8.

Chapter 46: Pain Management

1. **Answer:** 3. **Rationale:** During the transduction phase, tissue injury triggers the release of biochemical mediators such as prostaglandin. Ibuprofen works by blocking the production of prostaglandin. The coanalgesic medication in option 1 would affect the modulation phase because coanalgesics inhibit the reuptake of norepinephrine and serotonin, which increases the modulation phase that helps inhibit painful ascending stimuli. Opioids block the release of neurotransmitters, particularly substance P, which stops the pain at the spinal level that occurs during the transmission phase (option 2). Distraction is best used during the perception phase when the client becomes conscious of the pain. Distraction (e.g., music, guided imagery, TV) can help direct the client's attention away from the pain (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 46-2.
2. **Answer:** 2. **Rationale:** The client's pain intensity needs to be assessed first for effective pain management. In a postoperative client it is important to assess pain intensity frequently to manage the acute pain experience. Option 1: The most pain a person is willing to tolerate before taking action can be discussed with the client after the pain intensity has been assessed. Option 3, location of pain, is important, but it is not the priority. Option 4: This information is important but not for a client in acute pain. The priority would be to assess the pain intensity. **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 46-5.
3. **Answer:** 3. **Rationale:** A rating of 7 is considered severe and demands immediate attention. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 46-5.
4. **Answer:** 1. **Rationale:** This indicates an increasing level of sedation, which can be an early sign of impending respiratory depression. Option 2 is normal. Option 3 can indicate increasing sedation; however, option 1 describes a higher level of sedation and an intervention such as notifying the primary care provider. Option 4 indicates pain management that may be tolerable for the client. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 46-7.
5. **Answer:** 4. **Rationale:** The client's perception/intensity rating of his pain is the most important even though other signs may suggest he is not having pain. His pain rating warrants a higher dose of the as-needed (prn) morphine. With option 1, you would be undermedicating the client based on his perception or rating of the pain. Option 2: Research shows that few clients become addicted, plus there are no signs of addiction. This answer, based on the data, would lead to the client being undermedicated. Option 3 does not address the intensity as well as option 4. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 46-7.
6. **Answer:** 4. **Rationale:** Options 2 and 3 are subcategories of physiological pain (option 1). A clue to the answer is that the client has diabetes, which often leads to diabetic peripheral neuropathy. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 46-1.
7. **Answer:** 2, 4, and 5. **Rationale:** Massage, heat and cold, and acupressure are cutaneous stimulation techniques that can "close" the gates and inhibit the transmission of further pain. Options 1 and 3 are pharmacologic interventions, which are important; however, they inhibit the pain during the transmission phase of nociception. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 46-3.
8. **Answer:** 2. **Rationale:** The words *pain* or *complain* may have emotional or sociocultural meanings (options 1 and 4). It is better to ask clients if they are having any discomfort—they can then elaborate in their own words. Option 3 is too general and expects clients to report their pain without being asked. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 46-5.
9. **Answer:** 3 and 5. **Rationale:** Older clients may deny complaints of pain because it may indicate a worsening of their condition that may threaten their independence. Older adults may use words other than *pain*. Although many perceive pain as a natural outcome of aging, it is not a natural part of aging (option 1). Pain perception may decrease (option 2) and narcotics can be used with careful monitoring by the nurse (option 4). **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 46-7.
10. **Answer:** 1. **Rationale:** Based on the information provided, the nurse needs to determine the client's understanding of the effects of pain on recovery and if the client has misconceptions about pain. Option 2 usually pertains more to chronic pain and fatigue. Options 3 and 4 could be true, but the priority is option 1. Movement enhances respiratory, cardiovascular, and GI recovery from general anesthesia and the outcomes associated with a surgical procedure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 46-6.

Chapter 47: Nutrition

1. **Answer:** 2. **Rationale:** A BMI of 30 to 40 indicates moderate to severe obesity. A BMI of less than 18.5 indicates underweight (option 1). The nursing diagnosis of *Overweight* is defined by a BMI of 25–29.9. (option 3). There is no evidence to support a diagnosis of *Deficient Knowledge* (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Diagnosing. **Learning Outcome:** 47-13.
2. **Answer:** 4. **Rationale:** This client needs more grains in the diet. The client should have 6 to 7 oz grains per day, 3 cups/week dark green vegetables, 2 cups/week orange vegetables, 3 cups/week legumes, 3 cups/week starchy vegetables, 1.5 to 2 cups fruit per day, 5 to 6 oz meat and beans per day, and 3 cups milk, yogurt, and cheese per day. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 47-5.
3. **Answer:** 2, 3, 4, 6, and 8. **Rationale:** A full liquid diet contains only liquids or foods that turn to liquid at body temperature. Pudding, juices, hard candy, Cream of Wheat cereal, and fruit smoothies are permitted on a full liquid diet. Scrambled eggs (option 1), mashed potatoes (option 5), and oatmeal cereal (option 7) are not permitted until the client advances to a soft diet. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 47-9.
4. **Answer:** 3. **Rationale:** Gastric secretions are acidic as evidenced by a pH of less than 6. If the tube were improperly placed in the client's airway, speaking would usually be impaired (option 1). Gagging during insertion is common and does not indicate that the tube is in the stomach (option 2). Ability to easily instill fluid into the tube does not relate to its placement. The lungs would offer no resistance to the flow of liquid (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 47-10a.
5. **Answer:** 1. **Rationale:** For proper flow, the feeding container hangs 1 foot above the tube insertion. Feedings may be administered if there is less than 90 to 100 mL of residual volume (unless agency policy specifies otherwise) (option 2). To prevent or reduce the risk of aspiration, the client should be placed in Fowler's position during feeding (option 3). The feeding should be warmed to room temperature before administration to decrease cramping and diarrhea (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 47-10c.
6. **Answer:** 1. **Rationale:** The Dietary Guidelines recommend 30 minutes of physical activity on most days of the week to achieve optimal weight.

Some individuals benefit from a low-carbohydrate diet, but no particular diet is the solution for all individuals (option 2). A reasonable diet emphasizes balance and portion control rather than forbidding or requiring any specific foods (option 3). Fresh and chemical-free foods may be healthier than preserved foods but do not automatically assist with weight loss (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 47-8.

7. **Answer:** 3. **Rationale:** Always inquire into the client's favorite foods when planning a diet. Dairy may not be indicated for this client due to the high incidence of lactose intolerance in individuals of Asian heritage (option 1). Beer can be a source of calories and, in moderation, is not harmful, and may maintain the client's satisfaction with the dietary changes. The nurse will need to assess the ability to swallow beer safely, however (option 2). Calories from lipid sources should be kept below 35% and, when enhanced wound healing is indicated (not so with a stroke), increased protein and carbohydrates are needed rather than fats (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 47-9.
8. **Answer:** This client has lost 13 pounds which is 6.7%: $(195 - 182)/195$. If the weight loss has been steady during the past 2 months, that would indicate a 3.3% loss per month. Less than 5% loss in 1 month is not significant, but if this loss continues, the client will reach a 10% loss in 3 months, which is a severe loss. A more detailed assessment is indicated to determine the client's nutritional status. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 47-6; 47-7; 47-8.
9. **Answer:** 2. **Rationale:** A small-bore nasal feeding tube tip is most commonly placed in the stomach. Option 1 indicates the esophagus. A tube tip placed there can lead to aspiration. Option 3 indicates the postpyloric duodenum. Small-bore nasal tubes can be advanced to this location if desired but such a placement is less common than gastric placement. Option 4 indicates the jejunum where feeding tubes can be placed but usually not from a nasally placed tube. **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 47-10a.
10. **Answer:** 4. **Rationale:** 3 ounces tuna + 2 slices whole wheat bread = 3.1 mg Fe; 1 ounce cheese = ~200 mg Ca^{2+} ; pear = 4.2 g fiber. Option 1: 1/3 cup raisins = 1.75 mg Fe; 3 ounces cottage cheese = 90 mg Ca^{2+} ; 1 banana = 2.1 g fiber. Option 3: 1/2 cup spaghetti + 2 ounces ground beef = 2.3 mg Fe; 1/2 cup ice cream = 97 mg Ca^{2+} ; 1/2 cup lima beans = 3.2 g fiber. Option 2: 3 ounces chicken + 1/2 cup peanuts = 2.9 mg Fe; 1/2 cup broccoli ~ 158 mg Ca^{2+} ; 1/2 cup broccoli = 2.4 g fiber. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 47-1.

Chapter 48: Urinary Elimination

1. **Answer:** 4. **Rationale:** The capacity of the bladder may decrease with age but the muscle is weaker and can cause urine to be retained (option 4). Older adults do not ignore the urge to void and may have difficulty in getting to the toilet in time (option 2). The kidney becomes less able to concentrate urine with age (option 3). **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 48-2.
2. **Answer:** 1, 2, 4, and 5. **Rationale:** The perineum may become irritated by the frequent contact with urine (option 1). Normal fluid intake is at least 1,500 mL/day and clients often decrease their intake to try to minimize urine leakage (option 2). UTIs can contribute to incontinence (option 4). A fecal impaction can compress the urethra, which can result in small amounts of urine leakage (option 5). Antihistamines can cause urinary retention rather than incontinence (option 3). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 48-4.
3. **Answer:** 2. **Rationale:** The penis and condom should be checked one-half hour after application to ensure that it is not too tight. A 1-in. space should be left between the penis and the end of the condom (option 1). The condom is changed every 24 hours (option 3), and the tubing is taped to the leg or attached to a leg bag (option 4). An indwelling catheter is secured to the lower abdomen or upper thigh. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 48-10a.
4. **Answer:** 1. **Rationale:** The catheter in the vagina is contaminated and cannot be reused. If left in place, it may help avoid mistaking the vaginal opening for the urinary meatus. A single failure to catheterize the meatus does not indicate that another nurse is needed although sometimes a second nurse can assist in visualizing the meatus (option 2). **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 48-10b.
5. **Answer:** 3. **Rationale:** Soaking in a bathtub can increase the risk of exposure to bacteria. The bag should be below the level of the bladder to promote proper drainage (option 1). Intake of cranberry juice creates an environment that inhibits infection (option 2). Clean technique is appropriate for touching the exterior portions of the system (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 48-7.
6. **Answer:** 4. **Rationale:** The key phrase is "the urge to void." Option 1 occurs when the client coughs, sneezes, or jars the body, resulting in accidental loss of urine. Option 2 occurs with involuntary loss of urine at somewhat predictable intervals when a specific bladder volume is reached. Option 3 is involuntary loss of urine related to impaired function. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 48-6.
7. **Answer:** 2 and 4. **Rationale:** Option 2 validates the diagnosis. Cotton underwear promotes appropriate exposure to air, resulting in decreased bacterial growth (option 4). Increased fluids decrease concentration and irritation (option 1). The client should wipe the perineal area from front to back to prevent spread of bacteria from the rectal area to the urethra (option 3). Showers reduce exposure of area to bacteria (option 5). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 48-7.
8. **Answer:** 2. **Rationale:** The ileal conduit and vesicostomy (options 1 and 4) are incontinent urinary diversions, and clients are required to use an external ostomy appliance to contain the urine. Clients with a neobladder can control their voiding (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 48-9.
9. **Answer:** 3. **Rationale:** Because the bladder muscles will not contract to increase the intrabladder pressure to promote urination, the process is initiated manually. Options 1, 2, and 4: To promote continence, bladder contractions are required for habit training, bladder training, and increasing the tone of the pelvic muscles. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 48-9.
10. **Answer:** 2 and 5. **Rationale:** It is important for the client to inhibit the urge-to-void sensation when a premature urge is experienced. Some clients may need diapers; this is not the BEST indicator of a successful program (option 3). Citrus juices may irritate the bladder (option 4). Carbonated beverages increase diuresis and the risk of incontinence (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 48-6.

Chapter 49: Fecal Elimination

1. **Answer:** 1. **Rationale:** Habitually ignoring the urge to defecate can lead to constipation through loss of the natural urge and the accumulation of feces. Diarrhea will not result—if anything, there is increased opportunity for water reabsorption because the stool remains in the colon, leading to firmer stool (option 2). Ignoring the urge shows a strong voluntary sphincter, not a weak one that could result in incontinence (option 3). Hemorrhoids would occur only if severe drying out of the stool occurs and, thus, repeated need to strain to pass stool (option 4). **Cognitive Level:** Understanding. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 49-1.
2. **Answer:** 2. **Rationale:** The standard of practice in assisting older adults to maintain normal function of the gastrointestinal tract is regular ingestion of a well-balanced diet, adequate fluid intake, and regular exercise. If the bowel pattern is not regular with these activities, this abnormality should be reported. Stimulant laxatives can be very irritating and are not the preferred treatment for occasional constipation in older adults (option 2). In addition, a normal stool pattern for an older adult may not be daily elimination. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcome:** 49-3.
3. **Answer:** 4. **Rationale:** Small-volume enemas along with other preparations are used to prepare the client for this procedure. An oil retention enema is used to soften hard stool (option 1). Return flow enemas help expel flatus (option 2). Because of the risk of loss of fluid and electrolytes, high, large-volume enemas are seldom used (option 3). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 49-8.
4. **Answer:** 3. **Rationale:** An established stoma should be dark pink like the color of the buccal mucosa and is slightly raised above the abdomen. The skin under the appliance may remain pink/red for a while after the adhesive is pulled off. Feces from an ascending ostomy are very liquid, less so from a transverse ostomy, and more solid from a descending or sigmoid stoma. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 49-9.
5. **Answer:** 2. **Rationale:** Once the cause of diarrhea has been identified and corrected, the client should return to his or her previous elimination pattern. This is not an example of an allergy to the antibiotic but a common consequence of overgrowth of bowel organisms not killed by the drug (option 1). Antidiarrheal medications are usually prescribed according to the number of stools, not routinely around the clock (option 3). Increasing intake of soluble fiber such as oatmeal or potatoes may help absorb excess liquid and decrease the diarrhea, but insoluble fiber will not (option 4). **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 49-6.
6. **Answer:** 2. **Rationale:** The client has assessment findings consistent with complications of surgery. Option 1: Irrigating the stoma is a dependent nursing action, and is also intervention without appropriate assessment. Option 3: Assessing the peristomal skin area is an independent action, but administering an antiemetic is an intervention without appropriate assessment. Antiemetics are generally ordered to treat immediate postoperative nausea, not several days postoperative. Option 4: Administering a bulk-forming laxative to a nauseated postoperative client is contraindicated. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 49-6.
7. **Answer:** 3. **Rationale:** This provides relief of postoperative flatus, stimulating bowel motility. Options 1, 2, and 4 manage constipation and do not provide flatus relief. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 49-8.

8. **Answer:** 3. **Rationale:** Blood in the upper GI tract is black and tarry. Option 1 can be a sign of malabsorption in an infant, option 2 is normal stool, and option 4 is characteristic of an obstructive condition of the rectum. **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 49-2.
9. **Answer:** 1, 3, 4, and 5. **Rationale:** Option 1 is the most appropriate. The client is unable to decide when stool evacuation will occur. In option 3, client thoughts about self may be altered if unable to control stool evacuation. In option 4, client may not feel as comfortable around others. In option 5, increased tissue contact with fecal material may result in impairment. Option 2 is more appropriate for a client with diarrhea. Incontinence is the inability to control feces of normal consistency. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 49-6.
10. **Answer:** 5. **Rationale:** Option 5 is a sigmoidostomy site. Option 1 is an ileostomy site, option 2 is ascending colostomy, option 3 is transverse colostomy, and option 4 is descending colostomy. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 49-9.

Chapter 50: Oxygenation

1. **Answer:** 4. **Rationale:** A bluish tinge to mucous membranes is called cyanosis. This is most accurate because it is what the nurse observes. The nurse can only observe signs/symptoms of hypoxia (option 1). More information is needed to validate this conclusion. Hypoxemia requires blood oxygen saturation data to be confirmed (option 2), and dyspnea is difficult breathing (option 3). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 50-5.
2. **Answer:** 3. **Rationale:** Huff coughing helps keep the airways open and secretions mobilized. Huff coughing is an alternative for clients who are unable to perform a normal forceful cough (e.g., postoperatively). Deep breathing and coughing should be performed at the same time. Only at mealtimes is not sufficient (option 1). Extended forceful coughing fatigues the client, especially postoperatively (option 2). Diaphragmatic and pursed-lip breathing are techniques used for clients with obstructive airway disease (option 4). **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 50-8.
3. **Answer:** 1. **Rationale:** Prior to starting the procedure, it is important to develop a means of communication by which the client can express pain or discomfort. The twill tape is not changed until after performing tracheostomy care (option 2). Cleaning the incision should be done after cleaning the inner cannula (option 3). Checking the tightness of the ties and knot is done after applying new twill tape (option 4). **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 50-11d.
4. **Answer:** 3. **Rationale:** Rotating the catheter prevents pulling of tissue into the opening on the catheter tip and side. Suction catheters may only be lubricated with water or water-soluble lubricant (petroleum jelly, e.g., Vaseline, has an oil base) (option 1). No suction should ever be applied while the catheter is being inserted because this can traumatize tissues (option 2). The client should be hyperoxygenated for only a few minutes before and after suctioning and this is generally limited to clients who are intubated or have a tracheostomy (option 4). **Cognitive Level:** Analyzing. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 50-9.
5. **Answer:** 2. **Rationale:** Proper use of an SMI requires the client to take slow, steady inhalations, every hour or two, 5 to 10 breaths each time. Only the mouthpiece can be successfully rinsed or wiped clean. The device should not be submerged in water (option 4). **Cognitive Level:** Analyzing. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Evaluation. **Learning Outcome:** 50-8.

6. **Answer:** 2. **Rationale:** The tube should be reconnected to the water seal as quickly as possible. Assisting the client back to bed (option 1) and assessing the client's lung (option 3) are possible actions after the system is reconnected. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Implementation. **Learning Outcome:** 50-9.
7. **Answer:** 1. **Rationale:** Anemia is a condition of decreased red blood cells and decreased hemoglobin. Hemoglobin is how the oxygen molecules are transported to the tissues. Option 2 would depend on where the infection is located. Option 3: A fractured rib would interrupt transport of oxygen from the atmosphere to the airways. Option 4: Damage to the medulla would interfere with neural stimulation of the respiratory system. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Assessment. **Learning Outcome:** 50-7.
8. **Answer:** 3. **Rationale:** Respiratory difficulty related to a reclining position without other physical alterations is defined as orthopnea. **Cognitive Level:** Remembering. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Diagnosis. **Learning Outcome:** 50-5.
9. **Answer:** 4. **Rationale:** Glucocorticoids are prescribed because of their anti-inflammatory effect. Options 1, 2, and 3 are not achieved with glucocorticoids. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 50-9.
10. **Answer:** 1. **Rationale:** Postural drainage results in expectoration of large amounts of mucus. Clients sometimes ingest part of the secretions. The secretions may also produce an unpleasant taste in the oral cavity, which could result in nausea/vomiting. This procedure should be done on an empty stomach to decrease client discomfort. **Cognitive Level:** Applying. **Client Need:** Safe, Effective Care Environment. **Nursing Process:** Planning. **Learning Outcome:** 50-8.

Chapter 51: Circulation

1. **Answer:** 1. **Rationale:** Regular physical activity will help promote healthy cardiac functioning and will also promote tissue perfusion. With physical activity the heart muscle becomes more powerful and efficient, and the client has cardiovascular risk factors. Option 2: Improving tissue perfusion may also improve renal perfusion but it is not the primary goal. Option 3: Red, not white, blood cells carry oxygen. Option 4: Effective breathing and airway clearance focus primarily on the respiratory system. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Planning. **Learning Outcome:** 51-4.
2. **Answer:** 3, 1, 4, 2, and 5. **Rationale:** See sequence described on page 1290. **Cognitive Level:** Remembering. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Assessment. **Learning Outcome:** 51-1.
3. **Answer:** 3. **Rationale:** Capillary refill is an assessment of capillary blood flow and thus tissue perfusion. Symmetrical chest expansion (option 1) is an assessment of respiratory function; pursed-lip breathing (option 2) is a technique used to assist clients with obstructive lung diseases to keep alveoli open during respirations. Activity intolerance (option 4) can occur because of low cardiac output (e.g., heart failure). Activity tolerance would indicate adequate tissue perfusion. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 51-4.
4. **Answer:** 3 and 5. **Rationale:** Creatine kinase (CK) and troponin are enzymes that are released into the blood when there is hypoxia and myocardial damage. Option 1 reflects renal function. Option 2 reflects the number of red blood cells. Option 4 reflects level of atherosclerosis, which if increased reflects a risk for myocardial infarction and other cardiovascular diseases. Altered levels 1, 2, and 4 do not cause chest pain. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 51-4.
5. **Answer:** 3. **Rationale:** Very rapid heart rates do not allow adequate time for the ventricles to fill, causing cardiac output to fall. Option 1 is a normal response to exercise and does not reflect poor cardiac output. It could reflect poor cardiac output if the client was experiencing difficulty in breathing. Option 2 is a normal cardiac output of 4,900 mL/min. The formula is $SV \times HR = CO$, which is about 5 L/min. Option 4 is incorrect because positive inotropic drugs (e.g., digoxin) increase contractility of the cardiac muscle and thus increase stroke volume, which increases cardiac output. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 51-1.
6. **Answer:** 3. **Rationale:** Because the clients would experience impaired tissue perfusion resulting in respiratory compensation, they are most likely to experience the sign/symptom of shortness of breath. The client with the MI will experience cardiac impairment resulting in decreased cardiac output as well as severe chest pain resulting in increased oxygen demand with decreased availability. Clients with heart failure will have decreased pumping ability of the cardiac muscle resulting in pulmonary congestion and decreased cardiac output. Clients with anemia have fewer RBCs to carry the oxygen to the tissues, resulting in hypoxia. Options 1 and 4 would be signs for the client with the MI. Option 2 is seen in heart failure. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Planning. **Learning Outcome:** 51-3.
7. **Answer:** 4. **Rationale:** The three cardinal signs of cardiac arrest are apnea, absence of a carotid or femoral pulse, and dilated pupils. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 51-5.
8. **Answer:** 1, 3, and 5. **Rationale:** Option 1: An example of *Ineffective Tissue Perfusion* is a decrease in arterial circulation in the legs related to atherosclerosis. Option 3: Examples of *Decreased Cardiac Output* are clients with MI, heart failure, or tachycardia. Option 5: Not enough blood is being pumped by the heart to meet the demands of the body. *Activity Intolerance* is when the client doesn't have physiological energy for ADLs. Common reasons can be anemias and heart failure. Options 2 and 4: *Acute Confusion* and *Sleep Pattern Disturbance* are not directly related to cardiovascular disease. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosing. **Learning Outcome:** 51-4.
9. **Answer:** 2. **Rationale:** SCDs promote venous return from the legs to the heart. They inflate and deflate plastic sleeves wrapped around the legs to promote venous flow. The sequential inflation and deflation counteract blood stasis in the lower extremities. Option 1: Arterial flow is from the heart to the general circulation. Option 3: Afterload is related to the ventricles' ability to eject blood forward. These devices affect peripheral circulation. Option 4: There is no relationship between pain and the purpose of the devices. **Cognitive Level:** Applying. **Client Need:** Health Promotion and Maintenance. **Nursing Process:** Implementation. **Learning Outcome:** 51-6.
10. **Answer:**

Cognitive Level: Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 51-1.

Chapter 52: Fluid, Electrolyte, and Acid–Base Balance

1. **Answer:** 2. **Rationale:** All other options are indicative of fluid volume excess. A client who has not eaten or drunk anything for several days would be experiencing fluid volume deficit. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 52-4; 52-5.
2. **Answer:** 2. **Rationale:** Further assessment is needed to determine appropriate action. While the nurse may perform some of the interventions in options 1, 3, and 4, assessment is needed initially. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 52-8.
3. **Answer:** Hypertonic. **Cognitive Level:** Remembering. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 52-1.
4. **Answer:** 2. **Rationale:** Because of the retention of CO_2 , the clinical profile of respiratory acidosis includes decreased $\text{pH} < 7.35$, $\text{PaCO}_2 > 42$ mmHg, with varying levels of HCO_3^- related to hypoventilation. Option 1 is respiratory alkalosis, which occurs because of blowing off of CO_2 resulting in a decreased level of acid and retention or production of bicarbonate, which in turn results in $\text{pH} > 7.45$, $\text{PaCO}_2 < 38$ mmHg, $\text{HCO}_3^- > 26$ mEq/L related to hyperventilation. Option 3: Metabolic acidosis occurs because of a gain of hydrogen ions or a loss of HCO_3^- with a $\text{pH} < 7.35$, normal PaCO_2 of 35–45 mmHg, and $\text{HCO}_3^- < 22$ mEq/L, often caused by diarrhea, bicarbonate infusion, or retention related to kidney failure. Option 4: Metabolic alkalosis is caused by gain of bicarbonate or loss of hydrogen ions related to vomiting, gastric suction, or loss of upper gastrointestinal secretions by various other methods. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 52-2; 52-5.
5. **Answer:** 1, 3, and 5. **Rationale:** Options 1, 3, and 5 relate to fluid volume deficit. The data indicate an actual problem, which excludes option 2. Option 4 relates more to fluid volume excess. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Diagnosis. **Learning Outcome:** 52-6.
6. **Answer:** 4. **Rationale:** Salt substitutes contain potassium. The client can still use it within reason. Option 1: Avocado is higher in potassium than most foods. Option 2: Hypokalemia can potentiate digoxin toxicity and checking the pulse will help the client avoid this. Option 3: It is important to take potassium with food to avoid gastric upset. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Evaluation. **Learning Outcomes:** 52-7; 52-8.
7. **Answer:** 2. **Rationale:** Sodium contributes to the function of neural tissue. Because calcium contributes to the function of voluntary muscle contraction, options 1 and 4 are more appropriate for calcium imbalances. Option 3: Because potassium and calcium contribute to cardiac function, irregular pulse is more likely to be associated with those alterations. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 52-5.
8. **Answer:** 2. **Rationale:** Because of CO_2 retention the PaCO_2 is elevated. CO_2 is involved in production of acid, which will result in a decreased pH. HCO_3^- will vary. Option 1: Metabolic acidosis involves a loss of bicarbonate, but no retention of CO_2 . Option 3: Metabolic alkalosis involves a loss of acid or retention of HCO_3^- , but no retention of CO_2 . Option 4: Respiratory alkalosis involves a loss of CO_2 resulting in an increased pH. **Cognitive Level:** Applying. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcome:** 52-5.
9. **Answer:** 4. **Rationale:** The major clinical signs and symptoms of hypocalcemia are due to increased neuromuscular activity and not the renal, cardiac, or GI systems. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Implementation. **Learning Outcome:** 52-8.
10. **Answer:** 2, 4, and 5. **Rationale:** Options 1 and 3 relate to hypermagnesemia. **Cognitive Level:** Analyzing. **Client Need:** Physiological Integrity. **Nursing Process:** Assessment. **Learning Outcomes:** 52-4; 52-5.

Appendix B

Single Measurement Scales Used in NOC

Scale Code*

01	Severely compromised	Substantially compromised	Moderately compromised	Mildly compromised	Not compromised
02	Severe deviation from normal range	Substantial deviation from normal range	Moderate deviation from normal range	Mild deviation from normal range	No deviation from normal range
06	Not adequate	Slightly adequate	Moderately adequate	Substantially adequate	Totally adequate
07	10 and over	7–9	4–6	1–3	None
09	None	Limited	Moderate	Substantial	Extensive
11	Never positive	Rarely positive	Sometimes positive	Often positive	Consistently positive
12	Very weak	Weak	Moderate	Strong	Very strong
13	Never demonstrated	Rarely demonstrated	Sometimes demonstrated	Often demonstrated	Consistently demonstrated
14	Severe	Substantial	Moderate	Mild	None
17	Poor	Fair	Good	Very good	Excellent
18	Not at all satisfied	Somewhat satisfied	Moderately satisfied	Very satisfied	Completely satisfied
19	Consistently demonstrated	Often demonstrated	Sometimes demonstrated	Rarely demonstrated	Never demonstrated
20	No knowledge	Limited knowledge	Moderate knowledge	Substantial knowledge	Extensive knowledge

*Scale numbers are not continuous due to retirement of previous scales.

From *Nursing Outcomes Classification (NOC): Measurement of Health Outcomes*, 5th ed., by S. Moorhead, M. Johnson, M. L. Maas, and E. Swanson, Eds., St. Louis, MO: Mosby, 2012, pp. 12–17. Used with permission.

Glossary

24-hour food recall client recall of all the food and beverages consumed during a typical 24-hour period

Abdominal paracentesis a procedure to obtain a specimen of ascetic fluid for laboratory study and to relieve pressure on the abdominal organs due to the presence of excess fluid

Absorption the process by which a drug passes into the bloodstream

Accommodation a process of change whereby cognitive processes mature sufficiently to allow a person to solve problems that were previously unsolvable

Accountability the ability and willingness to assume responsibility for one's actions and to accept the consequences of one's behavior

Acculturation the involuntary process that occurs when people adapt to or borrow traits from another culture

Acid a substance that releases hydrogen ions (H^+) in solution

Acidosis a condition that occurs with increases in blood carbonic acid or with decreases in blood bicarbonate; blood pH below 7.35

Acquired immunity see Passive immunity

Action stage occurs when a person actively implements behavioral and cognitive strategies to interrupt previous behavior patterns and adopt new ones; this stage requires a great commitment of time and energy

Active euthanasia actions that directly bring about the client's death with or without consent

Active immunity a resistance of the body to infection in which the host produces its own antibodies in response to natural or artificial antigens

Active range-of-motion exercises Isotonic exercises in which the client independently moves each joint in the body through its complete range of movement, maximally stretching all muscle groups within each plane, over the joint

Active transport movement of substances across cell membranes against the concentration gradient

Activity theory the best way to age is to stay active physically and mentally

Activity tolerance the type and amount of exercise or daily activities an individual is able to perform

Activity-exercise pattern refers to a person's pattern of exercise, activity, leisure, and recreation

Actual loss can be identified by others and can arise either in response to or in anticipation of a situation

Acupressure a technique that uses the fingers to apply pressure to specific points along meridians throughout the body

Acupuncture a form of healing in which the therapist applies needles to stimulate specific sites of the body

Acute confusion abrupt onset of confusion that has a reversible cause; also called *delirium*

Acute illness typically characterized by severe symptoms of relatively short duration

Acute infection those that generally appear suddenly or last a short time

Acute pain pain that lasts only through the expected recovery period (as opposed to chronic)

Adaptation the process of modifying to meet new, changing, or different conditions

Adaptive mechanism learned behaviors that assist an individual to adjust to the environment

Adherence the extent to which an individual's behavior (for example, taking medications, following diets, or making lifestyle changes) coincides with medical or health advice; commitment or attachment to a regimen

Adolescence the period during which a person becomes physically and psychologically mature and acquires a personal identity

Adolescent growth spurt the period during puberty when sudden and dramatic physical changes occur

Adult day care a day care center that provides health and social services to older adults

Advance health care directive a variety of legal and lay documents that allow individuals to specify aspects of care they wish to receive should they become unable to make or communicate their preferences

Adventitious breath sounds abnormal breath sounds that occur when air passes through narrowed airways or airways filled with fluid or mucus, or when pleural linings are inflamed

Adverse effects severe side effects that may justify the discontinuation of a drug

Advocate individual who pleads the cause of another or argues or pleads for a cause or proposal

Aerobic growing only in the presence of oxygen

Aerobic exercise any activity during which the body takes in more or an equal amount of oxygen than it expends

Aesthetic knowing providing care and meeting the needs of clients through creativity and style

Afebrile absence of a fever

Affective domain known as the "feeling" domain and is divided into categories that specify the degree of a person's depth of emotional response to tasks; includes feelings, emotions, interests, attitudes, and appreciations

Afterload the resistance against which the heart must pump to eject blood into the circulation

Ageism deep and profound prejudice in American society against older adults

Agglutinins specific antibodies formed in the blood

Agglutinogens a substance that acts as an antigen and stimulates the production of agglutinins

Agnostic a person who doubts the existence of God or a supreme being or believes the existence of God has not been proved

Agonist a drug that interacts with a receptor to produce a response

Agonist analgesic pure opioid drugs that bind slightly to mu receptor sites, producing maximum pain inhibition (morphine, oxycodone, hydromorphone)

Agonist-antagonist analgesic a drug that can act like opioids and relieve pain (agonist effect) when given to a client who has not taken any pure opioids

Airborne precautions used for clients known to have or suspected of having serious illnesses transmitted by airborne droplet nuclei smaller than 5 microns

Alarm reaction the initial reaction of the body to stress, which alerts the body's defenses

Algor mortis the gradual decrease of the body's temperature after death

Alkalosis a condition that occurs with increases in blood bicarbonate or decreases in blood carbonic acid; blood pH above 7.45

Allodynia when nonpainful stimuli (e.g., contact with linen, water, or wind) produce pain

Allopathic medicine term used to describe Western medical practice

Alopecia the loss of scalp hair (baldness) or body hair

Alternative medicine an unrelated group of nonorthodox practices, often with explanatory systems that do not follow conventional biomedical explanations

Alzheimer's disease disease that involves progressive dementia, memory loss, and inability to care for self

Amblyopia reduced visual acuity in one eye

Ambulation the act of walking

Ampule a glass container usually designed to hold a single dose of a drug

Anabolism a process in which simple substances are converted by the body's cells into more complex substances (e.g., building tissue, positive nitrogen balance)

Anaerobic growing only in the absence of oxygen

Anaerobic exercise involves activity in which the muscles cannot draw out enough oxygen from the bloodstream; used in endurance training

Anal stimulation stimulation applied to anus for sexual pleasure

Anaphylactic reaction a severe allergic reaction that usually occurs immediately after the administration of a drug

Andragogy the art and science of helping adults learn

Androgyny belief that most characteristics and behaviors are human qualities and not limited to a gender

Anemia a condition in which the blood is deficient in red blood cells or hemoglobin

Anger an emotional state consisting of a subjective feeling of animosity or strong displeasure

Angiography a diagnostic procedure enabling x-ray visual examination of the vascular system after injection of a radiopaque dye

Angle of Louis the junction between the body of the sternum and the manubrium; the starting point for locating the ribs anteriorly

Animal-assisted therapy the use of specifically selected animals as a treatment modality in health and human service settings

Anions ions that carry a negative charge; includes chlorine (Cl^-), bicarbonate (HCO_3^-), phosphate (HPO_4^{2-}), and sulfate (SO_4^{2-})

Ankylosed permanently immobile joints

Anorexia loss of appetite

Anorexia nervosa a disease characterized by a prolonged inability or refusal to eat, rapid weight loss, and emaciation in individuals who continue to believe they are fat

Anoscopy visual examination of the anal canal using an anoscope (a lighted instrument)

Answer (legal) a written response made by a defendant

Antagonist drug that inhibits cell function by occupying the drug's receptor sites

Antibodies part of the body's plasma proteins, that defend primarily against the extracellular phases of bacterial and viral infections; also called *immunoglobulins*

Anticipatory grief grief experienced in advance of an event

Anticipatory loss the experience of loss before the loss actually occurs

Antigen a substance capable of inducing the formation of antibodies

Antihelix the anterior curve of the auricle's upper aspect

Antiseptic an agent that inhibits the growth of some microorganisms

Anuria the failure of the kidneys to produce urine, resulting in a total lack of urination or output of less than 100 mL/day in an adult

Anxiety a state of mental uneasiness, apprehension, or dread producing an increased level of arousal caused by an impending or anticipated threat to self or significant relationships

Apgar scoring system a scoring system to assess newborn babies

Aphasia any defects in or loss of the power to express oneself by speech, writing, or signs, or to comprehend spoken or written language due to disease or injury of the cerebral cortex

Apical pulse a central pulse located at the apex of the heart

Apical-radial pulse measurement of the apical and radial pulse simultaneously

Apnea a complete absence of respirations

Apocrine glands sweat glands located largely in the axillae and anogenital areas; they begin to function at puberty under the influence of androgens

Approximated closed tissue surfaces

Aromatherapy therapeutic use of essential oils of plants in which odor or fragrance plays an important part

Arrhythmia an irregular heart rhythm

Arterial blood gases specimen of arterial blood that assesses oxygenation, ventilation, and acid-base status

Arterial blood pressure the measure of the pressure exerted by the blood as it pulsates through the arteries

Arteriosclerosis a condition in which the elastic and muscular tissues of the arteries are replaced with fibrous tissue

Ascites a large amount of fluid accumulation in the abdominal cavity

Asepsis freedom from infection or infectious material

Asphyxiation lack of oxygen due to interrupted breathing

Aspiration withdrawal of fluid that has abnormally collected (e.g., pleural cavity, abdominal cavity) or to obtain a specimen (e.g., cerebrospinal fluid)

Assault an attempt or threat to touch another person unjustifiably

Assessing the process of collecting, organizing, validating, and recording data (information) about a client's health status

Assimilation the process by which an individual develops a new cultural identity and becomes like the members of the dominant culture

Assisted living facility with various degrees of personal care assistance designed to meet the needs of an older person

Assisted suicide a form of active euthanasia in which clients are given the means to kill themselves

Astigmatism an uneven curvature of the cornea that prevents horizontal and vertical light rays from focusing on the retina

Atelectasis collapse of the air sacs

Atheist one who denies the existence of God

Atherosclerosis buildup of fatty plaque within the arteries

Atria two upper hollow chambers of the heart

Atrioventricular (AV) node conduction pathways that slightly delay transmission of the impulse from the atria to the ventricles of the heart

Atrioventricular (AV) valves between the atria and ventricles of the heart, the tricuspid valve on the right and the bicuspid or mitral valve on the left

Atrophy wasting away; decrease in size of organ or tissue (e.g., muscle)

Attentive listening listening actively, using all senses, as opposed to listening passively with just the ear

Attitudes mental stance that is composed of many different beliefs; usually involving a positive or negative judgment toward a person, object, or idea

Audit examination or review of records

Auditory related to or experienced through hearing

Auricle flap of the ear; also called *pinna*

Auscultation the process of listening to sounds produced within the body, such as with the use of a stethoscope that amplifies sounds and conveys them to the nurse's ears

Auscultatory gap the temporary disappearance of sounds normally heard over the brachial artery when the sphygmomanometer cuff pressure is high, followed by the reappearance of sounds at a lower level

Authoritarian leader the individual who makes decisions for the group

Authority the power given by an organization to direct the work of others; the right to act

Autoantigen an antigen that originates in a person's own body

Autocratic leader see Authoritarian leader

Automaticity an electrical impulse and contraction independent of the nervous system and generated by the cardiac muscle

Autonomy the state of being independent and self-directed, without outside control, to make one's own decisions

Autopsy an examination of the body after death to determine the cause of death and to learn more about a disease process; also called *postmortem examination*

Awareness the ability to perceive environmental stimuli and body reactions and to respond appropriately through thought and action

Ayurveda Indian system of medicine where illness is viewed as a state of imbalance among the body's systems

Baby boomers generation that includes those born in years 1945–1964

Bacteremia bacteria in the blood

Bacteria the most common infection-causing microorganisms

Bactericidal bacteria-killing action

Balance a state of equilibrium in which opposing forces counteract each other

Bandage a strip of cloth used to wrap some part of the body

Basal metabolic rate (BMR) the rate of energy utilization in the body required to maintain essential activities such as breathing

Base of support the foundation on which an object rests

Bases (alkalis) have low hydrogen ion concentration and can accept hydrogen ions in solution

Battery (legal) the willful or negligent touching of a person (or the person's clothes or even something the person is carrying), which may or may not cause harm

Bed rest strict confinement to bed (complete bed rest), or the client may be allowed to use a bedside commode or have bathroom privileges

Bedpan a receptacle for urine and feces

Behaviorist theory includes the careful identification of what is to be taught and the immediate identification of and reward for correct responses

Beliefs interpretations or conclusions that one accepts as true

Beneficence the moral obligation to do good or to implement actions that benefit clients and their support people

Bereavement a subjective response of a person who has experienced the loss of a significant other through death

Bevel the slanted part at the tip of a needle

Bicultural used to describe a person who crosses two cultures, lifestyles, and sets of values

Bier block see Intravenous block

Binder a type of bandage applied to large body areas (abdomen or chest) that are designed for a specific body part (e.g., arm sling); used to provide support

Bioelectromagnetics science that studies how living organisms interact with electromagnetic fields

Bioethics ethical rules or principles that govern right conduct concerning life

Biofeedback a stress management technique that brings under conscious control bodily processes normally thought to be beyond voluntary command

Biomedical health belief see Scientific health belief

Biomedicine term used to describe Western medical practice

Biopsy removal and examination of tissue

Biorhythms inner rhythms that appear to control a variety of biologic processes

Bioterrorism intentional attack using biologic weapons such as viruses, bacteria, or other germs

Biotransformation process by which a drug is converted to a less active form; also called *detoxification*

Biot's respirations shallow breaths interrupted by apnea

Bladder training client postpones voiding, resists or inhibits the sensation of urgency, and voids according to a timetable rather than according to the urge to void

Blanch test a test during which the client's fingertip is temporarily pinched to assess capillary refill and peripheral circulation

Blood chemistry a number of tests performed on blood serum (the liquid portion of the blood)

Blood pressure (BP) the force exerted on arterial walls by blood flowing within the vessel

Blood urea nitrogen (BUN) a measure of blood level of urea, the end product of protein metabolism

Bloodborne pathogens potentially infectious organisms that are carried in and transmitted through blood or materials containing blood

Body image how a person perceives the size, appearance, and functioning of his or her body and its parts

Body mass index (BMI) indicates whether weight is appropriate for height

Body temperature the balance between the heat produced by the body and the heat lost from the body

Bodymind a state of integration that includes body, mind, and spirit

Boomerang kids slang term used for young adults who move back into their parents' homes after an initial period of independent living

Bottle mouth syndrome describes the decay of an infant's teeth caused by constant contact with sweet liquid from a bottle

Boundary the real or imaginary lines that differentiate one system from another system or a system from its environment

Bowel (fecal) incontinence loss of voluntary ability to control fecal and gaseous discharges through the anal sphincter

Bradycardia abnormally slow pulse rate, less than 60 beats per minute

Bradypnea abnormally slow respiratory rate, usually less than 10 respirations per minute

Brand name name of the drug given by the drug manufacturer; also called the *trade name*

Breach of duty a standard of care that is expected in the specific situation but that the nurse did not observe; this is the failure to act as a reasonable, prudent nurse under the circumstances

Bronchoscopy visual examination of the bronchi using a bronchoscope

Bruit a blowing or swishing sound created by turbulence of blood flow

Buccal a medication (e.g., a tablet) that is held in the mouth against the mucous membranes of the cheek until the drug dissolves

Buffers prevent excessive changes in pH by removing or releasing hydrogen ions

Bulimia an uncontrollable compulsion to eat large amounts of food and then expel it by self-induced vomiting or by taking laxatives

Bundle of His the right and left bundle branches of the ventricular conduction pathways

Burden of proof the duty of proving an assertion

Bureaucratic leader does not trust self or others to make decisions and instead relies on the organization's rules, policies, and procedures to direct the group's work efforts

Burn results from excessive exposure to thermal, chemical, electric, or radioactive agents

Burnout a complex syndrome of behaviors that can be likened to the exhaustion stage of the general adaptation syndrome; an overwhelming feeling that can lead to physical and emotional depletion, a negative attitude and self-concept, and feelings of helplessness and hopelessness

Calculi renal stones

Callus a thickened portion of the skin

Caloric value the amount of energy that nutrients or foods supply to the body

Calorie (c, cal, kcal) a unit of heat energy equivalent to the amount of heat required to raise the temperature of 1 kg of water 1°C

Cancer pain pain associated with cancers; can be related or unrelated to the disease or its treatment

Cannula a tube with a lumen (channel) that is inserted into a cavity or duct and is often fitted with a trocar during insertion for abdominal paracentesis; the part of the needle that is attached to the hub; also called a *shaft*

Carbon monoxide an odorless, colorless, tasteless gas that is very toxic

Cardiac arrest the cessation of heart function

Cardiac output (CO) the amount of blood ejected by the heart with each ventricular contraction

Cardinal signs see Vital signs

Caregiver a role that has traditionally included those activities that assist the client physically and psychologically

Caregiver burden responses to long-term stress, such as chronic fatigue, sleeping difficulties, and high blood pressure, in family members who undertake the care of a person in the home for a long period

Caregiver role strain physical, emotional, social, and financial burdens that can seriously jeopardize the caregiver's own health and well-being

Caries tooth cavities

Caring intentional action that conveys physical and emotional security and genuine connectedness with another person or group of people

Caring practice nursing care that includes connection, mutual recognition, and involvement

Carminative an agent that promotes the passage of flatus from the colon

Carrier a person or animal that harbors a specific infectious agent and serves as a potential source of infection, yet does not manifest any clinical signs of disease

Case management a method for delivering nursing care in which the nurse is responsible for a caseload of clients across the health care continuum

Case manager a nurse who works with the multidisciplinary health care team to measure the effectiveness of the case management plan and monitor outcomes

Catabolism a process in which complex substances are broken down into simpler substances (e.g., breakdown of tissue)

Cataract an opacity of the eye lens or its capsule that blocks light rays

Cathartics drugs that induce defecation

Cations ions that carry a positive charge; includes sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), and magnesium (Mg^{2+})

Causation a fact that must be proven that the harm occurred as a direct result of the nurse's failure to follow the standard of care and the nurse could have (or should have) known that failure to follow the standard of care could result in such harm

Cell-mediated defenses see Cellular immunity

Cellular immunity occurs through the T-cell system; also known as *cell-mediated defenses*

Center of gravity the point at which all of the mass (weight) of an object is centered

Central neuropathic pain pain that results from malfunctioning nerves in the central nervous system (e.g., spinal cord injury pain, poststroke pain, or multiple sclerosis)

Central venous access device defined by the location of the catheter tip in a central vein, in the lower one third of the superior vena cava, above the right atrium

Central venous catheter catheter that is usually inserted into the subclavian or jugular vein, with the distal tip of the catheter resting in the superior vena cava just above the right atrium

Cephalocaudal proceeding in the direction from head to toe

Cerebral death occurs when the cerebral cortex is irreversibly destroyed; also called *higher brain death*

Cerumen earwax

Change process of making something different from what it was

Change agents individuals (or groups) who initiate change or who assist others in making modifications in themselves or in the system

Change-of-shift report a report given to nurses on the next shift

Charismatic leader characterized by an emotional relationship between the leader and the group members; personality of the leader evokes strong feelings of commitment to both the leader and the leader's cause and beliefs

Chart a formal, legal document that provides evidence of a client's care

Charting the process of making an entry on a client record

Charting by exception (CBE) a documentation system in which only significant findings or exceptions to norms are recorded

Chemical name the name by which a chemist knows a drug; describes the constituents of the drug precisely

Chemical restraints medications used to control socially disruptive behavior

Cheyne-Stokes respirations rhythmic waxing and waning of respirations from very deep breathing to very shallow breathing with periods of temporary apnea, often associated with cardiac failure, increased intracranial pressure, or brain damage

Chiropractic from the Greek meaning "done by hand"; involves adjustments of the spine and joints and is grounded in the assumption that maintaining the alignment of the spine and joints facilitates the flow of energy throughout the body, including the nervous, circulatory, respiratory, gastrointestinal, and limbic systems

Cholesterol a lipid that does not contain fatty acid but possesses many of the chemical and physical properties of other lipids

Chronic illness illness that lasts for an extended period of time, usually longer than 6 months

Chronic infection infection that occurs slowly, over a very long period, and may last months or years

Chronic pain prolonged pain, usually recurring or persisting over 6 months or longer, that interferes with functioning

Chyme contents of the colon

Circulating immunity see Humoral immunity

Circulating nurse coordinates activities and manages client care by continually assessing client safety, aseptic practice, and the environment (e.g., temperature, humidity, and lighting); with the scrub nurse, is responsible for accounting for all sponges, needles, and instruments at the close of surgery

Civil action deals with the relationship between individuals in society

Civil law the body of law that deals with relationships among private individuals; also known as *private law*

Clara Barton a schoolteacher who volunteered as a nurse during the Civil War. Most notably, she organized the American Red Cross, which linked with the International Red Cross when the U.S. Congress ratified the Geneva Convention in 1882

Clean free of potentially infectious agents

Clean voided specimen urine specimens for routine urinalysis

Clean-catch specimen urine specimens for urine culture; also called *midstream urine specimen*

Cleansing bath a bath given for hygienic purposes

Client a person who engages the advice or services of another person who is qualified to provide this service

Client record see Chart

Climacteric the point in development when reproduction capacity in the female terminates (menopause) and the sexual activity of the male decreases (andropause)

Clinical aromatherapy the controlled use of essential oils for specific measurable outcomes

Clinical judgment decision-making process to ascertain the right nursing action to be implemented at the appropriate time in the client's care

Clinical reasoning cognitive process that uses thinking strategies to gather, analyze, and evaluate the relevance of client information, and decide on possible nursing actions to improve the client's physiological and psychosocial outcomes

Closed awareness a type of awareness in which the client is unaware of impending death

Closed questions restrictive question requiring only a short answer

Closed suction system a method for suctioning an endotracheal tube or tracheostomy in which the suction catheter, enclosed in a plastic sheath, attaches to the ventilator tubing, and the client does not need to be disconnected from the ventilator

Closed wound drainage system consists of a drain connected to either electric suction or a portable drainage suction

Clubbing elevation of the proximal aspect of the nail and softening of the nail bed

Coanalgesic a medication that is not classified as a pain medication but has properties that may reduce pain alone or in combination with other analgesics, relieve other discomforts, potentiate the effect of pain medication, or reduce the pain medication's side effects

Cochlea a seashell-shaped structure found in the inner ear; essential for sound transmission and hearing

Code blue term used by an agency such as a hospital to indicate a medical emergency such as a cardiac or respiratory arrest

Code of ethics a formal statement of a group's ideals and values; a set of ethical principles shared by members of a group, reflecting their moral judgments and serving as a standard for professional actions

Cognitive development refers to the manner in which people learn to think, reason, and use language

Cognitive domain the "thinking" domain, includes six intellectual abilities and thinking processes beginning with knowing, comprehending, and applying to analysis, synthesis, and evaluation

Cognitive skills intellectual skills that include problem solving, decision making, critical thinking, and creativity

Cognitive theory recognition of developmental levels of learners, and acknowledgments of the learner's motivation and environment

Coinsurance an insurance plan in which the client pays a percentage of the payment and some other group (e.g., employer, government) pays the remaining percentage

Collaboration a collegial working relationship with another health care provider in the provision of client care

Collaborative care plans see Critical pathways

Collaborative interventions actions the nurse carries out in collaboration with other health team members, such as physical therapists, social workers, dietitians, and physicians

Collagen a protein found in connective tissue; a whitish protein substance that adds tensile strength to a wound

Colloid osmotic pressure a pulling force exerted by colloids that help maintain the water content of blood; also called *oncotic pressure*

Colloids substances such as large protein molecules that do not readily dissolve into true solutions

Colonization the presence of organisms in body secretions or excretions in which strains of bacteria become resident flora but do not cause illness

Colonoscopy visual examination of the interior of the colon with a colonoscope

Colostomy a temporary or permanent opening into the colon (large bowel) to divert and drain fecal material

Commode a portable chair with a toilet seat and a receptacle underneath that can be emptied; often used for the adult client who is able to get out of bed but is unable to walk to the bathroom

Common law the body of principles that evolves from court decisions

Communicable disease a disease that can spread from one person to another

Communication a two-way process involving the sending and receiving of messages

Communicator a nurse identifies client problems and then communicates them verbally or in writing to other members of the health team

Community a collection of people who share some attribute of their lives

Community health nursing the synthesis of nursing and public health practice as applied to promoting and preserving the health of populations

Community nursing centers (CNCs) provide primary care to specific populations and are staffed by nurse practitioners and community health nurses

Community-based health care (CBHC) a system that provides health-related services within the context of people's daily lives; that is, in places where people spend their time in the community

Community-based nursing (CBN) nursing care directed toward a specific population or group within the community; primary, secondary, or tertiary care may be provided to individuals or groups

Compensation defense mechanism in which a person substitutes an activity for one that he or she would prefer doing or cannot do

Compensatory counterbalancing

Complaint (legal) a document filed by a plaintiff

Complementary and alternative medicine (CAM) those practices that do not form part of the dominant system for managing health and disease

Complementary medicine see Alternative medicine

Complementary therapies therapeutic practices that are not currently considered an integral part of conventional allopathic medical practice

Complete blood count (CBC) specimens of venous blood; includes hemoglobin and hematocrit measurements, erythrocyte (RBC) count, leukocyte (WBC) count, red blood cell indices, and a differential white cell count

Complete proteins a protein that contains all of the essential amino acids as well as many nonessential ones

Compliance the extent to which an individual's behavior coincides with medical or health advice

Complicated grief pathologic grief; exists when coping strategies are maladaptive

Compress a moist gauze dressing applied frequently to an open wound, sometimes medicated

Compromised host any person at increased risk for an infection

Computed tomography (CT) a painless, noninvasive x-ray procedure that has the unique capability of distinguishing minor differences in the density of tissues

Computer-based patient records (CPRs) electronic client data retrievable by caregivers, administrators, accreditors, and other individuals who require the data

Concept map a visual tool in which ideas or data are enclosed in circles or boxes of some shape and relationships between these are indicated by connecting lines or arrows

Concepts abstract ideas or mental images of phenomena or reality

Conceptual framework a group of related concepts

Conceptual model a graphic illustration of the relationships among concepts

Concurrent audit evaluation of a client's health care while the client is still receiving care from the agency

Conduction the transfer of heat from one molecule to another in direct contact

Conductive hearing loss the result of interrupted transmission of sound waves through the outer and middle ear structures

Confidentiality any information a subject relates will not be made public or available to others without the subject's consent

Congruent communication occurs when the verbal and nonverbal aspects of the message match

Conjunctivitis inflammation of the bulbar and palpebral conjunctiva

Conscious sedation a minimal depression of level of consciousness during which the client retains the ability to consciously maintain a patent airway and respond appropriately to verbal and physical stimuli

Consequence-based (teleological) theories the ethics of judging whether an action is moral

Constant fever a state in which the body temperature fluctuates minimally but always remains above normal

Constipation passage of small, dry, hard stool or passage of no stool for a period of time

Consultative leader see Democratic leader

Consumer an individual, a group of people, or a community that uses a service or commodity

Contact precautions used for clients known or suspected to have serious illnesses easily transmitted by direct client contact or by contact with items in the client's environment (GI, respiratory, skin or wound infections, etc.)

Contemplation stage stage in which a person acknowledges having a problem, seriously considers changing a specific behavior, actively gathers information, and verbalizes plans to change the behavior in the near future

Continuing education (CE) formalized experiences designed to enlarge the knowledge or skills of practitioners

Continuity of care the coordination of health care services by health care providers for clients moving from one health care setting to another and between and among health care professionals

Continuity theory people maintain their values, habits, and behavior in old age

Contract a written or verbal agreement between two or more people to do or not do some lawful act

Contract law the enforcement of agreements among private individuals or the payment of compensation for failure to fulfill the agreement

Contractility the inherent ability of cardiac muscle fibers to shorten or contract

Contractual obligations duty of care established by the presence of an expressed or implied contract

Contractual relationships vary among practice settings; may be as an independent or employer–employee relationship

Contracture permanent shortening of a muscle

Convection the dispersion of heat by air currents

Conventional medicine term used to describe Western medical practice

Coordinating the process of ensuring that plans are carried out and evaluating outcomes

Coping dealing with change

Coping mechanism an innate or acquired way of responding to a changing environment or specific problem or situation

Coping strategy see Coping mechanism

Core self-concept the beliefs and images that are most vital to an individual's identity

Core temperature the temperature of the deep tissues of the body (e.g., abdominal cavity, pelvic cavity). When measured orally, the average body temperature of an adult is between 36.7°C and 37°C (98°F and 98.6°F)

Corn a conical, circular, painful, raised area on the toe or foot

Coronary arteries a network of vessels known as the coronary circulation

Coroner a physician who is authorized by the county or other government agency to determine causes of deaths under unusual circumstances

Costal (thoracic) breathing movement of the chest upward and outward

Counseling the process of helping a client to recognize and cope with stressful psychological or social problems, to develop improved interpersonal relationships, and to promote personal growth

Countershock phase second part of the alarm reaction in which the changes the body experienced during the shock phase are reversed

Covert data (systems, subjective data) information (data) apparent only to the person affected that can be described or verified only by that person

Creatine kinase (CK) enzyme that is released into the blood during a myocardial infarction

Creatinine a nitrogenous waste that is excreted in the urine

Creativity thinking that results in the development of new ideas and products

Credentialing the process of determining and maintaining competence in practice; includes licensure, registration, certification, and accreditation

Credé's maneuver manual exertion of pressure on the bladder to force urine out

Creptitation (1) a dry, crackling sound like that of crumpled cellophane, produced by air in the subcutaneous tissue or by air moving through fluid in the alveoli of the lungs; (2) a crackling, grating sound produced by bone rubbing against bone

Crime an act committed in violation of public (criminal) law and punishable by a fine and/or imprisonment

Criminal actions deal with disputes between an individual and the society as a whole

Criminal law deals with actions against the safety and welfare of the public

Crisis counseling therapy focused on solving immediate problems involving individuals, groups, or families in crisis

Crisis intervention a short-term helping process of assisting clients to work through a crisis to its resolution and restore their precrisis level of functioning

Critical analysis a set of questions one can apply to a particular situation or idea to determine essential information and ideas and discard superfluous information and ideas

Critical pathways multidisciplinary guidelines for client care based on specific medical diagnoses designed to achieve predetermined outcomes

Critical theory describes theories that help elucidate how social structures affect a wide variety of human experiences from art to social practices

Critical thinking a cognitive process that includes creativity, problem solving, and decision making

Cross-dresser individual of one gender (typically male) who dresses in clothing specific to the opposite gender

Crystalloids salts that dissolve readily into true solutions

Cues any piece of information or data that influences decisions

Cultural care deprivation lack of culturally assistive, supportive, or facilitative acts

Cultural deprivation see Cultural care deprivation

Culturally appropriate application of underlying background knowledge that must be possessed to provide a given client with the best possible health care

Culturally competent within the delivered care the nurse understands and attends to the total context of the client's situation and uses a complex combination of knowledge, attitudes, and skills

Culturally sensitive care that demonstrates basic knowledge of and constructive attitudes toward the health traditions observed among the diverse cultural groups found in the setting

Culture a worldview and set of traditions used and transmitted from generation to generation by a particular group; includes related attitudes and institutions

Culture shock a disorder that occurs in response to transition from one cultural setting to another

Cultures laboratory cultivations of microorganisms in a special growth medium

Cumulative effect the increasing response to repeated doses of a drug that occurs when the rate of administration exceeds the rate of metabolism or excretion

Curanderismo cultural healing tradition found in Latin America that uses Western medicine beliefs, treatments, and practices at three levels of care: material level, spiritual level, and mental level

Cyanosis a bluish tinge of skin color

Cystoscope a lighted instrument used to visualize the interior of the urinary bladder

Cystoscopy visual examination of the urinary bladder with a cystoscope

Dacryocystitis inflammation of the lacrimal sac

Damages if professional negligence caused an injury, the nurse is held liable for compensation in the form of damages

Dandruff a diffuse scaling of the scalp, often accompanied by itching

Data information

Data warehousing the accumulation of large amounts of data that are stored over time

Database all information about a client, includes nursing health history and physical assessment, physician's history, physical examination, and laboratory and diagnostic test results

Debridement removal of infected and necrotic material

Decision (legal) outcome made by a judge

Decision making the process of establishing criteria by which alternative courses of action are developed and selected

Decode to relate the message perceived to the receiver's storehouse of knowledge and experience and to sort out the meaning of the message

Decubitus ulcers see Pressure ulcers

Deductive reasoning making specific observations from a generalization

Defamation (legal) a communication that is false, or made with careless disregard for the truth, and results in injury to the reputation of another

Defecation expulsion of feces from the anus and rectum

Defendant (legal) person against whom a plaintiff files a complaint

Defense mechanism method the ego uses to fulfill the needs of the id in a socially acceptable manner; also called *adaptive mechanism*

Defining characteristics client signs and symptoms that must be present to validate a nursing diagnosis

Dehiscence the partial or total rupturing of a sutured wound; usually involves an abdominal wound in which the layers below the skin also separate

Dehydration insufficient fluid in the body

Delegation transference of responsibility and authority for an activity to a competent individual

Delirium abrupt onset of confusion that has a reversible cause; also called *acute confusion*

Demand feeding the feeding of a child when the child is hungry

Dementia a global impairment of cognitive function that usually is progressive and may be permanent; interferes with normal social and occupational activities

Democratic leader encourages group discussion and decision making

Demography the study of population, including statistics about distribution by age and place of residence, mortality, and morbidity

Dental caries tooth decay

Denver Developmental Screening Test (DDST-II) a screening test used to assess children from birth to 6 years of age

Dependent functions with regard to medical diagnoses, physician-prescribed therapies and treatments nurses are obligated to carry out

Dependent interventions activities carried out on the orders or supervision of a licensed physician or other health care provider authorized to write orders for nurses

Dependent variable the behavior, characteristic, or outcome that the researcher wishes to explain or predict

Depression feelings of sadness and dejection, often accompanied by physiological change such as decreased functional activity

Descriptive statistics procedures that summarize large volumes of data; used to describe and synthesize data, showing patterns and trends

Desire phase part of the response cycle, which starts in the brain, with conscious sexual desires

Desired effect see Therapeutic effect

Detoxification see Biotransformation

Detrusor muscle the smooth muscle layers of the bladder

Development an individual's increasing capacity and skill in functioning, related to growth

Developmental stage level of achievement for a particular segment of a person's life

Developmental task skill or behavior pattern learned during stages of development

Diagnosis a statement or conclusion concerning the nature of some phenomenon

Diagnosis-related groups (DRGs) a Medicare payment system to hospitals and physicians that establishes fees according to diagnosis

Diagnostic labels title used in writing a nursing diagnosis; taken from the NANDA International standardized taxonomy of terms

Dialysis the technique by which blood is filtered for the removal of body wastes and excess fluid

Diaphragmatic (abdominal) breathing breathing that involves the contraction and relaxation of the diaphragm, as observed by the movement of the abdomen

Diarrhea defecation of liquid feces and increased frequency of defecation

Diastolic pressure the pressure of the blood against the arterial walls when the ventricles of the heart are at rest

Diastole in measuring blood pressure, the period during which the ventricles relax

Diet history a comprehensive assessment of a client's food intake that involves an extensive interview by a nutritionist or dietitian

Differentiated practice a system in which the best possible use of nursing personnel is based on their educational preparation and resultant skill sets

Diffusion the mixing of molecules or ions of two or more substances as a result of random motion

Directing a management function that involves communicating the task to be completed and providing guidance and supervision

Directive interview a highly structured interview that uses closed questions to elicit specific information

Dirty denotes the likely presence of microorganisms, some of which may be capable of causing infection

Disaccharides sugars that are composed of double molecules

Discharge planning the process of anticipating and planning for client needs after discharge

Discovery (legal) pretrial activities to gain all of the facts of a situation

Discrimination the differential treatment of individuals or groups

Discussion an informal oral consideration of a subject by two or more health care personnel to identify a problem or establish strategies to resolve a problem

Disease an alteration in body function resulting in a reduction of capacities or shortening of the normal life span

Disease prevention behavior motivated by a desire to actively avoid illness, detect it early, or maintain functioning within the constraints of illness (also called *health protection*)

Disengagement theory aging involves mutual withdrawal (disengagement) between an older individual and others in that individual's environment

Disinfectant agent that destroys microorganisms other than spores

Dissatisfaction problems dissatisfaction with sexual encounters despite desire, arousal, and orgasm

Distance learning learning in which people communicate effectively across long distances

Distribution the transportation of a drug from its site of absorption to its site of action

Diuresis the production of large amounts of urine by the kidneys without an increased fluid intake; also known as *polyuria*

Diuretics agents that increase urine secretion

Diversity the fact or state of being different

Documenting the process of making an entry on a client record; charting, recording

Dorothea Dix woman leader who provided nursing care during the Civil War

Dorsal position a back-lying position without a pillow; also called the *supine position*

Dorsal recumbent (back-lying) position a supine position with the head and shoulders slightly elevated

Drop factor the number of drops that equal 1 mL as specified on the package of IV tubing

Droplet nuclei residue of evaporated droplets emitted by an infected host, such as someone with tuberculosis, that can remain in the air for long periods of time

Droplet precautions used for clients known or suspected to have serious illnesses transmitted by particle droplets larger than 5 microns (diphtheria, mycoplasma, pneumonia)

Drug a chemical compound taken for disease prevention, diagnosis, cure, or relief or to affect the structure or function of the body

Drug abuse excessive intake of a substance either continually or periodically

Drug allergy an immunologic reaction to a drug

Drug dependence inability to keep the intake of a drug or substance under control

Drug habituation a mild form of psychological dependence on a drug

Drug half-life the time required for the elimination process to reduce the concentration of a drug to one half of what it was at initial administration; also called *elimination half-life*

Drug interaction the beneficial or harmful interaction of one drug with another drug

Drug tolerance a condition in which successive increases in the dosage of a drug are required to maintain a given therapeutic effect

Drug toxicity the quality of a drug that exerts a deleterious effect on an organism or tissue

Dullness (of sound) a thudlike sound produced by dense tissue such as the liver, spleen, or heart

Durable medical equipment (DME) companies companies that provide health care equipment for clients at home

Duration (of sound) Its length (long or short) during auscultation

Duty (legal) the nurse must have (or should have had) a relationship with the client that involves providing care and following an acceptable standard of care

Dysesthesia an unpleasant abnormal sensation that mimics the pathology of central neuropathic pain disorder, such as pain that follows a stroke or spinal cord injury

Dysmenorrhea painful menstruation

Dyspareunia difficult or painful intercourse

Dysphagia difficulty swallowing

Dyspnea difficult or labored breathing

Dysrhythmia a pulse with an irregular rhythm

Dysuria painful or difficult voiding

Eccrine glands glands that produce sweat; found over most of the body

Echocardiogram a noninvasive test that uses ultrasound to visualize structures of the heart and evaluate left ventricular function

Ectoderm the outer layer of tissue formed in the second week of life

Edema the presence of excess interstitial fluid in the body that makes skin appear swollen, shiny, and taut, and tends to blanch color

Effectiveness a measure of the quality or quantity of services provided

Efficiency a measure of the resources used in the provision of nursing services

Effleurage a stroking massage technique

Ego the realistic part of the person that balances the gratification demands of the id with the limitations of social and physical circumstances

Ejaculation expulsion of seminal fluid and sperm

Elasticity of the arterial wall expansibility or stretching of the vessels

Elderspeak speech style similar to babytalk; gives the message of dependence and incompetence to older adults

Elective surgery performed when surgical intervention is the preferred treatment for a condition that is not imminently life threatening or to improve the client's life

Electric shock occurs when a current travels through the body to the ground rather than through electric wiring, or from static electricity that builds up on the body

Electrocardiogram (ECG, EKG) a graph of the electric activity of the heart

Electrocardiography provides a graphic recording of the heart's electrical activity

Electroencephalogram (EEG) a graph of the electrical activity of the brain

Electrolytes chemical substances that develop an electric charge and are able to conduct an electric current when placed in water; ions

Electromyogram (EMG) a graph of the electrical activity of muscles

Electronic communication communication involving computers and technology (i.e., e-mail)

Electronic health records (EHRs) see Computer-based patient records (CPRs)

Electro-oculogram (EOG) a graph of the electrical activity of eye to eye movement

Elimination half-life see Drug half-life

Embolus a blood clot (or a substance such as air) that has moved from its place of origin and is causing obstruction to circulation elsewhere (plural: *emboli*)

Embryonic phase the phase during which the fertilized ovum develops into an organism with most of the features of a human

Emergency surgery surgery that is performed immediately to preserve function or the life of the client

Emmetropic normal refraction so that the eyes focus images on the retina

Empathy the ability to discriminate what the other person's world is like and to communicate to the other this understanding in a way that shows that the helper understands the client's feelings and the behavior and experience underlying these feelings

Emphysema a chronic pulmonary condition in which the alveoli are dilated and distended

Empirical data information collected from the observable world

Empirical knowing knowledge that comes from science; ranges from factual, observable phenomena to theoretical analysis

Encoding involves the selection of specific signs or symbols (codes) to transmit the message, such as which language and words to use, how to arrange the words, and what tone of voice and gestures to use

Endocardium a layer of the heart wall lining the inside of the heart's chambers and great vessels

Endoderm the inner layer of tissue formed in the second week of life

End-of-life care the care provided in the final weeks before death

Endogenous developing from within

Enema used most often as a treatment for constipation, it distends the intestine and sometimes irritates the intestinal mucosa, thereby increasing peristalsis and the excretion of feces and flatus

Energy the force that integrates the body, mind, and spirit

Enteral through the gastrointestinal system

Entoderm see Endoderm

Enuresis bed-wetting; involuntary passing of urine in children after bladder control is achieved

Environment all of the conditions, circumstances, and influences surrounding and affecting the development of an organism or person

Enzymes biologic catalysts that speed up chemical reactions

Epicardium the visceral pericardium adhering to the surface of the heart, forming the heart's outermost layer

Epidural the injection of an anesthetic agent into the epidural or intrathecal (subarachnoid) space

Epidural anesthesia the injection of an anesthetic agent into the epidural space; also known as *peridural anesthesia*

Equianalgesia refers to the relative potency of various opioid analgesics compared to a standard dose of parenteral morphine

Equilibrium a state of balance

Erectile dysfunction the inability to achieve or maintain an erection sufficient for sexual satisfaction for oneself or one's partner

Erythema a redness tinge of skin color associated with a variety of skin rashes

Erythrocytes red blood cells (RBCs)

Eschar necrotic tissue

Essential amino acids amino acids that cannot be manufactured in the body and must be supplied as part of the protein ingested in the diet

Ethical knowing knowledge that focuses on matters of obligation or what ought to be done

Ethics the rules or principles that govern right conduct

Ethnic belonging to a specific group of individuals who share a common social and cultural heritage

Ethnocentrism the belief that one's own culture or way of life is better than that of others

Ethnography research that provides a framework to focus on the culture of a group of people

Ethnopharmacology study of the effect of ethnicity on responses to prescribed medicines

Etiology the causal relationship between a problem and its related or risk factors

Eupnea normal, quiet breathing

Eustachian tube the part of the middle ear that connects the middle ear to the nasopharynx; stabilizes air pressure between the external atmosphere and the middle ear

Euthanasia the act of painlessly putting to death individuals suffering from incurable or distressing disease

Evaluating a planned ongoing, purposeful activity in which clients and health care professionals compare expected outcomes to actual outcomes

Evaluation statement a statement that consists of two parts: a conclusion and supporting data

Evidence-based practice (EBP) the use of some form of substantiation in making clinical decisions

Evisceration extrusion of the internal organs

Exacerbation the period during a chronic illness when symptoms reappear after remission

Excitement/plateau phase part of the response cycle, involves vasocongestion and myotonia

Excoriation loss of the superficial layers of the skin

Excretion elimination of a waste product produced by the body cells from the body

Exercise a type of physical activity; a planned, structured, and repetitive bodily movement done to improve or maintain one or more components of physical fitness

Exhalation (expiration) breathing out, or the movement of gases from the lungs to the atmosphere

Exogenous developing from outside sources

Exophthalmos a protrusion of the eyeballs with elevation of the upper eyelids, resulting in a startled or staring expression

Expectorate spit out

Expert witness one who has special training, experience, or skill in a relevant area and is allowed by the court to offer an opinion on some issue within that area of expertise

Expiration (exhalation) the outflow of air from the lungs to the atmosphere

Express consent an oral or written agreement

Extended family family that includes the relatives of the nuclear family (e.g., grandparents, aunts, uncles)

External auditory meatus the entrance to the ear canal

Extinction the failure to perceive touch on one side of the body when two symmetric areas of the body are touched simultaneously

Extracellular fluid (ECF) fluid found outside the body cells

Exudate purulent drainage

Fabiola a wealthy Roman matron; viewed by some as the patron saint of early nursing who used her position and wealth to establish hospitals for the sick

Fad a widespread but short-lived interest, or a practice followed with considerable zeal

Failure to thrive (FTT) a unique syndrome in which an infant falls below the fifth percentile for weight and height on a standard growth chart or is falling in percentiles on a growth chart

Faith an active "mode of being-in-relation" to another or others in which we invest commitment, belief, love, and hope

False imprisonment the unlawful restraint or detention of another person against his or her wishes

Family the basic unit of society that consists of those individuals, male or female, youth or adult, legally or not legally related, genetically or not genetically related, who are considered by others to represent their significant individuals

Family-centered nursing nursing that considers the health of the family as a unit in addition to the health of individual family members

Fats lipids that are solid at room temperature

Fat-soluble vitamins A, D, E, and K vitamins that the body can store

Fatty acids the basic structural units of most lipids made up of carbon chains and hydrogen

Fear an emotional response to an actual, present danger

Feasibility the availability of time as well as the material and human resources needed to investigate a research problem or question

Febrile pertaining to a fever; feverish

Fecal impaction a mass or collection of hardened, putty-like feces in the folds of the rectum

Fecal incontinence see Bowel incontinence

Feces excreted waste products; also called *stool*

Feedback the response or message that the receiver returns to the sender during communication

Felony a crime of a serious nature, such as murder, punishable by a term in prison

Female orgasmic disorder when the female sexual response stops before orgasm occurs

Female sexual arousal disorder when lack of vaginal lubrication causes discomfort or pain during intercourse

Fetal phase characterized by a period of rapid growth in the size of the fetus; both genetic and environmental factors affect its growth

Fever elevated body temperature

Fever spike a temperature that rises to fever level rapidly following a normal temperature and then returns to normal within a few hours

Fibrin an insoluble protein formed from fibrinogen during the clotting of blood

Fidelity a moral principle that obligates the individual to be faithful to agreements and responsibilities one has undertaken

Fifth vital sign pain, as viewed by many health facilities

Filtration process whereby fluid and solutes move together across a membrane from one compartment to another

Filtration force see Hydrostatic pressure

Filtration pressure the pressure in a compartment that results in the movement of fluid and substances dissolved in fluid out of the compartment

First-level manager a manager responsible for managing the work of nonmanagerial personnel and the day-to-day activities of a specific work group or groups

Fissures deep grooves that occur as a result of dryness and cracking of the skin

Fixation immobilization or the inability of the personality to proceed to the next developmental stage because of anxiety

Flaccid weak or lax

Flatness (of sound) an extremely dull sound produced, during percussion, by very dense tissue, such as muscle or bone

Flatulence the presence of excessive amounts of gas in the stomach or intestines

Flatus gas or air normally present in the stomach or intestines

Florence Nightingale considered the founder of modern nursing, she was influential in developing nursing education, practice, and administration

Flow sheet a record of the progress of specific or specialized data such as vital signs, fluid balance, or routine medications; often charted in graph form

Fluid volume deficit (FVD) (hypovolemia) loss of both water and electrolytes in similar proportions from the extracellular fluid

Fluid volume excess (FVE) (hypervolemia) retention of both water and sodium in similar proportions to normal extracellular fluid (ECF)

Focus charting a method of charting that uses key words or foci to describe what is happening to the client

Folk medicine beliefs and practices relating to illness prevention and healing that derive from cultural traditions rather than from modern medicine's scientific base

Fontanelles unossified membranous gaps in the bone structure of the skull of a newborn that make molding of the head possible

Food diary a detailed record of measured amounts (portion sizes) of all food and fluids a client consumes during a specified period, usually 3 to 7 days

Food frequency record a checklist that indicates how often general food groups or specific foods are eaten

Foot drop plantar flexion contracture

Foreseeability a link that must exist between the nurse's act and the injury suffered

Formal leader an appointed leader selected by an organization and given official authority to make decisions and act

Formal nursing care plan a written or computerized guide that organizes information about the client's care

Fowler's position a semisitting position in which the head of the bed is raised to an angle between 45° and 60°, typically at 45°

Friction rubbing; the force that opposes motion

Full disclosure a basic right, which means that deception, either by withholding information about a client's participation in a study or by

giving the client false or misleading information about what participating in the study will involve, must not occur

Functional strength ability of the body to perform work

Fungi infection-causing microorganisms that include yeasts and molds

Gait the way a person walks

Gastrocolic reflex increased peristalsis of the colon after food has entered the stomach

Gastrostomy an opening through the abdominal wall into the stomach

Gastrostomy tube a tube that is surgically placed directly into the client's stomach and provides another route for administering nutrition and medications

Gauge the diameter of the shaft of a needle; the larger the gauge number, the smaller the diameter of the shaft

Gender indicates biologic male or female status

Gender identity a person's sense of being masculine or feminine, as distinct from being male or female

Gender-role behavior outward expression of a person's sense of maleness or femaleness

General adaptation syndrome (GAS) (Selye) a general arousal response of the body to a stressor characterized by certain physiological events and dominated by the sympathetic nervous system

General anesthesia the induced loss of all sensation and consciousness

Generation X generation that includes those born in years 1965–1978

Generation Y generation that includes those born in years 1979–2000

Generativity concern for establishing and guiding the next generation

Generic name (of drug) given before a drug officially becomes an approved medication; generally used throughout the drug's lifetime

Genital intercourse penile/vaginal intercourse (coitus)

Geragogy the term used to describe the process involved in stimulating and helping older adults to learn

Geriatrics medical care of older adults

Gerontology the study of aging and older adults

Gingival of or relating to the gums

Gingivitis red, swollen gingivae (gums)

Glaucoma a disturbance in the circulation of aqueous fluid that causes an increase in intraocular pressure

Global self refers to the collective beliefs and images one holds about oneself; the most complete description that individuals can give of themselves at any one time

Global self-esteem how much one likes one's perceived self as a whole

Glomerulus a tuft of capillaries in the kidney surrounded by Bowman's capsule

Glossitis inflammation of the tongue

Glycerides the most common form of lipids consisting of a glycerol molecule with up to three fatty acids

Glycogen the chief carbohydrate stored in the body, particularly in the liver and muscles

Glycogenesis the process of glycogen formation

Goals/desired outcomes a part of a care plan that describes, in terms of observable client responses, what the nurse hopes to achieve by implementing the nursing interventions

Goniometer a handheld device used to measure the angle of a joint in degrees

Governance the establishment and maintenance of social, political, and economic arrangements by which practitioners control their practice, self-discipline, working conditions, and professional affairs

Grand theories articulate a broad range of the significant relationships among the concepts of a discipline

Granulation tissue young connective tissue with new capillaries formed in the wound healing process

- Grief** emotional suffering often caused by bereavement
- Gross negligence** involves extreme lack of knowledge, skill, or decision making that the person clearly should have known would put others at risk for harm
- Grounded theory** research to understand social structures and social processes; this method focuses on the generation of categories or hypotheses that explain patterns of behavior of people in the study
- Group** two or more people with shared purposes and goals
- Group dynamics** forces that determine the behavior of the group and the relationships among the group members
- Growth** physical change and increase in size
- Guaic** a test performed for occult (hidden) blood in the stool to detect gastrointestinal bleeding not visible to the eye
- Guided imagery** state of focused attention that encourages changes in attitudes, behavior, and physiological reactions
- Gustatory** referring to the sense of taste
- Habit training** attempts to keep clients dry by having them void at regular intervals; also referred to as *timed voiding* or *scheduled toileting*
- Hardware** the physical parts of a computer
- Harm** (injury) the client or plaintiff must demonstrate some type of harm or injury (physical, financial, or emotional) as a result of the breach of duty owed the client; the plaintiff will be asked to document physical injury, medical costs, loss of wages, “pain and suffering,” and any other damages
- Harriet Tubman** African American woman known as “the Moses of Her People” for her work with the Underground Railroad; during the Civil War she nursed the sick and suffering of her own race
- Haustra** pouches that form in the large intestine when the longitudinal muscles are shorter than the colon
- Haustral churning** (shuffling) movement of the chyme back and forth within the haustra in the large intestine
- Health behaviors** the actions a person takes to understand his or her health state, maintain an optimal state of health, prevent illness and injury, and reach his or her maximum physical and mental potential
- Health beliefs** concepts about health that an individual believes are true
- Health care proxy** a legal statement that appoints a proxy to make medical decisions for the client in the event the client is unable to do so
- Health care system** the totality of services offered by all health disciplines
- Health literacy** ability to read, understand, and act on provided health information
- Health maintenance organization (HMO)** a group health care agency that provides basic and supplemental health maintenance and treatment services to voluntary enrollees
- Health promotion** any activity undertaken for the purpose of achieving a higher level of health and well-being
- Health protection** behavior motivated by a desire to actively avoid illness, detect it early, or maintain functioning within the constraints of illness
- Health risk assessment (HRA)** an assessment and educational tool that indicates a client’s risk for disease or injury during the next 10 years by comparing the client’s risk with the mortality risk of the corresponding age, sex, and racial group
- Health status** the health of a person at a given time
- Heart failure** a condition that develops if the heart cannot keep up with the body’s need for oxygen and nutrients to the tissues; usually occurs because of myocardial infarction, but it may also result from chronic overwork of the heart
- Heart-lung death** the traditional clinical signs of death: cessation of the apical pulse, respirations, and blood pressure
- Heat balance** the state a person is in when the amount of heat produced by the body exactly equals the amount of heat lost
- Heat exhaustion** condition that is the result of excessive heat and dehydration
- Heat stroke** life-threatening condition with body temperature greater than 41°C (106°F)
- Heimlich maneuver** abdominal thrusts used to clear an obstructed airway
- Helix** the posterior curve of the auricle’s upper aspect
- Helping relationships** the nurse–client relationship
- Hematocrit** the proportion of red blood cells (erythrocytes) to the total blood volume
- Hematoma** a contusion or “black eye” resulting from injury
- Hemoglobin (Hg)** the red pigment in red blood cells that carries oxygen
- Hemoglobin A_{1C}** measurement of blood glucose that is bound to hemoglobin
- Hemolytic transfusion reaction** destruction of red blood cells as a result of transfusion of incompatible blood
- Hemoptysis** the presence of blood in the sputum
- Hemorrhage** excessive loss of blood from the vascular system
- Hemorrhagic exudate** see Sanguineous exudate
- Hemorrhoids** distended veins in the rectum
- Hemostasis** cessation of bleeding
- Hemothorax** the accumulation of blood in the pleural cavity
- Herbal medicine** treating illness with herbs
- Heritage consistency** the degree to which one’s lifestyle reflects his or her respective tribal culture
- Heritage inconsistency** the observance of the beliefs and practices of one’s acculturated belief system
- Hernia** a protrusion of an organ or tissue through an opening such as the abdominal or inguinal muscles
- Higher brain death** see Cerebral death
- High-Fowler’s position** a bed-sitting position in which the head of the bed is elevated 60° to 90°
- Hirsutism** the growth of excessive body hair
- Holism** all living organisms are seen as interacting, unified wholes that are more than the sums of their parts
- Holistic health** a model of health based on the belief that the whole is more than the sum of its parts
- Holistic health belief** holds that the forces of nature must be maintained in balance or harmony
- Holistic health care** a system that considers all components of health: health promotion, health maintenance, health education and illness prevention, and restorative–rehabilitative care
- Holistic nursing** nursing practice that has as its goal the healing of the whole person
- Holy day** a day set aside for special religious observance
- Homans’ sign** pain in calf with passive dorsiflexion of the foot
- Home care** providing care in the client’s home
- Home health care nursing** services and products provided to clients in their homes that are needed to maintain, restore, or promote their physical, psychological, and social well-being
- Homeopathy** an alternative therapy based on the theory that the cure for the disease lies in the disease itself; thus, treatment is with highly diluted amounts of substances that at a higher concentration would produce the same symptoms as the disease
- Homeostasis** the tendency of the body to maintain a state of balance or equilibrium while continually changing; a mechanism in which deviations from normal are sensed and counteracted
- Hope** a multidimensional concept that includes perceiving realistic expectations and goals, having motivation to achieve goals, anticipating outcomes, establishing trust and interpersonal relationships, relying on internal and external resources, having determination to endure, and being oriented to the future
- Hordeolum** redness, swelling, and tenderness of the hair follicle and glands that empty at the edge of the eyelids; also called a *sty*

Horticultural therapy adjunct therapy to occupational and physical therapy that may involve viewing nature, visiting a healing garden or wander garden, or actively gardening; also called *gardening or healing garden*

Hospice care that focuses on support and care for the dying person and family, with the goal of facilitating a peaceful and dignified death

Hospice nursing care frequently given to terminally ill clients in their home; often considered a subspecialty of public health nursing

Hospital information system (HIS) computer software program suite used to manage client, financial, and administrative data

Hub the part of the needle that fits onto the syringe

Humanism learning that focuses on the feelings and attitudes of learners, the importance of the individual in identifying learning needs and taking responsibility for them, and the self-motivation of the learners to work toward self-reliance and independence

Humanist a perspective that includes propositions such as the mind and body are indivisible, people have the power to solve their own problems, and people are responsible for their lives and well-being

Humidifier a device that adds water vapor to inspired air

Humoral immunity antibody-mediated defense; resides ultimately in the B lymphocytes and is mediated by the antibodies produced by B cells

Hydrostatic pressure the pressure a liquid exerts on the sides of the container that holds it; also called *filtration force*

Hygiene the science of health and its maintenance

Hyperalgesia a heightened response to painful stimuli

Hypercalcemia an excess of calcium in the blood plasma

Hypercapnia a condition in which carbon dioxide accumulates in the blood

Hypercarbia (hypercapnia) accumulation of carbon dioxide in the blood

Hyperchloremia an excess of chloride in the blood plasma

Hyperemia increased blood flow to an area

Hyperinflation giving the client breaths that are greater than the client's normal tidal volume set on the ventilator through the ventilator circuit or via a manual resuscitation bag

Hyperkalemia an excess of potassium in the blood plasma

Hypermagnesemia an excess of magnesium in the blood plasma

Hypernatremia an excess of sodium in the blood plasma

Hyperopia farsightedness

Hyperoxygenation increasing the oxygen flow before suctioning and between suction attempts to avoid suction-related hypoxemia

Hyperpathia heightened response to a painful stimulus; hyperalgesia

Hyperphosphatemia an excess of phosphate in the blood plasma

Hyperpyrexia an extremely high body temperature (e.g., 41°C [105.8°F])

Hyperresonance an abnormal booming sound produced during percussion of the lungs

Hypersomnia excessive sleep

Hypertension an abnormally high blood pressure; over 140 mmHg systolic and/or 90 mmHg diastolic

Hypothermia a body temperature above the usual range

Hypertonic solutions that have a higher osmolality than body fluids

Hypertrophy enlargement of a muscle or organ

Hyperventilation very deep, rapid respirations

Hypervolemia increased blood volume

Hypnotherapy application of hypnosis (trance state or altered state of consciousness) to a medical or psychological disorder

Hypoactive sexual desire disorder involves a persistent or recurring absence of sexual thoughts or disinterest in sexual activity

Hypocalcemia deficiency of calcium in the blood plasma

Hypochloremia deficiency of chloride in the blood plasma

Hypodermic under the skin

Hypodermic syringe a type of syringe that comes in 2-, 2.5-, and 3-mL sizes; the syringe usually has two scales marked on it: the minim and the milliliter

Hypokalemia deficiency of potassium in the blood plasma

Hypomagnesemia deficiency of magnesium in the blood plasma

Hyponatremia deficiency of sodium in the blood plasma

Hypophosphatemia deficiency of phosphate in the blood plasma

Hypotension an abnormally low blood pressure; less than 100 mmHg systolic in an adult

Hypothalamic integrator the center in the brain that controls the core temperature; located in the preoptic area of the hypothalamus

Hypothermia a core body temperature below the lower limit of normal

Hypothesis a prediction of the relationships among two or more variables

Hypotonic solutions that have a lower osmolality than body fluids

Hypoventilation very shallow respirations

Hypovolemia an abnormal reduction in blood volume

Hypoxemia low partial pressure of oxygen or low saturation of oxyhemoglobin in the arterial blood

Hypoxia insufficient oxygen anywhere in the body

Iatrogenic disease disease caused unintentionally by medical therapy

Iatrogenic infections infections that are the direct result of diagnostic or therapeutic procedures

Id the source of instinctive and unconscious psychological urges

Ideal body weight (IBW) the optimal weight recommended for optimal health

Ideal self how we would prefer to be; the individual's perception of how one should behave based on certain personal standards, aspirations, goals, or values

Identification perceiving one's self as similar to and behaving like another person

Idiosyncratic effect a different, unexpected, or individual effect from the normal one usually expected from a medication; the occurrence of unpredictable and unexplainable symptoms

Ileal conduit (ileal loop) urinary diversion in which the client must wear an external pouch over the stoma to collect the continuous flow of urine

Ileostomy a colostomy that generally empties from the distal end of the small intestine

Illicit drugs drugs that are sold illegally; street drugs

Illness a highly personal state in which a person feels unhealthy or ill; may or may not be related to disease

Illness behavior the course of action a person takes to define the state of his or her health and pursue a remedy

Imagery the internal experience of memories, dreams, fantasies, and visions that serve as a bridge connecting body, mind, and spirit

Imagination an important part of preschoolers' life (the preschooler has an active imagination and fantasizes in play)

Imitation copying the behaviors and attitudes of another person

Immobility prescribed or unavoidable restriction of movement in any area of a person's life

Immune defenses see Specific defenses

Immunity a specific resistance of the body to infection; it may be natural, or resistance may develop after exposure to a disease agent

Immunoglobulins see Antibodies

Impaired nurse a nurse whose practice has deteriorated because of chemical abuse

Implementing the phase of the nursing process in which the nursing care plan is put into action

Implied consent consent that is assumed in an emergency when consent cannot be obtained from the client or a relative

Implied contract a contract that has not been explicitly agreed to by the parties but that the law nevertheless considers to exist

Incentive spirometer a device that measures the flow of air inhaled through a mouthpiece; also called a *sustained maximal inspiration device (SMI)*

Incomplete proteins protein that lacks one or more essential amino acids; usually derived from vegetables

Incus the anvil bone of the middle ear

Independent functions areas of health care unique to nursing, separate and distinct from medical management

Independent interventions activities that the nurse is licensed to initiate as a result of the nurse's own knowledge and skills

Independent practice associations (IPAs) provide care in offices; clients pay a fixed prospective payment and IPA pays the provider; earnings or losses are assumed by the IPA

Independent variable the presumed cause or influence on a dependent variable

Indicator an observable client state, behavior, or self-reported perception or evaluation; similar to desired outcomes in traditional language

Individualized care plan a plan tailored to meet the unique needs of a specific client—needs that are not addressed by the standardized plan

Individualized exercise prescription exercise mode and dose tailored to a specific individual to ensure greater adherence to an exercise program

Inductive reasoning making generalizations from specific data

Infection the disease process produced by microorganisms

Inferences interpretations or conclusions made based on cues or observed data

Infiltration occurs when the tip of an IV is outside the vein and the fluid is entering the tissues instead; manifested by local swelling, coolness, pallor, and discomfort at the IV site

Inflammation local and nonspecific defensive tissue response to injury or destruction of cells

Influence an informal strategy used to gain the cooperation of others without exercising formal authority

Informal leader an individual selected by a group as its leader because of seniority, age, special abilities, or charisma

Informal nursing care plan a strategy for action that exists in the nurse's mind

Informed consent a client's agreement to accept a course of treatment or a procedure after receiving complete information, including the risks of treatment and facts relating to it, from the health care provider

Infrared photoenergy therapy treatment to improve sensory impairment associated with peripheral neuropathy

Ingestion the act of taking in food or medication

Ingrown toenail the growing inward of a nail into the soft tissues around it; most often results from improper nail trimming

Inhalation the intake of air into the lungs; also called *inspiration*

Inhibiting effect the decreased effect of one or both drugs

Injury see Harm

Input consists of information, material, or energy that enters a system

Inquest a legal inquiry into the cause or manner of a death

Insensible fluid loss fluid loss that is not perceptible to an individual

Insensible heat loss heat loss that occurs from evaporation (vaporization) of moisture from the respiratory tract, mucosa of the mouth, and the skin

Insensible water loss continuous and unnoticed water loss

In-service education education that is designed to upgrade the knowledge or skills of employees

Insomnia inability to obtain a sufficient quality or quantity of sleep

Inspection visual examination, which is assessing by using the sense of sight

Inspiration see Inhalation

Insulin syringe syringe that has a scale specially designed for insulin and is the only type of syringe that should be used to administer insulin

Integrated delivery system (IDS) a system that incorporates acute care services, home health care, extended and skilled care facilities, and outpatient services

Integrated health care system one that makes all levels of care available in an integrated form—primary care, secondary care, and tertiary care

Intensity (amplitude) the loudness or softness of auscultated sound

Intention tremor involuntary trembling when an individual attempts a voluntary movement

Intermittent fever a body temperature that alternates at regular intervals between periods of fever and periods of normal or subnormal temperatures

Internet a worldwide computer network

Interpersonal skills all verbal and nonverbal activities people use when communicating directly with one another

Interpreter an individual who mediates spoken communication between people speaking different languages without adding, omitting, or distorting meaning or editorializing

Intersex ambiguous gender

Interstate compact an agreement between two or more states

Interstitial fluid fluid that surrounds the cells, includes lymph

Interview a planned communication; a conversation with a purpose

Intimacy a close friendship

Intracellular fluid (ICF) fluid found within the body cells; also called *cellular fluid*

Intractable pain pain that is resistant to cure or relief

Intradermal under the epidermis (into the dermis)

Intradermal (ID) injection the administration of a drug into the dermal layer of the skin just beneath the epidermis

Intramuscular into the muscle

Intramuscular (IM) injection the administration of a drug into the muscle tissue

Intraoperative phase the phase of surgery that begins when the client is transferred to the operating room and ends when the client is admitted to the postanesthesia care unit

Intrapleural pressure pressure in the pleural cavity surrounding the lungs

Intrapulmonary pressure pressure within the lungs

Intraspinal (intrathecal) into the spinal canal

Intrathecal see Intraspinal

Intravascular fluid plasma

Intravenous within a vein

Intravenous block anesthesia used most often for procedures involving the arm, wrist, and hand

Intravenous pyelography (IVP) x-ray filming of the kidney and ureters after injection of a radiopaque material into the vein

Introjection the assimilation of the attributes of others

Intuition the understanding or learning of things without the conscious use of reasoning

Invasion of privacy a direct wrong of a personal nature, it injures the feelings of the person and does not take into account the effect of revealed information on the standing of the person in the community

Ions atoms or group of atoms that carry a positive or negative electric charge; electrolytes

Iron deficiency anemia a form of anemia caused by inadequate supply of iron for synthesis of hemoglobin

Irrigation a flushing or washing out with a specified solution; administration of a solution to wash out the conjunctival sac to remove secretions or foreign bodies or to remove chemicals that may injure the eye

Ischemia deficiency of blood supply caused by obstruction of circulation to the body part

Isokinetic (resistive) exercises muscle contraction or tension against resistance

Isolation practices that prevent the spread of infection and communicable diseases

Isometric (static or setting) exercise muscle contraction without moving the joint (muscle length does not change), which involves exerting pressure against a solid object.

Isotonic solutions that have the same osmolality as body fluids

Isotonic (dynamic) exercise exercise in which muscle tension is constant and the muscle shortens to produce muscle contraction and active movement

Jaundice a yellowish tinge to skin color

Jejunostomy a tube that is placed surgically or by laparoscopy through the abdominal wall into the jejunum for long-term nutritional support

Justice fairness

Kardex the trade name for a method that makes use of a series of cards to concisely organize and record client data and instructions for daily nursing care—especially care that changes frequently and must be kept up to date

Keloid a hypertrophic scar containing an abnormal amount of collagen

Kidneys/ureters/bladder (KUB) x-ray of the kidneys, ureters, and bladder

Kilocalorie (kcal) see Calorie

Kilojoule (kJ) a metric measurement referring to the amount of energy required when a force of 1 newton (N) moves 1 kg of weight 1 m of distance

Kinesthetic refers to awareness of the position and movement of body parts

Knights of Saint Lazarus an order of knights that dedicated themselves to the care of people with leprosy, syphilis, and chronic skin conditions

Korotkoff's sounds the five phases of blood pressure sounds

Kosher acceptable or prepared according to Jewish law

Kussmaul's breathing hyperventilation that accompanies metabolic acidosis in which the body attempts to compensate (give off excess body acids) by blowing off carbon dioxide through deep and rapid breathing

Kyphosis excessive convex curvature of the thoracic spine

Laissez-faire leader recognizes a group's need for autonomy and self-regulation; also called *nondirective leader* or *permissive leader*

Lanugo the fine, woolly hair or down on the shoulders, back, sacrum, and earlobes of the unborn child that may remain for a few weeks after birth

Large calorie (Calorie, kilocalorie [kcal]) see Calorie

Laryngoscopy visual examination of the larynx with a laryngoscope

Lateral (side-lying) position position in which a person lies on one side of the body

Lavage an irrigation or washing of a body organ, such as the stomach

Lavinia L. Dock a nursing leader and suffragist who was active in the protest movement for women's rights that resulted in the U.S. Constitution amendment allowing women to vote in 1920

Law a rule made by humans that regulates social conduct in a formally prescribed and binding manner

Laxatives medications that stimulate bowel activity and assist fecal elimination

Leader a person who influences others to work together to accomplish a specific goal

Leadership style describes traits, behaviors, motivations, and choices used by individuals to effectively influence others

Leading question a question that influences the client to give a particular answer

Learning a change in human disposition or capability that persists over a period of time and cannot be solely accounted for by growth

Learning need a desire or a requirement to know something that is currently unknown to the learner

Leukocytes white blood cells

Leukocytosis an increase in the number of white blood cells

Liability the quality or state of being legally responsible for one's obligations and action and to make financial restitution for wrongful acts

Libel defamation by means of print, writing, or pictures

Libido urge or desire for sexual activity

License a legal permit granted to individuals to engage in the practice of a profession and to use a particular title

Licensed vocational (practical) nurse (LVN/LPN) a nurse who practices under the supervision of a registered nurse, providing basic direct technical care to clients

Lifestyle the values and behaviors adopted by a person in daily life

Lift an abnormal anterior movement of the chest related to enlargement of the right ventricle

Lillian Wald founder of the Henry Street Settlement and Visiting Nurse Service, which provided nursing and social services and organized educational and cultural activities; considered the founder of public health nursing

Linda Richards America's first formally trained nurse

Line of gravity an imaginary vertical line drawn through an object's center of gravity

Lipids organic substances that are greasy and insoluble in water but soluble in alcohol or ether

Lipoproteins soluble compounds made up of various lipids

Litigation the action of a lawsuit

Living will a document that states medical treatments(s) the client chooses to omit or refuse in the event that the client is unable to make these decisions

Livor mortis discoloration of the skin caused by breakdown of the red blood cells; occurs after blood circulation has ceased; appears in the dependent areas of the body

Lobule earlobe

Local adaptation syndrome (LAS) the reaction of one organ or body part to stress

Local anesthesia an anesthetic agent used for minor surgical procedures that is injected into a specific area

Local area network (LAN) personal computers (PCs) linked directly to nearby PCs and servers by wires or wireless communication devices

Local infection an infection that is limited to the specific part of the body where the microorganisms remain

Locus of control (LOC) a concept about whether clients believe their health status is under their own or others' control

Logrolling a technique used to turn a client whose body must at all times be kept in straight alignment

Long-term memory the repository for information stored for periods longer than 72 hours and usually weeks and years

Lordosis an exaggerated concavity in the lumbar region of the vertebral column

Loss an actual or potential situation in which a valued ability, object, or person is inaccessible or changed so that it is perceived as no longer valuable

Low Fowler's position a bed-sitting position in which the head of the bed is elevated between 15° and 45°, with or without knee flexion

Lumbar puncture (LP) procedure in which cerebrospinal fluid is withdrawn through a needle inserted into the subarachnoid space of the spinal canal between the third and fourth lumbar vertebrae, or between the fourth and fifth lumbar vertebrae; also called a *spinal tap*

Lung compliance expansibility of the lung

Lung recoil the tendency of lungs to collapse away from the chest wall

Lung scan records the emissions from radioisotopes that indicate how well gas and blood are traveling through the lungs; also known as a V/Q (ventilation/perfusion) scan

Maceration the wasting away or softening of a solid as if by the action of soaking; often used to describe degenerative changes and eventual disintegration

Macrominerals any of the minerals that people require daily in amounts over 100 mg

Macronutrients carbohydrates, fats, and protein that are needed in large amounts to provide energy

Magico-religious health belief a belief system in which people attribute the fate of the world and those in it to the actions of God, the gods, or other supernatural forces for good or evil

Magnetic resonance imaging (MRI) a noninvasive diagnostic scanning technique in which the client is placed in a magnetic field

Maintenance stage stage at which a person integrates newly adopted behavior patterns into his or her lifestyle

Major surgery surgery that involves a high degree of risk for a variety of reasons; it may be complicated or prolonged; large losses of blood may occur; vital organs may be involved; postoperative complications may occur

Male erectile disorder when a man has erection problems during 25% or more of his sexual interactions

Male orgasmic disorder disorder where a man can maintain an erection but has difficulty ejaculating

Malleus hammer bone of the middle ear

Malnutrition the lack of necessary or appropriate food substances that includes both undernutrition and overnutrition

Malpractice the negligent acts of individuals engaged in professions or occupations in which highly technical or professional skills are employed

Managed care a method of organizing care delivery that emphasizes communication and coordination of care among all health care team members

Management information system (MIS) software designed to facilitate the organization and application of data used to manage an organization or department

Manager one who is appointed to a position in an organization that gives the power to guide and direct the work of others

Mandated reporters a role of the nurse in which he or she identifies and assesses cases of violence against others, and in every case the situation must be reported to the proper authorities

Manometer a glass or plastic tube calibrated in millimeters that is used to take cerebrospinal pressure readings

Manslaughter second-degree murder

Manubrium the handle-like superior part of the sternum that joins with the clavicles

Margaret Higgins Sanger considered the founder of Planned Parenthood, was imprisoned for opening the first birth control information clinic in Baltimore in 1916

Mary Breckinridge a nurse who practiced midwifery in England, Australia, and New Zealand; founded the Frontier Nursing Service in Kentucky in 1925 to provide family-centered primary health care to rural populations

Mary Mahoney first African American professional nurse

Mass peristalsis involves a wave of powerful muscular contraction that moves over large areas of the colon; usually occurs after eating

Mastoid a bony prominence behind the ear

Masturbation sexual self-stimulation

Maturity the state of maximal function and integration; the state of being fully developed

Mean a measure of central tendency, computed by summing all scores and dividing by the number of subjects; commonly symbolized as \bar{X} or M

Measures of central tendency measures that describe the center of a distribution of data, denoting where most of the subjects lie; include the mean, median, and mode

Measures of variability measures that indicate the degree of dispersion or spread of the data; include range, variance, and standard deviation

Meatus referring to the urinary meatus, which is the external opening from the urethra to the surface of the body

Meconium the first fecal material passed by a newborn, normally up to 24 hours after birth

Median a measure of central tendency, representing the exact middle score or value in a distribution of scores; the median is the value above and below which 50% of the scores lie

Medicaid a U.S. federal public assistance program paid out of general taxes and administered through the individual states to provide health care for those who require financial assistance

Medical asepsis all practices intended to confine a specific microorganism to a specific area, limiting the number, growth, and spread of microorganisms

Medical examiner a physician who usually has advanced education in pathology or forensic medicine who determines causes of death

Medicare a national and state health insurance program for U.S. residents older than 65 years of age

Medication a substance administered for the diagnosis, cure, treatment, or relief of a symptom or for prevention of disease

Medication reconciliation process of creating the most accurate list possible of all medications a client is taking—including drug name, dosage, frequency, and route—and comparing that list against the physician's admission, transfer, and/or discharge orders, with the goal of providing correct medications to the client at all transition points within the hospital

Meditation mental exercise that directs the mind to think inwardly by closing the sense organs to external stimulation

Menarche onset of menstruation

Meniscus the crescent-shaped upper surface of a column of liquid

Menopause cessation of menstruation

Menstruation the monthly discharge of blood through the vagina occurring in nonpregnant women from puberty to menopause

Mentor a person who serves as an experienced guide, adviser, or advocate and assumes responsibility for promoting the growth and professional advancement of a less experienced individual

Mesoderm middle layer of the embryonic tissue that forms during the first 3 weeks of life

Metabolic acidosis a condition characterized by a deficiency of bicarbonate ions in the body in relation to the amount of carbonic acid in the body; the pH falls to less than 7.35

Metabolic alkalosis a condition characterized by an excess of bicarbonate ions in the body in relation to the amount of carbonic acid in the body; the pH rises to greater than 7.45

Metabolism the sum of all physical and chemical processes by which a living substance is formed and maintained and by which energy is made available for use by the organism

Metabolites end products or enzymes

Metaparadigm originates from the Greek *meta*, meaning "with," and *paradigm*, meaning "pattern"; based on four theoretical concepts of nursing: person, environment, health, and nursing

Metered-dose inhaler (MDI) a handheld nebulizer that is a pressurized container of medication that can be used by the client to release the medication through a mouthpiece

Microminerals a vitamin or mineral

Micronutrients those vitamins and minerals required in small amounts to metabolize the energy-providing nutrients

Micturition see Urination

Mid-arm circumference (MAC) a measure of fat, muscle, and skeleton

Mid-arm muscle circumference (MAMC) calculated by using reference tables or by using a formula that incorporates the triceps skinfold and the MAC

Middle-level manager a manager who supervises a number of first-level managers and is responsible for the activities in the departments supervised

Midlevel theories focus on exploration of concepts such as pain, self-esteem, learning, and hardiness

Midstream urine specimen see Clean-catch urine specimen

Milliequivalent one thousandth of an equivalent, which is the chemical combining power of a substance

Minerals a substance found in organic compounds, as inorganic compounds and as free ions

Minor surgery surgery that involves little risk, produces few complications, and is often performed in a "day surgery" facility

Miosis constricted pupils

Misdemeanor a legal offense usually punishable by a fine or a short-term jail sentence, or both

Mixed hearing loss a combination of conduction and sensorineural loss

Mobility ability to move about freely, easily, and purposefully in the environment

Mode the score or value that occurs most frequently in a distribution of scores

Modeling observing the behavior of people who have successfully achieved a goal that one has set for oneself and, through observing, acquiring ideas for behavior and coping strategies

Monosaccharides sugars that are composed of single molecules

Monotheism belief in the existence of one God

Monounsaturated fatty acids a fatty acid with one double bond

Moral relating to right and wrong

Moral behavior the way a person perceives the requirements necessary for people to live together and how he or she responds to them

Moral development process of learning to tell the difference between right and wrong and of learning what ought and ought not to be done

Moral rules specific prescriptions for actions

Morality a doctrine or system denoting what is right and wrong in conduct, character, or attitude

Mortician a person trained in the care of the dead; also called an *undertaker*

Motivation the desire to learn

Mourning the process through which grief is eventually resolved or altered

Multidisciplinary care plan a standardized plan that outlines the care required for clients with common, predictable—usually medical—conditions

Music therapy the behavioral science concerned with the systematic application of music to produce relaxation and desired changes in emotions, behavior, and physiology

Mutual pretense a type of awareness in which the client, family, and health personnel know that the prognosis is terminal but do not talk about it and make an effort not to raise the subject

Mutual recognition model a regulatory model developed by the National Council of State Boards of Nursing, which allows for multistate licensure

Mydriasis enlarged pupils

Myocardial infarction (MI) heart attack; cardiac tissue necrosis owing to obstruction of blood flow to the heart

Myocardium a layer of the heart wall; cardiac muscle cells that form the bulk of the heart and contract with each beat

Myopia nearsightedness

Narcolepsy an uncontrollable desire for sleep or attacks of sleep during the day

Narrative charting a descriptive record of client data and nursing interventions, written in sentences and paragraphs

Nasoenteric tube a tube inserted through one of the nostrils, down the nasopharynx, and into the alimentary tract

Nasogastric (NG) tube a tube inserted by way of the nasopharynx or the oropharynx; it is placed into the stomach for the temporary purpose of feeding the client or to remove gastric secretions

Naturopathic medicine practice that focuses on nutrition, herbs, homeopathy, acupuncture, hydrotherapy, physical medicine, counseling, and minor surgical interventions

Negative feedback feedback that inhibits change

Negligence failure to behave in a reasonable and prudent manner; an unintentional tort

Nephrostomy diversion of urine from a kidney to a stoma

Nerve block chemical interruption of a nerve pathway effected by injecting a local anesthetic

Network linkages

Networking a process by which people develop linkages throughout a profession to communicate, share ideas and information, and offer support and direction to each other

Neurectomy surgery in which peripheral or cranial nerves are interrupted to alleviate localized pain

Neurogenic bladder interference with the normal mechanisms of urine elimination in which the client does not perceive bladder fullness and is unable to control the urinary sphincters; the result of impaired neurologic function

Neuropathic pain experienced by people who have damaged or malfunctioning nerves as a result of illness, injury, or undetermined reasons

Neutral question a question that does not direct or pressure a client to answer in a certain way

Nitrogen balance a measure of the degree of protein anabolism and catabolism; net result of intake and loss of nitrogen

Nociception the physiological processes related to pain perception

Nociceptor a pain receptor

Nocturia voiding two or more times at night

Nocturnal emissions orgasm and emission of semen during sleep

Nocturnal enuresis involuntary urination at night

Nocturnal frequency the need for older adults to arise during the night to urinate

Nondirective interview an interview using open-ended questions and empathetic responses to build rapport and learn client concerns

Nondirective leader see Laissez-faire leader

Nonessential amino acids an amino acid that the body can manufacture

Nonmaleficence the duty to do no harm

Nonspecific defenses bodily defenses that protect a person against all microorganisms, regardless of prior exposure

Nonsteroidal anti-inflammatory drugs (NSAIDs) drugs such as aspirin and ibuprofen that have anti-inflammatory, analgesic, and antipyretic effects

Nonverbal communication communication other than words, including gestures, posture, and facial expressions

Norm an ideal or fixed standard; an expected standard of behavior of group members

Normocephalic normal head size

Normocephaly normal head circumference at birth; usually 35 cm (14 in.)

Nosocomial infections infections that originate in a hospital

NPO Nothing by mouth; literally, "nil per os"

NREM (non-REM) sleep a deep restful sleep rate; also called *slow wave sleep*

Nuclear family a family of parents and their offspring

Nurse informaticist an expert who combines computer, information, and nursing science to develop policies and procedures that promote

effective use of computerized records by nurses and other health care professionals

Nursing the attributes, characteristics, and actions of a nurse providing care on behalf of, or in conjunction with, a client

Nursing diagnosis the nurse's clinical judgment about individual, family, or community responses to actual and potential health problems/life processes to provide the basis for selecting nursing interventions to achieve outcomes for which the nurse is accountable

Nursing ethics ethical issues that occur in nursing practice

Nursing informatics the science of using computer information systems in the practice of nursing

Nursing intervention any treatment, based on clinical judgment and knowledge, that a nurse performs to enhance patient/client outcomes

Nursing Interventions Classification (NIC) a taxonomy of nursing actions each of which includes a label, a definition, and a list of activities

Nursing Outcomes Classification (NOC) a taxonomy for describing client outcomes that respond to nursing interventions

Nursing process a systematic rational method of planning and providing nursing care

Nutrients organic, inorganic, energy-producing substances found in foods and required for body functioning

Nutrition the sum of all interactions between an organism and the food it consumes

Nutritive value the nutrient content of a specified amount of food

Nystagmus rapid involuntary rhythmic eye movement

Obese (obesity) when body mass index (BMI) is greater than 30 kg/m²

Objective data information (data) that is detectable by an observer or can be tested against an accepted standard; can be seen, heard, felt, or smelled; also called *signs*

Obligatory losses essential fluid losses required to maintain body functioning

Occult blood hidden blood

Occupational exposure skin, eye, mucous membrane, or parenteral contact with blood or other potentially infectious materials that may result from the performance of an employee's duties

Official name (of drug) the name under which a drug is listed in one of the official publications (e.g., the *United States Pharmacopeia*)

Oils lipids that are liquid at room temperature

Olfactory related to smell

Oliguria production of abnormally small amounts of urine by the kidney

Oncotic pressure see Colloid osmotic pressure

One-point discrimination the ability to sense whether one or two areas of the skin are being stimulated by pressure

Online connected to a computer network

Onset of action the time after drug administration when the body initially responds to the drug

Open awareness a type of awareness in which a client and people around know about an impending death

Open-ended questions questions that specify only a broad topic to be discussed and invite clients to discover and explore their thoughts and feelings about the topic

Operational definitions definitions that specify the instruments or procedures by which concepts will be measured

Ophthalmic pertaining to medications for the eye

Opportunistic pathogen a microorganism causing disease only in a susceptible individual

Oral a method of administration in which the drug is swallowed

Oral-genital sex oral stimulation of either female or male genitals

Organizing determining responsibilities, communicating expectations, and establishing the chain of command for authority and communication

Orgasmic phase part of the response cycle, the involuntary climax of sexual tension, accompanied by physiological and psychological release

Orthopnea ability to breathe only when in an upright position (sitting or standing)

Orthopneic position a sitting position to relieve respiratory difficulty in which the client sits either in bed or on the side of the bed, leaning over an overbed table across the lap; an adaptation of the high-Fowler's position

Orthostatic hypotension decrease in blood pressure related to positional or postural changes from lying to sitting or standing positions

Osmolality the concentration of solutes in body fluids

Osmosis passage of a solvent through a semipermeable membrane from an area of lesser solute concentration to one of greater solute concentration

Osmotic pressure pressure exerted by the number of nondiffusible particles in a solution; the amount of pressure needed to stop the flow of water across a membrane

Ossicles the three middle ear bones of sound transmission

Osteoporosis demineralization of the bone

Ostomy an opening on the abdominal wall for the elimination of feces or urine

Otic refers to instillations or irrigations of the external auditory canal

Otoscope an instrument used to view the ear

Outcome evaluation focuses on demonstrable changes in a client's health status as a result of nursing care

Output energy, matter, or information from a system given out by the system as a result of its processes

Overhydration occurs when water is gained in excess of electrolytes, resulting in low serum osmolality and low serum sodium levels, also known as *hypo-osmolar imbalance* or *water intoxication*

Overnutrition refers to a caloric intake in excess of daily energy requirements, resulting in storage of energy in the form of increased adipose tissue

Overweight a BMI of 25 to 29.9 kg/m²

Oxyhemoglobin the compound of oxygen and hemoglobin

Pace number of steps taken per minute or the distance taken in one step when walking

Packing filling an open wound or cavity with a material such as gauze

Pain whatever the experiencing person says it is, existing whenever he or she says it does

Pain threshold the least amount of stimuli that is needed for a person to label a sensation as pain

Pain tolerance the maximum amount of painful stimuli that a person is willing to withstand without seeking avoidance of the pain or relief

Palliative care the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial, and spiritual

Pallor paleness

Palpation the examination of the body using the sense of touch

Papanicolaou (Pap) test a method of taking a sample of cervical cells for microscopic examination to detect malignancy

Paradigm a pattern of shared understandings and assumptions about reality and the world

Parasites microorganisms that live in or on another from which it obtains nourishment

Parasomnia a cluster or pattern of waking behavior that appears during sleep, such as somnambulism (sleepwalking), sleepwalking, and enuresis (bed-wetting)

Parenteral drug administration using a medication route other than the alimentary or digestive tract; injected into the body intradermally, subcutaneously, intramuscularly, or intravenously

Paresis slight or incomplete paralysis

Parotitis inflammation of the parotid salivary gland

Partial pressure the pressure exerted by each individual gas in a mixture according to its percentage concentration in the mixture

Partially complete proteins proteins that contain less than the required amount of one or more essential amino acids; cannot alone support continued growth

Participative leader see Democratic leader

Passive (acquired) immunity a resistance of the body to infection in which the host receives natural or artificial antibodies produced by another source

Passive euthanasia allowing a person to die by withholding or withdrawing measures to maintain life

Passive range-of-motion (ROM) exercise exercise in which another person moves each of the client's joints through their complete range of movement, maximally stretching all muscle groups within each plane over each joint

Pathogenicity the ability to produce disease; a pathogen is a microorganism that causes disease

Pathologic fractures spontaneous fractures to which older adults are prone

Patient a person who is waiting for or undergoing medical treatment and care

Patient-controlled analgesia (PCA) an interactive method of pain management that permits clients to treat their pain by self-administering doses of analgesics

Patient-focused care delivery model that brings all services and care providers to the client

Patient Self-Determination Act (PSDA) legislation requiring that every competent adult be informed in writing on admission to a health care institution about his or her rights to accept or refuse medical care and to use advance directives

Peak level indicates the highest concentration of the drug in the blood serum

Peak plasma level the concentration of a drug in the blood plasma that occurs when the elimination rate equals the rate of absorption

Pedagogy the discipline concerned with helping children learn

Pediculosis (lice) infestation with head lice, *Pediculus capitis*; body lice, *Pediculus corporis*; or crab lice, *Pediculus pubis*

Peer groups assume great importance and have a number of functions: provide a sense of belonging, pride, social learning, and sexual roles; most peer groups have well-defined, gender-specific modes of acceptable behavior and in adolescence, the peer groups change with age

Penrose drain a flat, thin, rubber tube inserted into a wound to allow for fluid to flow from the wound; it has an open end that drains onto a dressing

Perceived loss the loss experienced by a person that cannot be verified by others

Perception the ability to interpret the environment through the senses

Percussion (in assessment) a method in which the body surface is struck to elicit sounds that can be heard or vibrations that can be felt

Percutaneous route of absorption of a topical medication through the skin

Percutaneous endoscopic gastrostomy (PEG) a procedure in which a PEG catheter is inserted into the stomach through the skin and subcutaneous tissues of the abdomen; used as a feeding tube

Percutaneous endoscopic jejunostomy (PEJ) a procedure in which a PEJ catheter is inserted into the jejunum through the skin and subcutaneous tissues of the abdomen; used as a feeding tube

Perfusion passage of blood constituents through the vessels of the circulatory system

Pericardium double layer of fibrous membrane of the heart; the parietal, or outermost, pericardium serves to protect the heart and anchor it to surrounding structures

Peridural anesthesia see Epidural anesthesia

Perineal (peri-) care cleansing of the perineum (genitalia)

Periodontal disease disorder of the supporting structures of the teeth

Perioperative period refers to the three phases of surgery: preoperative, intraoperative, and postoperative

Peripheral neuropathic pain phantom pain, post-herpetic neuralgia, or carpal tunnel syndrome that follows damage and/or sensitization of peripheral nerves

Peripheral pulse a pulse located in the periphery of the body (e.g., foot, hand, or neck)

Peripheral vascular resistance (PVR) impedance or opposition to blood flow to the tissues; determined by viscosity, or thickness, of the blood; blood vessel length; blood vessel diameter

Peripherally inserted central catheter (PICC) a long venous catheter inserted in an arm vein and extending into the distal third of the superior vena cava

Peripherals at the edge or outward boundary

Peristalsis wavelike movements produced by circular and longitudinal muscle fibers of the intestinal walls; the movement propels the intestinal contents onward

Permissive leader see Laissez-faire leader

Personal computer (PC) an individual microcomputer system referred to as a desktop, portable, laptop, notebook, or handheld computer

Personal knowing promotes wholeness and integrity in the personal encounter to achieve engagement

Personal protective equipment (PPE) barriers such as gloves, mask, and gown used to protect individuals from contact with potentially infective materials

Personal space the distance people prefer in interactions with others

Personal values values internalized from the society or culture in which one lives

Personality the outward expression of the inner self

PES format the three essential components of nursing diagnostic statements including the terms describing the *problem*, the *etiology* of the problem, and the defining characteristics or cluster of *signs* and *symptoms*

pH a measure of the relative alkalinity or acidity of a solution; a measure of the concentration of hydrogen ions

Phagocytes cells that ingest microorganisms, other cells, and foreign particles

Pharmacist a person licensed to prepare and dispense drugs and prescriptions

Pharmacodynamics the process by which a drug alters cell physiology

Pharmacogenetics process by which the effect of a drug is influenced by genetic variations such as gender, size, and body composition

Pharmacokinetics the study of the absorption, distribution, biotransformation, and excretion of drugs

Pharmacology the scientific study of the actions of drugs on living animals and humans

Pharmacopoeia a book containing a list of drug products used in medicine, including their descriptions and formulas

Pharmacy the art of preparing, compounding, and dispensing drugs; also refers to the place where drugs are prepared and dispensed

Phenomenology research that investigates people's life experiences and how they interpret those experiences

Philosophy an early effort to define phenomena that serves as the basis for later theoretical formulations

Phlebotomist a person from a laboratory who performs venipuncture, collecting the blood specimen for the tests ordered by the primary care provider

Physical activity bodily movement produced by skeletal muscles that requires energy expenditure and produces progressive health benefits

Physical restraints any manual method or physical or mechanical device, material, or equipment attached to a client's body that cannot be removed easily and that restricts the client's movement

Physiological dependence biochemical changes occurring in the body as a result of excessive use of a drug

Physiological pain experienced when an intact, properly functioning nervous system sends signals that tissues are damaged, requiring attention and repair

PIE an acronym for a charting model that follows a recording sequence of *problems, interventions, and evaluation* of the effectiveness of the interventions

Piggyback a secondary IV setup that connects a second container to the tubing of a primary container at the upper port; used solely for intermittent drug administration

Pilates method of physical movement and exercise designed to stretch, strengthen, and balance the body, in particular the core of the body

Pinna see Auricle

Pitch the frequency (number of the vibrations per second) heard during auscultation

Pitting edema edema in which firm finger pressure on the skin produces an indentation (pit) that remains for several seconds

Placebo any medication or procedure that produces an effect in a client because of its implicit or explicit intent, and not because of its specific physical or chemical properties

Placenta a flat, disc-shaped organ that is highly vascular and normally forms in the upper segment of the endometrium of the uterus; exchanges nutrients and gases between the fetus and the mother

Plaintiff a person claiming infringement of legal rights by one or more individuals

Planned change an intended, purposive attempt by an individual, group, organization, or larger social system to influence its own status quo or that of another organism or situation

Planning an ongoing process that involves (a) assessing a situation, (b) establishing goals and objectives based on assessment of a situation or future trends, and (c) developing a plan of action that identifies priorities, delineates who is responsible, determines deadlines, and describes how the intended outcome is to be achieved and evaluated

Plantar wart a wart on the sole of the foot

Plaque an invisible soft film consisting of bacteria, molecules of saliva, and remnants of epithelial cells and leukocytes that adheres to the enamel surface of teeth

Plasma the fluid portion of the blood in which the blood cells are suspended

Plateau a maintained concentration of a drug in the plasma during a series of scheduled doses

Pleximeter in percussion, the middle finger of the dominant hand that is placed firmly on the client's skin

Plexor in percussion, the middle finger of the nondominant hand or a percussion hammer used to strike the pleximeter

Pneumothorax accumulation of air in the pleural space

Point of maximal impulse (PMI) the point where the apex of the heart touches the anterior chest wall and heart movements are most easily observed and palpated

Policies rules developed to govern the handling of frequently occurring situations

Polycythemia a condition in which clients with chronic hypoxia may develop higher than normal counts of red blood cells

Polydipsia excessive thirst

Polypnea abnormally fast respirations

Polysaccharides a branched chain of dozens, sometimes hundreds, of glucose molecules; starches

Polysomnography a cluster or pattern of waking behavior that appears during sleep, such as somnambulism (sleepwalking), sleepwalking, and enuresis (bed-wetting)

Polytheism the belief in more than one God

Polyunsaturated fatty acids fatty acid with more than one double bond (or many carbons not bonded to a hydrogen atom)

Polyuria see Diuresis

Population includes all possible members of a group who meet the criteria for a study

Positive feedback feedback that stimulates change

Positive reinforcement giving rewards such as praise for a learner's achievements

Positron emission tomography (PET) a noninvasive radiologic study that involves the injection or inhalation of a radioisotope

Possible nursing diagnosis one in which evidence about a health problem is incomplete or unclear

Postanesthesia care unit (PACU) unit the client is transferred to after surgery

Postanesthesia room (PAR) see Postanesthesia care unit (PACU)

Postmortem care care of the body after death

Postmortem examination see Autopsy

Postoperative phase the period of surgery that begins with the admission of a client to the postanesthesia area and ends when healing is complete

Postural drainage positioning of a client to allow the drainage, by gravity, of secretions from the lungs

Potentiating effect the increased effect of one or both drugs

Practice discipline field of study in which the central focus is performance of a professional role (nursing, teaching, management, making music)

Prayer human communication with divine and spiritual entities

Preceptor an experienced nurse who assists the novice nurse in improving nursing skill and judgment

Precontemplation stage a person typically denies having a problem and instead views others as having a problem and therefore wants to change the other person's behavior

Precordium an area of the chest overlying the heart

Preemptive analgesia the administration of analgesics prior to an invasive or operative procedure in order to treat pain before it occurs

Preferred provider arrangements (PPAs) similar to preferred provider organizations, but PPAs can contract with individual health care providers; the plan can be limited or unlimited

Preferred provider organization (PPO) a group of physicians or a hospital that provides companies with health services at a discounted rate

Prefilled unit-dose system disposable units that provide injectable medications that are available as prefilled syringes ready for use, or as prefilled sterile cartridges and needles that require the attachment of a reusable holder before use

Prejudice a negative belief or preference that is generalized about a group and that leads to "prejudgment"

Preload the degree to which muscle fibers in the ventricle are stretched at the end of diastole

Preoperative phase the period of surgery that begins when the decision for surgery has been made and ends when the client is transferred to the operating room bed

Preparation stage occurs when the person undertakes cognitive and behavioral activities that prepare the person for change

Presbycusis generalized loss of hearing related to aging

Presbyopia loss of elasticity of the lens and thus loss of ability to see close objects as a result of the aging process

Prescription the written direction for the preparation and administration of a drug

Presencing being present, being there, or just being with a client

Pressure a compressing downward force on a body area

Pressure ulcers reddened areas, sores, or ulcers of the skin occurring over bony prominences

Primary care (PC) the point of entry into the health care system at which initial health care is given

Primary health care (PHC) essential health care based on practical, scientifically sound, and socially acceptable methods and technology made universally accessible to individuals and families in the community

through their full participation and at a cost that the community and country can afford to maintain at every stage of their development in the spirit of self-reliance and self-determination

Primary intention healing tissue surfaces are approximated (closed) and there is minimal or no tissue loss, formation of minimal granulation tissue and scarring

Primary prevention activities directed toward the protection from or avoidance of potential health risks

Primary sexual characteristics relate to the organs necessary for reproduction, such as the testes, penis, vagina, and uterus

Principles-based (deontological) theories emphasize individual rights, duties, and obligations

Priority setting the process of establishing a preferential order for nursing strategies

Private (civil) law the body of law that deals with relationships between private individuals

Prn order “as needed order”; permits the nurse to give a medication when, in the nurse’s judgment, the client requires it

Problem solving obtaining information that clarifies the nature of the problem and suggests possible solutions

Problem-oriented medical record (POMR) data about the client are recorded and arranged according to the client’s problems, rather than according to the source of the information

Problem-oriented record (POR) see Problem-oriented medical record (POMR)

Procedures steps used in carrying out policies or activities

Process evaluation a component of quality assurance that focuses on how care was given

Process recording the verbatim (word-for-word) account of a conversation

Proctoscopy the viewing of the rectum

Proctosigmoidoscopy the viewing of the rectum and sigmoid colon

Productivity in health care, frequently measured by the amount of nursing resources used per client or in terms of required versus actual hours of care provided

Profession an occupation that requires extensive education or a calling that requires special knowledge, skill, and preparation

Professional values values acquired during socialization into nursing from codes of ethics, nursing experiences, teachers, and peers

Professionalism a set of attributes, a way of life that implies responsibility and commitment

Professionalization the process of becoming professional; acquiring characteristics considered to be professional

Progress notes chart entries made by a variety of methods and by all health professionals involved in a client’s care for the purpose of describing a client’s problems, treatments, and progress toward desired outcomes

Prompted voiding supplements habit training by encouraging the client to try to use the toilet (prompting) and reminding the client when to void

Prone position position in which a client lies on his or her abdomen with the head turned to one side

Proprioception awareness of posture, movement, and changes in equilibrium; knowledge of position, weight, and resistance of objects in relation to body

Proprioceptors sensory receptors that are sensitive to movement and the position of the body

Protein-calorie malnutrition (PCM) an imbalance between nutritional intake and the body’s protein requirements

Protocols a predetermined and preprinted plan specifying the procedure to be followed in a particular situation

Proxemics the study of distance between people in their interactions

Psychological dependence a state of emotional reliance on a drug to maintain one’s well-being; a feeling of need or craving for a drug

Psychological homeostasis emotional or psychological balance or state of mental well-being

Psychomotor domain the “skill” domain; includes motor skills such as giving an injection

Puberty the first stage of adolescence in which sexual organs begin to grow and mature

Public law refers to the body of law that deals with relationships between individuals and the government and governmental agencies

Pulse the wave of blood within an artery that is created by contraction of the left ventricle of the heart

Pulse deficit the difference between the apical pulse and the radial pulse

Pulse oximeter a noninvasive device that measures the arterial blood oxygen saturation by means of a sensor attached to the finger or other location

Pulse pressure the difference between the systolic and the diastolic blood pressure

Pulse rhythm the pattern of the beats and intervals between the beats

Pulse volume the strength or amplitude of the pulse, the force of blood exerted with each heartbeat

Pureed diet a modification of the soft diet wherein liquid may be added to the food, which is then blended to a semisolid consistency

Purkinje fibers fibers of the ventricular conduction pathways that terminate in ventricular muscle, stimulating contraction

Purulent exudates an exudate consisting of leukocytes, liquefied dead tissue debris, and dead and living bacteria

Pus pooled exudates

Pyogenic bacteria bacteria that produce pus

Pyorrhea advanced periodontal disease in which teeth are loose and pus is evident when the gums are pressed

Pyrexia a body temperature above the normal range; fever

Qi body’s vital energy

Qigong breathing and mental exercises combined with body movements

Qualifiers words that have been added to some NANDA labels to give additional meaning to the diagnostic statement

Quality a subjective description of an auscultated sound (e.g., whistling, gurgling, or snapping)

Quality assurance (QA) program an ongoing systematic process designed to evaluate and promote excellence in the health care provided to clients

Quality improvement an organizational commitment and approach used to continuously improve all processes in the organization with the goal of meeting and exceeding customer expectations and outcomes; also known as *total quality management (TQM)* and *continuous quality improvement (CQI)*

Race classification of people according to shared biologic characteristics and physical features

Radiating pain pain perceived at the source and in surrounding or nearby tissues

Radiation the transfer of heat from the surface of one object to the surface of another without contact between the two objects

Radiopharmaceutical a pharmaceutical (targeted to a specific organ) labeled with a radioisotope, administered through various routes, to determine hyperfunction or hypofunction of the organ

Random access memory (RAM) data and instructions stored on chips; RAM storage is temporary and cleared when the computer is turned off

Range a measure of variability, consisting of the difference between the highest and lowest values in a distribution of scores

Range of motion (ROM) the maximum degree of movement possible for each joint

Rapport a relationship between two or more people of mutual trust and understanding

Rationale the scientific reason for selecting a specific action

RBC indices may be performed as part of the CBC to evaluate the size, weight, and hemoglobin concentration of red blood cells

Reactive hyperemia a bright red flush on the skin occurring after pressure is relieved

Readiness behaviors or cues that reflect a learner's motivation to learn at a specific time

Reagent a substance used to produce a chemical reaction to detect or measure other substances

Recent memory deals with activities of the recent past of minutes to a few hours

Receptor a location on the surface of a cell membrane or within a cell (usually a protein) to which a drug chemically binds

Reconstitution the technique of adding a diluent to a powdered drug to prepare it for administration

Record a written communication providing formal, legal documentation of a client's progress

Recording the process of making written entries about a client on the medical record

Red blood cell (RBC) count number of red blood cells per cubic millimeter of whole blood

Red blood cell (RBC) indices evaluate size, weight, and hemoglobin concentrations of RBCs

Referred pain pain perceived to be in one area but whose source is another area

Reflection thinking from a critical point of view, analyzing why one acted in a certain way, and assessing the results of one's actions

Reflex an automatic response of the body to a stimulus

Reflexology a treatment based on massage of the feet to relieve symptoms in other parts of the body

Reflux backward flow

Regeneration renewal, regrowth, the replacement of destroyed tissue cells by cells that are identical or similar in structure and function

Regional anesthesia the temporary interruption of the transmission of nerve impulses to and from a specific area or region of the body; the client loses sensation in an area of the body but remains conscious

Registry private duty agency that contracts with individual practitioners

Regression a defense mechanism in which one adapts behavior that was comforting earlier in life to overcome the discomfort and insecurity of the present situation

Regurgitation the spitting up or backward flow of undigested food

Relapsing fever the occurrence of short febrile periods of a few days interspersed with periods of 1 or 2 days of normal temperature

Relationship-based (caring) theories stress courage, generosity, commitment, and the need to nurture and maintain relationships

Relaxation response physiological state achieved through deep relaxation breathing

Reliability the degree to which an instrument produces consistent results on repeated use

Religion an organized system of worship

REM sleep sleep during which the person experiences *rapid eye movements*

Remission a period during a chronic illness when there is a lessening of severity or cessation of symptoms

Remittent fever the occurrence of a wide range of temperature fluctuations, more than 2°C (3.6°F) over a 24-hour period, all of which are above normal

Renin-angiotensin-aldosterone system system initiated by specialized receptors in the juxtaglomerular cells of the kidney nephrons that respond to changes in renal perfusion

Report oral, written, or computer-based communication intended to convey information to others

Repression a defense mechanism in which painful thoughts, experiences, and impulses are removed from awareness

Res ipsa loquitur "the thing that speaks for itself"; a legal doctrine that relates to negligence in which the harm cannot be traced to a specific health care provider or standard but does not normally occur unless there has been a negligent act

Researchability the problem can be subjected to scientific investigation

Reservoir a source of microorganisms

Resident flora microorganisms that normally reside on the skin and mucous membranes, and inside the respiratory and gastrointestinal tracts

Residual urine the amount of urine remaining in the bladder after a person voids

Resolution phase the part of the response cycle period of return to the unaroused state, which may last 10 to 15 minutes after orgasm, or longer if there is no orgasm

Resonance a hollow sound as produced by lungs filled with air during percussion

Respiration the act of breathing; includes the intake of oxygen and the output of carbon dioxide from the cells to the atmosphere

Respiratory acidosis (hypercapnia) a state of excess carbon dioxide in the body

Respiratory alkalosis a state of excessive loss of carbon dioxide from the body

Respiratory character see Respiratory quality

Respiratory membrane where gas exchange occurs between the air on the alveolar side and the blood on the capillary side; the alveolar and capillary walls form the respiratory membrane

Respiratory quality refers to those aspects of breathing that are different from normal, effortless breathing, includes the amount of effort exerted to breathe and the sounds produced by breathing

Respiratory rhythm refers to the regularity of expirations and inspirations

Respondeat superior a legal term meaning "let the master answer"; an employer assumes responsibility for the conduct of its employees and can also be held responsible for malpractice by employees

Responsibility the specific accountability or liability associated with the performance of duties of a particular role

Resting energy expenditure (REE) the amount of energy required to maintain basic body functions

Resting tremor a tremor that is apparent when the client is at rest and diminishes with activity

Restraints protective devices used to limit physical activity of the client or a part of the body

Retrograde pyelography a radiographic study used to evaluate the urinary tract

Retrospective audit evaluation of a client's record after discharge from an agency

Review of systems see Screening examination

Rhizotomy interruption of the anterior or posterior nerve root between the ganglion and the cord; generally performed on cervical nerve roots to alleviate pain of the head and neck

Right (legal) a privilege or fundamental power to which an individual is entitled unless it is revoked by law or given up voluntarily

Right of self-determination subjects feel free from constraints, coercion, or any undue influence to participate in a study

Rigor mortis stiffening of the body that occurs 2 to 4 hours after death

Risk factors factors that cause a client to be vulnerable to developing a health problem

Risk management having in place a system to reduce danger to clients and staff

Risk nursing diagnosis clinical judgment that a problem does not exist, but the presence of risk factors indicates that a problem is likely to develop unless nurses intervene

Risk of harm exposure to the possibility of injury going beyond everyday situations

Role the set of expectations about how a person occupying a specific position behaves

Role ambiguity unclear role expectations; people do not know what to do or how to do it and are unable to predict the reactions of others to their behavior

Role conflict a clash between the beliefs or behaviors imposed by two or more roles fulfilled by one person

Role development involves socialization into a particular role

Role mastery performance of role behaviors that meet social expectations

Role model providing an example of acceptable behavior(s) through demonstration

Role performance what a person does in a particular role in relation to the behaviors expected of that role

Role strain a generalized state of frustration or anxiety experienced with the stress of role conflict and ambiguity

Root cause analysis process for identifying factors that bring about deviations in practices that lead to an event

S₁ the first heart sound; occurs when the atrioventricular valves (mitral and tricuspid) close

S₂ the second heart sound; occurs when the semilunar valves (aortic and pulmonic) close

Safety monitoring device an electronic sensor or monitor that detects when clients are attempting to get out of a bed or chair and triggers an alarm

Sairy Gamp a character in the Charles Dickens book *Martin Chuzzlewit* who represented the negative image of nurses in the early 1800s

Saliva the clear liquid secreted by the salivary glands in the mouth

Sample (statistics) segment of the population from whom data will be collected

Sanguineous exudate an exudate containing large amounts of red blood cells; also called *hemorrhagic exudate*

Sarcopenia steady decrease in muscle fibers

Saturated fatty acids those in which all carbon atoms are filled to capacity (i.e., saturated) with hydrogen

Scabies a contagious skin infestation by the itch mite that produces intense itching, especially at night

Scald a burn from a hot liquid or vapor, such as steam

Scientific health belief based on the belief that life and life processes are controlled by physical and biochemical processes that can be manipulated by humans

Screening examination a brief review of essential functioning of various body parts or systems; also called *review of systems*

Scrub person usually UAP but can be a registered nurse (RN) or LPN; assists the surgeons by draping the client with sterile drapes and handling sterile instruments and supplies; with the circulating nurse, is responsible for accounting for all sponges, needles, and instruments at the close of surgery

Sebaceous glands active under the influence of androgens in both males and females, which secrete sebum and become most active on the face, neck, shoulder, upper back, and chest; are often the cause of an increased incidence of acne

Sebum the oily, lubricating secretion of sebaceous glands in the skin

Secondary intention healing wound in which the tissue surfaces are not approximated and there is extensive tissue loss; formation of excessive granulation tissue and scarring

Secondary prevention activities designed for early diagnosis and treatment of disease or illness

Secondary sexual characteristics physical characteristics that differentiate the male from the female but do not relate directly to reproduction

Seizure a sudden onset of excessive electrical discharges in one or more areas of the brain

Seizure precautions safety measures taken to protect clients from injury should they have a seizure

Selectively permeable cell membranes that allow substances to move across them with varying degrees of ease

Self-awareness the relationship between one's perception of oneself and others' perceptions of oneself

Self-concept the collection of ideas, feelings, and beliefs one has about oneself

Self-esteem the value one has for oneself; self-confidence

Self-regulation homeostatic mechanisms that come into play automatically in the healthy person

Semicircular canals in the inner ear; contain the organs of equilibrium

Semi-Fowler's (low-Fowler's) position a bed-sitting position in which the head of the bed is raised 15° to 45°, typically at a 30° angle

Semilunar valves crescent moon-shaped valves between the cardiac ventricles and the pulmonary artery (pulmonic valve) and the aorta (aortic valve)

Sensorineural hearing loss the result of damage to the inner ear, the auditory nerve, or the hearing center in the brain

Sensoristasis the need for sensory stimulation

Sensory deficit partial or complete impairment of any sensory organ

Sensory deprivation insufficient sensory stimulation for a person to function

Sensory memory momentary perception of stimuli by the senses

Sensory overload an overabundance of sensory stimulation

Sensory perception the organization and translation of stimuli into meaningful information

Sensory reception process of receiving environmental stimuli

Sentinel event an unexpected occurrence involving death or serious physical or psychological injury, or the risk thereof

Separation anxiety the fear and frustration experienced by young children that comes with parental absences

Sepsis the presence of pathogenic organisms or their toxins in the blood or body tissues

Septicemia occurs when bacteremia results in systemic infection

Septum a dividing structure such as that between the cardiac chambers or between the two sides of the nose

Serosanguineous exudate inflammatory material consisting of a combination of clear and blood-tinged drainage

Serous exudates inflammatory material composed of serum (clear portion of blood) derived from the blood and serous membranes of the body such as the peritoneum, pleura, pericardium, and meninges; watery in appearance and has few cells

Serum osmolality a measure of the solute concentration of the blood

Sexual aversion disorder severe distaste for sexual activity or thought of sexual activity

Sexual health the integration of the somatic, emotional, intellectual, and social aspects of sexuality, in ways that are positively enriching and that enhance personality, communication, and love

Sexual orientation the preference of a person for one gender or the other

Sexual pain disorders include dyspareunia, vaginismus, and genital pain

Sexual self-concept how one values oneself as a sexual being

Shaft the part of the needle that is attached to the hub; also called the *cannula*

Shaken baby syndrome (SBS) violent shaking of an infant by the arms or shoulders causing a whiplash, which can lead to severe injury

Shared governance a method that aims to distribute decision making among a group of people

Shared leadership a contemporary theory of leadership that recognizes the leadership capabilities of each member in a professional group

and assumes that appropriate leadership will emerge in relation to the challenges that confront the group

Shearing force a combination of friction and pressure that, when applied to the skin, results in damage to the blood vessels and tissues

Shock phase first part of the alarm reaction in which the stressor may be perceived consciously or unconsciously by the person

Short-term memory information held in the brain for immediate use or what one has in mind at a given moment

Shroud a large piece of plastic or cotton material used to enclose a body after death

Side effect the secondary effect of a drug that is unintended; usually predictable and may be either harmless or potentially harmful

Significance the potential to contribute to nursing science by enhancing client care, testing or generating a theory, or resolving a day-to-day clinical problem

Signs detectable by an observer or can be measured or tested against an accepted standard; can be seen, heard, felt, or smelled; also called *objective data*

Sims' (semiprone) position side-lying position with lowermost arm behind the body and the upper arm at the shoulder and the elbow, with the client's legs flexed in front

Single order an order that is to be carried out one time only at a specified time

Sinoatrial (SA or sinus) node the primary pacemaker of the heart located where the superior vena cava enters the right atrium

Situation, background, assessment, and recommendation (SBAR) process a structured approach to documentation used when nurses communicate with primary care providers and other nurses about client status

Situational leader adapts style according to consideration of the staff members' abilities, knowledge of the nature of the task to be done, and sensitivity to the context or environment in which the task takes place

Sitz bath a bath in which the client sits in warm water to help soothe and heal the perineum

Skinfold measurement an indicator of the amount of body fat, the main form of stored energy

Slander defamation by the spoken word, stating unprivileged (not legally protected) or false words by which a reputation is damaged

Sleep an altered state of consciousness in which the individual's perception of and reaction to the environment are decreased

Sleep apnea periodic cessation of breathing during sleep

Sleep architecture basic organization of normal sleep

Sleep hygiene refers to interventions used to promote sleep

Small calorie (c, cal) the amount of heat required to raise the temperature of 1 g of water 1°C

SOAP an acronym for a charting method that follows a recording sequence of *subjective* data, *objective* data, *assessment*, and *planning*

Socialization a process by which a person learns the ways of a group or society in order to become a functioning participant

Socratic questioning a technique one can use to look beneath the surface, recognize and examine assumptions, search for inconsistencies, examine multiple points of view, and differentiate what one knows from what one merely believes

Sojourner Truth an abolitionist, Underground Railroad agent, preacher, and women's rights advocate, she was a nurse for more than 4 years during the Civil War and worked as a nurse and counselor for the Freedman's Relief Association after the war

Solutes substances dissolved in a liquid

Solvent the liquid in which a solute is dissolved

Somatic pain originates in the skin, muscles, bone, or connective tissue

Somnology the study of sleep

Sordes accumulation of foul matter (food, microorganisms, and epithelial elements) on the teeth and gums

Source-oriented clinical record a record in which each person or department makes notations in a separate section or sections of the client's chart

Spastic describing the sudden, prolonged involuntary muscle contractions of clients with damage to the central nervous system

Specific defenses immune functions directed against identifiable bacteria, viruses, fungi, or other infectious agents; also called *immune defenses*

Specific gravity the weight or degree of concentration of a substance compared with that of an equal volume of another, such as distilled water, taken as a standard

Specific self-esteem how much one approves of a certain part of oneself

Spinal anesthesia anesthesia produced by injecting an anesthetic agent into the subarachnoid space surrounding the spinal cord; also referred to as a *subarachnoid block (SAB)*

Spinal cord stimulation (SCS) involves the insertion of a cable that allows the placement of an electrode directly on the spinal cord and is used with nonmalignant pain that has not been controlled with less invasive therapies

Spinal tap see Lumbar puncture (LP)

Spiritual distress a disturbance in or a challenge to a person's belief or value system that provides strength, hope, and meaning to life

Spiritual health see Spiritual well-being

Spiritual well-being a feeling of inner peace and of being generally alive, purposeful, and fulfilled; the feeling is rooted in spiritual values and/or specific religious beliefs

Spirituality belief in or relationship with some higher power, creative force, driving being, or infinite source of energy

Spreadsheet programs that manipulate primarily numbers

Sputum the mucous secretion from the lungs, bronchi, and trachea

Stage of exhaustion the third stage in the adaptation syndromes that occurs when the adaptation that the body made during the second stage cannot be maintained

Stage of resistance the second stage in the adaptation syndromes when the body's adaptation takes place

Standard a generally accepted rule, model, pattern, or measure

Standard deviation the most frequently used measure of variability, indicating the average to which scores deviate from the mean; commonly symbolized as SD or S

Standard precautions (SP) the risk of caregiver exposure to client body tissues and fluids rather than the suspected presence or absence of infectious organisms determines the use of clean gloves, gowns, masks, and eye protection

Standardized care plan formal plan that specifies the nursing care for groups of clients with common needs (e.g., all clients with myocardial infarction)

Standards of care the skills and learning commonly possessed by members of a profession

Standards of practice descriptions of the responsibilities for which nurses are accountable

Standards of professional performance as set by the American Nurses Association (ANA), describe behaviors expected in the professional nursing role

Standing order an order that may be carried out indefinitely until another order is written to cancel it, or that may be carried out for a specified number of days

Stapes stirrups bone of the middle ear

Stat order indicates an order that is to be carried out immediately and only once

Statistically significant term applied after data have been analyzed to determine whether the results had a probability less than 0.05, which is considered the acceptable level of significance

Statutory law a law enacted by any legislative body

Steatorrhea excessive amount of fat in the stool due to a malabsorption syndrome or pancreatic enzyme deficiency

Stereognosis the ability to recognize objects by touching and manipulating them

Stereotyping assuming that all members of a culture or ethnic group are alike

Sterile field a microorganism-free area

Sterile technique practices that keep an area or object free of all microorganisms; also called *surgical asepsis*

Sterilization a process that destroys all microorganisms, including spores and viruses

Sternum the breastbone

Stimulus-based stress model stress is defined as a stimulus, life event, or set of circumstances that arouses physiological and/or psychological reactions that may increase the individual's vulnerability to illness

Stoma an opening created in the abdominal wall by an ostomy

Stool see Feces

Strabismus cross-eye

Stress an event or set of circumstances causing a disrupted response; disruption caused by a noxious stimulus or stressor

Stress electrocardiography uses ECGs to assess a client's response to an increased cardiac workload during exercise

Stressor any factor that produces stress or alters the body's equilibrium

Stridor a harsh, crowing sound made on inhalation caused by constriction of the upper airway

Strike an organized work stoppage by a group of employees to express a grievance, enforce a demand for changes in condition of employment, or solve a dispute with management

Stroke volume (SV) the amount of blood ejected with each cardiac contraction

Structure evaluation focuses on the setting in which care is given

Subarachnoid block (SAB) see Spinal anesthesia

Subculture usually composed of people who have a distinct identity and yet are related to a larger cultural group

Subcutaneous beneath the layers of the skin; hypodermic

Subjective data data that are apparent only to the person affected; can be described or verified only by that person

Sublingual a method of drug administration in which the drug is placed under the tongue

Subsystems system components

Suctioning the aspiration of secretions through a catheter connected to a suction machine or wall suction outlet

Sudden infant death syndrome (SIDS) the sudden and unexpected death of an infant

Sudoriferous glands glands of the dermis that secrete sweat; also known as *sweat glands*

Superego the conscience of personality; the source of feelings of guilt, shame, and inhibition

Supine position see Dorsal position

Supplemental Security Income (SSI) special payments for people with disabilities, those who are blind, and people who are not eligible for Social Security; these payments are not restricted to health care costs

Suppositories solid, cone-shaped, medicated substances inserted into the rectum, vagina, or urethra

Suppuration the formation of pus

Suprapubic catheter an indwelling catheter that has been surgically placed in the bladder through the abdominal wall, either with or without a urethrally placed catheter

Suprasystem the system above another system

Surface anesthesia see Topical anesthesia

Surface temperature the temperature of tissue, the subcutaneous tissue, and fat

Surfactant a surface-active agent (e.g., soap or a synthetic detergent); in pulmonary physiology, a mixture of phospholipids secreted by alveolar cells into the alveoli and respiratory air passages that reduces the surface tension of pulmonary fluids and thus contributes to the elastic properties of pulmonary tissue

Surgical asepsis practices that keep an area or object free of all microorganisms; also called *sterile technique*

Sustained maximal inspiration device (SMI) see Incentive spirometer

Suture a thread used to sew body tissues together

Sutures junction lines of the skull bones

Sweat glands see Sudoriferous glands

Sympathectomy severance of the pathways of the sympathetic division of the autonomic nervous system; eliminates vasospasm, improves peripheral blood supply, and is effective in treating painful vascular disorders

Sympathetically maintained pain occurs occasionally when abnormal connections between pain fibers and the sympathetic nervous system perpetuate problems with both the pain and sympathetically controlled functions (e.g., edema, temperature, and blood flow regulation)

Symptoms see Covert data

Syndrome diagnosis a diagnosis that is associated with a cluster of other diagnoses

Synergistic when two different drugs increase the action of one or another drug

System a set of interacting identifiable parts or components

Systemic infection occurs when pathogens spread and damage different parts of the body

Systole the period during which the ventricles contract

Systolic pressure the pressure of the blood against the arterial walls when the ventricles of the heart contract

Tachycardia an abnormally rapid pulse rate; greater than 100 beats per minute

Tachypnea abnormally fast respirations; usually more than 24 respirations per minute

Tactile related to touch

T'ai chi discipline that combines physical fitness, meditation, and self-defense

Tandem a secondary IV setup in which a second IV container is attached to the line of the first container at the lower, secondary port to permit medications to be administered intermittently or simultaneously with the primary solution

Tartar a visible, hard deposit of plaque and dead bacteria that forms at the gum lines

Taxonomy a classification system or set of categories, such as nursing diagnoses, arranged on the basis of a single principle or consistent set of principles

Teacher a nurse who helps clients learn about their health and the health care procedures they need to perform to restore or maintain their health

Teaching system of activities intended to produce learning

Team nursing the delivery of individualized nursing care to clients by a team led by a professional nurse

Technical skills "hands-on" skills such as those required to manipulate equipment, administer injections, and move or reposition clients

Telecommunications the transmission of information from one site to another, using equipment to transmit information in the forms of signs, signals, words, or pictures by cable, radio, or other systems

Telemedicine technology used to transmit electronic medical data about clients to individuals at distant locations

Temperament the way individuals respond to their external and internal environment

Teratogen anything that adversely affects normal cellular development in the embryo or fetus

Termination stage the ultimate goal where the individual has complete confidence that the problem is no longer a temptation or threat

Territoriality a concept of the space and things that individuals consider their own

Tertiary intention healing that occurs in wounds left open for 3 to 5 days and then closed with sutures, staples, or adhesive skin closures

Tertiary prevention activities designed to restore individuals with disabilities to their optimal level of functioning

Theory a system of ideas that is proposed to explain a given phenomenon (e.g., theory of gravity)

Therapeutic bath a bath given for physical effects, such as to soothe irritated skin or to promote healing of an area (e.g., the perineum); two common types are the sitz bath and the medicated bath

Therapeutic communication an interactive process between nurse and client that helps the client overcome temporary stress, to get along with other people, to adjust to the unalterable, and to overcome psychological blocks that stand in the way of self-realization

Therapeutic effect the primary effect intended of a drug; reason the drug is prescribed

Third space syndrome fluid shifts from the vascular space into an area where it is not readily accessible as extracellular fluid

Thoracentesis a procedure to remove excess fluid or air from the pleural cavity to ease breathing or to introduce chemotherapeutic drugs intrapleurally

Thrill a vibrating sensation over a blood vessel that indicates turbulent blood flow

Thrombophlebitis inflammation of a vein followed by formation of a blood clot

Thrombus a solid mass of blood constituents in the circulatory system; a clot (plural: *thrombi*)

Throughput a transformation that occurs after input is absorbed by the system and is then processed in a way that is useful to the system

Ticks small gray-brown parasites that bite into tissue and suck blood and transmit several diseases to people, in particular Rocky Mountain spotted fever, Lyme disease, and tularemia

Tidal volume the volume of air that is normally inhaled and exhaled

Tinea pedis athlete's foot (ringworm of the foot), which is caused by a fungus

Tissue perfusion passage of fluid (e.g., blood) through a specific organ or body part

Topical applied externally (e.g., to the skin or mucous membranes)

Topical anesthesia applied directly to the skin and mucous membranes, open skin surfaces, wounds, and burns; also called *surface anesthesia*

Top-level manager organizational executive primarily responsible for establishing goals and developing strategic plans

Torr millimeters of mercury

Tort a civil wrong committed against a person or a person's property

Tort law law that defines and enforces duties and rights among private individuals that are not based on contractual agreements

Trade name name of the drug given by the drug manufacturer; also known as a *brand name*

Traditional observance of the beliefs and practices of one's heritage or cultural belief system

Traditional Chinese medicine (TCM) based on the premise that the body's vital energy circulates through pathways or meridians and can be accessed and manipulated through specific anatomic points along the surface of the body

Tragus the cartilaginous protrusion at the entrance to the ear canal

Transactional leader a contemporary theory of leadership in which resources are exchanged as an incentive for loyalty and performance

Transactional stress theory a theory that encompasses a set of cognitive, affective, and adaptive (coping) responses that arise out of person-environment transactions; the person and the environment are inseparable and affect each other

Transcellular fluid compartment of extracellular fluids; includes cerebrospinal, pericardial, pancreatic, pleural, intraocular, biliary, peritoneal, and synovial fluids

Transcendence a person's recognition that there is something other or greater than the self and a seeking and valuing of that greater other, whether it is an ultimate being, force, or value

Transcultural nursing providing care within the differences and similarities of the beliefs, values, and patterns of cultures

Transcutaneous electrical nerve stimulation (TENS) a method of applying low-voltage electrical stimulation directly over pain areas

Transdermal patch a dermatologic medication delivery system that administers sustained-action medications via multilayered films containing the drug and an adhesive layer

Transformational leader leader who fosters creativity, risk taking, commitment, and collaboration by empowering the group to share in the organization's vision

Transgenderism gradation of human characteristics that run from female to male

Translator a person who converts written material (such as client education pamphlets) from one language into another

Tremor an involuntary trembling of a limb or body part

Trial the period during which all relevant facts are presented to a jury or judge

Triangular fossa a depression of the antihelix

Triglycerides substances that have three fatty acids; they account for more than 90% of the lipids in food and in the body

Trigone a triangular area at the base of the bladder marked by the ureter openings at the posterior corners and the opening of the urethra at the anterior corner

Trimesters the 3-month periods during pregnancy marking certain landmarks for developmental changes in mother and the fetus; three trimesters occur during a pregnancy

Tripod (triangle) position the proper standing position with crutches; crutches are placed about 15 cm (6 in.) in front of the feet and out laterally about 15 cm (6 in.), creating a wide base of support

Trocar a sharp, pointed instrument

Troponin enzyme that is released into the blood during a myocardial infarction

Trough level represents the lowest concentration of a drug in the blood serum

Tuberculin syringe a narrow syringe, calibrated in tenths and hundredths of a milliliter on one scale and in sixteenths of a minim on the other scale that can be useful in administering other drugs, particularly when small or precise measurement is indicated

Two-point discrimination see One-point discrimination

Tympanic membrane the eardrum

Tympany a musical or drumlike sound produced during percussion over an air-filled stomach

Ultrasonography the use of ultrasound to produce an image of an organ or tissue

Unconscious mind the mental life of a person of which the person is unaware

Undernutrition intake of nutrients insufficient to meet daily energy requirements as a result of inadequate food intake or improper digestion and absorption of food

Undertaker see Mortician

Universal precautions (UP) techniques to be used with all clients to decrease the risk of transmitting unidentified pathogens

Unplanned change haphazard change that occurs without control by any person or group

Unprofessional conduct one of the grounds for action against a nurse's license; includes incompetence or gross negligence, conviction of practicing without a license, falsification of client records, and illegally obtaining, using, or possessing controlled substances

Unsaturated fatty acid a fatty acid that could accommodate more hydrogen atoms than it currently does

Upper-level managers organizational executives who are primarily responsible for establishing goals and developing strategic plans

Urea a substance found in urine, blood, and lymph; the main nitrogenous substance in blood

Ureterostomy type of urinary diversion that involves surgery of the ureters

Urgency the feeling that one must urinate

Urinary frequency the need to urinate often

Urinary hesitancy a delay and difficulty in initiating voiding; often associated with dysuria

Urinary incontinence a temporary or permanent inability of the external sphincter muscles to control the flow of urine from the bladder

Urinary reflux backward flow of urine

Urinary retention the accumulation of urine in the bladder and inability of the bladder to empty itself

Urinary stasis stagnation of urinary flow

Urination the process of emptying the bladder; also called *micturition* or *voiding*

Urine osmolality a measure of the solute concentration of urine, a more exact measurement of urine concentration than specific gravity

Utilitarianism a specific, consequence-based, ethical theory that judges as right the action that does the most good and least amount of harm for the greatest number of individuals; often used in making decisions about the funding and delivery of health care

Utility see Utilitarianism

Vaginismus involuntary spasm of outer one third of vaginal muscles; makes penetration of vagina painful

Validation the determination that the diagnosis accurately reflects the problem of the client, that the methods used for data gathering were appropriate, and that the conclusion or diagnosis is justified by the data

Validity the degree to which an instrument measures what it is intended to measure

Valsalva maneuver forceful exhalation against a closed glottis, which increases intrathoracic pressure and thus interferes with venous blood return to the heart

Value set all of the values (e.g., personal, professional, religious) that a person holds

Value system the organization of a person's values along a continuum of relative importance

Values something of worth; a belief held dearly by a person

Values clarification a process by which individuals define their own value

Vaporization continuous evaporation of moisture from the respiratory tract and from the mucosa of the mouth and from the skin

Variance a variation or deviation from a critical pathway; goals not met or interventions not performed according to the time frame

Vasoconstriction constricted blood vessels

Vasodilation an increase in the diameter of blood vessels

Vector-borne transmission transport of an infectious agent from an animal or flying or crawling insect that serves as an intermediate means via biting or depositing feces or other materials on the skin

Vehicle-borne transmission transport of an infectious agent into a susceptible host via any intermediate substance (e.g., fomites or food)

Venipuncture puncture of a vein for collection of a blood specimen or for infusion of therapeutic solutions

Ventilation the movement of air in and out of the lungs; the process of inhalation and exhalation

Ventricles two lower chambers of the heart

Veracity a moral principle that holds that one should tell the truth and not lie

Verbal communication use of verbal language to send and receive messages

Verdict the outcome made by a jury

Vernix caseosa a protective covering that develops over the unborn fetus's skin; a white, cheese-like substance that adheres to the skin and can become 1/8-inch thick by birth

Vesicostomy surgical production of an opening into the bladder

Vestibule contains the organs of equilibrium; found in the inner ear

Vestibulitis severe pain on touch or attempted vaginal entry

Vial a small glass medication container with a sealed rubber cap; used for single or multiple doses

Vibration a series of vigorous quiverings produced by hands that are placed flat against the chest wall to loosen thick secretions

Virulence ability to produce disease

Viruses nucleic acid-based infectious agents

Visceral internal organs

Visceral pain pain arising from organs or hollow viscera

Viscous thick, sticky

Vision the mental image of a possible and desirable future state

Visiting nursing delivery of services in the client's home

Visual related to sight

Visual acuity the degree of detail the eye can discern in an image

Visual fields the area an individual can see when looking straight ahead

Vital capacity the maximum amount of air that can be exhaled after a maximum inhalation

Vital signs body temperature, pulse, respiration, and blood pressure. Many agencies have designated pain as the fifth vital sign

Vitamin an organic compound that cannot be manufactured by the body and is needed in small quantities to catalyze metabolic processes

Vitiligo patches of hypopigmented skin, caused by the destruction of melanocytes in the area

Void urinate

Volume control infusion set small fluid containers (100 to 150 mL in size) attached below a primary infusion container so that a medication can be administered through the client's IV line

Volume expanders used to increase the blood volume following severe loss of blood, or loss of plasma

Vulvodynia constant and unremitting burning of the vulva

Water-soluble vitamins vitamins that the body cannot store, so people must get a daily supply in the diet; include C and B-complex vitamins

Well-being a subjective perception of balance, harmony, and vitality

Wellness a state of well-being; engaging in attitudes and behaviors that enhance quality of life and maximize personal potential

Wellness diagnosis (NANDA) describes human responses to levels of wellness in an individual, family, or community that have a readiness for enhancement

White blood cells (WBCs) body cells that are part of the body's defense against infection and disease

Wide area network (WAN) computers linked across large distances

World Wide Web (WWW) refers to the complex links among web pages or websites, accessed through "addresses" called *universal resource locators* (URLs)

Xenophobia the fear or dislike of people different from one's self

Xerostomia dry mouth as a result of a reduced supply of saliva

Yoga a type of meditation that is a system of exercises for attaining bodily or mental control and well-being

Z-track technique the recommended technique for administering intramuscular injections because it has been found to be less painful than the traditional injection technique and decreases leakage of irritating and discoloring medications into the subcutaneous tissue

Index

Page numbers followed by *f* indicate figures and those followed by *t* indicate tables, boxes, or special features. The titles of special features (e.g., Culturally Responsive Care, Lifespan Considerations; Skills) are also capitalized.

 peripheral vascular system, 566–567t
 skin, 525–527t
 skull and face, 532t
 thorax and lungs, 556–559t
- hygiene
 adult clients, bathing, 676–680t
 foot care, providing, 687–688t
 hair care, 700–701t
 hearing aids, removing, cleaning, and inserting, 705–706t
 occupied bed, changing, 713–714t
 oral care for the unconscious client, 686–687t
 perineal-genital care, 682–683t
 teeth, brushing and flossing, 692–695t
 unoccupied bed, changing, 710–712t
- medications
 adding medications to intravenous fluid containers, 803–805t
 administering intradermal injection for skin tests, 792–793t
 administering intramuscular injection, 801–802t
 administering intravenous medications using IV push, 808–811t
 administering ophthalmic instillations, 813–815t
 administering otic instillations, 815–817t
 administering subcutaneous injection, 794–796t
 administering vaginal instillations, 818–820t
 mixing medications using one syringe, 790–791t
 oral medications, administering, 775–778t
 preparing medications from ampules, 787–788t
 preparing medications from vials, 788–789t
- nutrition
 gastrostomy or jejunostomy feeding, administering, 1163–1164t
 nasogastric tube, inserting, 1154–1157t
 nasogastric tube, removing, 1166–1167t
 tube feeding, administering, 1160–1163t
- oxygenation
 oropharyngeal, nasopharyngeal, and nasotracheal suctioning, 1269–1271t
 oxygen administration by cannula, face mask, or face tent, 1262–1263t
 suctioning a tracheostomy or endotracheal tube, 1273–1275t
 tracheostomy care, providing, 1276–1279t
- pain management, back massage, 1116–1117t
- perioperative nursing
 antiemboli stockings, applying, 876–878t
 cleaning a sutured wound and changing a dressing on a wound with a drain, 892–894t
 gastrointestinal suction, managing, 889–891t
 teaching moving, leg exercises, deep breathing, and coughing, 871–873t
- safety
 bed or chair exit safety monitoring devices, using, 652–654t
- restraints, applying, 663–664t
 seizure precautions, implementing, 654–655t
- skin integrity and wound care
 wound, irrigating, 849–851t
 wound drainage specimen for culture, obtaining, 839–841t
- urinary elimination
 bladder irrigation, performing, 1200–1201t
 external urinary device, applying, 1189–1191t
 urinary catheterization, performing, 1194–1197t
- vital signs
 apical pulse, 492–494t
 apical-radial pulse, 495t
 blood pressure, 504–506t
 body temperature, 484–485t
 oxygen saturation, 508–509t
 peripheral pulse, 489–491t
 respirations, 498–499t

Answers to Anatomy & Physiology Review, Critical Thinking Checkpoints, and Applying Critical Thinking, and End-of-Unit Meeting the Standards Questions

Chapter 1

N/A.

Chapter 2: Critical Thinking Possibilities

1. The nurse needs to know what types of clients were involved in the research, e.g., medical diagnoses, age, and other health risk factors. Similarly, what are the characteristics of the research setting? Was it in a hospital or long-term care? How many clients participated in the study? What other standards or care were in place at the agency? The more different these are from your own population and setting, the greater the chance that different outcomes could result from the intervention. Also, did this research build on previous studies or is it the first of its kind?
2. How will the expertise of your clinicians affect this situation? Do they have the skill to use the overlay as compared to other possible interventions? How many clients in your setting are at risk for skin breakdown? Consider also the clients' values and preferences. What would be the cost to the client, if any? Are there related considerations such as the comfort of the overlay, any restrictions on positioning for its optimal use, etc.?

Chapter 3: Critical Thinking Possibilities

1. Some of the many concepts that can be identified are illness, disease, wellness, and nutrition.
2. The physician seems to view Tony as someone who has some choices in his own care. He also appears to be making a statement related to quality of life (wellness) that reflects a belief that the client would not be getting better and intravenous nutrition was, therefore, not indicated. The nurse appears to have expanded the definition of client to include family and friends and has a different prognosis in mind.
3. Florence Nightingale would focus Tony's care on the need for a clean environment, good water, and light as necessary for his health.
4. All of the nursing models recognize an interdependence of systems and relationships that would make controlling diarrhea a top priority. None of the nursing models is any more powerful than the others as a foundation for the nurse's plan of care.

Chapter 4: Critical Thinking Possibilities

1. The nurse needs to verify that the client received information from the primary care provider and that she understands the information. Can the client explain in her own words what the doctor told her? Does she have any questions?
2. The three exceptions of people who cannot provide consent are minors, individuals who are unconscious or injured in such a way that they are unable to give consent, and individuals with mental illness who have been judged to be incompetent. If this client is an alert, competent adult, she can provide consent.
3. The nurse will need to read the form to the client.
4. Unless the husband is the appointed guardian or has power of attorney for health care decisions, the client should sign the form. The client will need assistance as to where to sign the form. The client could even mark an "X." Remember, the nurse witnesses that the client gave her consent voluntarily and that the signature is authentic.
5. The nurse needs to include the following:
 - The consent form was read to the client before she signed it.

- A reference to the client's understanding of the procedure (e.g., "able to state reasons for surgery, pros and cons of surgery. Stated she had no questions. Aware that she can change her mind").
- If the husband helped the client sign (e.g., guided her hand), this information should be documented.
- Record any teaching as a result of nursing-related questions by the client (e.g., "discussed and demonstrated techniques for coughing and deep breathing after surgery").

Chapter 5: Critical Thinking Possibilities

1. Personal values are often based on family, cultural, religious, or other beliefs and attitudes. The nurse must not assume any particular values based on these characteristics, however. They must be validated with the individual. What appear to be the client's values must be confirmed with him through open and supportive discussion.
2. The nurse needs to review the variety of factors influencing the client's values and decisions such as family support, previous experience with health care situations, the meaning of illness (and of the foot) to the person, and his personal goals. The surgeon has information about the client's overall health status, possibly previous experiences with this client, and personal values and beliefs about the impact of an amputation.
3. The nurse's responsibility is to ensure that the client has all of the information required for him to make an informed decision and that the information is accurate. This may include information beyond his physiological condition such as facts about his health insurance coverage for acute and rehabilitative care. The nurse's personal beliefs about what the client should do or what the surgeon should recommend must not influence the nurse in carrying out this responsibility.
4. It is sometimes difficult to find the middle ground between advocating for the client and interfering in the client–primary care provider relationship. Also, the client's informed decision may be counter to standard or recommended medical practice.
5. The ANA's Code of Ethics or a patient bill of rights can help the nurse recall the standards that apply in guiding nurse decision making during possible ethical dilemmas. The nurse's actions should be based on ethical theory and standards, not on personal opinion.

Chapter 6: Critical Thinking Possibilities

1. It does not seem as though the client has used many health promotion or prevention services. He would have used secondary prevention services extensively in seeing the primary care provider for his blood pressure and joint problems and having surgery. His time at the skilled nursing facility, with the home health nurse, and the physical therapist visits were tertiary preventive care.
2. He has visited the primary care provider's office, which is useful for monitoring existing problems and screening for new ones; the hospital has the expert staff for performing his surgery and the nursing personnel for caring for him during the perioperative period. They have laboratories, therapeutic services (e.g., physical therapy), and nutrition services to meet his needs. Examples of other agencies would include the skilled nursing facility and home health care.
3. This client has health care needs in a variety of areas. His age and health problems suggest that he will continue to need health care for the foreseeable future. The case manager can become very familiar with the client and family situation so that the appropriate levels of care

can be provided when he needs them and within his insurance coverage. He would have Medicare but may also have supplemental coverage. Should he become unable to continue living in the current house, the case manager may assist with determining the type of living facility most appropriate. If the client needs to be readmitted to the hospital, the case manager serves as an excellent facilitator in the communication needed among the physician, hospital, rehabilitative setting, and home health care personnel.

4. Examples include these: Pharmacist—older adults often take many different medications. During an acute illness, there is a particular need to ensure that newly ordered medications that may be required for the current condition do not interfere with medications used for chronic conditions. Spiritual support—although we do not know Mr. Mendel's religious preference, he may be experiencing some spiritual concerns, for example, about dying. If he and his wife have a relationship with a church or other similar institution, it would be important to include this aspect in his care. Many other professionals may be included on the team.

Chapter 7: Critical Thinking Possibilities

There can be no traditional answers to these questions. What follow below are aspects to consider.

1. Overall, decreasing the time clients spend in dependent situations such as being in acute care hospitals is consistent with the agenda's aims at health care reform. However, the nurse must also consider the culture of the client and the environment. Active decision making by the client is a Western view that may not be shared by clients from Asian, African American, or Latino backgrounds. In European health care systems, clients often spend as much as five times longer in a hospital than do American clients. The client may not be accustomed to community-based care and have very different views of the health care professionals who provide community-based care. Also, the scenario does not address outcomes. A primary concern would be to measure the incidence of complications, need for rehospitalization, and client satisfaction with the short stays.
2. Individuals will have unique responses to this question. Answers should reflect consideration of the views and skills of nurses, clients, and systems.
3. In an integrated health care system, the client would move easily from the diagnostic phase through treatment and rehabilitation—possibly using a case manager to assess the client and family and follow her through the entire episode. A community coalition would focus more on the risk factors leading to the health problem and initiatives to educate the population on wellness, prevention, and early detection.
4. Communication with the client, family, and other health care providers would be key to determining that a particular client is appropriate for this “fast-track” approach to the surgery. If the parties disagree, shared decision making should be used in establishing the details of how the care will actually be provided. Mutual respect and trust are key—that the health care providers are skilled and knowledgeable about the procedure and that the client and family can carry out their respective roles once the decisions have been made and communicated. Collaboration with third-party payers can be more complex. Investigate their chain of command and try to find nurses with whom to discuss the cases.

Chapter 8: Critical Thinking Possibilities

1. Many aspects of the nurse's role will be the same. The techniques such as intravenous medication administration will have the same steps, but they may need to be modified to apply in situations where not all usual supplies or equipment are available (e.g., using a door hook for an IV pole). More so than in the acute care setting, the nurse needs to consider the client's family as a client in addition to the client.

2. The client has the same rights as any client but, in addition, has the right to direct that care be administered in a way that is acceptable within his or her environment, to decline to accept the nurse's recommendations, and to decline the nurse's assistance and care.
3. Safety issues: any aspects of his home or daily activities that could worsen his diabetes (e.g., inadequate heating/cooling) or potentially cause injury (unsafe railings). Infection control issues: lack of access to needed hygiene facilities; inability to participate in dressing changes and wound care due to poor vision, reduced dexterity, or other factors; lack of adequate caregiver support.
4. In addition to the intangible savings of emotional comfort provided by being in one's own home, the client is able to maintain many of his personal contacts and activities—including such important tasks as paying bills and caring for pets. While home, the client avoids large hospital room charges and does not incur the extra costs of having someone care for things at home.

Chapter 9: Critical Thinking Possibilities

1. Consider the uses of the computer in the following areas: searching the Internet and literature for research or case studies that might relate; sending queries to experts identified through university medical centers of excellence; e-mailing colleagues from relevant professional nursing organizations.
2. Ask the client to share exactly the nature of the concern. Discuss with the client whether any unique identifiers will be associated with the photos or query, for example, name, address. Suggest that your colleagues will be asked to delete the photo files as soon as the consultation is complete. Would the client find fax or hard copies more acceptable?
3. Use one of the documents available to critique the website yourself. Share with the client the criteria for determining the usefulness of the information found on health websites and discuss how they apply to the specific site. Also, provide the client with other reliable sources of health information such as printed pamphlets or referenced articles.
4. Consider issues such as the ability to do your studying and assignments at a time (and place) of your choosing rather than in a classroom on specific days and times; whether you prefer to work alone or in “real place” groups (online programs also use groups that may do synchronous or asynchronous work); how self-directed you are; the availability of local quality education programs; concern about privacy regarding your academic records and financial aid information; and so on.

Chapter 10: Critical Thinking Possibilities

1. Examples include the following: What evidence supports the assumption? What other explanations for his condition are possible? What might another nurse who sees the situation think? What evidence would suggest a different assumption?
2. This attitude says that critical thinking will lead to appropriate conclusions. It requires that you trust yourself, examine the influence of emotions on your thinking, and use logic to reach conclusions. Suggest how you can show that you have considered these things.
3. If your conclusion is correct and acted on, you have helped keep the client's problems at a minimum through early intervention. He can receive proper treatment and the nurse can develop a plan of care to assist the client and family with the impact of the condition. If you are incorrect in your assumption and do not consider other potential causes of the client's discomfort, time may be wasted and the real condition could worsen. Increased cost, emotional frustration, and other negative outcomes may result.
4. How does the client feel about his recent retirement? What is the impact of his retirement while his wife continues to work? Do the coming holidays play a role in his illness?

Chapter 11: Critical Thinking Possibilities

1. Extremely important areas to include are allergies, comorbidities (other health problems or diseases), and previous experience with surgery.
2. Because the musculoskeletal system is the reason she is in the hospital, it would be given priority. Due to her age and the immobility that will follow surgery, other priority systems would be cardiopulmonary and integumentary.
3. Many answers may be correct. The question should be open ended and prompt for the desired information (for example, it would not be helpful to ask her where she lives). One example would be “It may not be possible for you to be alone when you go home from the hospital. Tell me about who might be available to assist you?”
4. Consider family, friends, clergy, and her old charts.

Chapter 12: Critical Thinking Possibilities

1. Examples would include insomnia; fidgeting; dry mouth; increased pulse, blood pressure, and respirations; and poor attention span.
2. Examples include the uncertainty of the prognosis, lack of knowledge about the condition and its treatment, and fear of pain.
3. *Ineffective Airway Clearance* or *Breathing Patterns*, *Ineffective Coping*, *Spiritual Distress*, *Hopelessness*, *Readiness for Enhanced Comfort*, *Grieving*.
4. Although this may be a true statement, lung cancer is a medical diagnosis—not a nursing diagnosis, which is a response to health status or a health problem. In addition, the stressor (related to) should be something the nurse can treat independently.

Chapter 13: Critical Thinking Possibilities

1. The nurse assumes that the standardized care plan is comprehensive enough for this client with the individualization that is applied to it.
2. The last outcome for *Anxiety*, “Freely expressing concerns and possible solutions about work and parenting roles,” and the associated interventions are examples because the roles described occur between the client and her family in the home rather than in the hospital setting.
3. Several possibilities exist. The nurse needs to set aside time to discuss the plan with the client, alone or with other family and health care team members. The plan can be presented verbally or in writing. It can be initiated by the nurse who seeks validation from the client. Or the problem list, nursing diagnoses, goals, outcomes, and interventions can be decided on by the client and nurse together after the nurse presents assessment data.
4. If agency guidelines delineate the frequency of nursing interventions and the care plan does not require these more often than specified, no time frame is required. Also, if the intervention is performed during every interaction (e.g., the nurse remains calm and appears confident), no frequency need be written.
5. Nursing diagnoses related to airway are often the highest priority because they represent life-threatening conditions. In reassessing priorities, the nurse considers new problems as well as progress toward meeting existing goals. If the airway problem is in the process of improving, other diagnoses may become higher priority.

Chapter 14: Critical Thinking Possibilities

1. For *Ineffective Airway Clearance*, the overall outcome has not been met. Although the client is able to cough productively, the care plan requires modification and continuation in order to achieve all of the goals. For *Anxiety*, the overall outcome has been met for the most part. Ongoing assessment and data collection are indicated.
2. Some possibilities are that the interventions have not been adequately implemented (and still are needed) or more time is needed for their effects to be apparent.
3. It might be good to keep the diagnosis so it can be followed in case it reoccurs. On the other hand, the outcomes remaining may be

accomplished through plans for other nursing diagnoses (such as respiratory rate) or are ongoing (teaching).

4. Data collected are recorded in the chart on graphic records and nurses' notes (see Chapter 15 .

Chapter 15: Critical Thinking Possibilities

1. No date. Do not know if the hospital policy requires military time. Showed assumption and bias with use of the term “complainer.” Not complete (e.g., what did the nurse listen to . . . would that information be helpful in the care of the client? Were the BPs taken in two different positions or at two different times?). No information as to why the client refused lunch. Another assumption that client fell out of bed . . . did the nurse see it or walk in and find the client lying on the floor? No evidence of using the nursing process as a framework for documentation.
2. Use the nursing process as a framework. Document assessment findings that relate to the defining characteristics of pain. Chart those interventions that were done to help relieve the pain. Document the client's response to those interventions. If any teaching was done, be sure to document what the teaching was and the client's response.
 1. 6/6/15 #1 Pain
 2. S: “sharp, stabbing pain in lower back that radiates to left leg”
 3. States pain is 8 out of 10
 4. “I didn't sleep last night”
 5. “I feel better” (after interventions)
 6. O: BP 210/90 mmHg, P 72 beats/min, R 18/min
 7. Last medicated 5 hours previously
 8. Medicated with ordered analgesic
 9. Heating pad applied to lower back
 10. Positioned on side with pillows behind back
 11. A: Continues to need narcotic medication to progress toward goal of pain relief
 12. P: Add to plan of care to offer analgesic around the clock q4h versus prn
 13. 6/6/15 Pain
 14. D: “sharp, stabbing pain in lower back that radiates to left leg”
 15. States pain is 8 out of 10
 16. “I didn't sleep last night”
 17. BP 210/90, P 72, R 18
 18. Last medicated 5 hours previously
 19. Continues to need narcotic medication to progress toward goal of pain relief
 20. A: Medicated with ordered analgesic
 21. Heating pad applied to lower back
 22. Positioned on side with pillows behind back
 23. Add to plan of care to offer analgesic around the clock q4h versus prn
 24. R: “I feel better” (after interventions)

Chapter 16: Critical Thinking Possibilities

1. Key points to remember include, but are not limited to, the following:
 - Active listening is very important because it strengthens the rapport between the client and nurse. Careful listening can help check your understanding of what the client is saying or meaning with the responses.
 - It is important to emphasize that the client has personal choice and control. The client should decide what behavior, if any, to focus on.
 - Readiness to change, including importance and confidence, needs to be continually assessed.
 - It is not unusual for individuals to recycle through the stages of change.
2. Questions to consider include these:
 - “Take me through a typical day in your life and tell me where your [behavior] fits in.”
 - “You have mentioned smoking, exercise, food, and losing weight. Would you like to talk about one of these topics or is there

4 Answers

something else you would prefer to talk about?” (This gives clients the opportunity to choose the topic most important to them at the time.)

- “Which of these behaviors do you feel most ready to think about changing?”
 - “Sometimes it can be helpful to examine the pros and cons of [behavior]—would this be helpful?”
 - “What concerns you the most about [behavior]?”
 - “Would you like to know more about [behavior]?”
 - “How do you see the connection between [behavior] and [behavior]?”
3. Mr. W. is in the contemplation stage, because he wonders about changing and is willing to discuss it. Contemplators want to change; however, at the same time, they have a resistance to change. Consciousness raising is important during this stage. Find out if the client wants more information. Assist the client to increase his awareness of the behavior—why he wants to change, the pros and cons of changing, and so on.

Chapter 17: Critical Thinking Possibilities

1. Jerry has a positive outlook and views himself as “well,” whereas Joe has a negative outlook and views himself as “ill.” Identify and compare data indicating the psychological dimension (self-concept, mind–body interactions, and emotional response to health) for both clients. Speculate about how their differences in perception may affect their continuing recovery process.
2. Jerry is most likely an “internal” because he has taken charge of his own health by changing his diet, initiating an exercise program, and attempting to lower his stress. Joe is more likely an “external” because he has been unable to take control of his health. Joe may believe that his health is largely controlled by outside forces and is beyond his control.
3. At least one external factor is Jerry’s physician’s advice. Another may come from his work environment colleagues.
4. Joe’s perception of his illness, and thus his ability to respond in a positive manner, may be affected by a family history of heart disease and his perception that he is at high risk and there is nothing he can do to change his pattern of health.
 - a. Joe’s perceived barriers to action (cost, time, lack of social support)
 - b. Perhaps the benefit of assuming the sick role outweighs the benefit of recovery.
5. Verifying that Joe values the planned outcome achieved from smoking cessation; verifying Joe’s knowledge about the effects of smoking and providing needed information or correcting misconceptions; demonstrating genuine concern for Joe and reinforcing positive changes that he does make; allowing Joe to make his own decisions, thereby demonstrating trust and respect. Many other interventions are possible.

Chapter 18: Critical Thinking Possibilities

1. Rachel’s culture (values, beliefs, norms, and life practices that guide thinking, decisions, and actions) is mixed and can be referred to as bicultural because she has integrated practices and values from both her mother and father who were of different backgrounds.
2. Rachel’s ethnicity (consciousness of belonging to a group that is differentiated from others by symbolic markers) is most strongly associated with her Jewish background as evidenced by her return to the Jewish religion as an adult and by her obvious connection with this group.
3. Cultural values often determine the roles of family members, their interactions, who has authority to make decisions on the client’s behalf, and family involvement in the client’s care. Without clear guidelines on the cultural practices Rachel adheres to, it may be difficult to provide culturally sensitive care.
4. Rachel’s beliefs and values will strongly affect her approach to death and the way her family reacts toward her before and during the death process.
 - a. Rachel’s culture may dictate her choice of dying with family members present, rites, or rituals to be performed, and the degree of knowledge she wishes to have about the dying process.

- b. Rachel’s religion is likely to strongly influence the care of her body after death and burial procedures.
5. A cultural assessment is particularly important at this time in Rachel’s life so that her death can be congruent with her beliefs and traditions. It is also important to determine her primary support systems, to preserve her preferences, and to offer support to Rachel and her family in culturally acceptable ways.

Chapter 19: Critical Thinking Possibilities

1. Tim’s name suggests that he may be of Asian descent (and cancer of the stomach is more common in Asian populations than in some other ethnic groups). Tim’s parents do not speak English and this suggests that they are not from a North American culture. Many Asian people use CAM as a regular part of their health activities. Tim’s gastric cancer appears to be quite serious. Often, cancer clients whose disease is not responding to conventional therapy seek CAM to treat the disease or to cope with symptoms.
2. Certainly, touch, biofeedback, prayer, music, meditation, and similar CAM therapies might help Tim’s ability to cope with his pain and even increase his nutritional intake. There may also be herbs, homeopathic, and TCM products that are safe to use with his Western therapy although the nurse must investigate these carefully. Where would you look for this information?
3. The nurse may ignore finding the bags of “tea,” but there is a risk that the substance could be contraindicated with other medications Tim currently takes. The nurse can ask Tim or his wife what is in the bags and determine the safety of their use.
4. If the nurse is strongly in favor of or opposed to CAM, this may color interactions with the client and family. The nurse should review these biases and ensure that he or she can still provide professional care considering personal perspectives. The nurse should be open minded to hearing the client’s beliefs and supporting the client’s right to act in accordance with his beliefs.

Chapter 20: Critical Thinking Possibilities

1. Finnegan is in Erikson’s early childhood stage, where the task of developing “autonomy versus shame and doubt” is paramount. Through successful achievement of this task, the child will learn to express himself, cooperate with others, and self-regulate emotions and behaviors (demonstrate self-control). Unsuccessful mastery of this stage leads to a child who is unsure of the self, unable to limit behaviors, and is willful, resistant, or defiant.
2. Because Finnegan is not able to cognitively understand the implications of his condition, his parents should provide clear, simple statements of what is expected of him (e.g., “You will need to wear the eye patch every day”) and why the treatment is necessary (e.g., “Wearing the eye patch will help your eye learn to see better”). Their approach should be matter-of-fact and supportive, acknowledging his feelings and giving him specific praise and comfort (e.g., “Sometimes it is hard to wear glasses, isn’t it? You don’t complain much at all. That’s a good lesson to learn and a hard one. Come here, let’s have a hug together.”), without emotional drama (e.g., “Oh, you poor little thing! I am so sorry you have problems with your eyes! Here, let Mama hold you!”). His parents should also encourage Finnegan’s active decision making in his care, fostering his sense of control over the situation (e.g., “Finn, you need to wear the patch for two hours each day. Do you want to put it on after breakfast or after your nap? You get to decide.”). Parents should be counseled that Finnegan is in the midst of learning self-control; they should expect some resistance and defiance, but should use distraction and active support (above) when it occurs, not engage in a power struggle with the child.
3. Finnegan is in Piaget’s early preconceptual stage, where he is curious about the environment, exploring, learning language and concepts, and very self-focused. From a social learning perspective, he is

becoming increasingly aware of his relationship with others and is learning by observation and imitation. Use explanations with simple language and concepts the child understands; allow him to look at, manipulate, and explore the patch and glasses; provide play objects so he can express his feelings tactilely (e.g., dolls, puppets, drawing, or painting); read books about and encourage him to notice and talk with you about other people who wear glasses or eye patches; give him explicit praise and encouragement for success.

Chapter 21: Critical Thinking Possibilities

1. Eight-year-old children are in Piaget's stage of concrete cognitive thinking. They tend to see things as "right" and "wrong" and emphasize following rules, usually because doing so means they will be perceived as "good" and they will be rewarded.
2. A first step in talking with Shireena and her mother is to find out how the child understands her condition. Ask Shireena to tell you what she thinks has happened and what caused her problem. As you listen to her answer, validate those things that are accurate (e.g., "Yes, when you get water from a lake in your ears, it can cause an infection.") and add new knowledge (e.g., "But not everyone gets an infection from lake water; sometimes it just seems to happen."). Ensure that she does not feel at fault (e.g., "I know you tried hard not to put your head under water, but sometimes water splashes up no matter how hard you try."). Encourage Shireena to ask questions and explain to her what has happened. Drawing a picture of the ear can be a useful tool for both the child and her mother. Use words that are age appropriate and if a new word seems to confuse the child, explain what it means in simple, concrete terms. The mother should participate in the discussion, but the nurse should actively solicit input from both.
3. Provide clear, concrete directions on what is expected in the treatment plan. Ask for ideas from both mother and child about how they will implement the plan (e.g., When will the drops be put in? Where will the medicine be stored? How will they remember to put the drops in? Are there any activities pending that might disrupt the treatment plan [travel, sleep-overs, etc.]?). Again, validate those ideas that sound workable, and make other suggestions as appropriate (e.g., "Some of my patients find that making a 10-day calendar with three spots for each day helps. They cross off each spot after the drops are put in, and at the end of 10 days, they have a special treat planned."). Shireena is entering Erikson's stage of industry vs. inferiority and this experience could be an opportunity for her to take an active, creative role in her self-care. The nurse should point this out to her mother and make every effort to ensure that Shireena gains new skills at the same time she is recovering from her external ear infection.

Chapter 22: Critical Thinking Possibilities

1. Health promotion for the young, or emerging, adult should include a comprehensive health assessment (including physical exam) at least every 5 years. Mr. Jones stated he had not seen a health care provider since high school. The nurse should attempt to get the name of the previous provider, and ask if Mr. Jones has participated in any workplace health fairs or screenings, such as blood pressure, hearing, or blood glucose. Young adults need regular dental care, so the nurse should ask Mr. Jones when he last saw a dentist, what took place at the visit, and if he has another visit scheduled. If he does not, the nurse can suggest that he set up dental appointments for every 6 months, and may supply him with the names and phone numbers of local dentists if Mr. Jones does not have a regular source of dental care.

Several aspects of Mr. Jones's occupation put him at risk for injury or illness, so it is important to ask how he manages these threats. Particularly, his work exposes him to noise, sun, and falls. He should be asked about use of sunscreen, ear protection, and a hard hat. Exercise is not a major concern if he is engaged in strenuous physical labor on his job, but he should be asked about nutrient and water intake. It is

important that he take in adequate amounts of protein, iron, fruits, and vegetables. His fluid intake should be at least 64 ounces per day; more if he is perspiring heavily.

Mr. Jones has made several comments that bear further discussion in relation to his health promotion. His intake of alcohol should be investigated for the amount and frequency of intake, as well as signs of alcohol abuse. He should also be asked about the use of a designated driver, or other strategy for travel, when he has been using alcohol. His statement about "chasing women" should also be followed up on. He may be at risk for STIs (see below) and should be referred for STI testing and treatment. His ability to form mature and intimate relationships should also be investigated.

2. Sexual activity is a risk factor for STIs. If Mr. Jones is sexually active, the nurse should explain the rationale for asking questions that he may find embarrassing or intrusive. In a nonjudgmental manner, the nurse should ask the age at which Mr. Jones became sexually active, how many sexual partners he has had, and whether the partners have been men, women, or both. He should also be asked how many partners he currently has, and if he has engaged in oral or anal sex. Mr. Jones should be asked if he uses condoms with every sexual activity. The nurse should be careful not to lead Mr. Jones into a politically correct answer, so might ask "How often do you use condoms?" The nurse should then ask him to explain how he applies the condom, and instruct him on correct technique, if needed.
3. The nurse is promoting safe sexual practices. If the nurse identifies high-risk sexual behaviors that place Mr. Jones at risk for having an STI, the nurse needs to refer him for testing and possible treatment.
3. Young adults are typically very healthy, and the health risks they are exposed to are primarily from behavior. In addition, health problems in middle and old age may be prevented by health habits started now, and Mr. Jones should be advised of this fact.

Violence and substance abuse are major threats to the health of young adults. Mr. Jones should be asked if he feels safe at work and home, and if he has firearms in his possession. The presence of a gun in the home is strongly correlated with accidental injury and suicide. The risk of injury increases if alcohol or other substances are abused, so these practices are important to query. Tobacco, although not usually a cause of imminent injury, may precipitate health problems, particularly respiratory ones, later in life. Risks for STI and alcohol-related motor vehicle crashes were discussed in answers 1 and 2 above. Finally, Mr. Jones should be apprised of the heightened risk for suicide in young adults. He should be asked about suicidal ideation (particularly given his accident at work) and be given the telephone number of a suicide prevention hotline, if appropriate.

4. Young adults should have a comprehensive physical exam at least every 5 years, with testicular exam, hearing and vision assessment, blood pressure and cholesterol measurement, tuberculin test, and administration of needed immunizations. Monthly testicular self-exam is no longer recommended by the American Cancer Society unless the man has specific testicular cancer risk factors. Some primary care providers, however, believe that a monthly testicular self-exam is a factor in helping men seek early treatment. Each man needs to decide whether or not to do a monthly self-exam. As a result, nurses need to know how to teach men how to perform this self-exam. Because Mr. Jones has not seen a health care provider in several years, by his report, it is important to conduct all of these assessments today, including the testicular examination. The American Cancer Society recommends that a testicular exam be a part of the annual physical exam. His work-related risks of noise and sun exposure indicate a need for a careful hearing screening and examination of the skin for sun damage. The purpose for conducting these exams is to identify signs of developing disease or dysfunction, as well as to reveal any areas where health promotion or protection is needed.

- The developmental milestones of psychosocial function in young adults are feeling independent, having a realistic self-image, having positive regard for self and life direction, coping with stress, interacting well with one's family, being responsible for one's self, and developing lasting relationships with others. Mr. Jones has displayed some bravado about drinking with friends and interacting with women, but it is difficult to ascertain the quality of the relationships. The nurse should ask more about these friendships, as well as if Mr. Jones has close friends, either male or female. Furthermore, although Mr. Jones has a job, there is no information about its adequacy to meet his financial needs, or how responsibly Mr. Jones manages his employment. No information is given about how Mr. Jones interacts with his family. He should be asked about the use of alcohol or other substances as coping mechanisms. He should also be asked if he is satisfied with his life and occupation. If he is not, the nurse should ask if Mr. Jones has the plans and resources needed to make a change.

Chapter 23: Critical Thinking Possibilities

- Osteoporosis means "porous bone," or bone that has gotten thinner and greatly increases the risk of fractures, particularly in older women. Pictures or actual x-rays can be shown to the client to facilitate learning the basics of osteoporosis. The seriousness of the condition should be stressed. At the same time, it should be stressed that following preventive measures and participating in treatment regimes, if this is indicated, will help to maintain bone health.
- Risk factors should include physical factors such as early menopause, small thin frame, use of steroids, history of rheumatoid arthritis, family history of disease, or history of fractures.
- Some risk factors are considered to be modifiable, including smoking, diet low in calcium, lack of exposure to sun (sunlight helps to increase vitamin D), increased intake of caffeine and alcohol, and lack of exercise.
- Most of the medications used to treat osteoporosis help to reduce bone resorption, which means that bone mass is at least maintained. Some of these medications have serious gastrointestinal side effects and some increase the risk of formation of blood clots. It is essential for the client to know the possible side effects and call the physician if any unusual symptoms are experienced. If the medication is an experimental medication, bone density scans may be done at regular intervals to determine effectiveness of the treatment.
- Measures to discuss for a decreased risk of fractures include the following: assessment of home environment to see what safety measures need to be instituted, making sure that hallways and stairwells are well lit, wearing well-fitting shoes with nonskid soles, removing loose rugs in the house, and keeping the floor free of cords (electrical and telephone) to prevent tripping over them. Measures to maintain bone mass include increasing calcium in the diet and taking a calcium supplement, increasing the amount of weight-bearing exercise, and taking medications to prevent further bone loss.

Chapter 24: Critical Thinking Possibilities

- Many illnesses can be affected by the client's emotional state. If her arthritis is the type called rheumatoid, it can flare when the client is under stress. Also, some medications used to treat arthritis can cause mood changes and other distressing adverse effects. Any aspect of the illness that interferes with daily functioning of a family member will affect the coping of all members.
- The family is affected because Linda's role functioning is impaired such that others might need to take on tasks that Linda would normally perform. In addition, Linda's emotional response to her illness can interfere with her ability to provide psychological support to her children and spouse and thus cause them severe distress.
- Facing illness as a family often draws the members, including those normally at some physical or emotional distance, closer together. A disadvantage of facing an illness with the family is the additional

stress, cost, and responsibilities members may have to take on. The ill member may feel great guilt about the extra work that falls to others. Members may become fatigued and be unable or unwilling to support the ill person.

- Each family member exists as a part of the whole. They interact with each other and with their human and nonhuman environment. The family has become a more closed system (with thicker boundaries) than usual due to the parents' desire to avoid assistance or interference from previous spouses. Linda's biological systems may be malfunctioning, leading to altered function of her other systems and those of the family. For example, feedback in the form of pain will serve as input to her in deciding how much and what types of physical activity she can perform.

Chapter 25: Critical Thinking Possibilities

- Possible examples describing which aspect of the nurse's approach relates to each of the following "Six C's of Caring in Nursing" as outlined by Roach:
 - Compassion: The nurse prioritizes care to alleviate pain before continuing to other tasks.
 - Competence: The nurse draws up the correct dose of morphine and administers it safely.
 - Confidence: The nurse does not hesitate to provide essential care, and expresses her belief in this treatment to the client.
 - Conscience: The nurse follows safety procedures and protocols at all times, putting the welfare of the client first.
 - Commitment: The nurse has made arrangements in her personal life (for her own child), so that she can focus on her professional role.
 - Comportment: The nurse dresses and acts in a professional manner, communicating who she is to the child and mother.
- Possibilities for descriptions of how each type of knowing prepared the nurse, Megan, for her caring approach:
 - Personal knowing: The nurse is aware of her own strengths and limitations. She has made arrangements for her own child's care so that she can focus on her clients.
 - Empirical knowing: The nurse combines knowledge of growth and development, pathophysiology, medical treatments, and the nursing process to provide competent nursing care.
 - Aesthetic knowing: By knowing this client and what motivates him, the nurse can plan activities that he understands and appreciates, and that lead to healing and comfort.
 - Ethical knowing: The nurse appreciates the need to "do no harm" to the client and to promote health and healing.
- Possible descriptions of how each of the following aspects from Ray's theory influences the nurse's care:
 - Spiritual-ethical-caring: the importance of providing holistic, respectful, safe care that maintains the client's integrity and promotes healing
 - Physical: the client's acute illness (ruptured appendix) and his physical deviations from health
 - Technologic: the skills involved in nursing care, such as intravenous (IV) therapy, nasogastric tube to suction, IV medications
 - Social-cultural: the child's developmental level, family and peer relationships, and cultural background
 - Educational: the child's level of understanding as well as individual factors that motivate him to ambulate and participate in other aspects of care
 - Legal: practice guidelines that serve as standards of care for this medical diagnosis, as well as nursing policies and procedures that guide the nurse's actions.

Chapter 26: Critical Thinking Possibilities

- Mrs. Manasovitz's nonverbal behavior may include changes in posture, facial expression, lack of verbal expression, and so on. Mrs. Manasovitz's nonverbal communication most likely represents fear, disappointment, loss, anxiety, devastation, and so on.

- The nurse conveyed the following caring actions: sitting with Mrs. Manasovitz, listening to her, and giving her undivided attention. The nurse also conveyed comforting actions: using a soothing voice, reassuring, touching, offering presence, and offering a cup of coffee. The nurse's actions did communicate caring and comforting as evidenced by Mrs. Manasovitz's willingness to share her feelings.
- It is important to provide essential information and establish a trusting relationship during emotionally stressful times. Other advantages of effective communication are helping families with stress reduction, helping them understand treatment options, and helping them with decision making.
- The nurse conveyed attentive listening by sitting with Mrs. Manasovitz, paying attention to both her verbal and nonverbal language, remaining silent, and focusing solely on Mrs. Manasovitz. Other examples may include not interrupting the client, noting the congruency between verbal and nonverbal language, encouraging the client to talk, and thinking before responding.

Chapter 27: Critical Thinking Possibilities

- Mrs. Yorty seems preoccupied, so this may not be the ideal time to proceed with teaching. She needs time to adjust to the news that she has received and to come to terms with how her heart condition is going to affect her life. When she is ready to learn, she will give you her full attention, ask questions, talk to others, and show interest.
- A needs assessment provides information about numerous factors that affect learning, not just cognitive ability. Do not assume that well-educated individuals have all the information they need to make decisions about their health, or that individuals who are not as well educated do not have the capacity to understand.
 - A needs assessment would provide such information as Mrs. Yorty's baseline knowledge of cardiac disease, any health beliefs or cultural factors that may impact her acceptance or rejection of needed changes, the method of learning she prefers to use, and the support systems available to her.
- Using your learning needs assessment, consider how Mrs. Yorty prefers to learn.
 - Consider leaving material for Mrs. Yorty to read or videos for her to view.
 - Schedule short learning sessions rather than overwhelmingly long sessions, use teaching aids, repeat information often, and allow active learning. Allow Mrs. Yorty to set the pace.
- If Mrs. Yorty is able to accurately select foods in accordance with her prescribed diet, is able to accurately plan an exercise program, and can offer suggestions for stress reduction, your teaching has most likely been effective.
 - Do not confuse the client's lack of compliance with ineffective teaching. Clients may choose not to follow a prescribed regimen even though they have thorough knowledge of the regimen.
- Teaching strategies may differ depending on the availability of equipment; however, the principles of teaching would be similar.
 - A learning needs assessment would still be useful. The person's learning readiness and motivation remain important, and learning objectives would continue to serve as evaluation criteria.

Chapter 28: Critical Thinking Possibilities

- Mr. Caruso has characteristics of democratic or participative leadership. He is complimentary of his staff's ability to set goals and make decisions. He encourages your input and ideas. Mrs. Turner has characteristics of the autocratic leader. She explains her expectations and speaks of implementing her programs.
- Not sure which characteristics of your admired manager/leader you might want for yourself? If you didn't already, consider how they influence people; their interest in exploring new ideas; their ability to relate to others; how much freedom they allow or control they exert over

others; their use of authoritarian, democratic, or laissez-faire style; their energy level; and their creativity.

- Strategies for dealing with change may include acknowledging that some resistance to change is normal, examining the reasons for the change, focusing on the positive impact of the change, forming a support group, and examining the steps of the change process. Review Boxes 28-4 and 28-5 for more ideas.
- In both primary care and team nursing, registered nurses may delegate tasks to other nurses or to UAPs. However, in primary nursing, the nurse generally provides as much direct care as possible while present, accepts supervisory responsibility for the client's 24-hour care, and, by definition, delegates care to the other shifts. In team nursing, a designated set or pair of providers is assigned to care for a group of clients. These members will share care for the clients according to agreed-on assignments that include delegation of appropriate tasks by the nurse.

Chapter 29: Critical Thinking Possibilities

- You need to determine the source of the client's concern. Is this just a bad time for her? Inquire if she has ever had her blood pressure taken previously. If so, what was the experience like for her? What does she imagine will happen if you take her blood pressure?
 - Discuss factors that influence clients' views of having vital signs measured—especially factors such as setting: long-term care, hospitals, clinics, primary care providers' offices.
- Each nurse develops his or her own style for addressing problems such as this with clients. You need to develop yours or it will sound insincere. As a rule, however, explain the situation without assigning fault. For example, you might say, "I wasn't able to hear your blood pressure that time," rather than "I'm really new at this and not very good yet."
 - If you are confident that your equipment is functioning properly, you may wish to retake the pressure using palpation rather than auscultation since you will be able to establish the presence of the peripheral pulse before you begin.
 - If you are very new at taking blood pressures, you may wish to ask another nurse to take the blood pressure for you this time. If a teaching stethoscope is available, use it so both of you can listen at the same time.
 - Role-play this situation with fellow students or friends. Try several different responses until you feel comfortable and the "client" expresses trust in your approach.
- When you take a client's blood pressure for the first time, you need to relate it to previous or expected values. Determine the client's most recent BP—although this reading is elevated, it might actually be lower than previous readings. Also, assess for any stressors or medications that might currently be influencing the reading.
- The oxygen saturation value is inconsistent with her other vital signs. Begin by determining if the pulse oximeter equipment is functioning properly and you have applied it correctly to an appropriate location.

Chapter 30: Critical Thinking Possibilities

- A focused neurologic system assessment must be conducted, including determining her mental status, motor and sensory function, and pupillary reactions. The client may have had a stroke or have injured her head when/if she fell. The musculoskeletal system is also a priority since she may have injured herself or broken a hip either before or after falling. In an older adult who has apparently been injured, the integumentary system is a priority because of the high risk for skin damage, bruising, and skin breakdown. Assessment of other systems may also be justifiable.
- Be sure that you are asking open-ended questions that cannot be answered with yes or no. Open-ended questions often begin with the words "how" or "what" or "tell me about." Use good nonverbal communication skills such as being at her level when you speak and making eye contact.

8 Answers

3. Although you should still use the head-to-toe approach, it may be best to do all of the anterior assessment first and then turn her to perform posterior assessments. You can assess her upper extremities and much of her lower extremities without turning her at all. Do not omit the posterior assessment, however, just to reduce her discomfort. It is extremely important to determine if abnormal findings are there such as lung consolidation or skin breakdown.
4. Begin with family members. Although she lives alone, there may be children, grandchildren, or other relatives who are in contact with her regularly. Also, ask about the source of her regular health care. Other community sources may be neighbors or organizations with which she is affiliated (e.g., church, social groups). If she has a primary care provider, ensure that he or she has been notified of the client's admission and determine if she was seen recently or if the office can provide pertinent medical history data.

Chapter 31: Critical Thinking Possibilities

1. Examples include age (reduced immune defenses), dehydration, nutritional deficit (decreased ability to synthesize antibodies), and the chronic respiratory problem.
2. A full history and physical assessment are indicated.
 - a. In particular, explore her immunization status, chronic illnesses, exposure to others who may have had an infection, medications that could increase susceptibility to infection, stress level, and history of previous infections of any kind.
 - b. Assess her skin and mucous membranes and check vital signs that could indicate infection.
 - c. Determine spiritual, cultural, and educational characteristics that may influence her beliefs and understandings, care preferences, and practices.
3. Use of standard precautions (SP) alone will not prevent transmission of her respiratory infection (if contagious) to others since SP are designed to prevent the transmission of bloodborne pathogens. As such, SP do not apply to sputum, nasal secretions, or urine unless contaminated with blood.
4. Depending on the type of organism infecting Mrs. Cortez's respiratory tract, she may need to be placed on specific precautions. Identification of the organism will determine the type of mask and other precautions needed.
 - a. Interventions that protect all clients from the spread of disease include consistent and thorough hand cleansing, encouraging clients to cover their mouths with tissues when coughing or sneezing, disposal of soiled tissues in an appropriate bedside receptacle, making sure that reusable equipment is cleaned or sterilized appropriately, and handling soiled linens to prevent cross-contamination.
5. The assistant should be complimented on knowing the need to wash/cleanse her hands after contact with the client. However, her technique could be improved through the use of paper towels on the faucet handles and increasing the time spent washing to at least 10 seconds. Also, remind the assistant that the use of an alcohol-based rub is actually the preferred method of hand hygiene between clients.

Chapter 32: Critical Thinking Possibilities

1. Restraints should only be used as a last resort. Some of the reasons include, but are not limited to, the following: Research has not proven that restraining clients prevents falls or injury; they lessen the client's movement and independence, which infringes on their rights; restraints can increase agitation of the client; the restraints can cause injury (pressure ulcers, skin tears, or death); restraints can interfere with the client's treatment; restraints can potentially cause health problems such as poor circulation; and restraints can be embarrassing to both client and family members.

2. Several factors that could affect Mr. Moore's safety include, but are not limited to, the following:
 - a. He is older than age 65; he has a history of falls; recent surgery for a hip fracture may impair his mobility; he may be weaker now than before his surgery; and his medications may affect his safety (e.g., antihypertensives, diuretics, analgesics).
 - b. Mr. Moore may resume normal activities before he is strong enough.
 - c. Mr. Moore may not be able to meet his nutritional needs because he will need to prepare all but one meal per day. He is at greater risk for injury while preparing his own food.
 - d. Mr. Moore may not understand the precautions necessary to protect his own safety.
3. You need to perform a home hazard appraisal. Suggestions for safety enhancement include the following:
 - a. Because the majority of adult injuries stem from falls, caution Mr. Moore about using area rugs and to be aware of where his pets are when he is up moving about.
 - b. Use grip handles in the bathtub and toilet.
 - c. All rooms should be well lighted. Use night-lights.
 - d. Carpets should be in good condition and hardwood floors should not be waxed.
 - e. The house should have smoke alarms; telephones should be easily accessible in case of emergency.
4. He has been physically and socially active and independent; he has a strong family support system (his son will visit daily); he has access to community resources; his rooms are on one level and his house is small; he has pets to decrease his loneliness; he has no other chronic illnesses that would interfere with his healing process.

Chapter 33: Critical Thinking Possibilities

1. After reviewing the defining characteristics and related factors, there is little data to support that the client actually has an impaired ability to perform her own bathing and hygiene. She has been providing for her own needs, has been ambulating, and has no physical impairments.
 - a. The following factors influence an individual's hygienic practices: culture, religion, environment, developmental level, health and energy, and personal preference.
2. Assess the client for discomfort/pain, fatigue, embarrassment, cultural beliefs, or personal preferences that may affect her decision to omit her personal care.
 - a. Suggested questions for the client: "Are you uncomfortable?" "Are you more tired today than yesterday?" "Do you want to wait until you go home?"
3. In general, bathing and personal care are essential for maintenance of skin integrity and mucous membranes, decreasing potential for infections, enhancing comfort, fostering a feeling of well-being, enhancing relaxation, minimizing odor, and increasing circulation.
 - a. Benefits of personal care to the client include, but are not limited to, decreasing her risk of surgical wound infection and enhancing her comfort and ability to relax. Cleaning her teeth decreases the risk for infection and enables her to enjoy her food.
4. Offer the client several explanations regarding the benefits of proceeding with her bath and personal care, emphasizing the need to prevent infections.
 - a. Offer to assist her and seek her input on where she wants to bathe (e.g., at the bedside or in the bathroom); gather her toiletries and provide for privacy.
 - b. Make sure she has warm water and clean linens.
 - c. Provide intervention (e.g., pain medication), if appropriate, depending on her reason for not wanting to perform personal care.
5. You can gather information and perform assessments during the bathing process.
 - a. You can convey to clients that you have the time and the interest to make them feel better.

Chapter 34: Critical Thinking Possibilities

1. Consider the possible causes. Is the finger vasoconstricted because of decreased blood volume? Would warming it with a warm cloth and having the client hold her hand in a dependent position help? Check the equipment (e.g., lancet injector) to see that it is operating correctly. Was it poor technique? Frequently, a novice nurse does not use enough force to press the injector firmly against the skin or does not have the injector in a perpendicular position relative to the skin. Both are needed to obtain a deep, clean puncture. After you have ascertained the cause, you will need to do another finger-stick to obtain a large enough drop of blood to obtain an accurate reading.
2. The laboratory results suggest that an infection and dehydration are present. Having a previous HCT for comparison would be helpful. Nursing interventions would relate to both infection and dehydration: VS TPR, check for orthostatic hypotension, obtain urine for C&S, interventions to promote hydration.
3. Consider that the client has had no fluids for 3 days. There is no information about the antibiotic (e.g., route and classification), which can also be a factor. Some antibiotics can be nephrotoxic. It is important to obtain a specimen for C&S before starting antibiotics; otherwise the results may not be accurate. Therefore, priorities would be to first start the IV fluids, because this will begin rehydrating her and may also help with obtaining the urine specimen. Second, obtain the urine specimen. You will need to assess how much assistance she may need with providing the clean-catch urine specimen because of expected weakness as a result of not eating or drinking for 3 days. Assistance may include placing her on a bedpan with the nurse doing the cleansing of the perineal area and collecting the sample. Finally, the third priority would be administration of the antibiotic. All of these priorities would take place quickly because they are all important as is the order of the priorities.
4. The reduction in HCT reflects that she was dehydrated and the first HCT was elevated due to hemoconcentration. After being rehydrated, this HCT is more accurate. The WBC indicates that the infectious process is subsiding.
5. Assess her knowledge about an MRI and explain, if necessary, the purpose, procedure, benefits, and risks. Sedation is provided if the client is claustrophobic or unable to lie still during the procedure. Assure her that two-way communication is provided so that the client can provide feedback and be monitored. Inform her that there is a loud knocking noise during the procedure and earplugs are available if she desires. Document her concerns and the teaching you provided. If she continues to be anxious, inform the primary care provider.

Chapter 35: Critical Thinking Possibilities

1. Differences between an allergic reaction and a drug side effect can include these:
 - a. Side effects are not related to an allergic reaction and do not produce the same symptoms as are produced by allergies. Allergic reactions have a distinct pattern of reaction (e.g., skin rash, pruritus, angioedema, rhinitis, tearing, nausea, vomiting, wheezing, dyspnea, or diarrhea).
 - b. A severe reaction is called anaphylaxis and can produce respiratory collapse if emergency treatment is not immediately instituted.
 - c. Drug hypersensitivity or drug allergy is often listed as a systemic side effect in drug handbooks.
2. Mr. Ketron may have allergies to either of the drugs; he may be on another prescribed drug, tobacco, alcohol, or nonprescription drug that interferes with or potentiates one of the prescribed drugs; he may have a medical condition that limits the kinds of drugs he can take safely; he could be allergic to penicillin; and so on.
3. Make the following assessments:
 - a. Inspect and palpate the IV insertion site for signs of infection, infiltration, or a dislocated catheter.
 - b. Inspect the surrounding skin for redness, pallor, or swelling.

- c. Palpate the surrounding tissues for coldness and the presence of edema, which could indicate leakage of the IV fluid into the tissues.
 - d. Take vital signs for baseline data, especially respiratory rate.
 - e. Determine if the client has allergies to the medication.
 - f. Check the compatibility of the medication and IV fluid.
 - g. Determine specific drug action, side effects, normal dosage, recommended administration time, and peak action time of the morphine.
 - h. Check patency of the IV line by assessing flow rate.
4. All of the same precautions should be taken with intravenous medications as with other medications: correct client, correct dose, correct route, and so on. Additional precautions include, but are not limited to, confirming that the antibiotic is compatible with the intravenous fluid infusing, verifying sterility of the system and integrity of the medication bag, verifying that there is no air in the system, cleaning the port prior to placing a needle, and reviewing Mr. Ketron's medication history for possible allergies.
 5. Some drugs are better absorbed when given on an empty stomach, whereas others cause gastrointestinal irritation and should be given with meals or after meals.

Chapter 35: Anatomy & Physiology Review

GI System

1. A liquid medication is absorbed faster because it does not need to dissolve.
2. Diarrhea may decrease absorption because the drug is moving too rapidly through the small intestine to be absorbed.
3. The presence of food in the stomach will slow the rate of absorption and may decrease the amount of drug absorbed.

Cardiovascular System

1. The distribution of the drug depends on cardiac output and adequate blood flow to the organs and tissues of the body. The distribution of the oral medication may be hindered with a low cardiac output.

Liver

1. Age, especially the very young (immature organ) and the very old (diminished function); history of liver disease; chronic alcohol consumption.
2. If it is a hepatotoxic drug, the nurse would need to be vigilant about assessing the client and the client's lab values (e.g., liver enzymes) to avoid further organ dysfunction.

Kidneys

1. The very young have immature kidney function, and older adults have diminished organ function.
2. Monitor urine output, check lab values (e.g., bun and creatinine levels), and assess for signs of edema or fluid overload.

Chapter 36: Critical Thinking Possibilities

1. Mr. Johns' age, his decreased activity and mobility, his decreased sensation on the right, his incontinence, and his nutritional status (thin for his height) suggest he is vulnerable. In fact, he has evidence of possible stage I pressure ulcers over his hips, coccyx, and perineum.
2. You should assess the degree of his loss of sensation, his ability to recognize if he is incontinent, the frequency of his incontinence, how often he ambulates and his capacity for ambulation, his serum protein as an indicator of his nutritional status, and his ability to attend to his own needs.
3. You should undertake measures that include, but are not limited to, providing nutritious meals and snacks, assisting him if necessary, changing his position every 2 hours, avoiding shearing or friction when moving and positioning him, keeping his skin clean and dry, using pressure-relieving support devices, and encouraging activity. Ongoing skin assessment and evaluation of the effectiveness of his

overall treatment plan are also essential. Discuss the benefit of each of these measures. Consider their cost and the amount of caregiver time required. Prioritize the measures and include rationales.

4. Although the skin is not yet broken, he meets the description of having a stage I ulcer and will progress to further stages (and probably more areas of breakdown) if interventions are not initiated.

Chapter 37: Critical Thinking Possibilities

1. Factors that may increase Mr. Teng's risk include, but are not limited to, the following: He is 77 years old, placing him at greater risk than younger adults; his respiratory status is compromised and he runs a greater risk for developing postoperative atelectasis or lung infection; and he may be taking medications that will slow healing, such as corticosteroids.
2. A major disadvantage of general anesthesia is that it depresses the respiratory and circulatory systems, so the surgeon and anesthesiologist probably chose not to further complicate Mr. Teng's respiratory status. A client's preference for a particular anesthesia is also considered when selecting the type of anesthesia to use.
3. Mr. Teng's preoperative preparation most likely included, but was not limited to, preoperative teaching regarding preparation for surgery; what to expect following surgery; deep-breathing, coughing, and leg exercises; how to splint his abdomen when moving or coughing; fluid and nutritional support; a bath or shower; antiemboli stockings; and medications to enhance rest the night prior to the scheduled surgery.
4. Even though Mr. Teng had spinal anesthesia and is awake, the same general assessments will be made to detect actual or potential problems. He will not go through the stages of anesthesia arousal or experience altered gag reflexes. He will be assessed for return of feeling to his lower extremities to evaluate remaining spinal anesthesia effect. His postoperative monitoring will not differ from that of other clients.
5. Specific precautions may include, but are not limited to, promoting adequate hydration to replace fluids lost during surgery or fluid limitations prior to surgery, early movement and ambulation to foster maximum lung expansion and prevent lung infection, deep-breathing exercises to remove mucus and prevent stasis of lung secretions, pain control so that he can ambulate and cough more effectively, and leg exercises to prevent thrombophlebitis.

Chapter 37: Anatomy & Physiology Review

1. Assess skin integrity and the presence or absence of any breakdown or bruises. Assess the musculoskeletal, neurologic, and circulatory systems for previous injury or limitations. Assessment for positioning needs is done before the client is transferred to the operating table.
2. The potential pressure areas are the occiput, scapula, olecranon, sacrum, coccyx, and calcaneus. Special attention is paid to previously damaged tissues and diseased joints to prevent breakdown or deterioration due to positioning during the surgical procedure.
3. The priority nursing diagnosis is *Risk for Injury* related to sustained pressure and misalignment of specific body areas during surgery. Outcome: Client will be free from injury related to positioning.

Chapter 38: Critical Thinking Possibilities

1. Mrs. Dodd is at greatly increased risk for sensory overload due to her environment (critical care unit). She is being bombarded by the noise of her monitors and ventilator, which may be distorted and meaningless due to the sedation she is receiving. Her pain and inability to communicate also contribute to her sensory overload because they contribute to her feelings of being overwhelmed and out of control.
2. Signs of sensory overload may include, but are not limited to, restlessness, agitation, confusion, disorientation, hallucinations, or inability to sleep or rest. Signs of sensory deprivation may include apathy, emotional detachment, and depression. Many times the signs of sensory deprivation and overload are the same; consequently, the nurse must assess the client for factors that may be contributing to one problem over the other.

3. Interventions include, but are not limited to, reducing and dimming lights; decreasing noise to the degree possible (close doors or curtains); providing comfort measures; explaining all procedures; orienting the client to person, place, and time; speaking in a soft, unhurried manner; and limiting visitors.
4. Clients cared for at home may experience either sensory deprivation or overload depending on the environment. If it is a busy, active environment with several family members, they may experience overload. If clients live alone, have few supportive family members, or are seldom contacted, they are more likely to experience social isolation and become withdrawn or uncommunicative, or lose interest in their usual activities. Interventions for home care or ICU clients are similar and adapted to the specific needs of the client, regardless of setting.

2. Closed
3. Figure 38–3B
4. Figure 38–3C
5. Optic nerve (review Figure 38–3)

Chapter 39: Critical Thinking Possibilities

1. Because of his age, Craig's basic self-concept should be fairly well set and is not likely to be negatively affected. Body image and self-esteem, however, may be altered by his amputation. Body image is at risk because the amputation will change the way he views his body. Personal identity is at risk because he sees himself as an athlete.
2. If Craig's mood, inability to look at the stump, and unwillingness to discuss rehabilitation continue or new negative responses develop, a negative change in his self-esteem may be occurring. Because his father is also having difficulty with the loss, a strong source of support is unavailable to Craig.
3. There are many possibilities, including his nurses' attitudes; rehabilitation team and primary caregiver abilities; family and friends' support; and his internal ability to be adaptable, revise his goals, and use his resources. Craig's mother's presence is likely to be supportive unless she offers assistance while encouraging dependency.
4. Adapting to change may be more difficult for older clients. Older adults fear dependence more than younger clients; therefore, a large loss such as this puts them at greater risk for altered self-esteem. In addition, older adults do not heal and progress as quickly as younger clients—the additional time required may seem to them a negative factor. Much care, however, will be similar: encouragement and support, participation in their own care, identifying personal strengths, and so on.
5. Clients with chronic mental illnesses, cancer, socially stigmatized diseases (AIDS, TB, obesity, sexually transmitted infections), and other sources of disfigurement.

Chapter 40: Critical Thinking Possibilities

1. Many people are uncomfortable discussing such a private matter with strangers (such as their nurses) unless they are made to feel that sexuality is normal and okay. They need to be given permission to openly discuss their concerns without fear of being belittled or made fun. Discuss the benefits of "permission giving." How would you feel about discussing your sexuality with a stranger?
2. Factors include nurses' knowledge and comfort with their own sexuality, recognition and acceptance of sexuality as a normal and important human function, understanding of how health impacts sexuality, and nurses' ability to communicate in general.
3. There is a direct relationship between health and ability to function sexually in that the healthier you are the more likely you are to have the desire and ability to function sexually.
 - Both physical and mental status affect the ability to function sexually.

- Diseases such as heart disease, hypertension, diabetes, renal failure, spinal cord injury, or pain can lessen both sexual desire and ability. Mental disorders such as depression can lessen desire.
- 4. You will need to perform a complete sexual health assessment to provide baseline data.
 - Two primary problems need to be addressed: his fear of resuming sexual activity and the effects of his antihypertensive medication.
 - Specific interventions may include providing information, correcting misconceptions, reassurance that resuming sexual activity is safe, and suggesting alternative positions for sex that require less energy than other positions if sexual activity causes him fatigue.
 - Consult with Mr. Curry's primary care provider regarding anti-hypertensive medications that are less likely to produce sexual dysfunction.

Chapter 41: Critical Thinking Possibilities

1. Being religious means being part of an organized system of worship such as a church or synagogue. Terry may mean that he no longer attends the Methodist church or participates in organized religion. Spirituality refers to belief in or a relationship with some higher power, creative force, divine being, or infinite source of energy, such as God or Allah. Clients can be deeply spiritual without belonging to an organized system of worship. Terry admits that he is not very religious; however, there are no data to suggest that he is not spiritual. In fact, Terry's statement that he is being punished is evidence that he believes in a higher power who is punishing him for not going to church.
2. He states, "I can't see any reason for going on," "I know I'm not going to get well," "I guess I'm being punished." Terry's spiritual distress is related to both his physiological situation as well as his concern over not being religious.
3. Spiritual beliefs and religious beliefs can assume greater importance during times of illness. Many individuals will return to their religious roots during times of illness in hopes that they will be cured through divine intervention.
4. A spiritual assessment will help both you and Terry by providing information relative to his spirituality, his religion, and his degree of spiritual distress, so that appropriate interventions can be planned and implemented. Possible benefits may include, but are not limited to, helping Terry draw on inner resources more effectively to deal with his present physical and emotional situation, helping him find meaning in living and hope for the future even though he is presently very ill, and providing appropriate spiritual resources such as a minister or priest.
5. What is taking away the reasons for going on? (That may lead to a need to probe deeper: What reasons kept you going before? For you, what has given life purpose? What has changed that?) Another line of questions can address the possible guilt Terry is experiencing, for example, "Tell me more about your thinking that you are being punished," which is a better question than "For what do you think you are being punished?" Again, this may open up the concept of forgiveness: What beliefs about taking away punishment or guilt do you have? How do you think one should go about finding forgiveness? (Notice the emphasis on asking about Terry's thoughts, instead of feelings—a more difficult topic for most.) How does the religion of your parents influence you now?
6. "It seems like you feel like throwing in the towel now." "I'd venture that it's hard to see a purpose for living when it is as painful as it has been lately for you." "If I'm getting the picture right, there's a question inside you about being guilty of something; and I'm guessing that question is making you feel very uncomfortable inside."

Chapter 42: Critical Thinking Possibilities

1. It is difficult to know whether Ruby's coping would differ if only a portion of the breast were going to be removed or whether this is merely the focus of her difficulty in coping with the diagnosis and need for surgery. It might depend on how large her breasts are and if the lump

represented a significant portion of the breast. Individuals may have very different emotional reactions to situations in which they can or cannot hide their condition or if the impact is directly linked to their role (such as the fact that she is a dress designer).

2. Ruby's situation fits with a stimulus-based model since the stressors of diagnosis, surgery, and implications of having cancer serve as stress stimuli causing physical and emotional outcomes (such as her ineffective mothering). However, her situation would also fit the response model since the surgery and any further cancer treatment required plus her alcohol use would create stress reactions in the mind and body.
3. The nurse will validate that she cannot know exactly what Ruby is experiencing (assuming the nurse has not actually had a mastectomy), but has worked with many clients undergoing extremely distressful and possibly life-threatening conditions. One of the interventions will include making a connection with other women who have had breast cancer, but that is a response to the content of her message. The nurse first needs to respond to the emotional part of the message—Ruby's anger, frustration, and lack of control.
4. The suddenness of this diagnosis and Ruby's extreme reaction of alcohol abuse and neglecting her children certainly may qualify the situation as a crisis. Her inability to discuss her feelings or plans supports the presence of a crisis situation. Under these circumstances, caregivers may need to be more assertive in providing her care and making decisions. She may benefit from referral for psychological therapy/counseling.
5. Many answers may be correct. She does not appear to be using denial. She might use projection in attempting to find a cause of her cancer, which could be maladaptive since, most commonly, the cause of breast cancer is unknown.

Chapter 43: Critical Thinking Possibilities

1. The eldest son most nearly approximates the "awareness of loss" phase. He is experiencing the loss but is able to resume normal activities. The middle son has characteristics of the "conservation/ withdrawal" phase. He has a need to be alone, and is experiencing both physical and psychological symptoms of bereavement. The younger son is experiencing "shock." He is having difficulty believing that his mother is dead and is experiencing several physical symptoms.
2. Factors include amount of conflict or closeness each brother felt to the mother, amount of time/caring each was able to provide, significance/meaning of the mother to each, spiritual beliefs and practices, and the amount of guilt each felt related to meeting the mother's needs during her later years or illness.
3. Cues might include wanting to talk about death, reminiscing or reviewing one's life, emotional withdrawal or becoming quiet and pensive, allowing others to take over physical care, voicing a sense of urgency about seeing loved ones, and so on.
4. One significant need she may have is for relief of shortness of breath. Both from the pneumonia and the dying process, normal respirations are impaired and she may feel as though she cannot get enough air. In addition, shortness of breath may instill fear—an important need the nurse must attend to. Although this client was not diagnosed as terminally ill, as she approached death, many of the physiological needs identified in Table 43–5 would occur.
5. If you have had mostly positive experiences, or ones similar to those the client is experiencing, these can be shared with others. Consider characteristics of the losses (e.g., if they were expected or unexpected, your age and that of the deceased) and effectiveness of sources of support during grieving.

Chapter 44: Critical Thinking Possibilities

1. His dyspnea on mild exertion is a worrisome sign, and his activity intolerance will worsen if he remains immobile. His edema indicates inadequate venous return, especially with his amount of time spent sitting, and will lead to other problems.

2. Check environment for possible safety hazards, get a walker light enough to handle easily and be sure it has been adjusted for proper height, keep the tips in good shape, do exercises to keep strength in the hands and arms.
3. Being overweight certainly contributes to his difficulties and should be addressed. More assessment is needed regarding how long he has been overweight and his eating patterns.
4. There is a relationship between physical and emotional health; that the client “wants” to be healthier.
5. With chronic illness, because the condition has existed for a longer time, the outcomes may require more time to achieve than with acute illnesses. Outcomes should be in smaller increments. Lower levels of expectations are often appropriate because full return to earlier levels of health is unlikely.

Chapter 44: Anatomy & Physiology Review

1. Because the upper and lower body are connected, any change in gait such as a limp will affect general alignment, and therefore affect musculoskeletal functioning in the back. Improper alignment throughout the body can lead to discomfort and injury.
2. When the right arm swings forward at the same time as the left leg swings through, a natural rotation of the hips and shoulders is demonstrated. This is a more energy-efficient gait, and makes use of the natural movement in the low back for locomotion. When people hold themselves “stiffly” as they walk, either not moving their shoulders or hips in a rhythmic, swinging fashion, they are interrupting the normal flow of energy through the spine and into the legs, and will likely become tired more quickly, or develop various discomforts throughout their body.

Chapter 45: Critical Thinking Possibilities

1. Other data that may be helpful include, but are not limited to, activities and bedtime habits, degree of noise in the environment, what foods or drinks he consumes just prior to bedtime, if he uses over-the-counter medications to help him sleep, if he has a regular pattern of arising, and whether he is a smoker.
2. Suggest that he read a book or other quiet activity (not watching TV or exercising) before going to sleep, maintain regular sleep and waking hours, explore nonpharmacologic sleep remedies, and so on.
3. Common causes of difficulty in sleeping are physical distress, noisy environment, severe fatigue, changing work shifts, emotional distress, alcohol and other stimulants, weight loss, and smoking.

Chapter 45: Anatomy & Physiology Review

1. When preparing for sleep, people close their eyes, place themselves into a relaxing position, turn out the lights, and so on. This decreases the amount of sensory stimuli to the RAS, which, in turn, relays few stimuli to the cerebral cortex, which promotes sleep.
2. The sensory stimuli (auditory from the noise of the alarm clock and light in the room) activate the RAS, which sends stimuli to the cerebral cortex and causes wakefulness.
3. Brainstem (location of reticular formation and RAS), cerebral cortex (an intact cerebral cortex is necessary for the regulation of sleep and waking states), and the hypothalamus. Injury to the hypothalamus may cause a person to sleep for abnormally long periods.

Chapter 46: Critical Thinking Possibilities

1. There are subjective data (rating her pain as 5) and objective data (vital signs, position, holding abdomen, lying in rigid position) to support that Mrs. Lundahl is experiencing pain; however, no conclusions can be drawn about the intensity, location, quality, or pattern of Mrs. Lundahl’s pain.
2. It would be incorrect to assume that Mrs. Lundahl needs no interventions for her pain. People rate their pain differently based on their past pain experiences, their pain tolerance, their ethnic/cultural values, and so on. Mrs. Lundahl should be asked if she needs pain intervention.

3. Mrs. Lundahl is most likely experiencing acute pain from her surgery. Depending on the amount of manipulation of bowel, blood vessels, and so on, within her abdomen, she may also be experiencing visceral pain.
4. Numerous interventions may be helpful, such as changing her body position, giving a back massage, or providing a distraction (e.g., soft music).
5. The most reliable method of determining that Mrs. Lundahl’s pain has been relieved is for her to tell you that her pain has been relieved. Objective data may include decreased pulse, blood pressure, and respirations when compared to preintervention values; Mrs. Lundahl resting quietly or sleeping; pink color; absence of nausea or perspiration; and relaxed facial expression.

Chapter 46: Critical Thinking Possibilities

1. Obtaining information regarding factors that affect a person’s pain experience. For example, previous hospitalizations, previous pain experiences, cultural values regarding pain, support people, effect of the environment, and anxiety and stress levels.
2. Consider ATC analgesia the first few days postoperatively. Make his pain assessment the fifth vital sign—assess each time you take vital signs. Assess his sense of control over his pain management.
3. Breakthrough pain even with ATC, and Mr. C. needing to have more of a sense of control over his pain management.

Chapter 47: Critical Thinking Possibilities

1. Being a woman means that her distribution of fat is generally higher than a man’s. At age 59, she is beginning to enter the age range when the body configuration changes somewhat, fewer calories are needed to maintain weight, but nutrients are still very important. Being alone contributes to poor eating habits since meals are often a social event. We do not know her ethnicity but this can influence her view of nutrition and weight.
2. What were her eating patterns before her husband died? What foods does she like and dislike most? What kinds of snacks is she eating? Does she have the financial means to buy food? Does her living situation allow her to make and store food?
3. Suggestions may be many, such as keeping busy with her hands while watching TV (e.g., folding laundry), choosing healthy snacks like carrot and celery sticks, and not buying snacks at the store.
4. Although there are many ways to determine her ideal weight from tables, charts, and calculators, her best weight is influenced by many other factors that are difficult to include in these (specific activity level, BMR, body configuration). Since she states she formerly was “petite,” she may wish to return to this state—as much as is possible as she ages. It is important that the nurse not tell her a specific weight that she should achieve. Goal setting must be collaborative.

Chapter 47: Anatomy & Physiology Review

1. Salivary glands secrete enzymes that begin the digestion of carbohydrates.
2. If the pyloric sphincter is obstructed, food cannot move from the stomach into the small intestine.
3. If the gallbladder has been removed, bile is not stored, although it is still made by the liver. The client may have difficulty digesting fats.
4. If the colon is removed, most of the water and many minerals will not be reabsorbed from the chyme into the body. What is eliminated from the small intestine will be very liquid and still contain many enzymes.

Chapter 48: Critical Thinking Possibilities

1. Urinary frequency could be a sign of infection due to causes other than prostate hypertrophy. No other data are given about his other health problems including medications that might be contributing factors. A thorough assessment is indicated.
2. The nurse needs to ensure that the client completely understands the proposed and intended outcomes. There is always a balance between

the expected positive result and the risk of the intervention. Is this surgery considered culturally appropriate? Although you may not know a great deal about the actual surgery, you realize that not every procedure is completely successful. How would the client react if he continued to have some incontinence following the operation?

- Often, a medical standard of care is followed unless there are contraindications. If the physician determines that the hypertrophy is severe, and knows that this is not a reversible condition, surgery may be the only logical option. Investigate what other treatments may be used in this situation and propose why they may be seen as less desirable than surgery.
- The nurse should fully explore the client's understanding of his condition and what measures can be taken to diminish impact on his ADLs and quality of life if the client truly understands and makes this informed choice. It is the nurse's responsibility to support the client.

Chapter 48: Anatomy & Physiology Review

- Yes. They are under voluntary control and they are just like any other muscles. Exercise can strengthen them.
- Urine can leak from the bladder when the pelvic floor muscles are weak. The pelvic floor muscles help control the external urethral sphincter, which closes the urethra to prevent leakage. Exercise can strengthen the pelvic muscles and decrease bladder control problems. See the Managing Urinary Incontinence section in this chapter.

Chapter 49: Critical Thinking Possibilities

- Ask her about the number and amount of stool she has in order to determine if she is actually having diarrhea or has an impaction. Assess her usual diet, daily fluid intake, amount of fiber in the diet, daily activities, medications, or other factors that could be contributing to constipation and possible impaction.
- A digital examination may be performed to verify or rule out the presence of a fecal impaction. Other interventions may include administering an oil retention enema followed by a cleansing enema, suppositories, or stool softeners. If all else fails, manual removal of the fecal impaction may be necessary.
- Consider interventions to promote regular defecation such as increasing intake of fluids, maintaining a regular schedule for defecation, paying attention to the urge to defecate, encouraging warm liquids with breakfast to stimulate the gastrocolic reflex, and so on. To add more fiber to the diet, teach the client about foods that are high in fiber; go through her kitchen with her pointing out what foods qualify. Suggest she interface with others in her complex to plan good menus, eat together, and so on. Also consider referral to physical therapy or other resources to increase activity appropriate for older adults, such as water exercises.
- The chronic use of laxatives will actually make her more prone to constipation and impaction because she loses muscle tone. Increased intake of fiber, fruits, and vegetables and other ways of naturally dealing with constipation are safer and more appropriate.

Chapter 49: Anatomy & Physiology Review

- The primary functions of the small intestine are the chemical breakdown of food (digestion) and the absorption of digested foods.
- The primary functions of the large intestine are absorbing water from indigestible food residue and eliminating the residue in the form of feces.
- Ileum. The ileocecal valve is between the ileum and the beginning of the large intestine.
- The stool would be liquid because it has not entered the large intestine and the water has not been reabsorbed.
- The transverse colostomy would discharge mushy, paste-like stool. The descending colostomy would have semisolid feces because more water has been reabsorbed.
- Solid, formed feces.

Chapter 50: Critical Thinking Possibilities

- The physical assessment reveals fever, use of accessory muscles, adventitious lung sounds, and yellow sputum, all of which suggest more than an average cold. The nurse certainly would have suspected a more significant underlying condition.
- Ms. Singh has quite a stressful lifestyle with work and school plus her physical stressors of a poor diet and smoking for more than 20 years. The nurse should perform discharge teaching that includes examination of which of these modifiable risk factors may be addressed in both short- and long-term plans.
- Alteration in mental status may be a very useful sign that the client is hypoxic. Also, increased respiratory and cardiac rates and substantial shortness of breath would be negative signs. If not already in place, continuous oxygen saturation monitoring should be initiated. Frequent assessments and notification of the primary care provider are required. The nurse should have nasotracheal suction equipment available. The client may require transfer to a higher acuity nursing station.
- Standard precautions must always be in place. The nurse should be careful to glove whenever coming into direct contact with the client's secretions. The nurse should also wear a mask if the client is unable to control her secretions and may cough or spit in the nurse's face.
- A face mask may be uncomfortable or cause the client to feel confined or claustrophobic. If she is not wearing it, it cannot help her. Discuss the face mask with her and determine why she is taking it off. Reassure her and provide measures to decrease her anxiety. If the mask cannot be modified to address these reasons, consider contacting the primary care provider for assistance (e.g., arranging for her to have oxygen by nasal cannula instead, with an appropriate change in the flow rate).

Chapter 50: Anatomy & Physiology Review

- (a) Hairs in the nose filter the air as it enters and traps particles to prevent them from traveling to the lower respiratory tract; (b) the sneeze reflex clears nasal passages; (c) lymph tissue in the nasopharynx and oropharynx traps and destroys pathogens entering with the inhaled air; (d) the epiglottis closes when swallowing to prevent food particles from entering the lungs.
- Defense mechanisms present in the lower respiratory tract include the thin layer of mucus (the "mucous blanket") that traps pathogens. The cilia on the epithelial cells then "sweep" the foreign particles toward the throat. The cough reflex helps dislodge the mucus and foreign particles and propel them out.
- Because the alveoli are filled with fluid, the gases (oxygen and carbon dioxide) cannot diffuse across the respiratory membrane. The client will have less oxygen in his blood and will experience symptoms of hypoxemia. One of the medical interventions will include administration of oxygen to increase the diffusion gradient from the alveoli so the oxygen molecules will diffuse faster, and hopefully improve oxygenation in the blood.

Chapter 51: Critical Thinking Possibilities

- This client has decreased arterial circulation to her feet. When the tissues become ischemic, lactic acid builds up and causes the discomfort. The pain she describes is consistent with the medical condition of intermittent claudication. Risk factors for peripheral vascular disease include cigarette smoking, high fat intake, obesity, sedentary lifestyle, hypertension, and diabetes.
- Ineffective Peripheral Tissue Perfusion* and *Activity Intolerance* are two likely diagnoses. Of these two, activity intolerance may be of highest priority for the nurse since there is a greater likelihood of developing a nursing care plan that can substantially affect her desired level of function and quality of life. Desired outcomes and interventions for the *Ineffective Peripheral Tissue Perfusion* nursing diagnosis will focus on implementing the medical treatment plan and protection from injury. However, remember that for a care plan to be effective, the client must

be an active participant in the process. Thus, the diagnoses of highest priority can only be suggested without her input.

3. The physiological impact of the plan must be weighed against the psychological impact—always a difficult thing to do. The nurse must explore the client's response to the recommendation. If it is unacceptable to her, consider whether any compromises such as fewer visits or use of a wheelchair are more agreeable.
4. Support stockings help increase venous return. This client has impaired arterial circulation. If the stockings are tight, they could actually interfere with the flow of arterial blood to her extremities. She requires client teaching explaining the differences at a level she can comprehend.

Chapter 51: Anatomy & Physiology Review

1. Right side of the heart.
2. Exercise, hypervolemia, mitral valve regurgitation, or insufficiency.
3. It has a positive effect or outcome when it increases cardiac output. For example, during exercise there is an increase in venous return, which causes the heart to contract more forcefully, with the result that stroke volume and cardiac output increase to supply the body with needed oxygen and nutrients.
4. The increase in the "stretch" of the heart muscle increases the contractility of the heart but only to a certain point (Frank-Starling law of the heart). Once it reaches that point, contractility and cardiac output decrease.
5. Diuretics decrease circulating volume, which decreases preload (the volume returning to the heart).
6. The left ventricle.
7. High blood pressure (hypertension)—the left ventricle has to create a pressure above the client's diastolic pressure to pump blood into the circulation. Arterial vasoconstriction—the left ventricle works harder

when it has to pump blood through narrowed vessels as opposed to wide or dilated vessels.

8. Decrease blood pressure (e.g., antihypertensives). Decrease peripheral resistance or vasoconstriction (e.g., vasodilators).

Chapter 52: Critical Thinking Possibilities

1. Suggestions may be many, such as finding a fluid that she likes or that helps her nausea, making sure fluids are served at the appropriate temperature, using a straw, and starting with small amounts. Administering an antiemetic medication as ordered may also help improve her oral intake.
2. Although there are many indicators of fluid balance, daily weights are an important way to provide more data about fluid. You can explain that a loss of 1 kg (2.2 lb) indicates a fluid loss of approximately 1 liter. It is an easy, quick way to get more information about fluid balance.

Chapter 52: Anatomy & Physiology Review

1. Respiratory problems such as pneumonia, atelectasis, narcotic overdose, and central nervous system depression due to anesthesia.
2. With shallow respirations, the CO₂ is not eliminated by the lungs, which causes two results: an increase in PaCO₂ and an increase in CO₂ in the blood, which reacts with H₂O to form carbonic acid, which increases the number of hydrogen ions causing a decrease in pH.
3. Respiratory acidosis.
4. Anxiety, fear, fever, respiratory infections.
5. The increase in respirations causes more carbon dioxide than normal to be exhaled. This results in a loss of CO₂ in the blood causing a low PaCO₂. Because of the low CO in the blood, the amount of carbonic acid in the blood is reduced, resulting in an increased pH.
6. Respiratory alkalosis.

Suggested Answers to End-of-Unit Meeting the Standards Questions

Unit 1

Suggested Answers:

1. Megan is an adult so the nurse cannot share any health information with her mother unless Megan gives permission.
2. The nurse will explain that Megan is legally an adult and competent to make her own health care decisions and cannot be forced to comply. The nurse's responsibility is to provide Megan with any information she needs to make an informed decision. Then Megan's choice must be respected.
3. The nurse must prevent Megan from harm (right not to be harmed), ensure that she is adequately informed about her role in the research study (right to full disclosure), confirm that her decision to participate or not participate is her own and she has not been coerced (right to self-determination), and that her privacy is maintained (right to privacy).
4. The nurse needs to make sure that Megan is familiar with the details of data collection protocols to maintain the integrity of data collected and with all aspects of care delivery requirements under the study plan.
5. The nurse should conduct a review of research journals to determine assessment techniques that have been validated through research that was conducted in settings that are similar to the nurse's own setting. This information should be taken to the standards and practice committee so they can update current facility policy.

Unit 2

Suggested Answers:

1. Rhett's situation has elements of more than one level of prevention but the nurse will most likely focus on the primary level because this emphasizes staying healthy and avoiding illness. He is already doing some of these things through his diet and exercise. He also has some secondary prevention in that he requires prescription medication for his cholesterol and blood pressure.
2. Community-based health resources for Rhett may include wellness classes sponsored by the HMO or public events offered by community health services and focused classes or support groups for individuals with diabetes or high blood pressure. You can also assist him in finding reputable web-based resources.
3. Visits from home care nurses are only appropriate for clients who are unable to care for themselves or not mobile enough to go to a health care facility. Neither is true for Rhett and that is a good thing!
4. Advantages of using technology to track his blood pressure include that the record will be easy to read and the data may be imported into a visual depiction such as a timeline or trend chart. The data can be sent and shared electronically with his primary care provider(s) or be uploaded into his personal health record. However, there is also a concern for privacy anytime personal data is sent electronically. Because Rhett uses computers extensively, if there is a way to share electronically, it may enhance his adherence to the regimen.

5. There will be many situations in nursing in which the client is a rich source of knowledge even beyond that of the nurse. Admit your knowledge limits and express your openness to learning from the client. If you cannot answer his question, be certain that you clearly understand what he wants to know and then use critical-thinking strategies to find out the answers for him.
- Most policies are written to promote consistent achievement of goals and avoid pitfalls. However, situations vary over time and policies need to be reviewed and revised at regular intervals. Consider whether there is a way to meet the requirement for the signature with the modern forms of electronic validation. Use your employer's administrative structure to determine who has responsibility for this policy and whether it can be modified. You should also consider how great an inconvenience the current policy is, and if it is a very important policy to change. Since there are so many policies, some will rank as higher priority than others.

Unit 3

Suggested Answers:

1. The orthopedist will perform a thorough history and physical examination as required for surgery. The nurse needs to focus assessment on baseline physiological parameters that will be reevaluated during the postoperative period, including a complete list of all current medications and possible allergies. In addition, the nurse gathers preoperative data to assist in the discharge plan areas of functional abilities, support systems, and psychological needs. Although no system would be inappropriate to assess, the nurse's time with Benjamin will be limited and a systematic head-to-toe examination should provide adequate physical data. The admission history will be very useful in guiding the interview because it ensures that the nurse obtains information about the physical environment at home (e.g., stairs, safety issues such as carpeting and bathrooms); who will be available to help at home; whether his employment provides disability insurance, sick leave, and physical therapy coverage; fears and concerns about functioning; previous experience with surgery; and so on.
2. A risk diagnosis implies that the problem is not current but factors are present that could lead to the diagnosis if the nurse does not intervene. Using critical thinking, the nurse considers how to obtain information about Benjamin's parenting responsibilities. We know that he is married but have no details regarding his spouse's role. Who is the primary caretaker? Do both parents work? Although the nurse may expect certain gender roles, those may not exist in this family. The best source of this data is Benjamin himself although the nurse may also discuss caretaking of the children with the spouse if available. Once the data is obtained, the nurse clusters the cues, examines all the real and potential problems concurrently, and then writes the diagnoses.
3. The standardized care plan will contain an estimate of the degree of mobility expected at each time point in the recovery. Benjamin is a young, athletic man whose employment is likely to play a significant role in the family's resources but this must be validated. Does he have sick leave benefits? How anxious is he to return to work? Since his job is primarily desk work, is it possible for him to work from home while in recovery? Does the 16-year-old child have a driver's license that might make it possible for the child to assist with transportation or chores? Also, consider the possible impact of the surgery on Benjamin's view of his role in the family. The plan may need to address ways he can continue to feel he is contributing.

Depending on whether Benjamin had a nursing admission record completed before surgery (sometimes clients arrive directly to the perioperative unit), the postoperative nurse may need to complete the initial assessment. Of course, vital signs, including pain assessment, must be recorded on the vital signs flow sheet, and medications must be recorded on the medication administration record. If he is

receiving intravenous fluids or medications, there will be an IV record. Postoperative clients may have intake and output measured and recorded to ensure they are taking adequate fluids (once permitted to do so following anesthesia) and their urine output is sufficient (through voiding or a catheter). He may also have special sheets for wound and skin assessment. The nurse's notes page is where you would record assessments, care, and client responses that cannot be written in the other documents described. A method such as SOAP or SOAPIER is used to help ensure that the nurse has included all relevant information. In all cases, the nurse uses only proper terminology and accepted/approved abbreviations.

Unit 4

Suggested Answers:

1. Appropriate outcomes for Manuela might focus on maintaining her current level of mobility so she is able to use her computer, go out to desired events, and socialize. In addition, although some of her functional limitations cannot be reversed, it would be appropriate to create expected outcomes that prevent or delay additional complications such as skin breakdown or infection.
2. The nurse creates expected outcomes and goals based on knowledge of both the physiological and psychological condition of the client. It would be inappropriate to set outcomes without knowing how Manuela sees her level of wellness and ability to influence her health status.
3. Manuela is at risk for further joint and pulmonary complications. Her physical environment needs to be examined and modified if necessary so it is protective and does not increase risk. She needs to be able to reach emergency help should she need it. Her family and friends should be incorporated into the plan. We need to know if she is currently living alone so that teaching includes not only Manuela, but also any roommates.
4. Other than physicians and nurses, Manuela's health care team should include social services personnel to assist her with disability and financial issues. If she wishes, a clergy of her faith or spiritual counselor should be considered. She may also benefit from physical and occupational therapy. If her condition worsens, home health assistance and hospice personnel should be involved.
5. Since Manuela's condition is chronic and progressive, her treatment is symptom focused. At the minimum, the nurse should consider evidence supporting the use of nonpharmacologic pain methodologies and stress-reduction techniques.

Unit 5

Suggested Answers:

1. The 19-year-old is a young adult and sleeping on the couch may impact his quality of sleep, interfering with the task of committing to work and relationships. The 15-year-old is an adolescent who is likely to have a strong need to fit in with others in his age range. Therefore, he may be embarrassed to bring friends to his home or be seen with his grandmother. The 10-year-old school-age child is seeking to develop senses of competence and perseverance, which could be encouraged if the child finds satisfaction in helping the grandmother meet daily needs. The 5-year-old is in the phase of initiative versus guilt, and must be carefully assessed to determine if the child is potentially feeling it is his or her fault that grandmother is sick. The 2-year-old is seeking to develop autonomy versus shame and doubt, but may develop too much autonomy leading to dangerous situations as a result of the mother being so busy caring for the client.
2. The family is likely to be experiencing high levels of stress, which will increase susceptibility to illness. The high level of stress felt by Mrs. Chavez' daughter is likely to impact her parenting skills, especially because she is sleep deprived due to staying up all night caring for her mother.

- Respite care, the importance of spending quality time together, use of day care facilities, the need for proper sleep and nutrition, and stress management strategies are all important teaching measures that the nurse can provide for this family.
- Each family member can provide some level of care or distraction that would allow the client's daughter more time to meet her own needs. The 2-year-old can sing to her grandmother, which is often very calming and pleasant for older adults diagnosed with Alzheimer's disease. It will also allow the child to express herself and develop self-esteem. The 5-year-old can be reassured that the grandmother's illness is not the result of magical thinking. The school-age child can read to the grandmother, which will improve the child's senses of competence and perseverance and also help the child develop language skills. The adolescent can be helped to understand that illness is not shameful and can use the experience to actualize the child's own abilities and clarify strengths. The young adult can be encouraged to commit to a helping relationship, which will help to avoid the risk of isolation.
- Alzheimer's disease will cause regression of behavior to that of a much younger person, making achievement of the normal tasks of maturity impossible for Mrs. Chavez.

Unit 6

Suggested Answers:

- The nurse shows compassion by recognizing the impact of Michael's illness on Michael, his wife, and others who love him. The nurse shows competence by providing the best care to maintain Michael's comfort while promoting communication between Michael and his wife. The nurse shows confidence by openly communicating with the couple in order to foster a trusting relationship, answering questions honestly while promoting hope. The nurse demonstrates conscience by following the nursing code of ethics in the delivery of client care and taking care of herself or himself in order to maintain good physical health. The nurse shows commitment by recognizing obligations to the client and his wife and acting in accordance. The nurse shows comportment by maintaining the client as the center for all nursing actions, behaving professionally in all interactions with Michael and his wife.
- Sitting with Michael and/or his wife, listening attentively to them, gentle and caring touch, maintaining a facial expression that demonstrates interest and concern, gestures such as nodding in agreement, and being physically present are all means the nurse can use to demonstrate caring.
- Readiness to learn is the demonstration of behaviors or cues that reflect the learner's motivation and ability to learn at a specific time. Statements by Michael's wife such as "He is so weak. It can't be much longer now" or "I'm worried about what his final minutes will be like" or other statements regarding Michael's imminent death indicate she is ready to hear more about what the final moments and his death will be like. Once readiness to learn is assessed, the nurse can begin to teach her what to expect.
- The nurse can delegate tasks such as performance of activities of daily living including measuring vital signs, bathing, toileting, meeting hygiene needs, and comfort measures. Tasks requiring advanced knowledge and skills such as medication administration, assessment, sterile procedures, and complex tasks cannot be delegated to the UAP.
- The UAP should be instructed to notify the nurse if the client is in pain, if anything unexpected occurs, or if the UAP notices anything abnormal. In this situation, the UAP should be instructed to notify the nurse if the client dies or is in any distress such as shortness of breath, bleeding, or change in level of consciousness.
- The nurse should instruct the UAP on the importance of turning and repositioning, the discomfort the client will experience if a pressure ulcer develops, demonstrate positions to maintain client comfort, and answer any questions the UAP may have related to the procedure. The nurse should assess the UAP's ability to perform this task and be sure to speak with the UAP privately to avoid embarrassment.

Unit 7

Suggested Answers:

- One of the very first things you need to consider is how the reported temperature fits with the other vital signs and with the client's previously reported temperature. How does the client feel and are there other signs of fever such as diaphoresis, chills, and skin color changes? If the other assessments do not seem to fit someone with a high fever, recheck the temperature yourself or have the assistant take it with another thermometer. If the temperature is accurate, what does it mean? Is the temperature higher or lower than it has been previously? What, if any, treatments for fever has the client received or have ordered? Some chemotherapy agents are known to cause a high fever. If this is the case, the primary care provider might not need to be notified since there would already be a care plan and orders to respond to this anticipated effect.
- There is no indication that the assistant should not have been expected to be able to measure vital signs on this client accurately. However, once you determine the answers to the questions in item 1, you should discuss the situation with the assistant and see if there are any "lessons learned" that should be shared. For example, would you expect that the assistant would already have double-checked the high temperature a few minutes later or with another thermometer or should she just have reported it to you immediately? If there are any indications that the assistant did not perform the assessment correctly, you would want to follow up, determine the reasons, and develop a plan to correct the deficiency.
- In this situation, one previous nurse reported findings inconsistent with your current assessment. It is unusual for a hospitalized client with COPD to have normal breath sounds throughout the lung fields. Thus, you might wish to have another nurse auscultate the client's lungs to validate your findings. And, it certainly is expected that each nurse caring for the client will assess and record findings related to lung sounds. It would be important to communicate both previous shift nurses' actions to the nurse in charge with the intent of improving practice. Possibly the one nurse could benefit from a review of lung sounds and assessment techniques, and the night shift nurse must be reminded to record assessments. Beyond this situation, what systems are in place to support nurses' ongoing competencies in assessment and safeguards to ensure that needed assessments are recorded in the chart? This example is an opportunity for quality improvement.
- Each nurse must perform self-assessment on a regular basis and participate in performance appraisal according to the employer's standards. As in item 3, you may ask another nurse to check the client's pedal pulses. This is important primarily for the client and secondarily for your skill assessment. If you have previously had difficulty palpating pedal pulses, you would want to work with a colleague to enhance your skill. Do you have difficulty in all situations or possibly only when there is edema, or when the pulses are faint?
Sometimes it is embarrassing to admit that you are unable to complete an expected nursing responsibility, whether it is feeling a pulse, performing venipuncture, or inserting a catheter. It can be even more difficult if you must report that you have made an error. However, self-evaluation and peer evaluation of practice are essential components of a career focused on personal growth, client safety, and quality care.

Unit 8

Suggested Answers

- Important data to obtain includes the types of products she normally uses, cultural beliefs related to the need for same sex caregivers, normal bathing frequency, ability to function using her nondominant left hand

to determine the amount of assistance required, desire to have friends bring her own products for use in the hospital, and understanding of normal hospital routine related to hygiene (i.e., AM care, PM care) and any preferences she may have.

2. Vital signs will serve as baseline data, appearance of the pin insertion site in her fractured leg, appearance and size of laceration on her fractured arm, color and temperature of fingers on casted hand and left foot, appearance and presence of any alterations in skin integrity, and amount of weight applied to traction. All of this information will serve as a baseline for comparison as the nurse assesses wound healing and recovery from injuries.
3. Priority assessments include vital signs to ensure that respirations are adequate to meet oxygen needs, airway is clear, and circulation is adequate to perfuse the tissues. Assessment of perfusion in the casted arm and fractured leg is also a priority assessment. Other important assessment data includes pain level, level of consciousness, and data related to safety such as proper body alignment, side rails up, bed in the low position, weights hanging freely off the floor, and elevation of casted arm to reduce risk of edema.
4. Likely nursing diagnoses for Fairuz include *Acute Pain*, *Risk of Infection* related to immobility secondary to traction, *Impaired Comfort*, *Risk for Constipation*, *Risk for Disuse Syndrome*, *Impaired Mobility* secondary to required bedrest, *Ineffective Role Performance* secondary to prolonged hospitalization and recovery period, *Bathing Self-Care Deficit*, *Toileting Self-Care Deficit*, *Impaired Skin Integrity*, and *Social Isolation*.

The client with a fracture will be likely to receive narcotic analgesics to manage pain. These medications can impair breathing pattern, cause sedation resulting in reduced mobility and deep breathing, and must be assessed to determine their effectiveness in controlling pain. Traction limits the client's ability to move because the left leg is immobilized. The client must make a conscious effort to reposition frequently, employ deep breathing and coughing exercises, and exercise other muscles such as arms and the right leg to avoid muscle atrophy.

Unit 9

Suggested Answers:

1. Christina's statements are the type common to individuals who are anxious and under stress. She has a somewhat fatalistic perspective and is seeking a cause for her cancer, which will most likely never be found. In this unit, you have learned strategies for helping her explore her concerns and putting them into perspective with her belief systems. Even if you believe that none of the three causes she mentions is a realistic one, you must respond in a respectful manner and not belittle her. You have an opportunity to assist her in identifying her strengths and resources, plus exploring a variety of coping strategies.
2. Many individuals wonder if external exposure to things like chemicals in personal care products or environmental conditions such as high-voltage wires can cause cancer. Considering the competencies for this standard, you would want to explore sources of evidence-based information to help answer the reality of such health risks. Beyond the evidence, there are her personal values and nurses know that values have a strong influence on health and health behaviors. Might Christina and her husband seriously consider moving their home away from the wires? If so, how might this worsen or alleviate her stress and feelings of loss? What other things might she do to make her feel safe and in control around her home?
3. Although you may have personal views of attractiveness, body image, and marital relationships at her age, first you must respond to Christina in a way that acknowledges the validity of her feelings and your openness to hearing her. These responses honor her with respect and dignity. When a client expresses concerns and the nurse cannot fully implement and evaluate the care plan, it is essential that the nurse initiate a plan that can be shared with other health care team members. In this case, you should document Christina's concern and ensure that this documentation is received by the primary care provider, social worker, clergy, and any other appropriate members of the team.
4. The nurse is never the sole member of the health care team. Depending on the structure of your work setting, there may be other nurses who specialize in cancer care such as clinical specialists and nurse practitioners. These nurses would be extremely knowledgeable about the physical effects of cancer and its treatment. Other colleagues with specialized knowledge include the medical oncologist, surgical oncologist, radiation therapist, sex therapist, social services personnel, psychologist, and clergy. You may also investigate local chapters of professional organizations with a cancer focus such as the American Cancer Society, Komen Foundation, or Oncology Nurses Society.

Unit 10

Suggested Answers:

1. Expected outcomes may include:
 - Activity and exercise: Agnes will regain the ability to ambulate independently within 2 months.
 - Pain management: Agnes will report pain or discomfort to the nurse when her pain tolerance is exceeded and she will maintain comfort and report a pain level less than 3 within 24 hours postoperatively.
 - Fecal elimination: Agnes will maintain normal fecal elimination based on her prior bowel elimination habits.
 - Circulation: Agnes will avoid development of a thrombus until returning to normal activity patterns.
2. Risks faced by Agnes include those related to immobility such as pneumonia, thrombophlebitis, muscle atrophy, and muscle weakness. Her sleep may be disturbed by hospital routine and pain. Nutrition must be monitored to assure she has adequate intake of nutrients to promote healing while reducing calorie intake secondary to immobility. Airway clearance must be carefully monitored in the immediate postoperative period and then coughing and deep breathing encouraged to reduce the risk of pneumonia.
3. Priorities of care will follow the ABC's including airway, breathing, and circulation followed by pain management, and monitoring of fluid, electrolyte and acid-base balance. Of importance, but lower in priority, are elimination, nutrition, sleep, and activity.
4. Based on Agnes's current condition, the greatest risk to her independence is related to activity and exercise, because if she is unable to regain mobility it will impact both her independence and her quality of life. Certainly, if a threat arises to airway, breathing, and circulation, these would be of highest priority, but in her current health status these considerations do not present a problem.
5. The nurse can promote independence by encouraging Agnes to do as much for herself as possible, and motivate her to attend physical therapy and follow the exercise regimen developed by the health care team caring for her.

Sleep 1080
Spiritual Distress 966
Urinary Elimination 1204

PRACTICE GUIDELINES

Administering Medications 769
Applying Restraints 662
Bandages or Binders 854

Bandaging 853
Bed-Making 709
Bed Pan 1224
Bladder Retraining 1188
Bloodborne Pathogen Exposure 636
Cleaning Wounds 849
Common Pressure Sites 834
Communication During Interview 167
Damp Gauze Versus Advanced Dressings 852
Documentation 236
Facilitating Fluid Intake 1335
Herbal Preparations 299
Home Health Care Documentation 233
Individualizing Care 1103
IV Starts 1338
Legal Protection for Nurses 69
Long-Term Care Documentation 233
Nasogastric or Gastrostomy Tube Medication Administration 780
Pain Report Response 1105
Passive ROM Exercises 1051
Praying with Clients 965
Preventing Falls 652
Religious Practices 963
Reporting a Crime, Tort, or Unsafe Practice 69
Respirator Mask 624
Restricting Fluid Intake 1335
Skin Care Preparations 812
Spiritual Beliefs 963
Stretchers 1046
Surgical Wounds 892
Treating Pressure Ulcers 846
Using an Interpreter 284
Vein Selection 1337
Vascular Access Device 1341
Verbal Communication 284
Voiding Habits 1188
Wheelchair Safety 1046
Wounds 837

SKILLS

Adding Medications to Intravenous Fluid Containers 803
Administering an Enema 1227
Administering an Intradermal Injection 792
Administering an Intramuscular Injection 801
Administering Medications Using IV Push 803
Administering Ophthalmic Instillations 813
Administering Oral Medications 775
Administering Otic Instillations 815
Administering Oxygen by Cannula, Face Mask, or Face Tent 1262
Administering a Subcutaneous Injection 794
Administering a Tube Feeding 1163
Administering a Vaginal Instillation 818
Applying Antiemboli Stockings 876
Applying an External Urinary Device 1189
Applying Restraints 663
Applying a Sterile Gown and Gloves (Closed Method) 633
Applying and Removing Personal Protective Equipment (Gloves, Gown, Mask, Eyewear) 621
Applying and Removing Sterile Gloves (Open Method) 632
Assessing the Abdomen 573
Assessing the Anus 596
Assessing an Apical Pulse 492
Assessing an Apical-Radial Pulse 495
Assessing Appearance and Mental Status 520
Assessing Blood Pressure 504
Assessing the Body Temperature 484
Assessing the Breasts and Axillae 568

Assessing the Ears and Hearing 540
Assessing the Eye Structures and Visual Acuity 534
Assessing the Female Genitals 591
Assessing the Hair 529
Assessing the Heart and Central Vessels 562
Assessing the Male Genitals 594
Assessing the Mouth and Oropharynx 546
Assessing the Musculoskeletal System 578
Assessing the Nails 530
Assessing the Neck 550
Assessing the Neurologic System 582
Assessing the Nose and Sinuses 544
Assessing a Peripheral Pulse 489
Assessing the Peripheral Vascular System 566
Assessing Respirations 498
Assessing the Skin 525
Assessing the Skull and Face 532
Assessing the Thorax and Lungs 556
Assisting Client to Ambulate 1053
Bathing an Adult Client 676
Blood Transfusion Using Y-Set 1361
Brushing and Flossing Teeth 692
Capillary Blood Specimen to Measure Glucose 726
Changing an Occupied Bed 713
Changing an Unoccupied Bed 710
Changing Bowel Diversion Ostomy 1233
Changing Intravenous Container, Tubing, and Dressing 1357
Cleaning Sutured Wound and Applying Sterile Dressing 892
Collecting Clean-Catch Urine Sample 732
Discontinuing an Intravenous Infusion 1354
Establishing and Maintaining a Sterile Field 628
Exit Safety Monitoring Device 652
Gastrostomy or Jejunostomy Tube Feeding 1163
Performing Hand Hygiene 614
Hearing Aid 705
Inserting a Nasogastric Tube 1154
Intravenous Catheter to Intermittent Lock 1356
Irrigating a Wound 849
Lateral or Prone Position 1041
Logrolling a Client 1042
Managing Gastrointestinal Suction 889
Measuring Oxygen Saturation 508
Mixing Medications Using Syringe 790
Monitoring an Intravenous Infusion 1350
Moving a Client Up in Bed 1040
Oropharyngeal/Nasopharyngeal/Nasotracheal Suctioning 1269
Performing Bladder Irrigation 1200
Performing Urinary Catheterization 1194
Preparing Medications from Ampules 787
Preparing Medications from Vials 788
Providing Back Massage 1116
Providing Foot Care 687
Providing Hair Care 700
Providing Perineal-Genital Care 682
Providing Special Oral Care 696
Providing Tracheostomy Care 1276
Removing a Nasogastric Tube 1166
Seizure Precautions 654
Sequential Compression Devices 1302
Shampooing the Hair 700
Sit on Side of Bed (Dangling) 1043
Starting an Intravenous Infusion 1344
Suctioning Tracheostomy or Endotracheal Tube 1273
Teaching Moving, Leg Exercises, Deep Breathing, and Coughing 871
Transferring Between Bed and Chair 1046
Transferring Between Bed and Stretcher 1048
Wound Drainage Specimen for Culture 839
