A young girl with curly hair, wearing a blue and white checkered halter top, is reaching up with her right hand towards a yellow height chart. The chart has markings for feet and inches, with '4 FT' and '3 FT' clearly visible. The background is a light blue wall with a white and red circular graphic.

Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner; the clinical treatments described and recommended may not be considered absolute and universal recommendations.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in his or her clinical practice.

This book is dedicated to all of the nursing students I have encountered through the years. They have inspired me to continue to grow as an educator and seek innovative methods of developing critical thinking in child health nursing. As always, my devoted family, my husband John, and my incredible children Christian and Caitlin have continued to support my writing efforts and inspire me daily. This book is also dedicated to them; I appreciate their continued faith in me.

—TERRI KYLE

This book is dedicated to all the children out there and the wonderful nurses who care for them. They inspire me to become a better nurse, educator, and person. This book is also dedicated to my loving and supportive husband, Chris, without whom I could not have reached this accomplishment; and my three beautiful girls, Grace, Ella, and Lily, who have allowed me to learn first-hand about growth and development and who truly amaze me each and every day. I would also like to dedicate this to my parents, Lene and Kishor Patel, who always taught me I could do whatever I put my mind to. A very special thanks to my mother-in-law, Susanne Carman, for her endless babysitting service. Knowing my children were in such wonderful hands allowed me to focus on my writing and accomplish this monumental task. To Terri Kyle, thank you for this opportunity, your endless support, and your incredible vision.

—SUSAN CARMAN

Acknowledgments

The thrilling and challenging experience of authoring this textbook would not have been possible without the tremendous support of the Lippincott Williams & Wilkins family. In particular, we want to thank Michelle McIlvain (Regional Sales Manager) for initially querying about this idea; Jean Rodenberger and Carrie Brandon (Acquisitions Editors) for continued belief in our ideas and convictions; and Helene Caprari (Product Manager) for her ongoing patience, flexibility, and gentle nudging. We would like to express immense gratitude to Sarah Kyle (Development Editor) for her clarity and organizational skills, as well as her tireless attention to detail. Thank you to Holly McLaughlin (Design Coordinator), Brett MacNaughton (Illustration Coordinator), and the entire art team for the beautiful illustrations, as well as Jacalyn Clay (Editorial Assistant) and Karin Duffield (Manufacturing Coordinator) and the production team for their diligent efforts. Special thanks to Amy Gellerman (Producer), Gus Freedman (Photographer), Newton-Wellesley Hospital pediatric department, and Boston Shriners's Hospital for the beautiful photography they contributed. We would also like to thank all of the pediatric nurses who contributed their wealth of knowledge and expertise to developing chapters for this book. This would not have been possible without all of you.

About the Authors

Terri Kyle

Terri Kyle earned a Bachelor of Science in Nursing from the University of North Carolina at Chapel Hill and a Master of Science in Nursing from Emory University in Atlanta, Georgia. She is a certified pediatric nurse practitioner and is currently seeking her Doctorate of Nursing Practice. Practicing pediatric nursing for over 27 years, Terri has had the opportunity to serve children and their families in a variety of diverse settings.

She has experience in inpatient pediatrics in pediatric and neonatal intensive care units, newborn nursery, specialized pediatric units, and community hospitals. She has worked as a pediatric nurse practitioner in pediatric specialty clinics and primary care. She has been involved in teaching nursing for over 20 years with experience in both undergraduate and graduate nursing education. Terri delights in providing innovative leadership to nursing educators and their students. She is a fellow in the National Association of Pediatric Nurse Practitioners and a member of Sigma Theta Tau International Honor Society of Nursing, the National League for Nursing, and the Society of Pediatric Nurses.

Susan Carman

Susan Carman earned a Bachelor of Science in Nursing from the University of Wisconsin-Madison and a Master of Science in Nursing and Master in Business Administration from the University of Colorado-Denver. As a pediatric nurse for over 16 years, Susan has had the opportunity to care for children in a variety of diverse settings and in many of the major children's hospitals throughout the United States. She also has provided volunteer nursing care in a variety of settings including the Dominican Republic and India. She has been involved in teaching nursing for the past 12 years and enjoys watching students transform into competent nurses with strong critical thinking skills. She is a member of Sigma Theta Tau and Beta Gamma Sigma.

Preface

In today's educational climate, with reduced class time being devoted to specialty courses like pediatric nursing, it is particularly important for nursing educators to focus on key concepts, rather than attempting to cover everything within a specific topic. *Essentials of Pediatric Nursing* was written to direct students to an understanding of critical concepts related to pediatric nursing. The book builds upon the student's prior knowledge base. As simpler and broader concepts are mastered first, the students are then able to progress to problem solving in more complex situations. The concepts-based approach to nursing education is time-efficient for nursing educators and fosters the development of critical thinking skills in student nurses.

The main objectives of the second edition of *Essentials of Pediatric Nursing* are to provide student nurses with the basis needed for sound nursing care of children and the ability to think critically within various health care environments. The book covers a broad scope of topics, placing emphasis on common issues and pediatric-specific content, including atraumatic care. The text presents the important differences when caring for children as compared to caring for adults. Rather than repeating medical-surgical content that the student has already mastered, the text builds upon that knowledge base. This approach is supported by many of the book's features, such as the reoccurring feature Thinking About Development. A nursing process approach provides relevant information in a concise and nonredundant manner. In [Unit 4](#), specific nursing process content is discussed as appropriate for a given disorder.*

Organization

Each chapter of *Essentials of Pediatric Nursing* focuses on a different aspect of pediatric nursing care. The book is divided into four units, beginning with general concepts related to pediatric nursing and followed by normal growth and development and specifics related to caring for children. The fourth unit focuses on nursing management of alterations in children's health.

Unit 1: Foundations of Pediatric Nursing

[Unit 1](#) presents the foundational material the nursing student needs to understand how nursing care of the child differs from that of the adult. The unit provides information about general concepts relating to child health. Perspectives on pediatric nursing, the nursing process, and factors influencing child health are key concepts covered in this unit.

Unit 2: Health Promotion of the Growing Child and Family

[Unit 2](#) provides information related to growth and development expectations of the well child from the newborn period through adolescence. Though not exhaustive in nature, this unit provides a broad knowledge base related to normal growth and development that the nurse can draw upon in any situation. Common concerns related to growth and development and child/family education are included in each age-specific chapter.

Unit 3: Working With Children and Families

[Unit 3](#) covers broad concepts that provide the foundation for providing nursing care to children. Rather than reiterating all aspects of nursing care, the unit focuses on specific details needed to provide nursing care for children in general. The family-centered approach, atraumatic care, communication, and teaching children and families are key concepts in this unit. Additional topics covered in this unit include anticipatory guidance and routine well-child care (including immunization and safety), health assessment, nursing care of the child in diverse settings, concerns common to special needs children, pediatric variations in nursing procedures, and pain management in children.

Unit 4: Nursing Care of the Child With a Health Disorder

[Unit 4](#) focuses on children's responses to health disorders. This unit provides comprehensive coverage of illnesses affecting children. It is arranged according to broad topics of disorders organized with a body systems approach and also includes infectious, genetic, and mental health disorders as well as pediatric emergencies. Each chapter follows a similar format to facilitate presentation of the information as well as reduce repetition. The chapter begins with a nursing process overview for the particular broad topic, presenting differences in children and how the nursing process applies. The approach provides a general framework for addressing disorders within the chapter. Individual disorders are then addressed with attention to specifics related to pathophysiology, nursing assessment, nursing management, and special considerations. Common pediatric disorders are covered in greater depth than less common

disorders. The format of the chapters allows for a strong knowledge base to be built and encourages critical thinking. Additionally, the format is nursing process driven and consistent from chapter to chapter, providing a practical and sensible presentation of the information.

*Nursing Process Overview contains NANDA-I approved nursing diagnoses. Material related to nursing diagnoses is from *Nursing Diagnoses—Definitions and Classification 2009–2011* © 2009, 2007, 2005, 2003, 2001, 1998, 1996, 1994 NANDA International. Used by arrangement with Wiley-Blackwell Publishing, a company of John Wiley & Sons, Inc. In order to make safe and effective judgments using NANDA-I nursing diagnoses it is essential that nurses refer to the definitions and defining characteristics of the diagnoses listed in this work.

Recurring Features

In order to provide the student and educator with an exciting and user-friendly text, a number of recurring features have been developed.

Key Terms

Each chapter includes a list of key terms that are considered to be vital to understanding the content in the chapter. Each key term appears in boldface, with the definition included in the text. The key terms may also be accessed on [thePoint](#).

Learning Objectives

The provision of learning objectives for each chapter helps to guide the student toward prioritizing information for learning. The objectives also provide a method for the student to evaluate understanding of the presented material.

Words of Wisdom

Each chapter opens with inspiring Words of Wisdom (WOW), which offer helpful, timely, or interesting thoughts. These WOW statements set the stage for the chapter and give the student valuable insight into the nursing care of children and their families.

Case Studies

Real-life scenarios present relevant child and family information that is intended to perfect the student's care-giving skills. Questions throughout the chapter about the scenarios provide an opportunity for the student to critically evaluate the appropriate course of action.

Healthy People 2020

Throughout the textbook, Healthy People 2020 objectives related to children's health and well-being are outlined in box format. Nursing implications or guidance related to working toward achievement of these objectives is provided.

New! Atraumatic Care

These highlights, located throughout the book, provide tips for providing atraumatic care to children in particular situations relating to the topic being discussed.

NEW! Evidence-based Practice

Throughout the chapters, pertinent questions addressed by current research have been highlighted into Evidence-Based Practice boxes, which discuss recent evidence-based research findings and provide recommendations for nurses.

Take Note!

The *Take Note!* feature draws the student's attention to points of critical emphasis throughout the chapter. This feature is often used to stress emergency, life-threatening or otherwise vitally important information.

Consider This!

In every chapter the student is asked to *Consider This!* These first-person narratives engage the student in real life scenarios experienced by their patients. The personal accounts evoke empathy and help the student to perfect caregiving skills. Each box ends with an opportunity for further contemplation, encouraging the student to think critically about the scenario.

NEW! Thinking About Development

The content featured in these boxes will encourage students to think critically about special developmental concerns relating to the topic being discussed.

Teaching Guidelines

Teaching Guidelines, presented in most of the chapters, serve as valuable health education tools. The guidelines raise the student's awareness, provide timely and accurate information, and are designed to ensure the student's preparation for educating children and their families about various issues.

Drug Guides

The Drug Guide tables summarize information about commonly used medications. The actions, indications, and significant nursing implications presented assist the student in providing optimum care to children and their families.

Common Laboratory and Diagnostic Tests

The Common Laboratory and Diagnostic Tests tables in each chapter of [Unit 4](#) provide the student with a general understanding of how a broad range of disorders is diagnosed. Rather than reading the information repeatedly throughout the narrative, the student is then able to refer to the table as needed.

Common Medical Treatments

The Common Medical Treatments tables in each chapter of [Unit 4](#) provide the student with a broad awareness of how a common group of disorders is treated either medically or surgically. The table serves as a reference point for common medical treatments.

Nursing Care Plans

Nursing Care Plans provide concrete examples of nursing diagnoses (including related or risk factors and defining characteristics), identified outcomes with evaluative criteria, and suggested nursing interventions with rationale. Found within the Nursing Process Overview section of each disorder chapter, these nursing care plans summarize issue- or system-related content, thereby minimizing repetition.

Comparison Charts

These charts compare two or more disorders or other easily confused concepts. They serve to provide an explanation that clarifies the concepts for the student.

Nursing Procedures

Step-by-step nursing procedures provide a clear explanation of pediatric variations to facilitate competent performance.

Key Concepts

At the end of each chapter, Key Concepts provide a quick review of essential chapter elements. These bulleted lists help the student focus on the important aspects of the chapter.

Icons

WATCH AND LEARN

A special icon throughout the book directs students to free video clips located on [thePoint](#) that highlight growth and development, communicating with children, and providing nursing care to the child in the hospital.

CONCEPTS IN ACTION ANIMATIONS

These unique animations, also located on [thePoint](#) bring physiologic and pathophysiologic concepts to life and enhance student comprehension.

Tables, Boxes, Illustrations, and Photographs

Tables and boxes are included throughout the chapters to summarize key content areas. Beautiful illustrations and photographs help the student to visualize the content. These features allow the student to quickly and easily access information.

References

References that were used in the development of the text are provided at the end of each chapter. The listings allow the student to further pursue topics of interest. Multiple online sources are provided on [thePoint](#) as a means for the student to electronically explore relevant content material.

Chapter Worksheets

Chapter worksheets at the end of each chapter assist the student to review essential concepts. Chapter worksheets include:

- **Multiple-choice questions**— these questions test the student’s ability to apply chapter material. The questions are styled similarly to the national licensing exam (NCLEX-RN®).
- **Critical thinking exercises**— these exercises serve to stimulate the student to incorporate the current material with previously learned concepts and reach a satisfactory conclusion. The exercises encourage students to think critically, problem solve, and consider their own perspective on given topics.
- **Study activities**— these activities promote student participation in the learning process. This section encourages increased interaction/learning via clinical, online, and community activities.
- **Answers**— answers to the worksheet are provided on [thePoint](#).

Teaching-Learning Package

Instructor’s Resources

Tools to assist you with teaching your course are available upon adoption of this text on [thePoint](#). Many of these tools are also included on the Instructor’s Resource DVD-ROM.

- An **E-Book** on [thePoint](#) gives you access to the book’s full text and images online.
- A **Test Generator** lets you put together exclusive new tests from a bank containing **over 800 questions** (twice as many as the last edition) to help you in assessing your students’ understanding of the material. Test questions link to chapter learning objectives.
- **PowerPoint presentations with Guided Lecture Notes** provide an easy way for you to integrate the textbook with your students’ classroom experience, either via slide shows or handouts. Multiple-choice and true/false questions are integrated into the presentations to promote class participation and allow you to use i-clicker technology.
- An **Image Bank** lets you use the photographs and illustrations from this textbook in your PowerPoint slides or as you see fit in your course.
- **New! Case Studies** with related questions (and suggested answers) give students an opportunity to apply their knowledge to a case similar to one they might encounter in practice.
- **Pre-Lecture Quizzes** (and answers) are quick, knowledge-based assessments that allow you to check students’ reading.
- **Discussion Topics** (and suggested answers) can be used as conversation starters or in online discussion boards.
- **Assignments** (and suggested answers) include group, written, clinical, and web assignments.
- **Sample Syllabi** provide guidance for structuring your pediatric nursing courses and are provided for four different course lengths: 4, 6, 8, and 10 weeks.
- **Journal Articles**, updated for the new edition, offer access to current research available in Lippincott Williams & Wilkins journals.

Contact your sales representative or check out LWW.com/Nursing for more details and ordering information.

Student Resources

An exciting set of free resources is available to help students review material and become even more familiar with vital concepts. Students can access all these resources on [thePoint](#) using the codes printed in the front of their textbooks.

- An **E-Book** on [thePoint](#) allows access to the book’s full text and images online.
- **NCLEX-Style Review Questions** for each chapter help students review important concepts and practice for NCLEX. **Over 700 questions** are included, more than twice as many as the last edition!
- **Multimedia Resources** appeal to a variety of learning styles. Icons in the text direct readers to relevant videos and animations:

- **Watch and Learn Videos**

A special icon throughout the book directs students to free video clips located on [thePoint](#) that highlight growth and development, communicating with children, and providing nursing care to the child in the hospital.

- **Concepts in Action Animations**

These unique animations, also located on [thePoint](#) bring physiologic and pathophysiologic concepts to life and enhance student comprehension.

- A **Spanish-English Audio Glossary** provides helpful terms and phrases for communicating with patients who speak Spanish.
- **Journal Articles** offer access to current research available in Lippincott Williams & Wilkins journals.
- **And more!**

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Compare the past definitions of health and illness to the current definitions.
2. Identify the key milestones in the history of child health.
3. Discuss different methods of measuring child health.
4. Discuss the philosophy of pediatric nursing care.
5. Identify the major roles and functions of pediatric nursing, including the scope of practice and the professional standards for pediatric nurses.
6. Explain the components of the nursing process as they relate to nursing practice for children and their families.
7. Identify ethical concepts related to providing nursing care to children and their families.
8. Describe legal issues related to caring for children and their families.

Isabelle Romano is a 6-year-old girl with cerebral palsy. She was born at 28 weeks' gestation and is currently

admitted to the hospital due to difficulty breathing secondary to pneumonia. Her parents are very active in her care. Isabelle lives at home with her parents and two brothers, Sergio and Tito. Consider how your role as a nurse can affect this family.

Children are the future of our society. Their overall health has improved, and rates of death and illness in some areas have decreased, but we still must focus on children's health both in the United States and globally. Habits and practices established in childhood have profound effects on health and illness throughout life. As a society, creating a population that cares about children and promotes preventative and quality health care and positive lifestyle choices is crucial. Pediatric nurses play a major role in this task. They are often "in the trenches" advocating on various issues, drawing attention to the importance of health care for children, encouraging a focus on education and prevention, and assisting families who lack resources or access to health care. This chapter provides an overview of child health, an introduction to pediatric nursing, and a discussion of ethical and legal issues related to caring for children.

Children are a gift to this world, and, as such, it is society's responsibility to nurture and care for them. In the past, health was defined simply as the absence of disease; health was measured by monitoring the mortality and morbidity of a group. Over the past century, however, the focus of health has shifted to disease prevention, health promotion, and wellness. The World Health Organization (2011) defines health as "a state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity."

The History of Child Health and Child Health Care

In past centuries in the United States, the health of the country was poorer than it is today; mortality rates were high and life expectancy was short. When a flood of immigrants from Europe settled in the eastern American cities, infectious diseases were rampant due to crowded living conditions, inadequate and unsanitary food (e.g., contaminated milk), lack of any childhood immunizations, and harsh working conditions (including child labor). Devastating epidemics of smallpox, diphtheria, scarlet fever, and measles hit children the hardest. During this period, the prevalent view was that children were a commodity; their role was to increase the population and share in the work to be done. This view changed over the years. Public schools were established and the court system began viewing children as minors. The health of children began to receive more and more attention.

As the end of the 19th century neared, doctors and scientists gained a much better understanding of the root causes of illness. This knowledge helped fuel public health efforts such as the campaign for safe milk supply, which led to pasteurizing milk and to dispensing free milk in some cities (Richter, 2004). Compulsory vaccination programs began during this time. In the late 1800s some states mandated smallpox vaccination as a condition of school attendance. These public health efforts led to a decrease in infant and child deaths (Richter, 2004).

In the late 19th and early 20th centuries, cities became healthier places to live due to urban public health improvements, such as sanitation services and treated municipal water (Richter, 2004). The threat of childhood diseases such as diphtheria, cholera, polio, and yellow fever began to take less of a toll on children (Richter, 2004). The turn of the 20th century brought new knowledge about nutrition, sanitation, bacteriology, pharmacology, medication, and psychology. Penicillin, corticosteroids, and increased numbers of vaccines, which were developed during this time, assisted with the fight against communicable diseases. Thus, by the end of the 20th century, unintentional injuries surpassed disease as the leading cause of death for children older than 1 year (Richter, 2004).

By the end of the 20th century, technological advances had significantly affected all aspects of health care. These trends have led to increased survival rates in children. However, many children who survive illnesses that were previously considered fatal are left with chronic disabilities. For example, before the 1960s, extremely premature infants did not survive because of the immaturity of their lungs. Mechanical ventilation and the use of medications to foster lung development have increased survival rates in premature infants, but survivors are often faced with myriad chronic illnesses such as chronic lung disease (bronchopulmonary dysplasia), retinopathy of prematurity, cerebral palsy, and developmental delay. This increased survival has resulted in a significant increase in chronic illness relative to acute illness as a cause of hospitalization and mortality.

In recent years there have been tremendous improvements in technology and biomedicine. This has created a trend toward earlier diagnosis and treatment of disorders and diseases. Throughout the 1990s remarkable progress was made linking genetics and pathophysiologic processes. For example, female fetuses diagnosed with congenital adrenal hyperplasia, a genetic disorder resulting in a steroid enzyme deficiency that can lead to disfiguring anatomic abnormalities of sexual characteristics, are able to receive treatment before birth. This can lead to fewer anatomic abnormalities and may even allow for normal female genitalia to develop (Mayo Foundation for Medical Education and Research, 2009). In addition, many genetic defects are being identified so that counseling and treatment may occur early.

In addition to improvement in technology and biomedicine, a number of national and international organizations have been formed in recent years to protect children's rights both in the United States and worldwide. These organizations focus on such issues as violence and abuse, child labor and soldiering, juvenile justice, child immigrants and orphaned children, and abandoned or homeless children—all of which have a negative impact on children's health. A child whose rights are restored and upheld has an improved opportunity for growth, development, education, and health.

The gains in child health have been huge, but, unfortunately, these gains are not shared equally among all children. Certain health concerns, such as poor nutrition, obesity, infections, lead poisoning, and asthma, affect poor children at higher rates and with greater severity than affluent and middle-class children (National Institute for Health Care Management, 2007). Unintentional injuries continue to be the leading cause of death in children older than 1 year, but children's health remains threatened by illnesses and other health-related conditions in the 21st century (Centers for Disease Control and Prevention [CDC]/National Center for Health Statistics, 2010). Obesity, environmental toxins, allergies, drug abuse, child abuse and neglect, and mental health problems are among some of the key issues that endanger children's health today.

Federal Legislation Affecting Child Health

Numerous federal programs have had a major impact on child health. President Theodore Roosevelt began the crusade to assist children and their families, especially the poor. The establishment of the Children's Bureau in 1912 began a period of studying economic and social factors related to infant mortality, infant care in rural areas, and other factors related to children's health. The goal of these legislative efforts was to improve the standards of health care. These actions demonstrate the value that society has placed on the welfare of children. [Table 1.1](#) lists several significant pieces of federal legislation and describes their impact on children's health.

Measurement of Children's Health Status

In 1979, the U.S. Surgeon General's Report *Healthy People* presented an agenda for the nation that identified the most significant preventable threats to health. With the series of updates that followed, including the present one, *Healthy People 2020: The Road Ahead*, the United States has a comprehensive health promotion and disease prevention agenda that is working toward improving the quantity and quality of life for all Americans (U.S. Department of Health and Human Services, 2010a). Overarching goals are to eliminate preventable disease, disability, injury, and premature death; achieve health equity, eliminate disparities, and improve the health of all groups; create physical and social environments that promote good health; and promote healthy development and behaviors across every stage of life (U.S. Department of Health and Human Services, 2010a). The principle behind this report is that setting national objectives and monitoring their progress can motivate action and change. The report incorporates input from public health and prevention experts; federal, state, and local governments; over 2,000 organizations; and the public in developing health objectives.

There are specific health topic areas, including children's health topics, which serve as a method for evaluation of progress made in public health. These topic areas also serve as focal points to coordinate national health improvement efforts. For example, one objective under the physical activity topic is to increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity (U.S. Department of Health and Human Services, 2010a). *Healthy People 2020* monitors four foundation health measures to assess the progress toward promoting health, preventing disease and disability, eliminating disparities, and improving quality of life (see the Healthy People 2020 feature for additional information on these health measures) (U.S. Department of Health and Human Services, 2010a).

HEALTHY PEOPLE 2020

Four Foundation Health Measures

1. General health status

- Measures include:
 - Life expectancy
 - Healthy life expectancy
 - Years of potential life lost
 - Physically and mentally unhealthy days
 - Self-assessed health status
 - Limitation of activity
 - Chronic disease prevalence

2. Health-related quality of life and well-being

- Measures include:
 - Physical, mental, and social health-related quality of life
 - Well-being/satisfaction
 - Participation in common activities

3. Determinants of health (a range of personal, social, economic, and environmental factors that influence health status)

- Include:
 - Biology
 - Genetics
 - Individual behavior
 - Access to health services
 - The environment in which people are born, live, learn, play, work, and age

4. Disparities

- Measures include differences in health status based on:
 - Race/ethnicity
 - Gender
 - Physical and mental ability
 - Geography

Healthy People Objectives based on data from <http://www.healthypeople.gov>. From U.S. Department of Health and Human Services. (2010). *HealthyPeople.gov*.

| Date | Action | Impact |
|-----------|---|--|
| 1909 | First White House Conference on Care of Dependent Children (convened by President Theodore Roosevelt) | Addressed the poor working and living conditions of many children in the United States. Aimed at improving the lives of children |
| 1912/1913 | U.S. Children's Bureau | Established the first governmental agency to oversee children's health and environmental conditions. Purpose is to research and report all issues pertaining to all children's well-being; to assist states and local government in preventing child abuse and neglect |
| 1921 | Maternity & Infancy (Sheppard-Towner) Act | Provided grants to states to establish maternal and child health divisions in state health departments |
| 1950 | White House Conference on Child Welfare Standards | Produced the Children's Charter, documenting the child's need for health, education, welfare, and protection |
| 1935 | The Social Security Act | Established federal-state partnership and provided Aid to Dependent Families and Children (ADFC), maternal-child health services, and child welfare services |
| 1946 | National School Lunch Program | Provided nutritious, well-balanced lunches to children each day at school for free or a low cost |
| 1962 | National Institute of Child Health and Human Development (NICHD) | Supported and performed research on child, maternal, adult, and family health issues |
| 1965 | Medicaid Program under Title XIX of Social Security Act; special programs such as Child Health Assessment Program | Provided state block grants to reduce financial barriers to health care for the poor and special services to pregnant women, young children, and people with disabilities |
| 1966/1974 | Women, Infants, Children (WIC) program | Provided nutritional supplementation and education to low-income families; pregnant, postpartum, and lactating women; and infants and children up to age 5 |
| 1969 | U.S. Children's Bureau moved to Office of Health, Education & Welfare (HEW) | Established greater presence for the programs |
| 1975 | Education for All Handicapped Children Act (Public Law 94-142) Title XX Social Services | Established federally mandated special education in public schools Provided block grants to day care, emergency shelters, counseling, family planning, and other services for children |
| 1981 | Alcohol, Drug Abuse & Mental Health block grants | Began funding services for children and adolescents with mental health issues |
| 1986 | Education of Handicapped Act Amendments (Public Law 99-457) | Established federal funding for states to create statewide, comprehensive, coordinated, and multidisciplinary early-intervention services for handicapped infants and toddlers |
| 1990 | Omnibus Budget Reconciliation Act | Extended Medicaid coverage to all children (6-18 years) with family income below 133% of poverty level |
| 1993 | Family & Medical Leave Act (FMLA) | Allowed eligible employees to take up to 12 weeks of unpaid leave from their jobs every year to care for newborns or newly adopted children or children, parents, or spouses who have a serious health condition; employee can return to previous job or a comparable job with the same conditions |

| Date | Action | Impact |
|------|---|---|
| 1995 | Early Head Start Program | Federally funded community-based program for low-income families (infants, toddlers, and pregnant women) that focused on child development |
| 1997 | Children's Health Insurance Program (CHIP) (formerly known as State Children's Health Insurance Program [SCHIP]) ^a | Offered federal assistance to state-based health insurance for low-income families that are not eligible for Medicaid but cannot afford private insurance |

Adapted from Yarrow, A. L. (2011). A history of federal child antipoverty and health policy in the United States since 1900. *Child Development Perspectives*, 5(1), 66-72.

Measuring a child's health status is not always a simple process. For example, some children with chronic illnesses do not see themselves as "ill" if their disease is under control. A traditional method of measuring health is to examine mortality and morbidity data. This information is collected and analyzed to provide an objective description of the nation's health.

Mortality Data

Mortality is the number of individuals who have died over a specific period. This statistic is generally presented as rates per 100,000 population and is calculated from a sample of death certificates. The National Center for Health Statistics, under the Department of Health and Human Services, collects, analyzes, and disseminates these data.

NEONATAL AND INFANT MORTALITY RATE

Neonatal mortality is the number of infant deaths occurring in the first 28 days of life per 1,000 live births. The infant mortality rate refers to the number of deaths occurring in the first 12 months of life. It also is documented as the number of deaths in relation to 1,000 live births. The infant mortality rate is used as an index of the general health of a country. Generally, this statistic is one of the most significant measures of children's health. In 2007, the infant mortality rate in the United States was 6.8 per 1,000 live births (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010). See [Figure 1.1](#).

The infant mortality rate varies greatly from state to state as well as between ethnic groups. The United States has one of the highest gross national products in the world and is known for its technological capabilities, but its infant mortality rate is much higher, in some cases double, compared to most other developed nations (MacDorman & Mathews, 2008; U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010). The main causes of early infant death in the United States include problems occurring at birth or shortly thereafter, such as prematurity, low birthweight, congenital anomalies, sudden infant death syndrome, respiratory distress syndrome, unintentional injuries, and bacterial sepsis (Stanton & Behrman, 2007; Xu, Kochanek, Murphy, & Tejada-Vera, 2010).

FIGURE 1.1 Infant and neonatal mortality from 1940 to 2007. (Adapted from Xu, J. Q., Kochanek, K. D., Murphy, S. L., & Tejada-Vera, B. [2010]. Deaths: Final data 2007. *National Vital Statistics Reports*, 58(19). Hyattsville, MD: National Center for Health Statistics. Retrieved February 16, 2011, from http://www.cdc.gov/nchs/data/nvsr/nvsr58/nvsr58_19.pdf)

Take Note!

Non-Hispanic African American infants have consistently had higher infant mortality rates compared to other ethnic groups (Xu et al., 2010).

Preterm births and low birthweight are key risk factors for infant death; the lower the birthweight, the higher the risk of infant mortality. The percentage of infants born preterm in the United States is increasing; thus, the impact of preterm-related causes of infant death has increased. This increase may play a role in the plateau in infant mortality rates seen from 2000 to 2007 and in the higher infant mortality rates in the United States compared with other developed countries (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010; Xu et al., 2010).

CHILDHOOD MORTALITY RATE

Childhood mortality is defined as the number of deaths per 100,000 population in children between 1 and 14 years of age. The childhood mortality rate in the United States has decreased by about 50% since 1980 (Child Trends, 2010). In 2007, the mortality rate for children between ages 1 and 4 years was 28.6 per 100,000, with the leading cause of death being unintentional injuries

followed by congenital malformations (CDC/National Center for Health Statistics, 2010). The mortality rate for children ages 5 to 14 years was 15.3 per 100,000, with the leading cause being unintentional injuries followed by cancer (CDC/National Center for Health Statistics, 2010). Other causes of childhood mortality include suicide, homicide, diseases of the heart, influenza, and pneumonia.

Even as research continues into the preventable nature of childhood injuries, unintentional injury, such as motor vehicle accidents, fires, drowning, bicycle or pedestrian accidents, poisoning, and falls, remains a leading cause of mortality and morbidity in children. These injuries have far-reaching consequences for children, families, and society in general. Risk factors associated with childhood injuries include young age, male gender, low socioeconomic status, parents who are unmarried or single, low maternal education level, poor housing, parental drug or alcohol abuse, or low support within the family. These deaths can often be prevented through education about the value of using car seats and seat belts, the dangers of driving under the influence of alcohol and other substances, and the importance of pedestrian and bicycle safety, fire safety, water safety, and home safety.

Take Note!

In the United States, Native American children, followed by African American children, have the highest unintentional injury death rate (Bishai et al., 2008).

Morbidity Data

Morbidity is the measure of prevalence of a specific illness in a population at a particular time. It is presented in rates per 1,000 population. Morbidity is often difficult to define and record because the definitions used vary widely. For example, morbidity may be defined as visits to the physician or diagnosis for hospital admission. Also, data may be difficult to obtain. Morbidity statistics are revised less frequently because of the difficulty in defining or obtaining the information.

In general, however, 57% of children in the United States enjoyed excellent health and 27% had very good health as reported in a summary of health statistics for children in 2009 (U.S. Department of Health and Human Services, 2010b). Factors that may increase morbidity include homelessness, poverty, low birthweight, chronic health disorders, foreign-born adoption, attendance at day care centers, and barriers to health care. For example, 20.7% of children live in poverty and have a higher incidence of disease, limited coordination of health services, and limited access to health care, except for visits to the emergency department (U.S. Census Bureau, 2010). The overall poverty rate is 14.3%, which is the highest poverty rate since 1994 (U.S. Census Bureau, 2010). However, the poverty rate among African Americans and Hispanics is 25.8% and 25.3%, respectively; these children are particularly at increased risk for illness (U.S. Census Bureau, 2010).

The most important aspect of morbidity is the degree of disability it produces, which is identified in children as the number of days missed from school or confined to bed. In 2009 about one quarter of school children, ages 5 to 17, did not miss any school due to illness or injury; however, approximately 5% missed 11 or more days of school because of injury or illness (U.S. Department of Health and Human Services, 2010b).

Common health problems in children include respiratory disorders, such as asthma; gastrointestinal disturbances, which lead to malnutrition and dehydration; and injuries. Asthma is the leading chronic disease in children, affecting 10% of children in the United States (U.S. Department of Health and Human Services, 2010b). Another 11% of children have respiratory allergies, 10% suffer from hay fever, 5% from food allergies, and 12% from other allergies (U.S. Department of Health and Human Services, 2010b). In 2005 to 2006 diseases of the respiratory system were the major cause of hospitalization for children 1 to 9 years of age, while mental health disorders were the leading cause for children 10 to 14 years of age (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010). In the United States during 2006, there were 4 hospital discharges for every 100 children (age 1 to 21 years) (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010). The age distribution for inpatient care has changed dramatically over the past 40 years. The percent of inpatients younger than 15 years of age declined from 13% to 7% in 2006 (DeFrances, Lucas, Buie, & Golosinskiy, 2008). [Figure 1.2](#) shows the major causes of hospitalization by age in the United States.

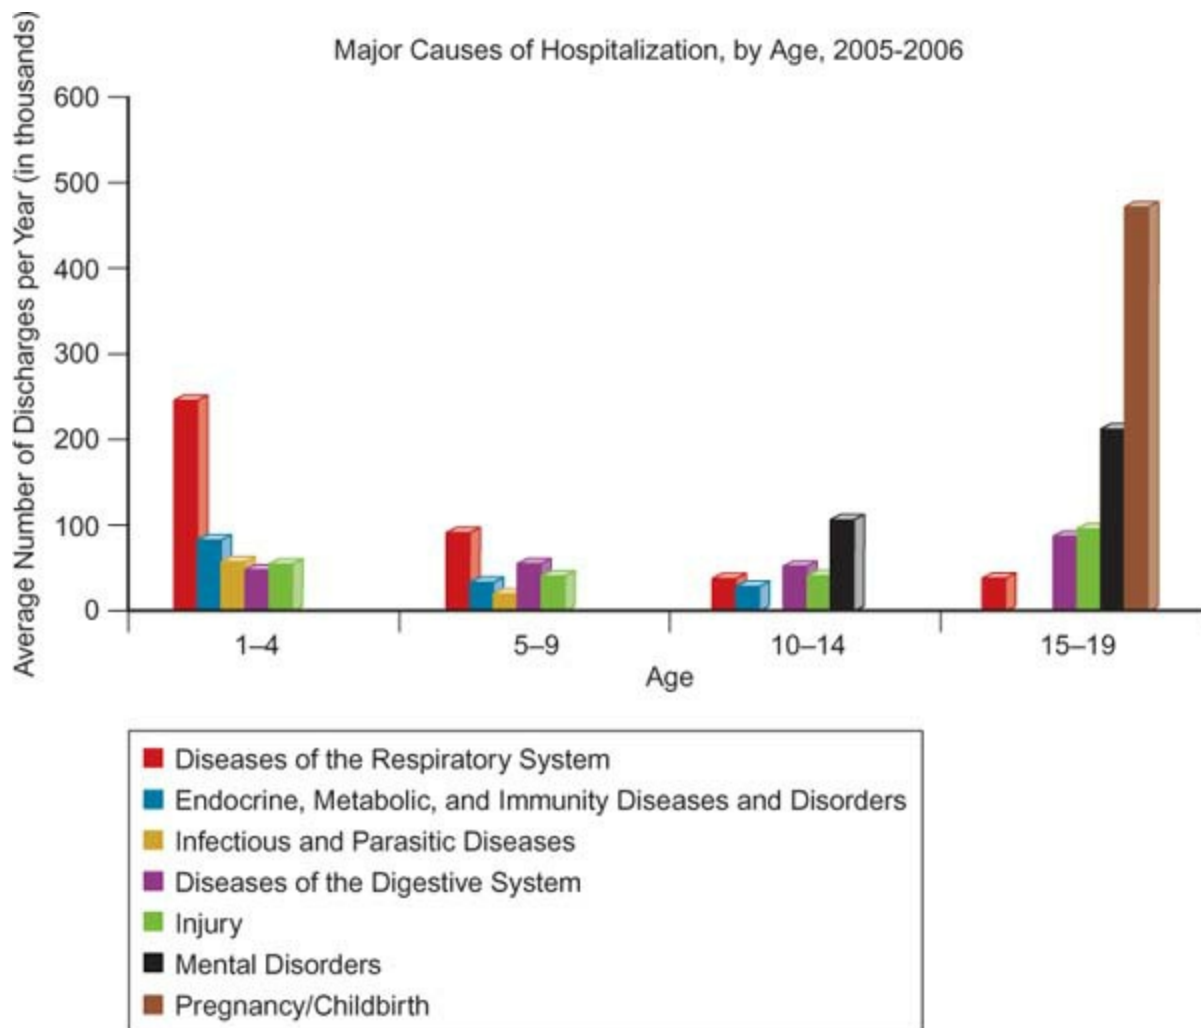

FIGURE 1.2 Causes of hospitalization in children, 2005–2006. (From U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau. (2010). *Child health USA 2010*. Rockville, MD: U.S. Department of Health and Human Services. Retrieved March 15, 2010, from <http://www.mchb.hrsa.gov/chusa10/index.html>)

As more immunizations become available, common childhood communicable diseases affect fewer children. The tracking of the leading topics from *Healthy People 2020* provides some positive information related to improving children’s health. Improvements have occurred in child health, but morbidity and disability from some conditions, such as asthma, diabetes, attention deficit disorders, and obesity, have increased in recent decades. Also, disparities in health status among US children according to race and socioeconomic status demonstrate widening social inequalities.

One trend in the United States is the increasing number of children with mental health disorders and related emotional, social, or behavioral problems. The American Academy of Pediatrics estimates that 14 million, or 1 in 5, children in the United States have mental health–related problems (American Academy of Pediatrics, n.d.). These problems may limit the child’s educational success. They also increase the child’s risk for significant mental health problems later in life or emotional problems and possible use of firearms, reckless driving, promiscuous sexual activity, and substance abuse during adolescence. Overall, these behavioral, social, and educational problems can interfere with children’s social and academic development. Often, insurance does not reimburse for these problems, leading to additional concerns such as lack of treatment.

Environmental and psychosocial factors are now an area of concern in children. They include academic difficulties, complex psychiatric disorders, self-harm and harm to others, use of firearms, hostility at school, substance abuse, HIV/AIDS, and adverse effects of the media.

Referring back to Isabelle Romano and her family from the beginning of the chapter, what changes in child health may have affected them?

PEDIATRIC NURSING

Pediatric nursing is the practice of nursing involved in the health care of children from infancy through adolescence. In the United States the number of children younger than age 18 years is approximately 74.5 million, accounting for 24% of the population (ChildStats.gov Forum on Child and Family Statistics, 2010). The definition of nursing, “the diagnosis and treatment of human responses to actual or potential health problems,” also applies to the practice of pediatric nursing (American Nurses Association, 2004). However, the overall goal of pediatric nursing practice is to promote and assist the child in maintaining optimal levels of health while recognizing the influence of the family on the child’s well-being. This goal involves the practice of health promotion and disease prevention as well as assisting with care during disease or illness.

Evolution of Pediatric Nursing

In 1870, the first pediatric professorship for a physician was awarded in the United States to Abraham Jacobi, who is known as the father of pediatrics. For the first time, the medical community realized there was a need to provide specialized training and education about children to physicians. In the early 1900s, Lillian Wald established the Henry Street Settlement House in New York City; this was the start of public health nursing. This facility provided medical and other services to poor families. These services included home nurse visits to teach mothers about health care.

During this time, health care personnel were trained to take care of children in hospitals, but parents of hospitalized children were discouraged from visiting to prevent the spread of infection. Restricting parents from being involved in their child’s care was also thought to minimize emotional stress.

Nursing in public schools began in 1902 with the appointment of Lina Rogers as a full-time public school nurse in New York. A professional course in pediatric nursing was started in the early 1900s at Teachers’ College of Columbia University.

In the 1960s, changes in the health care delivery system and shifts in the population’s health status led to the development of the nurse practitioner role. The 1970s brought cost-control systems from the federal government because of rapid escalation of health care expenditures. In addition, the considerable changes in the US health care system in the 1980s affected pediatric nursing and child health care. The emphasis of care was on quality outcomes and cost containment. Some of these changes brought more advanced-practice nurses into the field of pediatrics.

Finally, in the 1980s, the Division of Maternal-Child Health Nursing Practice of the American Nurses Association developed maternal-child health standards to provide important guidelines for delivering nursing care.

Philosophy of Pediatric Nursing

Children need access to care that is continuous, comprehensive, coordinated, family centered, and compassionate. This care needs to focus on their changing physical, developmental, and emotional needs. Pediatric nurses provide this care by focusing on the family, providing atraumatic therapeutic care, and using evidence-based practice. These three concepts represent an overarching philosophy of pediatric nursing care and are integrated throughout the chapters of this text.

Parents or guardians play a critical role in the health and well-being of children. Providing care through a family-centered approach leads not only to better outcomes but also to better consumer satisfaction. The family is the child’s primary source of support and strength. The knowledge that the family has about a child’s health or illness is vital. **Family-centered care** involves a mutually beneficial partnership between the child, the family, and health care professionals (Harrison, 2010; O’Malley, Brown, & Krug, 2008). It applies to the planning, delivery, and evaluation of health care for children of all ages in any setting (see [Chapter 8](#)).

Children may undergo a wide range of interventions, many of which can be traumatic, stressful, and painful. The various settings in which the child receives care can be scary and overwhelming to the child and family, and interacting with health care personnel in various settings can cause anxiety. Thus, another major component of the pediatric nursing philosophy is providing **atraumatic care**. This is a philosophy of providing therapeutic care through interventions that minimize physical and psychological distress for children and their families (see [Chapter 8](#)).

Evidence-based practice involves the use of research findings in establishing a plan of care and implementing that care. It is a clinical decision-making approach involving the integration of the best scientific evidence, patient values and preferences, clinical circumstances, and clinical expertise to promote best outcomes (Salmond, 2007). It is important that nurses develop the skills and knowledge necessary to ask pertinent clinical questions, search for current best evidence, analyze the evidence, integrate the evidence into practice when appropriate, and evaluate outcomes. Evidence-based practice may lead to a decrease in variations in care while at the same time increasing quality and improving health care.

Role of the Pediatric Nurse

The primary role of the pediatric nurse is to provide direct nursing care to children and their families, being an **advocate**, educator, and manager. As a child and family advocate, the nurse safeguards and advances the interests of children and their families by knowing their needs and resources, informing them of their rights and options, and assisting them to make informed decisions. In the role of educator, the nurse instructs and counsels children and their families about all aspects of health and illness. The pediatric nurse ensures that communication with the child and family is based on the child's age and developmental level. The pediatric nurse uses and integrates research findings to establish evidence-based practice, managing the delivery of care in a cost-effective manner to promote continuity of care and an optimal outcome for the child and family.

The pediatric nurse also serves as a collaborator, care coordinator, and consultant. Collaborating with the interdisciplinary health care team, the pediatric nurse integrates the child's and family's needs into a coordinated plan of care. In the role of consultant, the pediatric nurse ensures that the child's and family's needs are met through such activities as support group facilitation or working with the school nurse to plan the child's care.

The dimensions of pediatric health care are changing. We live in a global community in which distances have been minimized, enabling all of us to learn, share, and exchange information. The pediatric nurse needs to be alert to the wide-ranging developmental and mental health needs of children as well as to the traits and behaviors that may lead to serious health problems. The scope of pediatric health care practice is much broader today, and pediatric nurses must include quality evidence-based interventions when developing the plan of care. In addition, pediatric nurses must incorporate new information about genetics and neurobiology and must continue to keep up with the technology explosion.

Providing Culturally Focused Care

The United States is no longer a "melting pot" of various cultures and ethnicities but a society in which each distinct individual brings a diversity and richness that as a whole enriches the country. Today, children do not fit into a set category or group. Children and families vary in terms of culture, family structure, socioeconomic status, background, and circumstances, so each child enters the health care system as a unique individual. Pediatric nurses must have greater sensitivity to the background of each child and must be able to provide care that addresses the child's uniqueness.

Providing Care Across the Health–Illness Continuum

As a result of improved diagnosis and treatment, the pediatric nurse now cares for children who have survived once-fatal situations, are living well beyond the usual life expectancy for a specific illness, or are functioning and attending school with chronic disabilities. While positive and exciting, these advances and trends pose new challenges for the health care community. For example, as care for premature newborns improves and survival rates have increased, so too has the incidence of long-term chronic conditions such as respiratory airway dysfunction or developmental delays. As a result, pediatric nurses care for children at all stages along the health–illness continuum, from well children, to those who are occasionally ill, to those with chronic, sometimes disabling conditions.

Providing Family-Centered Care

Due to the influence of managed care, the focus on prevention, better education, and technological advances, people have taken increased responsibility for their own health. Parents now want information about their child's illness, they want to participate in making decisions about treatment, and they want to accompany their children to all health care situations. As child advocates who value family-centered care, pediatric nurses can provide such empowerment and can address specific issues for children and families. Pediatric nurses must respect the family's views and concerns, address those issues and concerns, regard the parents as important participants in their child's health, and always include the child and family in the decision-making process (see [Chapter 8](#) for more information).

Providing Preventative Care

Efforts to reduce costs have also led to an increased emphasis on preventive care. Anticipatory guidance is vital during each health contact with children and their families. Education of the family includes everything from keeping the home safe to preventing illness. These are major points of emphasis for pediatric nurses as they deliver care to children and their families.

Providing Continuum of Care

In an effort to become more cost-effective and to provide care more efficiently, the nursing care of children now encompasses a

continuum of care that extends from acute care settings such as hospitals to outpatient settings such as ambulatory care clinics, primary care offices, rehabilitative units, community care settings, long-term facilities, homes, and schools. For example, after an acute hospital stay, a child may be able to complete therapy at home, school, or another community setting and can re-enter the hospital for short periods for specific treatments or illness. This continuum of care works well for children, since current statistics indicate that among children who have a regular place for care, 75% usually receive their medical care in doctors' offices, 24% in clinics, 1% in hospital-based clinics, and 1% in hospital emergency rooms (U.S. Department of Health and Human Services, 2010b).

Providing Child and Family Teaching

The nurse's role in relation to morbidity and mortality in children involves educating the family and community regarding the usual causes of deaths, the types of childhood illnesses, and the symptoms that require health care. The goal is to raise awareness and provide guidance and counseling to prevent unnecessary deaths and illnesses in children. The health of children is basic to their well-being and development, and the attention given to children's health in this country has slowly increased over the years. The pediatric nurse is in an excellent position to improve the future health of children.

Participating in Research

Pediatric nursing involves all the essential components of contemporary nursing practice. The pediatric nurse makes use of theories and research pertaining specifically to children as well as general nursing concepts and research. Nurses must know about current trends in child health so that they can provide appropriate anticipatory guidance, counseling, and teaching for children and families and can identify high-risk groups so that interventions can be initiated early, before illness or death occurs.

Implementing the Nursing Process

The pediatric nurse performs all of these tasks using the framework of the **nursing process**. The nursing process is used to care for the child and family during health promotion, maintenance, restoration, and rehabilitation. It is a problem-solving method based on the scientific method that allows nursing care to be planned and implemented in a thorough, organized manner to ensure quality and consistency of care. The nursing process is applicable to all health care settings and consists of five steps: assessment, nursing diagnosis, outcome identification and planning, implementation, and outcome evaluation.

1. **Assessment.** Assessment involves collecting data about the child and family and performing physical assessment during community-based health services, at admission to an acute care setting, at periodic times during the child's hospitalization or care, and during home care visits.
2. **Nursing diagnosis.** The nurse analyzes the data to make judgments about the child's health and developmental status. The nursing diagnoses that result from this judgment process describe health promotion and health patterns that pediatric nurses can manage.
3. **Planning and expected outcomes.** The next step in the process involves developing nursing care plans that incorporate goals or expected outcomes that improve the child's dysfunctional health patterns, promote appropriate health patterns, or provide for optimal developmental outcomes. The care plan includes the specific nursing actions that assist in obtaining the outcomes.
4. **Implementation.** These interventions are implemented, adapted to the child's developmental level and family status, and modified if the child's response indicates the need. The care plan incorporates the family in addition to the child.
5. **Evaluation.** The process is continually evaluated and updated during the partnership with the child and family.

Standardized care plans for specific nursing diagnoses and critical pathways for case management are often used in various pediatric settings. In general, care plans and critical pathways are becoming more evidence based, using a combination of research, group consensus, and past health care decisions to identify the most effective interventions for the child and family. The nurse is responsible for individualizing these standardized care plans based on the data collected during the assessment of the child and family and for evaluating the child's and family's response to the nursing interventions.

Nursing Practice Roles in Various Health Care Settings

The professional pediatric registered nurse provides care for children in a variety of settings. Acute care focuses on the diagnosis and treatment of illness and occurs in such settings as general pediatric hospital units, pediatric intensive care units, emergency departments, ambulatory clinics, surgical centers, and psychiatric centers. In the community the focus is usually on health promotion and illness prevention. Various community settings include health clinics or offices, schools, homes, day care centers, and summer camps. Care involving restorative, rehabilitative, or quality-of-life care generally takes place in rehabilitation centers or hospice programs or through service with a home health agency.

There are various practice roles where the nurse's experience, competence, and educational level determine the nurse's position. For example, a clinical coordinator typically holds a baccalaureate degree and fills a leadership role in a variety of settings. The case manager, also usually a baccalaureate-prepared nurse, is responsible for integrating care from before admission to after discharge. The case manager coordinates the implementation of the interdisciplinary team in a collaborative manner to ensure continuity of care that is cost-effective, quality oriented, and outcome focused.

Various changes in the health care system continue to encourage the development of the advanced practice role for pediatric nursing. The advanced practice role is an expanded nursing role that requires additional education and skills in the assessment and management of children and their families. The pediatric nurse practitioner (PNP) has a master's degree and national certification in the specialty area. The PNP is an independent and autonomous practitioner. The PNP provides health maintenance care for children (such as well-child examinations and developmental screenings) and diagnoses and treats common childhood illnesses. He or she manages children's health in primary, acute, or intensive care settings or provides long-term management of the child with a chronic illness. The family nurse practitioner (FNP) and neonatal nurse practitioner (NNP) function in a similar manner to the PNP but provide care to individuals throughout the lifespan and to newborns, respectively. The clinical nurse specialist has a master's degree and provides expertise as an educator, clinician, or researcher, meeting the needs of staff, children, and families.

Take Note!

The American Academy of Colleges of Nursing has recommended that nurse practitioner education be moved from the master's to the doctoral level by the year 2015 (Sperhac & Clinton, 2008).

Standards of Care and Performance in Today's Environment

In any role, the professional pediatric nurse is held accountable for nursing actions that adhere to the standards of care. A **standard of care** is a minimally accepted action expected of an individual of a certain skill or knowledge level and reflects what a reasonable and prudent person would do in a similar situation. Professional standards from regulatory agencies, state or federal laws, nurse practice acts, and other specialty groups regulate nursing practice in general. The National Association of Pediatric Nurse Practitioners (NAPNAP), the Society of Pediatric Nurses (SPN), and the American Nurses Association (ANA) have formulated specific standards of care and professional performance for pediatric clinical nursing practice (Table 1.2).

These standards are tools that determine if care constitutes adequate, effective, and acceptable nursing practice. They also serve as guides and legal measures for this special area of practice. These standards promote consistency in practice, provide important guidelines for care planning, assist with the development of outcome criteria, and ensure quality nursing care. The ANA-SPN standards specify what is adequate and effective for general pediatric nursing and promote consistency in practice.

Parents and guardians generally make choices about their child's health and services. As the legal custodians of minor children, they decide what is best for their child. Nurses caring for children and their families make the child's and family's needs a priority. Moral development (the ability to function in an ethical manner) and the legal requirements involved in working with children affect pediatric nurses on a daily basis. Pediatric nurses must function within ethical and legal boundaries related to their care. They must understand their state's legal requirements for routine care, consent for treatment, hospitalization, and research.

Take Note!

As advocates for children, nurses support policies that protect children's rights and improve children's health care.

Ethical Issues Related to Working With Children and Their Families

Pediatric nurses must examine their own values so that they can provide nursing care in an ethical manner. Each situation must be evaluated individually. The nurse's relationship with the child and family is of prime importance. Every day pediatric nurses encounter families from a wide variety of religious, cultural, and ethnic backgrounds, and it is critical to treat each family with respect. Family-centered care focuses on the needs of the child and family together and involves ethical treatment of the child. Advances in science and technology have led to an increased number of ethical dilemmas in health care. Many facilities have formed institutional ethics committees. These committees not only provide case-by-case review and resolution of ethical dilemmas but also review existing institutional policies and provide education to staff, physicians, children, and families on ethical issues (Nelson, 2007).

Practicing ethically begins with being sensitive to the sanctity and quality of human life. An ethical nurse is accountable and uses sound reasoning to resolve ethical challenges. Ethics includes the basic principles of autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity. The nurse must understand these principles in order to analyze and respond to ethical dilemmas. Autonomy refers to the freedom to choose and self-determination in regard to making health care decisions. Generally, parents have the autonomy to make health care decisions for their child. In certain situations, however, older children have the autonomy to give assent to care (see below), and in special situations, adolescents are granted the autonomy to consent to health care procedures without the parents' knowledge. Beneficence refers to actions that will benefit others. In pediatric care this means actions of kindness that will benefit the child rather than harming him or her. Nonmaleficence means avoiding causing harm, intentionally or unintentionally. Justice refers to acting fairly. Treatment decisions will not be based on factors such as age, gender, religion, socioeconomic status, or ethnic group. Veracity is telling the truth and fidelity is keeping promises and maintaining confidentiality and privacy. The pediatric nurse must balance these ethical components when dealing with families from a variety of cultural and religious backgrounds who are making health care decisions for their children. The process is as follows:

TABLE 1.2

NATIONAL ASSOCIATION OF PEDIATRIC NURSE PRACTITIONERS, SOCIETY OF PEDIATRIC NURSES, AMERICAN NURSES ASSOCIATION SCOPE AND STANDARDS OF PEDIATRIC NURSING PRACTICE

Standard: Description

Standards of Practice

1. **Assessment:** The pediatric nurse collects comprehensive health data.
2. **Diagnosis:** The pediatric nurse analyzes the assessment data in determining diagnosis.
3. **Outcomes identification:** The pediatric nurse identifies expected outcomes individualized to the client.
4. **Planning:** The pediatric nurse develops a plan of care that prescribes interventions to attain expected outcomes.
5. **Implementation:** The pediatric nurse implements the interventions identified in the plan of care, including coordination of care and case management; health teaching, health promotion, restoration, and health maintenance; and consultation to physicians and others to influence the plan of care for children, enhance the abilities of others to provide health care, and effect changes in the health care system.
6. **Evaluation:** The pediatric nurse evaluates the child's and family's progress toward attainment of outcomes.

Standards of professional performance

7. **Quality of practice:** The pediatric nurse systematically improves the quality and effectiveness of pediatric nursing practice.
8. **Professional practice evaluation:** The pediatric nurse evaluates his or her own nursing practice in relation to professional practice standards and relevant statutes and regulations.
9. **Education:** The pediatric nurse acquires and maintains current knowledge and competency in pediatric nursing practice.
10. **Collegiality:** The pediatric nurse contributes to the professional development of peers, colleagues, and others.
11. **Collaboration:** The pediatric nurse collaborates with the child, family, and other health care providers in providing client care.
11. **Ethics:** The pediatric nurse's decisions and actions in all areas of practice are determined in an ethical manner.
13. **Research, evidenced-based practice, and clinical scholarship:** The pediatric nurse uses research findings in practice and participates in the generation of new knowledge.
14. **Resource utilization:** The pediatric nurse considers factors related to safety, effectiveness, cost in planning and delivering care, and the impact on practice.
15. **Leadership:** The pediatric nurse demonstrates leadership in the practice setting and the profession.
16. **Advocacy:** The pediatric nurse is an advocate for the client and family.

1. Identify the problem.
2. Gather information about the problem.
3. Weigh the risks against the benefits.
4. Choose a solution.
5. Implement the solution.
6. Evaluate the outcome of the situation.

Many pediatric institutions have adopted a "bill of rights" for children's health care. This might include the right:

- To be called by name
- To receive compassionate health care in a careful, prompt, and courteous manner
- To know the names of all providers caring for the child
- To have basic needs met and usual schedules or routines honored
- To make choices whenever possible
- To be kept without food or drink when necessary for the shortest time possible
- To be unrestrained if able
- To have parents or other important persons with the child
- To have an interpreter for the child and family when needed
- To object noisily if desired
- To be educated honestly about the child's health care
- To be respected as a person (not having people talk about the child within earshot unless the child knows what is happening)
- For all physicians to respect the child's confidentiality about his or her illness at all times (adapted from University of California—Irvine, n.d.)

Legal Issues Related to Working With Children and Their Families

Minors (children younger than 18 years of age) generally require adult guardians to act on their behalf. Parents ultimately are the decision makers for their children. Biological or adoptive parents are usually considered to be the child's legal guardian. When divorce

occurs, one or both parents may be granted custody of the child. In certain cases (such as child abuse or neglect, or during foster care), a guardian *ad litem* may be appointed by the courts. This person generally serves to protect the child's best interests. States generally require parental or guardian consent for minors to receive medical treatment, but some exceptions exist (refer to the section on consent below). Confidentiality of patient information should always be maintained within the context of the state law and the institution's policies.

Consent

Generally, only persons over the age of majority (18 years of age) can legally provide consent for health care. Since children are minors, the process of consent involves obtaining written permission from a parent or legal guardian. In cases requiring a signature for consent, usually the parent gives consent for care for children younger than 18 years of age except in certain situations (see below).

Take Note!

Never assume that the adult accompanying the child is the parent or legal guardian. Always clarify the relationship of the accompanying adult.

INFORMED CONSENT

Most care given in a health care setting is covered by the initial consent for treatment signed when the child becomes a patient at that office or clinic or by the consent to treatment signed upon admission to the hospital or other inpatient facility. Certain procedures, however, require a specific process of **informed consent**. Procedures that require informed consent include major and minor surgery; invasive procedures such as lumbar puncture or bone marrow aspiration; treatments placing the child at higher risk, such as chemotherapy or radiation therapy; procedures or treatments involving research; application of restraints; and photography involving children.

The informed consent process, which must be done before the procedure or specific care, addresses the legal and ethical requirement of informing the child and parent about the procedure. It originates from the right of the child and family to direct their care and the ethical responsibility of physicians to involve the child and family in health care decisions. Nurses should involve children and adolescents in the decision-making process to the extent possible, though the parent is still ultimately responsible for giving consent. The physician or advanced practitioner providing or performing the treatment and/or procedure is responsible for informing the child and family about the procedure and obtaining consent by providing a detailed description of the procedure or treatment, the potential risks and benefits, and alternative methods available. The nurse's responsibility related to informed consent includes the following:

- Determining that the parents or legal guardians understand what they are signing by asking them pertinent questions
- Ensuring that the consent form is completed with signatures from the parents or legal guardians
- Serving as a witness to the signature process

Box 1.1 describes the key elements of informed consent, although laws vary from state to state.

Nurses must become familiar with state laws as well as the policies and procedures of the health care agency. Treating children without obtaining proper informed consent may result in charges of assault, battery, or negligence, and the physician and/or facility may be held liable for any damages (American Medical Association [AMA], n.d.).

BOX 1.1

KEY ELEMENTS OF INFORMED CONSENT

- The decision maker must be of legal age in that state, with full civil rights, and be competent (have the ability to make the decision).
- Present information that is simple, concise, and appropriate to the level of education and language of the individual responsible for making the decision.
- The decision must be voluntary, without coercion, force, or influence of duress.
- Have a witness to the process of informed consent.
- Have the witness sign the consent form.

SPECIAL SITUATIONS TO INFORMED CONSENT

There are special situations related to informed consent. If the parent is not available, then the person in charge (relative, babysitter, or

teacher) may give consent for emergency treatment if that person has a signed form from the parent or legal guardian allowing him or her to do so. During an emergency situation, a verbal consent via the telephone may be obtained. Two witnesses must be listening simultaneously and will sign the consent form, indicating that consent was received via telephone. Physicians can provide emergency treatment to a child without consent if they have made reasonable attempts to contact the child's parent or legal guardian (American Academy of Pediatrics, 2007c). In urgent or emergent situations, appropriate medical care never should be delayed or withheld due to an inability to obtain consent (American Academy of Pediatrics, 2007c). Certain federal laws, such as the Emergency Medical Treatment and Labor Act (EMTALA), require that every child who presents at an emergency department is given a medical examination regardless of informed consent or reimbursement ability (American Academy of Pediatrics, 2007c). [Table 1.3](#) gives further information about other special situations.

EXCEPTIONS TO PARENTAL CONSENT REQUIREMENT

In some states, a **mature minor** may give consent to certain medical treatment. The physician must determine that the adolescent (usually older than 14 years of age) is sufficiently mature and intelligent to make the decision for treatment. The provider also considers the complexity of the treatment, its risks and benefits, and whether the treatment is necessary or elective before obtaining consent from a mature minor (American Academy of Pediatrics, 2007c).

State laws vary in relation to the definition of an **emancipated minor** and the types of treatment that may be obtained by an emancipated minor (without parental consent). The nurse must be familiar with the particular state's law. Emancipation may be considered in any of the following situations, depending on the state's laws:

- Membership in a branch of the armed services
- Marriage
- Court-determined emancipation
- Financial independence and living apart from parents
- College attendance
- Pregnancy
- Mother younger than 18 years of age
- Runaway

| Issue | Definition | Nursing Considerations |
|--|--|--|
| Child not living with biological or adoptive parents | Child living: <ul style="list-style-type: none"> • In foster care • With potential adoptive parent • With a relative | Legally appointed guardian must provide consent. Verify authority and include documentation of legally appointed guardian in child's medical record. |
| Parent consent after divorce | Ability to give consent for health care rests with parent who has legal custody by divorce decree. | Determine if the parents have joint custody or if there is sole custody by one parent. Even the parent with only physical custody may give consent for emergency care. Court involvement may be needed if there is joint legal custody but parents disagree on care. |
| Consent for organ donation | For a minor to donate, the parents must be aware of the risks and benefits and must provide emotional support to the child, and there should be a close relationship between the donor and recipient, if living-related donation is occurring. | Potential donors should be referred to local organ procurement organization. Educate family about policies related to organ donation. Legal guardian or parent consents to organ donation. ^a |
| Consent for medical experimentation | Requirements include consent of parents, assent of child, and a perceived benefit to the child. ^b | Comply with all federal regulations if federal funds are received. Refer to section on assent. |

The emancipated minor is considered to have the legal capacity of an adult and may make his or her own health care decisions (American Academy of Pediatrics, 2007c).

Many states do not require consent or notification of parents or legal guardians when providing specific care to minors. Depending

on the state law, health care may be provided to minors for certain conditions, in a confidential manner, without including the parents. These types of care may include pregnancy counseling, prenatal care, contraception, testing for and treatment of sexually transmitted infections and communicable diseases (including HIV), substance abuse and mental illness counseling and treatment, or health care required as a result of a crime-related injury (American Academy of Pediatrics, 2007c). These exceptions allow children to seek help in a confidential manner; they might otherwise avoid care if they were required to inform their parents or legal guardian. Again, laws vary by state, so the nurse must be knowledgeable about the laws in the state where he or she is licensed to practice.

PARENTAL REFUSAL OF MEDICAL TREATMENT

Parental autonomy (the right to decide for or against medical treatment) is a fundamental, constitutionally protected right but not an absolute one. The general assumption is that parents act in the best interest of their children. Ideally, medical care without informed consent should be given only when the child's life is in danger. In some cases parents may refuse medical treatment for their child. This refusal may arise when treatment conflicts with their religious or cultural beliefs, and the nurse should be aware of some of these common beliefs. Some religions, such as Jehovah's Witnesses, Christian Science, Pentecostal, Faith Assembly, and Evangelical Healers, prefer prayer or faith healing over allopathic medicine (Linnard-Palmer & Kools, 2004). Jehovah's Witnesses refuse blood product administration based on their religious beliefs. The Black Muslim culture advocates vegan diets and refuses pork-based medicines or treatments. Hindus may refuse beef-based foods and medicines. Persons from an Islamic background may refuse the use of any potentially addictive substances such as narcotics or medicines containing alcohol (Linnard-Palmer & Kools, 2004). Sometimes common ground may be reached between the family's religious or cultural beliefs and the health care team's recommendations; communication and education are the keys in this situation.

In other cases, parents may refuse treatment if they perceive that their child's quality of life may be significantly impaired by the medical care that is offered. The health care team must appropriately educate the family and communicate with them on a level that they can understand. The child and family should be informed of what to expect with certain tests or treatments. The health care team should make a clinical assessment of the child's and family's understanding of the situation and their reasons for refusing treatment. Active listening may allow the physician to address the concerns, fears, or reservations the family may have regarding their child's care.

Refusal of medical care may be considered a form of child neglect. If providing medical treatment may prevent substantial harm or suffering or save a child's life, physicians and the judicial system strive to advocate for the child. The state has an overriding interest in the health and welfare of the child and can order that medical treatment proceed without signed informed consent; this is referred to as *parens patriae* (the state has a right and a duty to protect children). If the parents refuse treatment and the health care team feels the treatment is reasonable and warranted, the case should be referred to the institution's ethics committee. If the issue remains unresolved or in complex cases, the judicial system may become involved (American Academy of Pediatrics, 2007a).

Assent

Assent means agreeing to something. In pediatric health care, the term **assent** refers to the child's participation in the decision-making process about health care (McCullough & Stein, 2009). The age of assent depends on the child's developmental level, maturity, and psychological state. The American Academy of Pediatrics recommends that children and adolescents be involved in the discussions about their health care and kept informed in an age-appropriate manner (American Academy of Pediatrics, 2007a). Federal guidelines do not suggest a specific age when assent should be obtained, but the American Academy of Pediatrics proposes that a child with an intellectual age of 7 years or older is competent to understand participation in research and therefore provide assent (Knox & Burkhart, 2007). As a child gets older assent or dissent should be given more serious consideration. The pediatric patient needs to be empowered by physicians to the extent of their capabilities, and as children mature and develop over time they should become the primary decision maker regarding their health care (American Academy of Pediatrics, 2007a). The American Academy of Pediatrics recommends that if a physician asks the child's opinion about the direction of treatment or participation in research, then the child's view and desires should be seriously considered (American Academy of Pediatrics, 2007a).

When obtaining assent, first help the child to understand his or her health condition, depending on the child's developmental level. Next, inform the child of the treatment planned and discuss what he or she should expect. Then determine what the child understands about the situation and make sure he or she is not being unduly influenced to make a decision one way or another. Lastly, ascertain the child's willingness to participate in the treatment or research (American Academy of Pediatrics, 2007a; McCullough & Stein, 2009). Assent is a process and should continue throughout the course of treatment or research protocol.

The converse of assent, dissent (disagreeing with the treatment plan), when given by an adolescent 13 to 17 years of age, is considered binding in some states. If the physician is not going to honor the child's dissent, the argument can be made that he or she should not ask for the child's assent. In some cases, such as cases of significant morbidity or mortality, dissent may need to be

overridden. These cases need to be looked at on an individual basis. If the decision is made to move forward with treatment despite the child's dissent, then this decision must be explained to the child in developmentally appropriate terms.

Since the late 1990s there has been an increased emphasis on including children in research studies (Society of Pediatric Nurses, 2007). In research studies investigators and investigation review boards (IRBs) are responsible for ensuring measures are taken to protect the children in the studies. The nurse caring for these children also has the responsibility to ensure protection at all stages of the research process. Nurses can become members of the IRB as well as becoming familiar with studies that have been approved in their work setting to help ensure their pediatric patients are protected.

Take Note!

Whenever possible assent for participation should be obtained from the child.

Advance Directives

The Patient Self-Determination Act of 1990 established the concept of advance directives. Advance directives determine the child's and family's wishes should life-sustaining care become necessary. Parents are generally the surrogate decision makers for children. If the child's interests are not served by prolonged survival, then the physician or advanced practitioner should educate the parents about the extent of the child's illness and potential for ongoing quality of life (Fost, 2006). After discussion with other family members, friends, and spiritual advisors, the parents may make the decision to forego life-sustaining medical treatment, either withdrawing treatment or deciding to withhold certain further treatment or opt not to resuscitate in the event of cardiopulmonary arrest (American Academy of Pediatrics, 2004).

Life-sustaining care may include antibiotics, chemotherapy, dialysis, ventilation, cardiopulmonary resuscitation, and artificial nutrition and hydration. Some families may choose to withdraw these treatments if they are already in place or not begin them should the need arise. **“Do not resuscitate (DNR)” orders** are in place for some children, particularly the terminally ill. Some institutions have started using the term AND (“Allow Natural Death”). No matter what term is used, these orders should include specific instructions regarding the child's and family's wishes (e.g., some families may desire oxygen but not chest compressions or code medications). When the child is hospitalized, the DNR order must be documented in the physician orders and updated according to the facility's policy. DNR orders may also be in place in the home, but only a few states allow emergency medical services to honor a child's DNR order in the home. Children with DNR orders may also still be attending school. In that case, the health care professionals involved should meet with the school officials (the board of education and its legal counsel) to discuss how the DNR request can be upheld in the school setting (American Academy of Pediatrics, 2000).

The Baby Doe regulations, which are an amendment to the US Child Abuse Protection and Treatment Act, provide specific guidelines on how to treat extremely ill, premature, terminally ill, and/or disabled infants regardless of the parents' wishes (Kopelman, 2005). These cases encompass complex ethical issues and continue to be surrounded by legal uncertainty. Therefore, physicians must continue to work with parents of extremely sick or premature infants to ensure they are accurately informed about the condition of their child and the risks and benefits to treatment. Physicians must also be aware of federal, state, and hospital policy regarding care of very ill, premature, and/or disabled newborns.

The nurse must be knowledgeable about the laws related to health care of children in the state where he or she practices as well as the policies of the health care institution. The nurse must be sensitive to the various ethical situations that he or she may become involved in and should apply knowledge of laws as well as concepts of ethics to provide appropriate care.

Confidentiality Issues in Caring for Children

With the establishment of the Health Insurance Portability and Accountability Act of 1996 (HIPAA), confidentiality of health care information is now required. The primary intent of the law was to maintain health insurance coverage for workers and their families when they change or lose jobs. Another aspect of the law requires the Department of Health and Human Services to establish national standards for electronic transactions for health information on individuals. Due to the increased use of electronic medical records and electronic billing, there was an increased possibility that personal health information might be inappropriately distributed. Patient confidentiality and privacy must be maintained as it is with paper documentation. Nurses can ensure that privacy is maintained when using computerized documentation and an electronic medical record (EMR) by doing the following:

- Always maintain the security of your personal log-in information; never share it with other nurses or other persons.
- Always log off when leaving the computer.
- Do not leave patient information visible on a monitor screen when the computer/monitor is unattended.
- Use safeguards, such as encryption, when using alternative means of communication, such as e-mail.

HIPAA also addresses security and privacy issues involving health information about individuals. In 2002 the Standards for Privacy of Individually Identifiable Health Information, known as the privacy rule, was finalized (U.S. Department of Health and Human Services, 2003). The goal of this regulation was to properly protect personal health information while allowing for the flow of health information needed to provide and promote high-quality care (U.S. Department of Health and Human Services, 2003). As long as reasonable precautions have been taken to protect the child's privacy, the privacy rule allows certain disclosures that assist in patient care. For example, full names may be placed outside of a child's room in order to ensure that the correct care is given to the correct child (Anderson, 2007). Also, placing medical records in bins outside of examination rooms, as long as identifying information is turned toward the wall, is also permitted (Anderson, 2007). State privacy laws and professional practice standards also exist to protect personal health information, and care providers must follow whichever guidelines are more stringent. In the pediatric area, information is shared only with the legal parents or guardians or individuals as established in writing by the parents. This law, along with professional obligation, promotes the security and privacy of children's health information.

Exceptions to Confidential Treatment in Children

There are exceptions to confidential treatment in children. For example, all states require reporting of suspicion of physical or sexual child abuse and injuries caused by a weapon or criminal act. Abuse cases are reported to the child welfare authorities, criminal acts to the police. If the minor is a threat to himself or herself, information may need to be disclosed to protect the child. The physician must also follow public health laws that require reporting certain infectious diseases to the local health department (e.g., tuberculosis, hepatitis, HIV, and other sexually transmitted infections). Finally, there is a duty to warn third parties when a specific threat is made to an identifiable person.

Physicians must strike a balance between confidentiality and required disclosure. Even if disclosure is required, it is recommended that the physician attempt to gain consent for the disclosure and when possible inform the minor of the limits to confidentiality and consent prior to the initiation of care (Neinstein, Gordon, Katzman, Rosen, & Woods, 2007).

In the beginning of the chapter you were introduced to the Romano family. How can you empower this family to help them provide the best care to Isabelle? What ethical and legal issues may arise?

KEY CONCEPTS

- In the past, health was defined simply as the absence of disease; health was measured by monitoring the mortality and morbidity of a group. Over the past century, however, the focus of health has shifted to disease prevention, health promotion, and wellness. The World Health Organization (2011) defines health as “a state of complete physical, mental, and social well-being, and not merely the absence of disease or infirmity.”
- In past centuries in the United States, the health of the country was poorer than it is today; mortality rates were high and life expectancy was short. Over the years the health of children received more and more attention, leading to a better understanding of sources of illness and improvements in sanitation, water, and nutrition. This led to, by the end of the 20th century, unintentional injuries as opposed to disease becoming the leading cause of death for children older than 1 year (Richter, 2004).
- In the 21st century unintentional injuries continue to be the leading cause of death in children older than 1 year, but health problems such as obesity, environmental toxins, allergies, drug abuse, child abuse and neglect, and mental health problems endanger children's health today (CDC/National Center for Health Statistics, 2010).
- *Healthy People 2020* provides a comprehensive health promotion and disease prevention agenda that emphasizes children's health. Overarching goals are to eliminate preventable disease, disability, injury, and premature death; achieve health equity, eliminate disparities, and improve the health of all groups; create physical and social environments that promote good health; and promote healthy development and behaviors across every stage of life (U.S. Department of Health and Human Services, 2010a).
- One method to establish the aggregate health status of infants, children, and adolescents is by using statistics such as mortality and morbidity rates.
- The infant mortality rate is low in the United States, but it is still higher than in other industrialized countries. This high rate may be the result of the number of preterm and low-birthweight infants born in this country.
- The three general concepts that form the philosophy of pediatric nursing care are family-centered care, atraumatic care, and evidence-based care. Pediatric nurses use these three concepts to provide quality, cost-effective care that is continuous, comprehensive, and compassionate.
- The primary role of the pediatric nurse is to provide direct nursing care to children and their families, being an **advocate**, educator, and manager. The pediatric nurse also serves as a collaborator, care coordinator, and consultant.

- A **standard of care** is a minimally accepted action expected of an individual of a certain skill or knowledge level and reflects what a reasonable and prudent person would do in a similar situation. Professional standards from regulatory agencies, state or federal laws, nurse practice acts, and other specialty groups regulate nursing practice in general.
- The nursing process, a problem-solving method based on the scientific method, is used to care for the child and family during health promotion, maintenance, restoration, and rehabilitation. The nursing process is applicable to all health care settings and consists of five steps: assessment, nursing diagnosis, outcome identification and planning, implementation, and outcome evaluation.
- Ethical nursing care includes the basic principles of autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity.
- Advances in science and technology have led to ethical dilemmas in health care; when parents refuse treatment or the child's desires conflict with the parents' decision, an ethical dilemma results.
- Children are entitled to a health care bill of rights just as adults are.
- Minor children (younger than age 18 years) must have their parents or legal guardians provide consent for health care in most cases.
- Nurses must be knowledgeable about the laws related to health care of children in the state where they practice as well as the policies of their health care institution.
- Informed consent is required for major and minor surgery; invasive procedures such as lumbar puncture or bone marrow aspiration; treatments placing the child at higher risk, such as chemotherapy or radiation therapy; procedures or treatments involving research; application of restraints; and photography involving children.
- The nurse's responsibility related to informed consent includes determining that the parents or legal guardians understand what they are signing by asking them pertinent questions, ensuring that the consent form is completed with signatures from the parents or legal guardians, and serving as a witness to the signature process.
- In certain states, mature minors and emancipated minors may consent to their own health care.
- Depending on state law, certain health care may be provided to adolescents without parental notification, including pregnancy counseling, prenatal care, contraception, testing for and treatment of sexually transmitted infections and communicable diseases (including HIV), substance abuse and mental illness counseling and treatment, or health care required as a result of a crime-related injury.

MULTIPLE CHOICE QUESTIONS

1. What is the number one cause for mortality among children?
 - a. Human immunodeficiency virus
 - b. Congenital anomalies
 - c. Motor vehicle accidents
 - d. Low birthweight
2. The nurse is assessing the vital signs of a child who is being evaluated in an urgent care center. The child is to be seen by the pediatric nurse practitioner (PNP). The mother asks, "Why is my child seeing the PNP and not the doctor?" What is the best response by the nurse?
 - a. "The PNP functions similar to the physician's assistant, so you should be perfectly at ease."
 - b. "The child may be seen by the physician instead if you'd like."
 - c. "Seeing the PNP is just one more step in having your child evaluated in this setting."
 - d. "The PNP is an experienced RN with advanced education in the diagnosis and treatment of children."
3. When caring for an adolescent, in which case must the nurse share information with the parents no matter which state the care is provided in?
 - a. Pregnancy counseling
 - b. Depression
 - c. Contraception
 - d. Tuberculosis
4. The school nurse is planning a screening program. What items should be included to address issues related to the "new morbidity"?
 - a. Academic difficulties, violence, and other mental health issues
 - b. The number of children with chronic illness at the school
 - c. Statistics related to health insurance coverage of the children
 - d. HIV infection, asthma, and respiratory allergy testing

CRITICAL THINKING EXERCISES

1. Detail how the nursing process fits into the framework of pediatric nursing.
2. Discuss how the role of the pediatric nurse differs from the role of the advanced practice pediatric nurse.
3. At your next staff meeting, you have been asked to present material to your nursing unit discussing special situations to informed consent related to children. Describe the topics that you should address.

STUDY ACTIVITIES

1. Research the IRB at the local hospital and become informed about which studies have been approved in your clinical setting.
2. Research a current policy, bill, or issue being debated on the community, state, or national level pertaining to child health or welfare. Summarize the major facts and supporting or opposing issues and present them in a class presentation or paper.
3. Obtain a standardized care plan from the hospital unit. Evaluate whether it is based on evidence-based practice. Develop an individualized care plan for a child you are caring for. Compare and contrast the two types of care plans.
4. The following events were milestones in the support of children's health. Place them in the correct sequence, from oldest to most recent:
 - _____ a. Declaration of the Rights of the Child approved
 - _____ b. WIC program established
 - _____ c. U.S. Children's Bureau established
 - _____ d. Sheppard-Towner Act passed
 - _____ e. Family and Medical Leave Act passed
 - _____ f. Education for all Handicapped Children Act passed.

Factors Influencing Child Health

Words of Wisdom Learning rather than accomplishing should be the focus of raising children.

KEY TERMS

cultural competence

culture

discipline

enculturation

ethnicity

ethnocentrism

family

family structure

foster care

genetics

heredity

punishment

race

religion

resilience

social capital

spirituality

temperament

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Discuss genetic influences on child health.
2. Compare and contrast the factors associated with health status and lifestyle that affect a child's health.
3. Explain the concept of resiliency as it relates to children and their health status.
4. Discuss health care and its effect on child health.
5. Delineate the structures, functions, and roles of families and the influence on children and their health.
6. Differentiate discipline from punishment.
7. Discuss culture and ethnicity in relation to child health.
8. Discuss community and its effects on a child's health.
9. Discuss the sources of violence and how exposure to violence affects children.
0. Describe the impact of poverty and homelessness on the health of children.

Miguel Delgado is a 10-month-old boy who is admitted to the pediatric unit for treatment of pneumonia. He is accompanied by his parents and 3-year-old sister, Luisa. Miguel's parents speak Spanish and very little English. The family is Roman Catholic. As the nurse admitting Miguel, how will you facilitate communication? What steps can you take to help ensure ongoing communication with this family despite the language barrier?

When they come into the world, children are members of a family and have already been influenced by myriad factors such as genetics and the environment. As members of a family, they are also members of a specific population, culture, community, and society. Children live, learn, and grow in an environment affected by ever-changing cultural, spiritual, community, and social factors. For example, changes in population demographics in the United States have led to shifts in minority population groups. It is projected that over the next four decades the United States will experience a dramatic increase in racial and ethnic diversity (Ortman & Guarneri, 2009). The Hispanic population is expected to double, the Asian population is expected to increase by 79%, and all other racial groups will see an increase with the exception of non-Hispanic whites, who are expected to decline (Ortman & Guarneri, 2009). Globalization has led to an international focus on the health of children. In addition, access to health care, and the types of health care available for children, has changed due to modifications in health care delivery and financing. Furthermore, the United States continues to grapple with issues such as violence, immigration, poverty, and homelessness. The interplay of all of these factors creates a situation unique to each child. These factors may affect the child positively, promoting healthy growth and development, or negatively, exposing the child to health risks.

Nursing care for children and their families involves astute assessment of all of the factors that may affect the health of children. Nurses play a key role in determining the impact of these factors on children and their families. Pediatric nurses need a sound knowledge base about the individual child, including genetics, race and temperament, and overall health status and lifestyle. Family, including the different structures, roles, and functions found in today's society, is also an important component to child health. Knowledge of special situations such as single-parent or adopted families is important to provide individualized care. The nurse should also assess the family's level of stress based on the demands they face and their ability to meet those demands. Do they have the coping behaviors, patterns, and strategies needed to have a positive impact on the child's health?

Other assessments need to focus on culture, ethnicity, and spirituality and the child's community and society, including social roles and socioeconomic status (e.g., poverty and homelessness). Information gathered from these assessments can help the nurse refer the family to community resources that may assist them with stability and health needs. Resources such as state and federal agencies and community agencies such as the United Way or Salvation Army may be of assistance to families.

Nurses work with children and their families in a variety of settings and need to be alert to subtle yet important indicators that may suggest a problem. For example, the child or family may give an inaccurate address or may give as their address a homeless shelter. Parents or children may be embarrassed or ashamed, feeling the stigma of poverty or homelessness. Other clues to problems may include a history of repeated infectious diseases, multiple health problems, or complaints that the child is always hungry. The key is to link children and their families with community resources that will assist with financial stability and with meeting the health needs of the children.

Due to changing demographics, immigration, and the global nature of society, nurses must make sure that the care they provide is culturally sensitive. Nursing interventions need to incorporate the family's unique values, beliefs, and actions to ensure that their needs are met. To gain the knowledge and skills needed to plan effective care for children, pediatric nurses need to understand how all these factors affect the quality of nursing care and children's health outcomes. By doing so, nurses can create appropriate strategies and

plan interventions for achieving the best possible outcomes for children and their families.

GENETIC INFLUENCE ON CHILD HEALTH

Genetics, the study of heredity and its variations, is a field that has applications to all stages of life and all types of diseases. **Heredity** is the process of transmitting genetic characteristics from parent to offspring. The child's gender and race; the child's biological traits, including some behavioral traits or aspects of temperament; and certain diseases or illnesses are directly linked to genetic inheritance.

Gender

A child's gender is established when the sex chromosomes join. A child's gender can influence many key aspects, such as physical characteristics and personal attributes. In addition to the development of male or female genitalia, body development, and hair distribution, some diseases or illnesses can be gender related: for example, scoliosis is more prevalent in females and color blindness is more common in males. An early influence of gender in children involves the survival rate of premature infants: premature girls have a higher survival rate than premature boys (Lee et al., 2010).

In addition to the specific biological and physical traits related to gender, there are also social effects. The child develops specific gender attitudes and behaviors that are appropriate in his or her culture. Interactions with family members and peers as well as activities and societal values affect how children perceive themselves as a specific gender (Fig. 2.1). If confusion develops with this process, various psychological and social difficulties can arise for the child (American Academy of Pediatrics, 2010).

FIGURE 2.1 The young child learns to identify with the parent of the same sex.

Race

Race indicates membership in a particular group of humans who have biological traits that are transmitted by descent; they may share physical features such as skin color, bone structure, or blood type. Some of the physical variations may be normal in a particular race but may be considered an identifying characteristic of a disorder in other races. For example, epicanthal folds (the vertical folds of skin that partially or completely cover the inner canthi of the eye) are normal in Asian children but may occur with Down syndrome or renal agenesis in other races. In addition, specific malformations and diseases are found in specific races. For example, sickle cell anemia occurs more often in African Americans.

Temperament

Temperament is the manner in which a child interacts with the environment. The way a child experiences a particular event will be influenced by his or her temperament, and the child's temperament will influence the responses of others, including the parents, to the child. Early on, infants demonstrate differences in their behavior in response to stimuli. These responses are an integral part of the infant's developing personality and individuality. Although a child's temperament is intrinsic and relatively resistant to change, it does stabilize as the child matures (Feigelman, 2007). Knowing a child's temperament can help parents understand and accept the

characteristics of the child without feeling responsible for having caused them.

The classic temperament theory proposes nine parameters of temperament: activity level, rhythmicity, approach and withdrawal, adaptability, threshold of responsiveness, intensity of reaction, quality of mood, distractibility, and attention span and persistence (Feigelman, 2007). This theory seeks to identify behavioral characteristics that lead the child to respond to the world in specific ways. Using the nine parameters, children's temperaments may be categorized into three major groups: easy, difficult, and slow to warm up; various temperaments exist that are a combination of these groups (Feigelman, 2007). Easy children are even-tempered and have regular biological functions, predictable behavior, and a positive attitude toward new experiences. Difficult children are irritable, highly active, and intense; they react to new experiences by withdrawing and are frustrated easily. Children in the slow-to-warm-up category are moody and less active and have more irregular reactions; they react to new experiences with mild but passive resistance and need extra time to adjust to new situations.

A child's temperament may cause problems in the family if it conflicts with that of the parents (e.g., a difficult 2-year-old with slow-to-warm-up parents). If parents want and expect their child to be predictable but that is not the child's style, parents may perceive the child to have problems; this conflict may then affect the child's health. The key is not to label the child but to recognize the strengths and limitations of each group. Knowing a child's temperament can help parents understand a child's characteristics and behaviors and allow parents to adjust their parenting style.

Genetically Linked Diseases

New technologies in molecular biology and biochemistry have led to better understanding of the mechanisms involved in hereditary transmission, including those associated with genetic disorders. These advances are now leading to better diagnostic tests and management options.

Two major areas of study in genetics that are important to pediatrics are cytogenetics and the Human Genome Project. Cytogenetics is the study of genetics at the chromosome level. Chromosomal anomalies occur in 0.4% of all live births and are the most prevalent cause of cognitive impairment and congenital anomalies or birth defects (Elias, Tsai, & Manchester, 2007); anomalies are even more common among spontaneous abortions and stillbirths. The Human Genome Project is an international research effort involving the localization, isolation, and characterization of human genes and investigation of the function of the gene products and their interaction with one another. This research project will provide information about genetic diseases to aid in developing new ways to identify, treat, cure, or even prevent them. [Chapter 29](#) offers a more detailed discussion of genetics.

HEALTH STATUS AND LIFESTYLE

Obviously, the general health status of a child and specific lifestyles can influence a child's health. Health status may be a factor soon after birth. For example, the incidence of multiple births has been increasing in this country due to the increased use of in vitro fertilization and other assisted reproductive technologies along with women delaying childbearing until they are older (Ben-Joseph, 2007). Potential complications of multiple births include prematurity and intrauterine growth retardation, which may lead to chronic health problems in the child. Children with chronic health conditions may also have developmental delays, especially in acquiring skills related to cognition, communication, adaptation, social functioning, and motor functioning. Thus, the beginning health status of a child may affect his or her long-term health and development.

Development and Disease Distribution

The way a child develops is the result of genetics and the environment within the context of a variety of biopsychosocial forces. The biological influences include genetics, in utero exposure to teratogens, postpartum illnesses, exposure to hazardous substances, and maturation. [Chapters 3 through 7](#) discuss the forces affecting growth and development for each age group.

Developmental level has a major impact on the health status of children. In general, the distribution of diseases varies with age. For example, certain communicable diseases are more commonly associated with certain age groups. Roseola, which is a viral illness resulting in high fevers and rash, is most often seen in infants 6 to 15 months old, whereas scarlet fever, which is an infection from group A streptococci, is a disease that primarily affects children from 4 to 8 years old. The physiologic immaturity of an infant's body systems increases the risk for infection. Ingestion of toxic substances and risk of poisoning are major health concerns for toddlers as they become more mobile and inquisitive. Because preschool- and school-age children are, generally, very active, they are more prone to injury and accidents. Adolescents are establishing their identity, which may lead them to separate from the family values and traditions for a period of time and attempt to conform to their peers. This journey may lead to risk-taking behaviors, resulting in injuries or other situations that may impair their health.

Nutrition

Adequate nutrition can provide a rich environment for the developing child; conversely, nutritional deprivation can seriously interfere with brain development and other functions. Nutritional requirements change over the child's life and have a great influence on the child's physical growth and intellectual development. Nutrition provides the essentials required to maintain health and prevent illness ([Fig. 2.2](#)). [Chapters 3 through 7](#) discuss the specific nutritional requirements and the impact of deficiencies for each developmental stage.

FIGURE 2.2 The dietary habits established early in life can have a long-lasting impact on the health of the child and the quality of life.

Nutritional deficiencies, such as iron deficiency anemia, or excesses, such as the increasing incidence of childhood obesity, are still common problems in the United States. Some factors contributing to poor nutrition include inadequate food intake, nutritionally unsound social and cultural food practices, the easy accessibility of processed and nutritionally inadequate foods, lack of nutrition education in homes and schools, and the presence of illness that interferes with ingestion, digestion, and absorption of food. In a growing child, inadequate nutrition is associated with lower cognitive ability, poor emotional and mental health, increased susceptibility to childhood illnesses, increased risk for mortality, and stunted physical growth (Heird, 2007). “Fast food” or “junk food” diets are one cause of childhood obesity and are linked to the recent increases in the number of cases of childhood type 2 diabetes.

Lifestyle Choices

Lifestyle choices that can affect a child’s health include patterns of eating; exercise; use of tobacco, drugs, or alcohol; and methods of coping with stress. For children, the lifestyle of the parents basically is the lifestyle of the child. Inactive parents who eat poorly commonly have children with the same habits, which can result in diabetes, obesity, and early heart disease. These typically adult problems are being diagnosed more frequently in children and adolescents today. Parents should first self-evaluate their own dietary and activity habits, make changes where necessary, and then strive to encourage healthy eating habits and an appropriate level of physical activity in the child’s life through sports, hobbies such as dancing, or family activities.

Environmental Exposure

Environmental exposures can have a detrimental impact on the child. In utero, the child can be affected by poor maternal nutrition or by exposure to the mother’s use of alcohol, tobacco, or drugs or infections. It is important for pregnant women to be aware of the risks associated with certain drugs, chemicals, and dietary agents as well as maternal illnesses that may lead to problems for the child. These agents, known as teratogens, may be linked to birth defects in children. Not all drugs or agents are associated with fetal effects, however, and research is ongoing to identify the correlations between teratogens and other variables.

The environment continues to affect a child’s health after birth. Exposure to air pollution, tobacco, and water or food contaminants

can impair a child's health status. Safety hazards in the home or community can contribute to falls, burns, drowning, or other accidents. Exposure to secondhand smoke and other pollutants, such as from radiation or chemicals, is a health hazard for children. Because children are smaller and still developing, environmental exposures can cause more health problems for them. For example, lead exposure is a common preventable poisoning in children, especially children younger than 6 years of age. Due to young children's rapidly developing nervous systems, they are more sensitive to the effects of lead. Sources include lead paint, lead-contaminated dust, and lead contained in soil and water. Lead exposure can result in developmental and behavioral problems ranging from inattentiveness and hyperactivity to permanent brain damage and death, depending on level of exposure.

Take Note!

A recent study found that residual tobacco smoke and carcinogens remain after a cigarette is extinguished (referred to as third-hand smoke). These toxins cling to the smoker's hair and clothes and can be present on any surface in the house, such as carpet and cushions. Children are particularly susceptible to third-hand smoke since they breathe near, crawl, touch, and mouth contaminated surfaces (Winickoff et al., 2009).

Stress and Coping

Children are exposed to various situations and events that can produce stress. These events can be associated with the normal problems associated with growth and development, such as entering a new classroom, learning a new skill, or being teased by a classmate. However, they can also be associated with problems such as poverty, divorce, violence, illness, or trauma. Some children can adapt and respond to the stress, while others cannot. The term **resilience** refers to the qualities that enable an individual to cope with significant adverse events or stresses and still function competently (Lietz, 2007).

Various internal and external protective factors promote resiliency. Internal factors include the person's ability to take control and be proactive, to be responsible for his or her own decisions, to understand and accept his or her own limits and abilities, and to be goal directed, knowing when to continue or when to stop. External factors include caring relationships with a family member; a positive, safe learning environment at school (including clubs and social organizations); and positive influences in the community (see the discussion later in this chapter about protective factors and violence). Promoting the development of resiliency in children aids in the achievement of positive developmental outcomes (Yates & Masten, 2004).

Access to Health Care

The health care system, including the delivery and financing of this system, continues to change and evolve. In the United States, changes in the health care system result from pressures from many directions. These changes reflect shifts in the social and economic realities and results of biomedical and technological progress over the past several decades. The effects are felt by everyone who seeks health care in any form. The method of providing medical care in a high-tech environment has changed to providing health care within a limited-resource environment. Allocating the limited health care resources continues to be the theme.

Access to health care is affected negatively by lack of health insurance. Parents with uninsured children often delay care for their children, are less likely to take their children to a doctor or dentist in the last 2 years, and are five times less likely to have a usual place of care for their children (Kaiser Commission on Key Facts, 2007). The percentage of children without health insurance dropped slightly from 11.7% in 2006 to 11% in 2007 (Sherman, Greenstein, & Parrott, 2008). This decrease is attributed to states' ability to improve enrollment in Medicaid and the State Children's Health Insurance Program (Sherman et al., 2008). Medicaid is a joint federal and state program that provides health insurance to low-income children and their parents. It is state administered and each state has its own set of guidelines. In 1997 the US Congress passed legislation that led to the creation of the State Children's Health Insurance Program (SCHIP) (now known as the Children's Health Insurance Program [CHIP]). The purpose of this program is to help insure low-income children who are ineligible for Medicaid but cannot afford private health insurance. This program is also funded jointly by the federal and state governments, but administered by the individual states.

With the development of such public health insurance programs for children, the number of uninsured children declined by one third between 1997 and 2005 (Kaiser Commission on Key Facts, 2007). In 2007, 60.7% of children were insured by private or employer-based health insurance and 28.2% with Medicaid or SCHIP. Of the 11% of uninsured children, 44.8% were eligible for Medicaid, 23.6% were eligible for SCHIP, and 31.6% were not eligible for either primarily due to family income exceeding the programs' eligibility levels (American Academy of Pediatrics, 2008). In recent years Medicaid and SCHIP have focused on increasing enrollment by increasing outreach, simplifying enrollment procedures, and retaining eligible enrollees (Kaiser Commission on Key Facts, 2007).

Despite these efforts, three quarters of children uninsured are eligible for these public programs (Kaiser Commission on Key Facts, 2007). Lack of awareness, difficulty accessing the programs, uncertainty of how to apply for the programs, discomfort related

to receiving governmental assistance, and fear of jeopardizing the family's immigration status continue to be factors in failure to enroll children in these programs. Research has shown that enrollment of the children is facilitated when the entire family can obtain coverage (Kaiser Commission on Key Facts, 2007). Unfortunately, in most states, family enrollment is hampered because eligibility levels for parents are much lower than for children (Kaiser Commission on Key Facts, 2007). Also, as of 2006, many states, predominantly in the SCHIP program, began charging premiums, copayments, or enrollment fees, making coverage less affordable for eligible children (Kaiser Commission on Key Facts, 2007).

Recent fiscal concerns due to the economic downturn have led many states to limit enrollment in these programs. These programs rely on adequate state and federal funding. Therefore, the continued success of these programs depends on future legislation. Tough economic times along with decreases in employer-based health insurance will continue to challenge the nation to ensure adequate health care for all children.

Barriers to Health Care

Even with the federal and state programs available to assist children and families, barriers to appropriate, cost-effective, coordinated, and timely health care remain. Barriers can be financial, sociocultural, or ethnic, or part of the health care system itself.

Financial Barriers

After a decade of decline, the percentage of children living in low-income families has been on the rise since 2000. In 2009, 42% of children were living in low-income families and 21% were living in poor families (Chau, Thumpi, & Wright, 2010). Many children and families do not have insurance, do not have enough insurance to cover services obtained, or cannot pay for services. Nurses need to assess for financial barriers to health care and be aware of resources available to help these families overcome these barriers.

Ethnic and Sociocultural Barriers

Ethnic and sociocultural factors also pose barriers. For example, white, non-Hispanic children overall are more likely than African American and Hispanic children to be in very good or excellent health (U.S. Department of Health and Human Services, 2010). The proportion of children who are overweight is increasing, but the largest increase is occurring in African American and Mexican American children (ChildStats.gov Forum on Child and Family Statistics, 2010). This is just one example of the problems that different ethnic groups face in relation to health.

Lack of transportation and the need for both parents to work also pose barriers to seeking health care. Knowledge barriers (e.g., lack of understanding of the importance of prenatal care or preventive health care), language barriers (e.g., speaking a different language than the physician), and spiritual barriers (e.g., religious beliefs discouraging some forms of treatment) also exist.

Health Care Delivery System Barriers

The health care delivery system itself can create barriers, such as the cost containment movement. The majority of employed families with insurance are covered by some type of managed health care plan such as a health maintenance organization (HMO), a preferred provider organization (PPO), or a point-of-service (POS) plan. This prospective payment system, based on diagnosis-related groups (DRGs), limits the amounts of health care the family may receive. This also includes Medicaid reimbursement. As a result, the trend is to discharge children as soon as possible and deliver care in the home or through community-based services. The overall plan may improve access to preventive services but may limit the access to specialty care, which has a major impact on children with chronic or long-term illnesses.

FAMILY THEORY

The **family** is considered the basic social unit. The U.S. Census Bureau (2010) defines a family as a group of two or more persons related by birth, marriage, or adoption and living together. Traditional definitions of family emphasize the legal ties or genetic relationships of people living in the same household with specific roles. Given the diversity of families in today's society, however, some believe that family should be defined as whatever the child says it is (Patterson, 1995) (Fig. 2.3).

FIGURE 2.3 Nurses must recognize family dynamics when providing health care to children. There are many different family structures, and they influence child needs. **A.** The traditional nuclear family is composed of two parents and their biological or adopted children. **B.** The extended family includes the nuclear family plus other family members, such as grandparents, aunts, uncles, and cousins. **C.** Gay and lesbian families are composed of two people of the same sex sharing a committed relationship, with or without children.

The family into which a child is born greatly influences his or her development and health. Children learn health care activities, health beliefs, and health values from their family. The family's structure, the roles assumed by members, and societal changes that affect the family's life can affect the child and his or her health. Children and families are unique: each has different views and requires different methods for support.

Various theories and models have been generated to define a family, to understand its structure and function, and to assess a family's coping and adaptation (Table 2.1).

Family Structure

Family structure is the way that the family is organized and the way that the family members interact with one another on a regular, recurring basis in socially sanctioned ways. Family members can be gained or lost through divorce, marriage, birth, death, abandonment, and incarceration. With these events, the family structure changes and roles are redefined or redistributed.

The traditional nuclear family is no longer considered the dominant family structure. From 1970 to 2008, the percentage of children who were living with their own married parents decreased steadily from 68.7% to 61% (up slightly from 60.5% in 2000) (Institute for American Values and National Center on African American Marriage and Parenting, 2009). Table 2.2 lists some of the family structures found in today's society. Nurses working with children need to understand the child's family structure and any changes that are occurring in it so they can help the family to cope.

Special Family Situations

Families face complex challenges as they try to nurture, develop, and socialize their children. When the family structure changes, the effects on children can be lifelong. These special situations require astute assessment and proactive intervention to minimize the risk to the child and family.

| TABLE 2.1 SUMMARY OF MAJOR THEORIES RELATED TO FAMILY | | |
|---|---|--|
| Theory | Description | Key Components |
| Friedman's structural functional theory | Emphasizes the social system of family, such as the organization or structure of the family and how the structure relates to the function | Identified five functions of families: <ul style="list-style-type: none"> Affective function: meeting the love and belonging needs of each member Socialization and social placement function: teaching children how to function and assume adult roles in society Reproductive role: continuing the family and society in general Economic function: ensuring the family has necessary resources with appropriate allocation Health care function: involving the provision of physical care to keep family healthy |
| Duvall's developmental theory | Emphasizes the developmental stages that all families go through, beginning with marriage; the longitudinal career of the family is also known as the family life cycle | Described eight chronological stages with specific predictable tasks that each family completes: <ul style="list-style-type: none"> Marriage: beginning of family Childbearing stage Family with preschool children Family with school-aged children Family with adolescents Family with young adults Middle-aged parents Family in later years |
| Von Bertalanffy: general system theory applied to families | Emphasizes the family as a system with interdependent, interacting parts that endure over time to ensure the survival, continuity, and growth of its components; the family is not the sum of its parts but is characterized by wholeness and unity | Used to define how families interact with and are influenced by the members of their family and society and how to analyze the interrelationships of the members and the impact that change affecting one member will have on other members |
| Family stress theory | Addresses the way families respond to stress and how the family copes with the stress as a group and how each individual member copes | Described elements of stress as occurring internally within the family (e.g., values, beliefs, structure) that the family can control or change or externally from outside the family (e.g., culture of the surrounding community, genetics, the family's current time or place) over which the family has no control Described mobilization of family resources resulting in either a positive response of constructive coping or a negative response of a crisis Identified the main determinant of adequate coping based on the meaning of the stressful event to the family and its individual members |
| Resiliency model of family stress and family adjustment, and adaptation response model | Addresses the way families adapt to stress and can rebound from adversity | Identified the elements of risks and protective factors that aid a family in achieving positive outcomes |

| TABLE 2.2 TYPES OF FAMILY STRUCTURES | | |
|--|---|---|
| Structure | Description | Specific Issues |
| Nuclear family | Husband, wife, and children living in same household | May include natural or adopted children Once considered the traditional family structure; now decreased due to trends in divorce rates or other social situations such as nonmarital childbearing |
| Binuclear family | Child who is member of two families due to joint custody; parenting is considered a joint venture | Always works better when the interests of the child are put above the parents' needs and desires |
| Single-parent family | One parent responsible for care of children | May result from death, divorce, desertion, birth outside marriage, or adoption Likely to encounter several challenges because of economic, social, and personal restraints; one person as homemaker, caregiver, and financial provider |
| Commuter family | Adults in the family living and working apart for professional or financial reasons, often leaving the daily care of children to one parent | Similar to single-parent family |
| Step or blended family | Adults with children from previous marriages or from the new marriage | May lead to family conflict due to different expectations for the child and adults; may have different views and practices related to child care and health |
| Extended family | Nuclear family and grandparents, cousins, aunts, and uncles | Need to determine decision maker as well as primary caretaker of the children May be encouraged and supported by some cultures, such as Hispanic and Asian cultures |
| Same-sex family (also called homosexual or gay/lesbian family) | Adults of the same sex living together with or without children | May face prejudice against those with different lifestyles |
| Communal family | Group of people living together to raise children and manage household; unrelated by blood or marriage | May face prejudice against those with different lifestyles Need to determine the decision maker and caretaker of children |
| Foster family | A temporary family for children who are placed away from their parents to ensure their emotional and physical well-being | May include foster family's children and other foster children in the home Foster children more likely to have unmet health needs and chronic health problems because they may have been living in a variety of settings |
| Grandparents-as-parents families | Grandparents raising their grandchildren if parents are unable to do so | May increase the risk for physical, financial, and emotional stress on older adults May lead to confusion and emotional stress for child if biological parents are in and out of the child's life |
| Adolescent families | Young parents still mastering the developmental tasks of their own childhood | Greater risk to teenage girls for health problems during pregnancy and delivery of premature infants, leading to risk of subsequent health and developmental problems Probably still need support from their family related to financial, emotional, and school issues |

Divorced Family

Divorce is a common reason why the family structure changes. Today, 40% of marriages end in divorce and many of these marriages include children (Serwint, 2007). Divorce can have a great impact on the child, with chronic and devastating results. Typically, divorce is not a single event: changes have most likely been occurring in the family for years, and children may have been exposed to turmoil, violence, or changes in structure before the actual divorce. Children feel scared and confused by the threat divorce poses on their security. The initial response of children to divorce depends on their age; problems are most apparent the year after the divorce and diminish over the next couple of years (Serwint, 2007). However, about one third of children are still troubled and distressed 5 years after the divorce of their parents; after 10 years, 41% may have social, emotional, and/or academic problems (Serwint, 2007).

Parents need to understand the impact that divorce can have on their children so that they can place the children's interest in the forefront. The loss of a parent through divorce can leave children vulnerable to physical and mental illnesses (American Academy of Child and Adolescent Psychiatry, 2008b). However, by appropriately utilizing family strengths and providing care and attention, children can be helped to deal constructively with divorce (American Academy of Child and Adolescent Psychiatry, 2008b). Parents can use the rules in [Box 2.1](#) to help reduce tension and conflict, thereby minimizing the impact of separation and divorce on their children. Physicians can offer support, guidance, and resources to help make the strain of divorce easier on the entire family.

Single-Parent Families

Single-parent families can result from divorce or separation, death of a spouse, an unmarried woman raising her own child, or adoption by an unmarried man or woman. The U.S. Census Bureau (2007) found that approximately 26% of children younger than age 18 live with one parent, with 23% living with the mother only and 3% living with the father only (Kreider, 2008).

Single-parent families have several concerns that can affect the health of the children. Life in a single-parent household can be

stressful for both the adult and for the children. The single parent may feel overwhelmed with no one to share the day-to-day responsibilities of juggling the care of the children, maintaining a job, and keeping up with the home and finances. These issues may be compounded by other pressures, such as custody problems, decreased time available to spend with children, continuing conflicts between parents who are separated or divorced, or changes in relationships with extended family members.

BOX 2.1

10 RULES FOR DIVORCING PARENTS

1. Tell your children about the divorce and the reasons for the divorce in terms that they can understand. Be sure that you and your spouse are present together when telling the children; tell all the children at the same time.
2. Reassure your children that the divorce is not their fault. Repeat this as often as possible and as necessary.
3. Inform the children well in advance of anyone moving out of the house (except when abuse is present or there are concerns for immediate safety).
4. Clearly inform the children about the family structure after the divorce, such as who will live with whom and where; also discuss visitation clearly and honestly.
5. Do not make your children be or act like adults.
6. Do not discuss money or finances with your children.
7. Minimize unpredictable schedules and maintain routines, rules, and discipline, and be consistent in this area.
8. Never force or allow your children to take sides.
9. Avoid belittling your former spouse when the children can hear. However, do not lie to cover up for irresponsible behavior by the other parent.
10. Never put your children in the middle between you and your ex-spouse.

Adapted from Bryner, C. L. (2001). Children of divorce. *Journal of the American Board of Family Practice*, 14 (3), 176–183. Retrieved February 28, 2011, from <http://www.medscape.com/viewarticle/405852>; and New, M. (2007). *Helping your child through divorce*. KidsHealth for Parents. Retrieved February 28, 2011, from http://kidshealth.org/parent/positive/talk/help_child_divorce.html

Communication and support are essential to the optimal functioning of the single-parent family. The parent and children need to be able to express their feelings and work through the problems together. Single parents must provide greater support for their children. Even though single parents may feel alone, they need to ensure they treat their children as children and not a substitute for a partner. Support and comfort need to come from outside resources. Community resources can be helpful. Parents Without Partners, for instance, is an international organization that has over 200 chapters in the United States and Canada. It provides “single parents and their children with an opportunity for enhancing personal growth, self-confidence and sensitivity towards others by offering an environment for support, friendship, and the exchange of parenting techniques” (Parents Without Partners, n.d.).

Blended Families

Before the age of 18, one third of children in the United States are anticipated to live in a stepfamily (Jaffè, Segal, Hutman, & Barston, 2008). Creating a blended family (parents and their stepchildren), even though considered a form of “normal” these days, can be stressful for the parents and children alike. Although it creates a structure and stability and reduces some of the financial stresses of single parenthood, making the transition to a blended family takes time. Children may feel jealous of the stepparent or feel disloyal toward the previous biological parent. There may be competition or rivalry among the stepchildren. The child may fear that the stepparent is interfering with the child’s relationship with the parent or taking away his or her source of love, affection, and attention.

Mutual respect and open, honest communication among all individuals involved are key, and this should include the previous biological parent when possible. Responsibilities for parenting must be shared, including decisions about expectations, limits, and discipline. The continued role of the previous biological parent and the role of the stepparent in the child’s life are important to address.

Adopted Families

Adoption can occur domestically (through an agency or intermediary such as an attorney in the family’s own area or country), or the family may choose to adopt a child from another country. The child may be of a different culture, race, or ethnicity (Fig. 2.4). Most children in need of adoption in the United States and overseas are not infants. In recent years there has been an increasing number of children adopted from the US child welfare systems and internationally (Simms & Freundlich, 2007a; Singer & Krebs, 2008). Also,

there has been an increase in adoption by nontraditional families (single-parent families, blended families, families with gay or lesbian partners, and families with older parents) (Borchers et al., 2003).

FIGURE 2.4 An adoptive family with children from a different culture.

The amount of contact between the child and the birth mother can vary greatly. In a closed adoption there is no contact between the adoptive parents, the adopted child, and the birth mother. In an open adoption there is as much contact among the individuals as desired. Regardless of the method used to adopt a child, adoptive families may be faced with unique issues. Some adopted children have complex medical, developmental, behavioral, educational, and psychological issues (Borchers et al., 2003). They may have been exposed to poverty, neglect, infectious diseases, and lack of adequate food, clothing, shelter, and nurturing, placing them at risk for medical problems, physical growth and development delays or abnormalities, and behavioral, cognitive, and emotional problems. The adoptive parents may know about these problems, but in other situations little if any history may be available.

Differences in culture, ethnicity, or race can further influence the adopted child's sense of identity (Borchers et al., 2003). Children may be subjected to racism or bigotry. Extended family members may not accept the child as part of the family. Parents need to emphasize that the adopted child is their child and is as much a part of the family as any other member. Adopted adolescents and adults may feel a need to identify their biological parents. Children adopted from other countries may travel to the country of their birth, and children adopted domestically may search for biological relatives. Although this search is an indicator of healthy emotional growth, it can upset the adoptive parents, who may feel rejected.

As the adopted child grows older, he or she may feel the loss of a birth family or may question what he or she did that led to the birth parents' decision to proceed with adoption. Attachment to the adoptive family is important. In order to attach in future relationships, children must appropriately grieve past losses. This can be particularly complex and difficult for older children and children previously living in foster care or orphanages.

Take Note!

Adolescents face vast challenges adjusting to adoption at this age because of the added complexity of identity issues facing this age group (Singer & Krebs, 2008).

Clear, open, honest communication and discussion are essential to promote a healthy, strong relationship. Support, guidance, and open communication are key for all parties involved. Open acknowledgement of the adoptive relationship helps to nurture a child's self-esteem as he or she learns to understand what it means to be part of a family through adoption (Borchers et al., 2003).

The pediatric nurse needs to be sensitive, understanding, and supportive when interacting with adopted children and their families. "Positive" adoption language should be used. This includes saying "birth parent" when referring to biological parents instead of "natural" or "real parent" and just "parents" when talking about adoptive parents (Singer & Krebs, 2008). Also, do not refer to the child as their "adopted child" or other children as "natural children" (Singer & Krebs, 2008). When discussing adoption, using terms

such as “make an adoption plan” instead of “give away” or “give up for adoption” are preferred (Borchers et al., 2003). The nurse also needs to provide reassurance and understanding regarding missing health information and provide appropriate resources and referrals to resources that are knowledgeable about adoption and sensitive to the issues that may arise. Sources of information and support available are the Center for Adoption Support and Education at <http://www.adoptionsupport.org/> and the North American Council on Adoptable Children at <http://www.nacac.org/>.

Foster Care Family

Foster care is a situation in which a child is cared for in an alternative living situation apart from his or her parents or legal guardians. The child may be placed in this living situation because of difficulties in the family situation, such as abuse, neglect, abandonment, or the parents’ inability to meet the child’s needs due to illness, substance abuse, or death. The child may be sent to live with relatives (kinship care) or foster parents, who are strangers providing protection and shelter in a state-approved foster home.

There are about 423,773 children in the United States currently living in some form of foster care (U.S. Department of Health and Human Services, Administration for Children & Families, 2010). Through the 1990s use of foster care steadily rose but since then there has been a decline (Children’s Defense Fund, 2010). The goal of foster care is to provide temporary services until the child can return home to his or her family or be adopted. Unfortunately, children may remain in foster care for several years or longer and may be moved from one foster family to another.

Many children who are placed in foster care have been the victims of abuse or neglect. Children in foster care are more likely to exhibit a wide range of medical, emotional, behavioral, or developmental problems (Simms & Freundlich, 2007b). However, children are very resilient and most children in foster care are determined to live their lives, but they may struggle with certain issues, including:

- Unmet health care needs
- Significant mental health problems, such as depression, social problems, anxiety, and posttraumatic stress disorder
- Behavioral problems such as substance use, problems with the law, and self-destructive behaviors
- Interruptions in developmental stages
- Educational obstacles due to frequent moves
- Self-blame and feelings of guilt
- Feelings of being unwanted
- Feelings of helplessness and powerlessness
- Insecurity about the future
- Ambivalent feelings related to foster parents; feelings of being disloyal to birth parents (American Academy of Child and Adolescent Psychiatry, 2005; American Academy of Pediatrics, 2000).

Individual attention to the child in foster care is essential. A multidisciplinary approach to care that includes the birth parents, foster parents, child, health care professionals, and support services is important to meet the child’s needs for growth and development. Nurses play a key role in advocating for the child.

Family Roles and Functions

The role of the family in caring for the child includes not only providing physical and emotional care but also imparting the rules and expected behaviors of society through teaching and discipline techniques. These expected behaviors depend on the culture, values, and beliefs of the family and the child’s developmental stage and physical and cognitive abilities. Roles and functions are further defined by each family’s own traditions and values and the family’s set of standards for interaction within and outside the family. For instance, some families may value privacy more than others. These family members may tend to be more self-protective and secretive.

Caregiver–Child Interaction

The caregiver–child interaction is critical to the survival and healthy development of a young child (World Health Organization [WHO], 2004). Typically, the primary care-givers are the parents. Ideally, parents nurture their children and provide them with an environment in which they can become competent, productive, self-directed members of society. For young children in particular, growth, health, and their very personhood itself depend on the ability of the adults in their life to understand and respond to them (WHO, 2004).

Parental Roles

Typical parental roles and their functions include:

- Nurturer: the primary caregiver
- Provider: the person who is primarily responsible for generating the family's income
- Decision maker: the person who is responsible for making choices, especially related to lifestyle and leisure time
- Financial manager: the person who handles the money, such as paying bills and saving
- Problem solver: the person to whom other members go for help in solving problems
- Health manager: the person responsible for ensuring that family members maintain their health, such as scheduling doctor visits and ensuring that immunizations are current
- Gatekeeper: the person who manages information inflow and outflow (Pillitteri, 2007)

CHANGES IN PARENTAL ROLES OVER TIME

Parental roles evolve due to societal and economic changes as well as individual family changes. Traditionally, the role of provider was assigned to the father. However, with increased numbers of women in the workplace and more households with two parents working, today both parents are often the providers as well as the nurturers to the children. Technological innovations have provided parents with opportunities to work at home, allowing some parents to maintain the provider role while simultaneously fulfilling the nurturer and health manager roles. Fathers are taking on greater responsibilities related to household management and child care. Also, the number of children being raised by their grandparents is increasing (American Academy of Child and Adolescent Psychiatry, 2008a). Moreover, as baby boomers age, parents may find themselves caring for both their children and their aging parents.

PARENTING STYLES

Research in the 1960s by Baumrind, a psychologist, and further research in the 1980s by Maccoby and Martin led to the development of four major parenting styles seen in our society: authoritarian; authoritative; permissive; or uninvolved, rejecting, or neglecting (as cited in Cherry, n.d.; Ginsburg et al., 2009). The styles are defined by the amount of support and control exerted over the child during parenting. Many parents may use more than one parenting style and may fall somewhere in between styles instead of adhering strictly to one style. Also, some parents may change parenting styles as the child ages and matures. Whatever the style, sensitive and responsive caregiving is needed to promote appropriate physical, neurophysiologic, and psychological development (WHO, 2004). Nurses need to recognize different parenting styles and provide support to parents by discussing the effects of different parenting models and teaching parenting skills.

Authoritarian. The *authoritarian* parent expects obedience from the child and discourages the child from questioning the family's rules. The parent provides low support and high control over the child (Cherry, n.d.). The rules and standards set forth by the parents are strictly enforced and firm. The parents expect the child to accept the family's beliefs and values and demand respect for these beliefs. The parents are the ultimate authority and allow little, if any, participation by the child in making decisions. Behavior that does not adhere to the family's rules and standards is punished. This parenting style is associated with negative effects on self-esteem, happiness, and social skills and increased aggression and defiance (Barakat & Clark, 2007; Cherry, n.d.).

Authoritative. The *authoritative* or democratic parent shows some respect for the child's opinions. Although parents still have the ultimate authority and expect the child to adhere to the rules, authoritative parents allow children to be different and believe that each child is an individual. They exhibit warmth and consistently, fairly, and firmly enforce the family's rules and standards without emphasizing punishment. This type of parenting is associated with increased independence, happiness, and self-confidence and socially responsible individuals (Barakat & Clark, 2007; Cherry, n.d.).

Permissive. *Permissive* or *laissez-faire* parents have little control over the behavior of their children. Rules or standards may be inconsistent, unclear, or nonexistent. Permissive parents allow their children to determine their own standards and rules for behavior. Discipline can be lax, inconsistent, or absent. Parents can be warm, cool, or uninvolved. There are more negative than positive effects associated with this style of parenting. Negative effects include children being impulsive, low happiness, poor school performance, problems with authority, and lacking responsibility and independence (Barakat & Clark, 2007; Cherry, n.d.).

Uninvolved, Rejecting, or Neglecting. Uninvolved parents are indifferent. They do not provide rules or standards. The child's basic needs are often met but the parent is disconnected from the child's life. In some cases the parents may neglect or reject the child. They can be cold and uninterested in meeting the child's needs. They minimize their interactions and time with the children. This type of parenting is associated with negative effects such as the child lacking interest in school, lacking interest in the future, and lacking emotional and self-control (Cherry, n.d.). This type of parenting may also lead to lack of trust, low self-esteem, and anger toward others (Barakat & Clark, 2007; Cherry, n.d.).

Discipline

Much of parenting involves increasing desirable behavior and decreasing or eliminating undesirable behavior, a process generally known as **discipline**. There are various opinions in our society about the best or most effective method of discipline. Each child and family is unique. Discipline that works with one child or within one family may not work for another family. Discipline should focus on the development of the child while ensuring that their self-esteem and dignity are preserved. It should be based on age-appropriate expectations with clear, consistent guidelines while offering meaningful choices when possible. Discipline involves teaching and is ongoing, not something that is done just when the child misbehaves.

The American Academy of Pediatrics (2004) suggests three strategies for effective discipline (see also [Teaching Guidelines 2.1](#)):

- Maintaining a positive, supportive, nurturing care-giver–child relationship
- Using positive reinforcement to increase desirable behaviors
- Removing positive reinforcements or using punishment to reduce or eliminate undesirable behaviors

Teaching Guidelines 2.1

TEACHING TO PROMOTE EFFECTIVE DISCIPLINE

- Set clear, consistent, and developmentally appropriate expected behaviors; offer choices whenever possible.
- Maintain consistency in responding to behaviors; provide encouragement and affection.
- Role-model appropriate behaviors.
- Provide an age-appropriate explanation of the consequence that will occur if the child demonstrates unacceptable behavior.
- Always administer the consequence soon after the unacceptable behavior.
- Keep the consequence appropriate to the age of the child and the situation.
- Stay calm but firm without showing anger when administering the consequence.
- Always praise the child for displaying appropriate behavior.
- Set the environment to assist the child in accomplishing the appropriate behavior; remove temptations that may lead to inappropriate behavior.
- Reinforce that the child's behavior was bad, not that the child was bad.

POSITIVE REINFORCEMENT

Attention from parents is a very powerful form of positive reinforcement and can help increase desirable behaviors. The key is to focus on the child's appropriate behaviors rather than emphasizing the inappropriate ones. Immediate, consistent, and frequent feedback is crucial. This feedback can be in the form of smiles, praise, special attention, or rewards such as extra privileges or a special token or activity. Providing the feedback immediately is important so that the child learns to associate the feedback with the appropriate behavior, thereby reinforcing the behavior.

EXTINCTION

Another form of discipline is extinction, which focuses on reducing or eliminating the positive reinforcement for inappropriate behavior. Examples are ignoring the temper tantrums of a toddler, withholding or removing privileges, and requiring a "time-out." Withholding or removing privileges such as TV, music, or computer or phone use is most effective for older children and adolescents. The adolescent may be grounded for a short time or not allowed to drive the car. To be effective, the privilege being withheld or removed must be something that the child values.

FIGURE 2.5 Although he might not like it, quiet solitude helps the child develop inner control.

Time-out is an extinction discipline method that is most effective with toddlers, preschoolers, and early school-aged children. It involves removing the child from the problem area and placing him or her in a neutral, nonthreatening, safe area where no interaction occurs between the child and parents or others for a specifically determined period (Fig. 2.5).

Take Note!

The amount of time that a child spends in time-out is typically 1 minute per year of age; for example, a 3-year-old would spend 3 minutes in time-out (American Academy of Pediatrics, 2011).

PUNISHMENT

Discipline is often confused with **punishment**, but punishment involves a negative or unpleasant experience or consequence for doing or not doing something. Although punishment is sometimes a necessary element of discipline, to be an effective tool it must be coupled with rewards for good behavior (American Academy of Pediatrics, 2004).

Punishment may be verbal or corporal. Verbal punishment commonly takes the form of reprimands or scolding (the use of disapproving statements). The statements are intended to change or eliminate the inappropriate behavior. Verbal reprimands can be effective in the short term if they are used sparingly and are focused on the child's specific behavior. If verbal reprimands are used frequently and indiscriminately, they lose their effectiveness, can provoke anxiety in the child, and encourage the child to ignore the parent. Frequent use also may reinforce the behavior by providing the child with attention (American Academy of Pediatrics, 2004).

Corporal punishment involves the use of physical pain as a means to decrease inappropriate behavior. The most common form of corporal punishment is spanking (the use of an open hand to the buttocks or an extremity with the intention of modifying behavior without causing injury) (American Academy of Pediatrics, 2004). Research shows that many parents have spanked their children at some point. Spanking occurs most frequently in younger children, with 90% of parents of toddlers having spanked their child at least once (Grogan-Kaylor & Otis, 2007). Spanking decreases as children age, but is still used as a discipline strategy in adolescents. Over the past two decades a growing body of research has suggested that corporal punishment can cause an increase in behavior problems and have lasting effects into adulthood (Grogan-Kaylor & Otis, 2007).

Initially, spanking may be effective because of its sudden and shocking nature. However, over time it loses its effectiveness because its shock value declines. Spanking may stop the negative behavior, but it also increases the chance for physical injury, especially for infants and young children, and may lead to altered caregiver–child relationships (American Academy of Pediatrics, 2004). Because the effects of spanking diminish, the intensity of the spanking must be increased to achieve the same effects. Thus, it is important for parents to understand the consequences of its use.

Spanking is a controversial issue. Some argue that it provides children with a model of aggressive behavior as a solution for conflict, that it has been associated with increased aggression in children, and that it can lead to an altered parent–child relationship. Various studies have linked spanking in childhood with physical aggression and violence in childhood and persistent anger in adulthood (American Academy of Pediatrics, 2004, 2011). Because of the negative consequences of spanking and because it has been shown to be no more effective than other methods for managing inappropriate behavior, the American Academy of Pediatrics (2004) recommends that parents use methods other than spanking to respond to inappropriate behavior.

Take Note!

Other forms of discipline, if used incorrectly, can also cause problems for the child and interfere with the caregiver–child relationship. For example, disapproval using tone of voice, facial expression, or gestures can be effective in stopping inappropriate behavior, but if the disapproval comes in the form of verbal statements that attack the child rather than the behavior, negative consequences may occur (American Academy of Pediatrics, 2004).

CULTURE

Culture (the view of the world and implementation of a set of traditions that are used by a specific social group in order to pass these traditions along to the next generation) plays a critical role in shaping a child, including his or her health and health practices. Culture is a complex phenomenon involving the integration of many components such as beliefs, values, language, time, and personal space that shape a person's actions and behavior. Children learn these patterns of cultural behaviors from their family and community through a process called **enculturation**, which involves acquiring knowledge and internalizing values (Degazon, 1996).

Culture influences every aspect of development and is reflected in childrearing beliefs and practices designed to promote healthy adaptation. Typically, a child begins to understand his or her culture at approximately 5 years of age (Andrews & Boyle, 2008). The child's cultural background affects the way that he or she socializes, learns values, and experiences the world. The child's developing beliefs, customs, mode of communication, dress, and actions may all be shaped by his or her culture.

With today's changing demographic patterns, nurses must be able to incorporate cultural knowledge into their interventions so that they can care effectively for culturally diverse children. They must be aware of the wide range of cultural traditions, values, and ethics that exist in the United States today. All nurses must establish **cultural competence**, the ability to apply knowledge about a child's culture so that health care interventions can be adapted to meet the needs of the child (Table 2.3). The nurse should know about various culture-based health practices and how they may affect children, as well as the demographics of the local population. The goal is for the nurse to view culture as a point of congruence rather than a potential source of conflict.

Cultural Groups

A cultural group is a self-defined group of people who share a commonality such as religion, language, nationality, ethnicity, race, or physical trait. In a society there are typically dominant and minority groups. The dominant group, often the largest group, has the greatest authority to control the values and sanctions of the society (Taylor, Lillis, & LeMone, 2005). As a result, the dominant culture may have the largest impact on the child's health, while minority cultural groups may still maintain some of their own traditions and values.

| Component | Description |
|-------------------------------|---|
| Cultural self-awareness | Exploration of one's own culture and how values, beliefs, and behaviors have influenced personal life Examination of own biases and prejudices Identification of how own background is similar to and different from another's background |
| Cultural knowledge | Acquisition of information about other cultures from a variety of sources Familiarity with diverse groups and their beliefs, practices, world views, and strategies for decision making |
| Cultural skills and practices | Incorporation of knowledge of cultural background including specific practices for health Inclusion of family members' roles for decision making |
| Cultural encounter | Participation in and interaction with persons of diverse cultural backgrounds |

Adapted from Andrews, M. M., & Boyle, J. S. (2008). *Transcultural concepts in nursing care* (5th ed.). Philadelphia: Lippincott Williams & Wilkins.

The relationship of culture to health care can become obscured by the use of broad group titles. In reality, there are many distinct cultural groups, and within a group there may be many subcultures. Geographic differences also can occur. For example, the Latin Americans living in New York may be quite different from the Latin Americans living in Florida. Nurses must be aware of these distinct cultural groups so they can provide culturally competent care.

Nurses should also be aware of the traditional health care values and practices that are passed along from one generation to the next. For example, some cultures believe in consulting folk healers, and this belief may have a major influence on children's health (Table 2.4). The nurse must remember that diversity exists within cultures and this is as important as the diversity between cultures. Every child is a unique individual with his or her own beliefs, values, and history. Nurses need to avoid stereotyping, which can lead to misconceptions.

Ethnicity

Ethnicity, a term sometimes used synonymously with culture, involves group membership by virtue of common ancestry. The basic groups are differentiated by their customs, characteristics, language, or similar distinguishing factors. Ethnic groups have their own family structures, languages, food preferences, moral codes, and health care practices. Children learn the accepted mode of behavior by observing and imitating those around them. The influences of culture and ethnicity on children and families are highly variable and dynamic. Probably the most important characteristic of ethnicity is the sense of shared identity felt by members (Davidhizar, Havens, & Bechtel, 1999).

Children who come from a minority group may experience conflict because their native customs are different from those of the dominant culture. Many Americans in the dominant culture do not view themselves as belonging to a specific ethnic group, but many minority groups still identify closely with their ethnicity and emphasize their cultural or racial differences (Davidhizar et al., 1999).

Stereotyping or labeling can result from **ethnocentrism**, a belief that one's own ethnic group is superior to other ethnic groups. This attitude can lead to a slanted view of the world, and it may hinder the nurse's ability to provide culturally competent care.

Cultural Health Practices

Health practices are often the result of health beliefs derived from a person's culture. For example, do the child and family view health and illness as the result of natural forces, supernatural forces, or the imbalance of forces? Most cultures have remedies that people may use or consider before they seek professional health care. People from some cultures may go to folk healers who they believe can cure certain illnesses. For example, the *curandero* (male) or the *curandera* (female) of the Mexican American community is believed to have healing powers as a gift from God. Asian Americans may consult a practitioner who specializes in traditional Asian therapies such as acupuncture, acupressure, and moxibustion. These folk healers are often very powerful in their community, speak the language, and are very familiar with the culture's spiritual or religious aspects.

| TABLE 2.4 BELIEFS AND PRACTICES OF SELECTED CULTURAL GROUPS | |
|---|--|
| Cultural Group | Beliefs and Practices Affecting Children's Health |
| African Americans | <ul style="list-style-type: none"> Strong extended family relationships; mother as head of household; elder family members valued and respected Food as a symbol of health and wealth View of health as harmony with nature, illness as disruption in harmony Use of folk healing and home remedies common to treat body, mind, and spirit Strong church affiliation Belief in illnesses as natural (due to natural forces that the person hasn't protected self against) and unnatural (due to person or spirit) Illness commonly associated with pain Pain and suffering inevitable; relief achieved through prayers and laying on of hands Individuals vulnerable to external forces |
| Asian Americans | <ul style="list-style-type: none"> Strong loyalty to the family Family as the center, with members expected to care for one another Use of complementary modalities with Western health care practices View of life as a cycle, with everything connected to health Pain described by diverse body symptoms Health viewed as a balance between the forces of <i>yin</i> and <i>yang</i> resulting in <i>qi</i> (pronounced chee), which is a balanced state of harmony Respect for authority emphasized |
| Arab Americans | <ul style="list-style-type: none"> Women subordinate to men; young individuals subordinate to older persons Family loyalty is primary Good health associated with eating properly, consuming nutritious foods, and fasting to cure disease Illness due to inadequate diet, shifts in hot and cold, exposure of stomach while sleeping, emotional or spiritual distress, and "evil eye" Little emphasis on preventive care View of pain as unpleasant, requiring immediate control or relief Cleanliness important for prayer |
| Native Americans | <ul style="list-style-type: none"> High value on family and tribe; respect for elders Family as an extended network providing care for newborns and children Women as the verbal decision makers Celebrations to mark the stages of growth and development Use of food to celebrate life events and in healing and religious ceremonies Health as harmony with nature; illness due to disharmony, evil spirits; purification rituals (immersion in water, sweat lodges) to cleanse the body and spirit and maintain harmony with nature Prefer restoration of physical, mental, and spiritual balance through herbal medicines and healing ceremonies View of pain as something to be tolerated |
| Hispanics | <ul style="list-style-type: none"> Family important; father as the source of strength, wisdom, and self-confidence Mother as the caretaker and decision maker for health View of children as persons to continue the family and culture Use of food for celebrations and socialization Health as God's will maintainable with a balance of hot and cold food intake Cope with illness through prayer and faith in God Freedom from pain indicative of good health; pain tolerated stoically due to belief that it is God's will Folk medicine practices and prayers, herbal teas, and poultices for illness treatment |

Adapted from Rector, C. (2010). Chapter 5: Transcultural Nursing in the Community. In J.A. Allender, C. Rector, & K.D. Warner (Eds.), *Community Health Nursing. Promoting and Protecting the Public's Health* (7th ed) (pp. 91–112). Philadelphia, PA: Wolters Kluwer Health/Lippincott Wilkins & Williams.

If the folk remedies or practices of the folk healers are compatible with the health regimen and support appropriate health practices, these practices and beliefs do no harm; in fact, they may even benefit the child and family. However, use of a folk healer can lead to a delay in beneficial treatment or create other problems. Some traditional health practices may be misinterpreted as being harmful, and some actually are harmful. For example, the Vietnamese practice of coining, which involves rubbing the edge of a coin on an oiled symptomatic body area to rid the body of disease, may be misinterpreted as a sign of physical abuse (Allender, Rector, & Warner, 2010). This practice also can lead to burns, bruising, or weltlike lesions on the child's skin if it is done frequently. Azarcon and greta, powders containing high amounts of lead, are used as a folk remedy in Mexico to treat empacho, digestive problems such as diarrhea and indigestion, and can result in lead toxicity (Allender et al., 2010).

Take Note!

Pediatric nurses can help to shape an individual's lifelong perceptions of health and health services. An understanding of how the child's and family's culture affects their health practices gives the nurse an opportunity to incorporate appropriate and beneficial health practices into the family's cultural milieu, providing sources of strength rather than areas of conflict.

Recall Miguel, the infant described at the beginning of the chapter. Propose appropriate nursing interventions that would assist in providing culturally competent care. How can you best determine the child's and family's cultural preferences?

Changing Cultural Demographics

Although the proportion of children is decreasing in relationship to the adult population, the racial, ethnic, and cultural diversity among children is significantly increasing in the United States (ChildStats.gov Forum on Child and Family Statistics, 2010). Thus, the number of culturally diverse children entering the health care system in the United States is increasing. According to the U.S. Census Bureau, 66% of the population is White, 13.4% is Black or African American, 15.1% is Hispanic, and 5% is Asian (U.S. Census Bureau News, 2008b). The U.S. Census Bureau reports that the Hispanic population increased by 3.3% from July 1, 2006, to July 1, 2007; this is the fastest-growing population group, with the Asian population accounting for the second fastest (U.S. Census Bureau News, 2008b). At the same time, the non-Hispanic white population grew by 0.3% during the same time frame (U.S. Census Bureau News, 2008b). In addition, the increasing number of marriages between individuals from different ethnic origins is producing an increasing number of children who have a heritage that represents more than one cultural group.

Immigration

Employment and economic opportunities, expanded human rights, educational opportunities, and other types of freedoms and opportunities encourage many foreigners to move to the United States. There are a growing number of immigrants with approximately 15.7 million or one in five children in the United States being immigrants or members of an immigrant family (Kids Count Data Center, 2007). This includes both children born outside the United States and those with at least one foreign-born parent. Some communities welcome the new members, but others do not. Partly due to fears of terrorism, the United States is evaluating, enforcing, and changing many of its immigration laws.

Immigration can affect the health, educational, and social services provided in the United States. It also presents issues related to access to care and the types of care that need to be offered. Immigration imposes unique stresses on children and families, including:

- Depression, grief, or anxiety associated with migration and acculturation
- Separation from support systems
- Inadequate language skills in a society that is not tolerant of linguistic differences
- Disparities in social, professional, and economic status between the country of origin and the United States
- Traumatic events such as war or persecution that may have occurred in their native country (American Academy of Pediatrics, 2005)

Inability to speak English can hinder an immigrant's educational attainment, economic opportunities, and ability to join the mainstream of society. Nineteen percent of children born in immigrant families have difficulty speaking English, with 27% of children in immigrant families living in a linguistically isolated home (i.e., no person 14 years or older speaks English very well) (Kids Count Data Center, 2007). Immigrant parents who do not speak English may have trouble accessing health care and health insurance, enrolling their children in school or becoming involved in school activities, and accessing work or better-paying jobs.

Immigrant children also may arrive in the United States with significant health problems. They may present with diseases that are

more common in their country of origin and rarely seen in the United States, such as malaria. The health status of immigrant children may be compromised due to the lack of at-birth and early childhood screenings, which may manifest with problems such as inborn errors of metabolism, lack of preventive care, no immunizations, and no dental care. Due to financial, language, cultural, and other types of barriers that immigrant families sometimes face, the children may not receive the necessary preventive care or receive care for minor conditions until the conditions become more serious. Stresses experienced by immigrant children and their families, such as those associated with relocation, separation, and traumatic events, also can have a negative impact on their psychological health.

SPIRITUALITY AND RELIGION

Spirituality is a basic human quality involving the belief in something greater than one's self and a faith that affirms life positively. It is a major influence in many people's lives, providing a meaning or purpose to life and a foundation for and a source of love, relationships, and service. Spirituality is considered a universal human phenomenon with an assumption of the wholeness of individuals and their connectedness to a higher being. During life-changing events and crises, such as the birth of a child with a congenital defect or a serious or terminal illness, families often turn to spirituality for hope, comfort, and relief.

The word "religion" is often used interchangeably with spirituality in our society. However, spirituality is a more private and individual belief, whereas **religion** is an organized way of sharing beliefs and practicing worship. Between 85% and 90% of Americans believe in God (Baylor Institute for Studies of Religion, 2006); therefore, spirituality and religion are an important focus when working with children and their families. A person's reaction to health and illness may be affected by these beliefs. In some religions, illness is seen as a punishment for sin or wrongdoing. Other religions view illness as a test of strength (Allender et al., 2010).

Children view spirituality and religion differently at different developmental stages. Typically, children imitate their parents' rituals when they are toddlers and then develop an increasingly sophisticated understanding of their parents' views during the years up to adolescence. Refer to **Chapters 3** through **7** for a discussion on how children of different ages and developmental levels view spirituality and religion.

Families appreciate the recognition of, and respect for, their beliefs. Therefore, identifying the child's and family's religious beliefs and customs is important. Families may adhere to special dietary restrictions, rituals such as baptism or communion, use of amulets or icons, or practices related to dying that can be incorporated into the child's plan of care. Using open-ended questions and observing for the use of religious articles during assessment can provide clues to the family's beliefs and practices. Visits from spiritual leaders may also be noted. **Table 2.5** identifies some of the ways in which tenets of some major religious beliefs may affect children's health.

Recall the Delgado family described at the beginning of the chapter. What, if any, influence might the family's culture and religious beliefs have on Miguel's care?

Take Note!

Never make assumptions about a family's religious or spiritual affiliation. Although they may belong to a particular religion, they may not adhere to all of the beliefs or participate in all aspects of the religion.

Community encompasses a broad range of concepts, from a person's particular neighborhood or group to an individual's nation of residence. The community surrounding a child affects many aspects of his or her health, development, and general welfare. The child's community consists of the family, school, neighborhood, youth organizations, and other peer groups.

The quality of life within the community, positive or negative, has a great influence on a child's ability to achieve developmental tasks and become a functional member of society. The child's school, which is a community by itself, and peer groups are important influences. School programs and community centers can also affect the child's overall health and well-being.

Children need to feel supported by, cared for, and valued by their community. They need to be surrounded by supportive, loving parents; safe schools and neighborhoods; adult mentors and role models; and caring teachers. They need to know what is expected of them and what behaviors are outside the boundaries of the community.

Schools and Other Community Centers

Children today start school at an earlier age, spend more time in child care settings, and are involved in various community centers and activities. By age 3 or 4, many children are in a preschool setting for several hours a day. Some children spend more awake time in school and child care settings than in their family home. Thus, schools and child care settings have become major influences on children.

School also provides a means of socialization. School rules about attendance and authority relationships and the system of sanctions and rewards based on achievement help to teach children behavioral expectations that they will need for future employment and relationships in the adult world. Although the primary role of schools has always been academic education, today schools are performing more health-related functions. Schools play an important role in promoting healthy behaviors and educating children about proper exercise, nutrition, safety, sex, drugs, and mental health.

Academic success is linked to healthy behaviors. Academic success is a good indicator of child well-being and is a predictor of adult health outcomes (Center for Disease Control, Healthy Youth, 2008). Academic failure is linked to health risk behaviors such as substance use, violence, and physical inactivity (Center for Disease Control, Healthy Youth, 2008). School health programs have positive impacts on health outcomes and health risk behaviors along with educational outcomes (Center for Disease Control, Healthy Youth, 2008).

Because in many families both parents need to work, many children are enrolled in child care and afterschool programs. Thus, the socialization process begins earlier and involves a larger percentage of the child's waking hours (Fig. 2.6).

After-school hours are a critical time during which children may participate in risky health behaviors if they are not provided with supervised, structured activity where they can learn and grow. Community centers and after-school programs can provide an opportunity for children to learn new skills, have new experiences, and develop relationships with caring adults in a safe and supportive environment.

TABLE 2.5

SELECTED RELIGIOUS BELIEFS AFFECTING CHILDREN'S HEALTH

| Religion | Beliefs About Health and Illness | Dietary Practices | Beliefs About Birth and Death |
|---------------------|---|---|--|
| Buddhist | <p>Illness from karmic causes (ignorant craving)</p> <p>Illness as an opportunity to develop the soul</p> <p>Ultimate goal of achieving nirvana (state of supreme tranquility, purity, and stability)</p> <p>No restrictions for medications, vaccines, nutritional therapies, or other therapeutic interventions</p> | <p>Moderation in diet encouraged</p> <p>Some sects vegetarian; some branches have strict dietary regulations while others do not; therefore, important to inquire about child's preferences</p> | <p>No baptism</p> <p>Last rite chanting at bedside soon after death</p> <p>If there is hope for recovery and continuing the pursuit of enlightenment all means of intervention are encouraged</p> <p>Organ donation acceptable</p> <p>Cremation common</p> |
| Christian Scientist | <p>Disease viewed as error of human mind that can be dispelled by spiritual truth</p> <p>Health viewed within a spiritual framework; healing through prayer and spiritual regeneration</p> <p>Possible contact of own healing ministry (Christian Science practitioners) if child is hospitalized</p> <p>General opposition to human interventions with drugs or other therapies except for legally required immunizations</p> <p>Usually do not use blood or blood components, seek transplants or act as donors, or seek biopsies or physical examination</p> | <p>No special requirements or restrictions</p> | <p>No baptism or last rites</p> <p>Unlikely to seek medical means to prolong life; use of prayer for recovery</p> <p>Disposal of body in death left to family to decide</p> |
| Hindu | <p>Illness due to sins committed in previous life</p> <p>Acceptance of most medical practice/care</p> <p>Nonviolent approach to life</p> | <p>Meat consumption forbidden</p> <p>Some are strict vegetarians</p> | <p>No baptism</p> <p>View of death as a step in an ongoing cycle to reach nirvana</p> <p>Certain prescribed rites after death, such as washing the body by family and restrictions on who touches the body</p> <p>Cremation common</p> |
| Islam | <p>Belief that God cures but will accept treatment</p> <p>Compulsory prayers at dawn, noon, afternoon, after sunset, and after nightfall</p> | <p>Ingestion of pork and pork products and alcohol forbidden</p> <p>Fasting (by boys at age 7, girls at age 9, and adults) required during Ramadan (ninth month of Islamic year)</p> | <p>No baptism</p> <p>Special party (<i>Aqeeqa</i>) to celebrate birth</p> <p>Specific burial rituals (rinsing and washing, wrapping, special prayers, and burial)</p> |

| Religion | Beliefs About Health and Illness | Dietary Practices | Beliefs About Birth and Death |
|--|--|--|---|
| Judaism (orthodox and conservative) | Illness as possible reason for violating some dietary restrictions No treatments or procedures on Sabbath or holy days | Ingestion of blood (such as raw meat) prohibited Kosher dietary laws; highly individualized observance Abstinence from ingestion of pork and predatory fowl and no mixing of milk dishes with meat dishes; ingestion of only fish with fins and scales; no shellfish (strict followers) Fasting during Yom Kippur, and matzo replaces leavened bread during Passover week | No baptism Ritual circumcision of male infants on eighth day of life Ritual of washing body after death; family and close friends remain with the deceased for a period of time No cremation |
| Mormon (Church of Jesus Christ of Latter-Day Saints) | Belief in divine health via laying on of hands Medical therapy not prohibited Common use of herbal folk remedies | Ingestion of tea, coffee, and alcohol and use of tobacco prohibited Fasting (no food or drink including water) once a month for 24 hours on a designated day; exceptions made (pregnant women, very young or old, and ill) | No baptism; infant blessed by church official after the birth Death believed to be another step in eternal progression Cremation discouraged, but not forbidden |
| Roman Catholic | Care of sick encouraged Misuse of any substance considered harmful to the body and a sin Eucharist as the food of healing and health | Moderation in diet encouraged Fasting and abstinence from meat and meat products on Ash Wednesday and Good Friday Abstinence on Fridays during Lent, but exceptions made if ill | Infant baptism Sacrament of the sick if prognosis poor while child is alive; anointing of the sick Burial and treatment of the body with respect and honor Cremation acceptable in certain circumstances |

FIGURE 2.6 Day care centers can provide socialization and support for young children.

Peer Groups

A child's friends can have a major influence, positive or negative, on his or her growth and development. Peer group relationships

often begin early and are a large part of the child's world, particularly with school-age children and adolescents. This influence starts in play-groups in preschool or elementary school. The child is confronted with a variety of values and belief systems from interactions with his or her friends. To be accepted, the child must conform to the specific values and beliefs of the group. When these values and beliefs differ from those of the adults in the child's world, conflicts can occur, possibly separating children from the adults and strengthening their sense of belonging to the peer group.

When the child's friends are successful in school or other activities, the growth and development of the child continues in a healthy and positive way. When these groups demonstrate healthy behaviors, the influence is very positive, but peer groups can also exert negative influences on the child. Thus, it is vital to identify the important peer groups in a child's life and the positive or negative behaviors connected with these groups.

Connectedness in Neighborhoods and Communities

Social capital refers to the bonds between individuals that assist communities to achieve a variety of goals, including goals directed at improving children's health. It requires norms of reciprocity, mutual assistance, and trust (Putnam & Feldstein, 2003). It is a mechanism by which the resources of a community can be mobilized by and from the people, not for them (Looman & Lindeke, 2005). Common interests and relationships propel neighborhoods and communities toward engagement. One example is the Neighborhood Watch Program, in which a community invests in the safety of the whole neighborhood by bonding together and sending a message to potential intruders that community members look out for one another (Looman & Lindeke, 2005).

Evidence suggests that the degree of connectedness in neighborhoods and communities is associated with positive health outcomes (Baum, 1999). In connected communities, people find it easy to engage in health-promoting behaviors. Looman and Lindeke (2005) believe that a simple question such as, "How is your relationship with your neighbors?" can help the nurse to understand the child's social milieu. They suggest three areas to include in nursing interventions and strategies:

- Bringing families together in communities to set the stage for networking
- Disseminating knowledge about what helps create healthy, supported communities
- Thinking of relationships as investments, with social interactions as the processes by which resources for health are exchanged (Looman & Lindeke, 2005)

Violence in the Community

Youth violence affects the community as well as the child and family. Studies have shown that youth violence is associated with a disruption in social services, an increase in health care costs, and a decline in property values (Centers for Disease Control and Prevention [CDC], 2010a). Although the new century has shown an overall decline in violence by and against children, youth violence is still an important public health problem (Finkelhor, Turner, Ormrod, & Hamby, 2010).

Violent Crimes

Violent crimes include murder, rape, robbery, and aggravated assault. Statistics from the CDC (2010b) show that for people ages 10 to 24 years:

- Approximately 5,764 individuals were murdered in 2007; of those deaths, firearms accounted for 84%.
- More than 656,000 individuals were treated in emergency departments for injuries due to violence in 2008.
- Homicide remained the leading cause of death for African Americans, the second-leading cause of death for Hispanics, and the third-leading cause of death for American Indians, Alaska Natives, and Asian/Pacific Islanders.

Suicide

Suicide is a serious public health problem affecting young people today. Suicide is the third-leading cause of death in people ages 10 to 24 years, with 46% due to firearms, 39% due to suffocations, and 8% due to poisoning (CDC, 2008, 2009). Of these reported suicides, boys (83%) were much more likely than girls (17%) to die from suicide (CDC, 2008).

In 2007, a nationwide survey of students in grades 9 to 12 in public and private schools found that 15% reported seriously considering suicide in the previous 12 months (CDC, 2009).

Take Note!

Cultural variations in youth suicide rates are present; Native American/Alaskan Natives and Hispanic youths have the highest rate of suicide (CDC, 2009).

School Violence

In recent years, due to several high-profile cases of school shootings, much attention has been directed at school violence and concern for student safety has increased. However, statistically, over the past decade there has been a decline in school violence and schools in the United States have become even safer. Students are much less likely to be victims of crime at school than away, but some schools continue to have serious crime and violence problems (CDC, 2011). The CDC conducted a nationwide survey of high school students about risk behavior and found that in 2007, approximately 3.8% of the students reported that they had been involved in a physical altercation at least once in the previous year, while 1% reported a physical fight on school property (CDC, 2010a). The percentage of youths who reported carrying a weapon (gun, knife, or club) for at least one of the days in the month prior to the survey was 5.6%, while 7.7% reported being injured or threatened by a weapon on school grounds (CDC, 2010a).

Much of school violence involves bullying, which is repeated negative actions that are clearly malicious and unwarranted by one or more persons directed at a victim. It has been estimated that 20% of students between 9th and 10th grade in the United States are a target of bullying (CDC, 2010b). Many cases of bullying go unreported, but bullying can have long-lasting traumatic effects, such as depression, low self-esteem, and anxiety (McGuinness, 2007). School nurses need to be aware of bullying and offer support and guidance, and intervention when necessary, to the students and staff.

Safe schools are essential for proper learning, growth and development, development of healthy relationships, and overall health of children. Violence in schools has a negative effect not only on students but also on the school and the entire community. The continued coordination among schools, law enforcement, social services, and mental health systems and the development of effective programs will help to reduce these risk behaviors.

Violence in the Home

Violence that occurs in the home, known as domestic violence, affects the lives of many people in America, including children. Domestic violence includes intimate partner violence, which are crimes committed by current or former spouses, boyfriends, or girlfriends, including in same-sex relationships, as well as violence between family members. The rate of domestic violence has declined over the past decade but still accounts for 9% of all violent crime (National Center for Victims of Crime, 2008). Women are more likely than men to be victims of these types of crimes. This violence is also known as intimate partner abuse, family violence, wife beating, battering, marital abuse, and partner abuse.

Children often witness family violence, and they may be physically, sexually, or emotionally abused themselves (Holt, Buckley, & Whelan, 2008). The Federal Child Abuse Prevention and Treatment Act (CAPTA) defines child abuse and neglect as any recent act or failure to act on the part of a parent or caretaker that results in death, serious physical or emotional harm, or sexual abuse or exploitation, or an act or failure to act that presents an imminent risk of serious harm to a child (Child Welfare Information Gateway, 2007). In 2008, approximately 772,000 cases of child maltreatment occurred in the United States (CDC, 2010c). Of the number of children identified as being maltreated, 71% were victims of neglect, 16% were victims of physical abuse, 9% were victims of sexual abuse, and 7% were victims of emotional or psychological abuse (CDC, 2010c). Approximately 1,740 children died from abuse and neglect in 2008; 80% of those children were younger than 4 years of age (CDC, 2010c).

Take Note!

African American, American Indian, or Alaska Native children have higher rates of abuse and neglect (CDC, 2010c).

Children who are exposed to stressors such as domestic violence or who are victims of childhood abuse or neglect are at high risk for short- and long-term problems. These problems manifest differently based on the child's age and developmental ability; the younger the child and the longer the exposure, the more serious the problems seen. Short-term problems include sleep disturbances, headaches, stomachaches, depression, asthma, enuresis, aggressive behaviors such as increased peer aggression and bullying, decreased social competencies, withdrawal, avoidant attachment, developmental regression, fears, anxiety, and learning problems. Long-term problems may include poor school performance, truancy, absenteeism, and difficulty with adult relationships and tasks. There is a strong correlation between the number of exposures to adverse events and negative behaviors such as early initiation of smoking, sexual activity, and illicit drug use; adolescent pregnancies; and suicide attempts (CDC, 2010c).

Take Note!

Witnessing and being exposed to violence in childhood results in a higher tolerance, and greater use, of violence as an adult (Children's Defense Fund-Ohio, 2009).

Due to the potential impact of violence on children and families, it is important to perform a thorough assessment to identify

violence in the family (Box 2.2). Providing referrals to shelters and child advocacy centers and intervening to assist children in dealing with this issue are key.

Not all children exposed to violence suffer negative consequences. Children have resilience, and preliminary studies have identified protective factors that can help

BOX 2.2

ASSESSING FOR VIOLENCE

Questions for the Parent

- Do you ever feel afraid in your home?
- What happens when you and ___ (partner's name) argue?
- Do arguments ever become physical (hitting, kicking, pushing, throwing, or punching/breaking objects)?
- Have you ever been threatened with a weapon (gun, knife, other)?
- Have you ever felt trapped or like a prisoner in your own home? Does your partner ever lock you in/out of the house or take your car keys?
- Have your children ever seen or heard violence in the home?
- Have the police ever been involved due to violence in your home?
- Is the violence ever directed at the children? Does ___ (partner's name) ever hit, kick, push, or yell at your child when he/she is angry?
- How do you and ___ (partner's name) discipline the children?

Questions for the Child

- What happens when Mommy and Daddy (or appropriate partner names) argue/fight? Is there any hitting, pushing, etc.?
- How do you feel when Mommy and Daddy (or appropriate partner names) fight?
- What happens to you when you get in trouble?

If hitting or other physical forms of discipline occur, ask the following:

- What are you hit with? Where on your body? Does it ever leave a mark/bruise?
- Who hits/kicks you? How often does it happen? buffer children from the effects of violence and reduce the risk that the child will develop violent behaviors (Holt et al., 2008). Examples of protective factors include:

- Feelings of connectedness or a secure attachment to a nonviolent parent or caregiver
- Strong commitment to school and academic performance
- Involvement in social activities
- Social and community support
- Positive sibling and peer relationships
- Ability to discuss problems with parents or a supportive adult
- Consistent presence of a parent at least once during the day, such as in the morning on awakening, when getting home from school, at dinnertime, or when going to bed

Thus, interventions need to focus on reducing children's exposure to violence and fostering protective factors.

SOCIETY

Society has a major impact on the health of a child. Major components of a society that influence children and their health include social roles, socioeconomic status, the media, and the expanding global nature of society. Each of these areas may influence children's self-concept, the communities they live in, their choice of lifestyle, and their health. Pediatric nurses need to assess these areas and their influence on the child and family so that individualized strategies can be designed and implemented to enhance the positive effects and minimize the negative effects on the child's and family's health.

Social Roles

Society often dictates that specific people behave in specific ways: certain behaviors are permitted and others are prohibited. These patterns are identified as social roles and can be an important factor in the development of self-concept, and a person's self-concept can have a very positive or a very negative influence on his or her health.

For children, social roles influence their ideas about themselves. [Box 2.3](#) lists some typical roles children have in our society. These social roles are generally carried out in groups, such as the family, school, peers, or church or community organizations. At times there may be a conflict in how the different groups expect a child to behave. There also may be conflict for parents related to childrearing practices. For example, the child's family may believe in creationism, while the school the child attends is teaching evolution. Thus, the child may feel confused as he or she tries to practice the behaviors expected by the different groups.

BOX 2.3

EXAMPLES OF SOCIAL ROLES FOR CHILDREN

- Daughter or son
- Brother or sister
- Granddaughter or grandson
- School or day care roles, such as first-grader, honor student
- Ethnic community member
- Church roles, such as acolyte, altar server
- Specialized roles such as developing musician, artist, or athlete

Socioeconomic Status

An even more important influence on children is the family's socioeconomic status (relative position in society), which takes into account the family's economic, occupational, and educational levels. Children are raised differently by parents of different educational levels, occupations, and incomes. Despite advances and improvements in quality and access to health care, discrepancies in health status between socioeconomic classes have continued (National Institute for Health Care Management [NIHCM], 2007). Income inequality is an important factor in explaining this variation. Lowerclass parents may need to work long hours to provide basic necessities and have little time or money to enrich the child's life or make healthy lifestyle choices. However, lower-class families may have stronger family relationships if they need to rely on a family network to meet some of their physical and emotional needs. Lifestyle characteristics, such as cultural norms for health behaviors, may help buffer some lower-class children from health problems (Chen, Martin, & Matthews, 2006).

Low socioeconomic status can have an adverse influence on children's health. Some families may not be able to afford health insurance or health care. Meals may be unbalanced or irregular. The family's house or apartment may be overcrowded and may have poor sanitation or lead paint. These families may not understand the importance of preventive care or may not be able to afford it, and as a result the children may be inadequately immunized against communicable diseases. Studies have documented that children who come from low socioeconomic status are more likely to suffer from acute and chronic conditions and experience more limitations from these, as well as injuries and mental health conditions (Currie & Lin, 2007).

Poverty

Basic financial stability enhances the general health and well-being of children, and thus an important negative influence on children's health is poverty. Children living in poverty are more likely to have poor health, be retained in a grade or drop out of school, become teen parents, experience violent crimes, and become poor adults (Stanton & Behrman, 2007). They have greater rates of death and

illness from almost all causes, except suicide and motor vehicle accidents (Stanton & Behrman, 2007).

The poverty threshold is based on the family's size and income and is used to determine whether a family is living in poverty (Table 2.6). According to the U.S. Census Bureau in 2007, approximately 12.5% of individuals and 9.8% of families were living below the poverty level (Denavas-Walt, Proctor, & Smith, 2008). Overall, 18% of children younger than age 18 years were living in poverty (Denavas-Walt et al., 2008). Over the past decade the number and rate of children living in poverty have risen. According to the Children's Defense Fund (2008), 1 in 6, or 13.3 million, American children lives in poverty, with 1 in 13, or 5.8 million, living in extreme poverty. The rate of poverty is closely tied to the overall health of the economy; therefore, in times of recession, a rise is usually seen.

| Size of Family Unit | 48 Contiguous States and D.C. | Alaska | Hawaii |
|---------------------|-------------------------------|----------|----------|
| 1 | \$10,400 | \$13,000 | \$11,960 |
| 2 | \$14,000 | \$17,500 | \$16,100 |
| 3 | \$17,600 | \$22,000 | \$20,240 |
| 4 | \$21,200 | \$26,500 | \$24,380 |
| 5 | \$24,800 | \$31,000 | \$28,520 |

SOURCE: Federal Register, Vol. 73, No. 15, January 23, 2008, pp. 3971–3972.

Family structure is an important factor associated with poverty rates for children. The poverty rate for married-couple families is much less than that for families headed by a single parent. Of the families living below poverty level, 28.3% were single-mother families with no husband present, 13% were single-father families with no wife present, and only 4.9% were married couples (Denavas-Walt et al., 2008). Educational level is another important factor: as education increases, unemployment declines and annual income rises. However, a chronic physical or emotional problem in any wage earner may lead to unemployment, and this can cause the family to spiral downward into poverty.

The effects of poverty on children's health can be wide-ranging. The family may be able to afford only substandard housing or a house or an apartment in a dangerous neighborhood (e.g., unsanitary conditions, toxins, violence). Poverty may also lead to homelessness.

Homelessness

According to the National Law Center on Homelessness and Poverty, approximately 1.35 million children are likely to experience homelessness in a given year (National Coalition for the Homeless, 2008a). Families with children represent 23% of the homeless population, with half of these being children younger than 5 years of age (National Coalition for the Homeless, 2008b). It is impossible to measure homelessness with 100% accuracy. Therefore, looking at trends is important to demonstrate whether or not progress is being made. Recent research suggests that homelessness among families is increasing (National Coalition for the Homeless, 2008b). The typical homeless family is headed by a single mother in her late 20s with two children, one or both younger than age 6, and ethnic minorities are at the greatest risk (Rog & Buckner, 2007).

Homelessness occurs not only in large urban areas but also in midsize cities as well as suburban and rural areas. The principal causes of homelessness in families are poverty and lack of affordable housing. Other causes include cutbacks in public welfare programs, mental health issues, and traumatic events such as unemployment, illness, or accidents and personal crises such as divorce, domestic violence, or substance abuse. Children may be forced out of their houses or choose to run away and become homeless because they have been abused or neglected, lived in foster homes, or were placed in residential treatment or juvenile detention centers.

In homeless children, the basic need for a stable shelter goes unmet. Homelessness is not conducive to appropriate growth and development in children. Homeless children are more likely to suffer behavioral and emotional problems, be diagnosed with a mental illness, be victims of physical and sexual abuse, and suffer educational disabilities. They also have a higher incidence of acute and chronic health problems, such as an increased rate of asthma, ear infections, gastrointestinal disorders such as diarrhea, and speech

problems, and increased mental health problems, such as anxiety, depression, and withdrawal. They may be exposed to environmental hazards in homeless shelters or overcrowded housing, or, if they live on the street, there may be exposure to the elements, lack of sanitary facilities, and an increased risk of injuries. An unbalanced diet may place homeless children at risk for nutritional deficits, which can lead to delayed growth and development. Homeless teens often engage in risky behaviors such as drug use or unprotected sex with multiple partners, so they are more likely to need emergency care, be depressed, and become pregnant (American Academy of Pediatrics, 2005). They may also become teen parents, continuing the cycle of financial instability and homelessness.

Homeless children may have limited access to health care services, especially preventive care such as immunizations, dental care, and well-child services. Lack of immunizations can lead to delayed enrollment in school, and education is vital for these children to help break the cycle of homelessness. When the families do have money, often they need it for food and shelter instead of health care. If they do seek health care, it is usually in an emergency department or a free clinic and such sporadic care is not conducive to the ongoing health needs of a growing child. The family may not follow through with care because they cannot afford it, lack health insurance, or do not have transportation to the clinic or pharmacy.

Some of these children do not go to school or go to various schools because the family moves from place to place. The stress experienced by the family provides an environment that is not conducive to learning. As a result, children present with learning problems, socialization issues, or other behavioral issues.

Media

Today's children are inundated with various forms of media, such as television, video and computer games, iPods, the Internet, movies, magazines, books, and newspapers (Fig 2.7). Media has both positive and negative effects on the development of children and much depends on the content to which they are exposed (Wilson, 2008). Some of the images and information are not always in the best interests of children. Children may identify with, and mimic, characters who engage in risk-taking behaviors or lifestyles. Health risk behaviors, such as excessive caloric intake, physical inactivity, smoking, underage drinking, and violent behavior, have been linked to media exposure (Escobar-Chaves & Anderson, 2008). Research has established a very strong link between media violence and violent, aggressive behavior (Escobar-Chaves & Anderson, 2008). If an image or type of behavior is portrayed as the norm, children may view this as acceptable behavior without examining the potential health risks or other long-term consequences. For example, thinness is portrayed as the body type that is identified with beauty, leading some children to develop unhealthy dieting or other behaviors to develop that body type. For the child who has a body type that does not fit the ideal, depression or self-esteem issues may develop.

FIGURE 2.7 Computer games can be fun and educational, but the child should be monitored while using the computer or other forms of media to minimize negative effects.

Overall, the images children view every day will affect their behavior and possibly their health, and pediatric nurses should take this into account when working with children and their families.

The media's influence relates not only to the content but also to the total viewing time. For example, excessive TV viewing has been linked to obesity, poor cognitive skills, and irregular sleep patterns. Overuse of computer or video games may lead to poor school performance. The media can be a positive influence, such as when it offers educational programming or public service messages on the negative effects of substance abuse, smoking, or gang involvement. Also, public broadcasting networks offer valuable programming.

Take Note!

The American Academy of Pediatrics discourages any screen media before the age of 2 (American Academy of Pediatrics, 2001).

Widespread access to the Internet has fostered a connection to other areas of the world that would not have been possible in previous years. Children are no longer limited to their immediate surroundings, and they have access to a wealth of information. The Internet can be a valuable resource for parents and children to access information, learn new things, and communicate with friends and family. However, online threats exist that can affect the child's health and safety, such as sexual predators, pornography, violence, and racism. Parents need to be alert to these hazards and set up safety guidelines (see [Teaching Guidelines 2.2](#)).

Teaching Guidelines 2.2

TEACHING TO PROMOTE SAFE INTERNET USE

- Determine a time limit that your child can spend online each day or week and maintain consistency in enforcing this time limit.
- Ensure that use of the Internet does not replace or interfere with homework, friends, or household or school activities.
- Tell your child NEVER to share personal information with anyone online unless you are sure of the person and the child has your permission to do so.
- Urge your child NEVER to share his or her password with anyone, even friends.
- Review Internet sites with your child, and explain which sites are appropriate. Use the safety and parental controls offered by your Internet service provider.
- Avoid placing the computer in the child's room. Rather, place the computer in a public area of your home, such as the den or kitchen, so that you can monitor your child's use.
- Discuss with your child the need for safety while using the Internet. Explain potential hazards in terms the child can understand.
- Advise your child to immediately close any sites or stop any communication that makes him or her confused or uncomfortable. Tell your child NEVER to arrange any face-to-face meetings with persons met online. Urge your child to tell you if he or she encounters such a situation.
- Teach the child NEVER to open e-mail from any unknown senders.
- Be aware of computer use policies in your child's school.

Global Society

The world is connected in many ways today: people travel from one nation to another easily, new products and immigrants arrive each day, and the Internet makes worldwide communication simple. The United Nations Children's Fund and the WHO lead the world in dealing with the issues for the children of the world. Every year 10 million children die around the world, over 26,500 every day (Shah, 2008). Hundreds of thousands of children born in developing countries are moving to more developed nations such as the United States as refugees, immigrants, or international adoptees. These children become part of this nation.

Pediatric nurses need to be aware of the impact of worldwide events on children. The population explosion and health problems in developing nations and natural and man-made disasters around the world affect the United States and the world in terms of productivity, economics, and politics (WHO, 2004). Children can be displaced by events such as hurricanes or wars, placing them at increased risk for problems such as infectious diseases, malnutrition, and psychological trauma.

According to the United Nations Children's Fund (UNICEF, 2008), young children bear the brunt of the global burden of disease. These organizations have identified major problems affecting child growth and development and survival:

- Malnutrition, including micronutrient deficiency
- HIV/AIDS
- Acute respiratory infections, such as pneumonia

- Diarrhea related to lack of clean water and sanitation
- Vaccine-preventable diseases such as measles
- Malaria
- Poor health care of pregnant and nursing mothers (UNICEF, 2008)

These organizations work to propose ways to eradicate these conditions by improving the case management skills of providers with adapted guidelines; improving the health systems with good district health planning and management as well as appropriate supplies, medications, information systems, and referral systems; and improving the family and community practices (WHO, 2011).

Today, society as a whole, families, and children have concerns over world threats and safety. Disasters such as the terrorist attacks of Sept. 11, 2001, and the killings at Columbine High School, and devastating weather events such as Hurricane Katrina can have a significant impact on the well-being of children. The increase in stressors such as war, terrorism, school violence, and natural disasters puts children at risk for experiencing mental health difficulties. Children who have experienced these events are at risk for issues such as posttraumatic stress disorder, behavioral problems, depression, anxiety, sleep disturbances, physiologic responses such as gastrointestinal symptoms, changes in academic performance, and safety and security concerns (American Psychological Association Online Public Policy Office, 2008). Children's coping abilities may be reduced and alterations in growth and development may be seen. Children's reactions depend on age and developmental level and are highly influenced by the emotional state of their caregivers. Pediatric nurses must be aware of the effects of world threats on children so that they can assess for alterations and intervene to promote security and stability.

KEY CONCEPTS

- The child's gender and race; the child's biological traits, including some behavioral traits or aspects of temperament; and certain diseases or illnesses are directly linked to genetic inheritance.
- The way a child experiences a particular event will be influenced by his or her temperament, and the child's temperament will influence the responses of others, including the parents, to the child.
- Developmental level has a major impact on the health status of children. Generally, the distribution of diseases varies with age.
- Adequate nutrition can provide a rich environment for the developing child; conversely, nutritional deprivation can seriously interfere with brain development and other functions.
- Lifestyle choices that can affect a child's health include patterns of eating; exercise; use of tobacco, drugs, or alcohol; and methods of coping with stress. With advances in medicine, most chronic health problems today arise due to a person's lifestyle. In the case of children, the lifestyle of the parents basically is the lifestyle of the child.
- Environmental exposures can have a detrimental impact on the child.
- The term **resilience** refers to the qualities that enable an individual to cope with significant adverse events or stresses and still function competently (Lietz, 2007).
- Internal factors that promote resiliency include the person's ability to take control and be proactive, to be responsible for his or her own decisions, to understand and accept his or her own limits and abilities, and to be goal directed, knowing when to continue or when to stop.
- External factors that promote resiliency include caring relationships with a family member; a positive, safe learning environment at school (including clubs and social organizations); and positive influences in the community.
- Access to health care is affected negatively by lack of health insurance.
- Medicaid and the Children's Health Insurance Program (CHIP) are both public programs available to provide health insurance to low-income children and their parents.
- Even with the public programs available to assist children and families, barriers to appropriate, cost-effective, coordinated, and timely health care remain. Barriers can be financial, sociocultural, or ethnic, or part of the health care system itself.
- The family is considered the basic social unit. The family into which a child is born will greatly influence his or her development and health. Children learn health care activities, health beliefs, and health values from their family.
- Typical family roles include nurturer, provider, decision maker, financial manager, problem solver, health manager, and gatekeeper.
- Four major parenting styles are seen: authoritarian; authoritative; permissive; and uninvolved, rejecting, or neglecting. Each represents the amount of support and control exerted over the child by the parent.
- Discipline is a process that has as its goal increasing desirable behavior and decreasing or eliminating undesirable behavior. Punishment involves a negative or unpleasant experience or consequence for doing or not doing something.

- Culture plays a critical role in shaping a child, including his or her health and health practices.
- With today's changing demographic patterns, nurses must be able to incorporate cultural knowledge into their interventions so that they can care effectively for culturally diverse children.
- Ethnicity involves group membership by virtue of common ancestry. The basic groups are differentiated by their customs, characteristics, language, or similar distinguishing factors. Ethnic groups have their own family structures, languages, food preferences, moral codes, and health care practices.
- Spirituality, a major influence for many individuals, provides a meaning and purpose to life and is a foundation for and a source of love, relationships, and service. Spiritual and religious beliefs and views can provide strength and support to children and families during times of stress and illness. Religion also can determine the way in which a family interprets and responds to illness; for example, some religions view illness as a punishment for wrongdoing or as a test of strength.
- The community surrounding a child affects many aspects of his or her health, development, and general welfare. The child's community consists of the family, school, neighborhood, youth organizations, and other peer groups.
- Some children spend more awake time in school and child care settings than in their family home.
- A child's friends can have a major influence, positive or negative, on his or her growth and development.
- Suicide is a serious public health problem affecting young people today.
- Youth violence affects both the family and the community in terms of disrupted social services, increased health care costs, and decreased property values.
- Children may witness violent acts in the school, home, or community. They also may be victims of violence. However, not all children exposed to violence suffer negative consequences. In addition to resiliency, certain protective factors can help buffer them from the effects of violence, helping to reduce the risk that they too will develop violent behaviors.
- Basic financial stability enhances the general health and well-being of children, and thus an important negative influence on children's health is poverty. Children living in poverty are more likely to have poor health, be retained in a grade or drop out of school, become teen parents, experience violent crimes, and become poor adults.
- Children who are homeless are exposed to an environment that is not conducive to growth and development. Children who are homeless commonly have physical health problems such as upper respiratory, ear, and skin infections; gastrointestinal disorders; and infestations.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The parents of two school-age children state that they expect their children to adhere to their rules without question and that they

make all the decisions. Which type of parenting style does this reflect?

- a. Authoritarian
- b. Democratic
- c. Authoritative
- d. Permissive

2. A single mother asks the nurse for suggestions on disciplining her 2-year-old son. Which suggestion would be most appropriate?
 - a. Encourage the mother to emphasize the inappropriate behavior.
 - b. Wait an hour or so before enforcing the discipline.
 - c. Have the child spend 2 minutes in time-out.
 - d. Withhold a privilege from the toddler for a week.
3. The nurse is teaching a group of students about the possible effects of immigration on the health status of children. Which response by the group would indicate the need for additional teaching?
 - a. The children of immigrants have better access to preventive care.
 - b. The children of immigrants have limited involvement in activities due to the language barrier.
 - c. The children of immigrants lack adequate support systems.
 - d. The children of immigrants face increased stressors due to relocation.
4. Which would the nurse identify as a protective factor for youth violence?
 - a. Exposure to family violence
 - b. Limited involvement in social activities
 - c. Inconsistency of parental support
 - d. Commitment to academic performance
5. In an effort to control health care costs, what is the best recommendation by the nurse?
 - a. "Shop around to find the most inexpensive health insurance plan."
 - b. "Find a job that provides family health insurance at a minimal cost."
 - c. "Stress primary prevention, using the health care system for check-ups."
 - d. "Avoid seeing a physician until your child becomes ill."

CRITICAL THINKING EXERCISES

1. A couple has adopted an 11-month-old infant girl from China and has brought her to the health care facility for a check-up. The couple had no contact with the infant's birth parents. The infant spent 7 months in an orphanage before being adopted. Describe the issues that may affect this family.
2. Vanessa Walters brings her 3-year-old son, Tyler, for a well-child visit. Vanessa states, "Tyler is a handful. He always seems to be misbehaving. I just don't know what to do." How should the nurse respond, and what suggestions might be helpful?
3. You've been asked by the local school district to speak to a group of middle school students about Internet safety. Describe the topics that you should address.

STUDY ACTIVITIES

1. Discuss with fellow students the different types of family structures. Include information about your own family structure. Compare and contrast the roles assumed by each member in the different structures.
2. Create a culture diary or journal for use in clinical practice. Record observations made while caring for children and families of other cultures or ethnicities. Address the preferences that the children and families had relating to food, health care, decision making for the family, view of children, and general health practices.
3. Perform a "spiritual inventory" on yourself. Identify your beliefs about higher authority, life after death, purpose in life, and the value of others who have different beliefs.
4. Search the Internet for sites giving information about violence and its impact on children's health.
5. The nurse is preparing a class for a group of students about homeless children and families. Which of the following factors contribute to homelessness? Select all that apply.
 - a. Increase in family income

- b. Job loss
- c. Exposure to abuse or neglect
- d. Cutbacks in public welfare programs
- e. Development of community crisis centers

Health Promotion of the Growing Child and Family

Growth and Development of the Newborn and Infant

Words of Wisdom Of all the joys that lighten our hearts, what joy is welcomed like a newborn child?

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify normal developmental changes occurring in the newborn and infant.
2. Identify the gross and fine motor milestones of the newborn and infant.
3. Express an understanding of language development in the first year of life.
4. Describe nutritional requirements of the newborn and infant.

5. Develop a nutritional plan for the first year of life.
6. Identify common issues related to growth and development in infancy.
7. Demonstrate knowledge of appropriate anticipatory guidance for common developmental issues.

Allison Johnson is a 6-month-old girl brought to the clinic by her mother and father for her 6-month check-up. As new parents, they have a list of questions and concerns. On assessment you find that Allison's weight is 16 pounds, length 25 3/4 inches, and head circumference 17 inches. As the nurse caring for her, assess Allison's growth and development, and then teach the parents what changes to expect in Allison over the next few months.

The newborn or neonatal period of infancy is defined as the period from birth until 28 days of age. Infancy is defined as the period from birth to 12 months of age. Growth and development are interrelated, ongoing processes in infancy and childhood. **Growth** refers to an increase in physical size. **Development** is the sequential process by which infants and children gain various skills and functions. Heredity influences growth and development by determining the child's potential, while environment contributes to the degree of achievement. **Maturation** refers to an increase in functionality of various body systems or developmental skills.

Growth and developmental changes in the first year of life are numerous and dramatic. Physical growth, maturation of body systems, and gross and fine motor skills progress in an orderly and sequential fashion. Though timing may vary from infant to infant, the order in which developmental skills are acquired is consistent. Infants also exhibit vast amounts of learning in the psychosocial and cognitive, language and communication, and social/emotional domains. Adequate growth and development are indicative of health in the infant or young child. Nurses must be familiar with normal developmental milestones so that they can accurately assess the infant's development as well as provide age-appropriate anticipatory guidance to the parents.

Achievement of developmental milestones may be assessed in a variety of ways. While obtaining the health history, the nurse may ask the parent or caregiver if the skill is present and when it was attained. The infant may also demonstrate the skill during the interview or examination, or the nurse may elicit the skill from the infant. A number of screening tools are also used to assess development, such as the Denver II Developmental Screening Test (see [Appendix B](#)), Prescreening Developmental Questionnaire (PDQ II), Ages and Stages Questionnaire (ASQ), Infant Toddler Checklist for Language and Communication, and Infant Development Inventory.

Ill or premature infants may exhibit delayed acquisition of physical growth and developmental skills. When assessing the growth and development of a premature infant, use the infant's adjusted age to determine expected outcomes. To determine adjusted age, subtract the number of weeks that the infant was premature from the infant's chronological age. Plot growth parameters and assess developmental milestones based on adjusted age. For example, a 6-month-old boy who was born at 28 weeks' gestation was born 12 weeks early (3 months), so subtract 3 months from his chronological age of 6 months to obtain an adjusted age of 3 months. This infant would demonstrate healthy growth if he were the size of a 3-month-old, and he should be expected to achieve the developmental milestones of a 3-month-old rather than a 6-month-old.

Physical Growth

Ongoing assessments of growth are important so that too-rapid or inadequate growth can be identified early. With early identification, the cause can be diagnosed and the potential for further appropriate growth maximized. Infants grow very rapidly over the first 12 months of life. Weight, length, and head and chest circumference are all indicators of physical growth in the newborn and infant ([Table 3.1](#)).

Weight

The average newborn weighs 7 lb 8 oz (3,400 g) at birth. Newborns lose up to 10% of their body weight over the first 5 days of life. The average newborn then gains about 20 to 30 g per day and regains his or her birthweight by 10 to 14 days of age. Most infants double their birthweight by 4 to 6 months of age and triple their birthweight by the time they are 1 year old (Hagan, Shaw, & Duncan, 2008).

Height

The average newborn is 19 to 21 inches (48 to 53 cm) long at birth. During the first 6 months, length increases by 1 inch (2.5 cm) per month, then by about a half-inch per month in the second 6 months (Hagan et al., 2008).

| Age | Weight | Length | Head Circumference |
|-----------|------------------|-------------------------|---------------------------|
| Birth | 7.5 lb (3,400 g) | 19–21 in (48–53 cm) | 13–14 in (33–35 cm) |
| 6 months | 16 lb (7.3 kg) | 25–27 in (63.5–68.5 cm) | 16.5–17.5 in (42–44.5 cm) |
| 12 months | 23 lb (10.5 kg) | 28–30 in (71–76 cm) | 17.7–18.7 in (45–47.5 cm) |

Adapted from Hagan, J. F., Shaw, J. S., & Duncan, P. M. (Eds.). (2008). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (3rd ed., rev.). Elk Grove Village, IL: American Academy of Pediatrics.

Head and Chest Circumference

Average head circumference of the full-term newborn is 13 to 14 inches (33 to 35 cm). The head circumference is about 1 inch (2 to

3 cm) greater than the chest circumference, which averages 12 to 13 inches (30.5 to 33 cm). The head circumference increases rapidly during the first 6 months: the average increase is about 0.6 inch (1.5 cm) per month. From 6 to 12 months of age, the head circumference increases an average of 0.2 inch (0.5 cm) monthly. The chest circumference is not routinely measured after the newborn period but does increase in size as the child grows (Hagan et al., 2008).

Organ System Maturation

The newborn and infant's organ systems undergo significant changes as the infant grows. Systems that undergo significant change include the neurologic system, the cardiovascular system, the respiratory system, the gastrointestinal (digestive) system, the renal system, the hematopoietic system, the immunologic system, and the integumentary system.

Neurologic System

The infant experiences tremendous changes in the neurologic system over the first year of life. Critical brain growth and continued myelination of the spinal cord are occurring. Involuntary movement progresses to voluntary control, and immature vocalizations and crying progress to the ability to speak as a result of maturational changes of the neurologic system.

States of Consciousness

The normal term newborn's ability to move sequentially through states of consciousness reassures parents and physicians that the neurologic system, though immature, is intact. A normal newborn will ordinarily move through six states of consciousness:

1. Deep sleep: The infant lies quietly without movement.
2. Light sleep: The infant may move a little while sleeping and may startle to noises.
3. Drowsiness: Eyes may close; the infant may be dozing.
4. Quiet alert state: The infant's eyes are open wide and the body is calm.
5. Active alert state: The infant's face and body move actively.
6. Crying: The infant cries or screams and the body moves in a disorganized fashion (Brazelton & Nugent, 1995, p. 15).

Newborns usually progress through these states slowly, rather than going from deep sleep immediately into outright crying.

Brain Growth

The nervous system continues to mature throughout infancy, and the increase in head circumference is indicative of brain growth. The brain undergoes tremendous growth during the first 2 years of life. By 6 months of age the infant's brain weighs half that of the adult brain. At age 12 months, the brain has grown considerably, weighing 2½ times what it did at birth. Usually, the anterior fontanel remains open until 12 to 18 months of age to accommodate this rapid brain growth. However, the fontanel may close as early as 9 months of age, and this is not of concern in the infant with age-appropriate growth and development.

In general, the neurologic system matures a significant amount over the first year of life. Myelination of the spinal cord and nerves continues over the first 2 years. Maturation of the nervous system and continued myelination are necessary for the tremendous developmental skills that are achieved in the first 12 months. During the first few months of life, reflexive behavior is replaced with purposeful action.

Reflexes

Primitive reflexes are subcortical and involve a whole-body response. Selected primitive reflexes present at birth include Moro, root, suck, asymmetric tonic neck, plantar and palmar grasp, step, and Babinski. Except for the Babinski, which disappears around 1 year of age, these primitive reflexes diminish over the first few months of life, giving way to protective reflexes. Protective reflexes (also termed postural responses or reflexes) are gross motor responses related to maintenance of equilibrium. These responses are prerequisites for appropriate motor development and remain throughout life once they are established. The protective reflexes include the righting and parachute reactions. Appropriate presence and disappearance of primitive reflexes, as well as development of protective reflexes, are indicative of a healthy neurologic system. Persistence of primitive reflexes beyond the usual age of disappearance may indicate an abnormality of the neurologic system and should be investigated.

Table 3.2 gives descriptions and illustrations of several primitive and protective reflexes, as well as the timing of appearance and disappearance of these reflexes.

TABLE 3.2

SELECTED PRIMITIVE AND PROTECTIVE REFLEXES IN INFANCY

| | Description | Age Reflex Appears | Age Reflex Disappears |
|---------------------------|--|--------------------|-----------------------|
| <i>Primitive Reflexes</i> | | | |
| Root | When infant's cheek is stroked, the infant turns to that side, searching with mouth. | Birth | 3 months |
| |  | | |
| Suck | Reflexive sucking when nipple or finger is placed in infant's mouth. | Birth | 2-5 months |
| |  | | |

Moro

With sudden extension of the head, the arms abduct and move upward and the hands form a "C."

Birth

4 months

Asymmetric tonic neck

While lying supine, extremities are extended on the side of the body to which the head is turned and opposite extremities are flexed (also called the "fencing" position).

Birth

4 months

Palmar grasp

Infant reflexively grasps when palm is touched

Birth

4-6 months

Plantar grasp

Infant reflexively grasps with bottom of foot when pressure is applied to plantar surface.

Birth

9 months

| | | | |
|---|---|-------|-----------|
| Birth to 12 months | Stroking along the lateral aspect of the sole and across the plantar surface results in fanning and hyperextension of the toes. | Birth | 12 months |
|  | | | |
| Step | With one foot on a flat surface, the infant puts the other foot down as if to "step." | Birth | 4-8 weeks |
|  | | | |

| <i>Protective Reflexes</i> | | | |
|--|---|-------------|----------|
| Neck righting | Neck keeps head in upright position when body is tilted. | 4-6 months | Persists |
| Parachute (sideways) | Protective extension with the arms when tilted to the side in a supported sitting position | 6 months | Persists |
| Parachute (forward) | Protective extension with the arms when held up in the air and moved forward. The infant reflexively reaches forward to catch himself or herself. | 6-7 months | Persists |
|  | | | |
| Parachute (backward) | Protective extension with the arms when tilted backward | 9-10 months | Persists |

Adapted from Johns Hopkins Hospital, Custer, J. W., Rau, R. E., & Lee, C. K. (2008). *The Harriett Lane handbook* (18th ed.). St. Louis: Mosby.

Respiratory System

The respiratory system continues to mature over the first year of life. The respiratory rate slows from an average of 30 to 60 breaths in the newborn to about 20 to 30 in the 12-month-old. The newborn breathes irregularly, with periodic pauses. As the infant matures, the respiratory pattern becomes more regular and rhythmic.

In comparison with the adult, in the infant:

- The nasal passages are narrower.
- The trachea and chest wall are more compliant.
- The bronchi and bronchioles are shorter and narrower.
- The larynx is more funnel shaped.

- The tongue is larger.
- There are significantly fewer alveoli.

These anatomic differences place the infant at higher risk for respiratory compromise. The respiratory system does not reach adult levels of maturity until about 7 years of age. The lack of immunoglobulin A (IgA) in the mucosal lining of the upper respiratory tract also contributes to the frequent infections that occur in infancy.

Cardiovascular System

The heart doubles in size over the first year of life. As the cardiovascular system matures, the average pulse rate decreases from 120 to 140 in the newborn to about 100 in the 1-year-old. Blood pressure steadily increases over the first 12 months of life, from an average of 60/40 in the newborn to 100/50 in the 12-month-old. The peripheral capillaries are closer to the surface of the skin, thus making the newborn and young infant more susceptible to heat loss. Over the first year of life, thermoregulation (the body's ability to stabilize body temperature) becomes more effective: the peripheral capillaries constrict in response to a cold environment and dilate in response to heat.

Gastrointestinal System

Teeth

Occasionally, an infant is born with one or more teeth (termed natal teeth) or develops teeth in the first 28 days of life (termed neonatal teeth). The presence of natal or neonatal teeth may be associated with other birth anomalies. The vast majority of newborns do not have teeth at birth, nor do they develop them in the first month of life. On average, the first primary teeth begin to erupt between the ages of 6 and 8 months. The primary teeth (also termed deciduous teeth) are lost later in childhood and will be replaced by the permanent teeth. The gums around the emerging tooth often swell. The lower central incisors are usually the first to appear, followed by the upper central incisors (Fig. 3.1). The average 12-month-old has four to eight teeth.

Digestion

The newborn's digestive system is not developed fully. Small amounts of saliva are present for the first 3 months of life and ptyalin is present only in small amounts in the saliva. Gastric digestion occurs as a result of the presence of hydrochloric acid and rennin. The small intestine is about 270 cm long and grows to the adult length over the first few years of life (Wyllie, 2007). The stomach capacity is relatively small at birth, holding about one-half to 1 ounce. However, by 1 year of age the stomach can accommodate three full meals and several snacks per day. In the duodenum, three enzymes in particular are important for digestion. Trypsin is available in sufficient quantities for protein digestion after birth. Amylase (needed for complex carbohydrate digestion) and lipase (essential for appropriate fat digestion) are both deficient in the infant and do not reach adult levels until about 5 months of age.

FIGURE 3.1 Sequence and average age of tooth eruption.

The liver is also immature at birth. The ability to conjugate bilirubin and secrete bile is present after about 2 weeks of age. Conjugation of medications may remain immature over the first year of life. Other functions of the liver, including gluconeogenesis, vitamin storage, and protein metabolism, remain immature during the first year of life.

Stools

The consistency and frequency of stools change over the first year of life. The newborn's first stools (meconium) are the result of digestion of amniotic fluid swallowed in utero. They are dark green to black and sticky (Fig. 3.2). In the first few days of life the stools become yellowish or tan. Generally the formula-fed infant has stools the consistency of peanut butter. Breastfed infants' stools are usually looser in texture and appear seedy. Newborns may have as many as 8 to 10 stools per day or as few as one stool every day or two. After the newborn period, the number of stools may decrease, and some infants do not have a bowel movement for several days. Infrequent stooling is considered normal if the bowel movement remains soft. Due to the immaturity of the gastrointestinal system, newborns and young infants often grunt, strain, or cry while attempting to have a bowel movement. This is not of concern unless the stool is hard and dry. Stool color and texture may change depending on the foods that the infant is ingesting. Iron supplements may cause the stool to appear black or very dark green (National Association of Pediatric Nurse Practitioners [NAPNAP], 2011b).

Take Note!

Parents should call the primary care provider if the infant's stools are red, white, or black; mucuslike; frequent and watery; frothy or foul-smelling; or hard, dry, formed, or pelletlike; or if the baby is vomiting.

FIGURE 3.2 A. Meconium stool. B. Typical stool after the first few days. Note the yellowish, seedy stool of a breastfed infant.

Genitourinary System

In the infant, extracellular fluid (lymph, interstitial fluid, and blood plasma) accounts for about 35% of body weight and intracellular fluid accounts for 40%, compared with the adult quantities of 20% and 40%, respectively (Greenbaum, 2007). Thus, the infant is more susceptible to dehydration. Infants urinate frequently and the urine has a relatively low specific gravity. The renal structures are immature and the glomerular filtration rate, tubular secretion, and reabsorption as well as renal perfusion are all reduced compared with the adult. The glomeruli reach full maturity by 2 years of age.

Integumentary System

In utero the infant is covered with vernix caseosa, which protects the developing infant's skin. At birth, the infant may be covered with vernix (earlier gestational age) or vernix may be found in the folds of the skin, axilla, and groin areas (later gestational age). Production of vernix ceases at birth. Fine downy hair (lanugo) covers the body of many newborns. Often this hair is lost over time and is not replaced. Darker-skinned races tend to have more lanugo present at birth than those with light skin.

Acrocyanosis (blueness of the hands and feet) is normal in the newborn; it decreases over the first few days of life (Fig. 3.3). Newborns often experience mottling of the skin (a pink-and-white marbled appearance) because of their immature circulatory system. Mottling decreases over the first few months of life.

The newborn and young infant's skin is relatively thinner than that of the adult, with the peripheral capillaries being closer to the surface. This may cause increased absorption of topical medications.

Hematopoietic System

Significant changes in the hematopoietic system occur over the first year of life. At birth, fetal hemoglobin (HgbF) is present in large amounts. After birth the production of fetal hemoglobin nearly ceases, and adult hemoglobin (HgbA) is produced in steadily increasing amounts throughout the first 6 months. Since HgbF has a shorter lifespan than HgbA, infants may experience physiologic anemia at age 2 to 3 months (Glader, 2007). During the last 3 months of gestation, maternal iron stores are transferred to the fetus. The newborn typically has 0.3 to 0.5 g of iron stores available. As the high hemoglobin concentration of the newborn decreases over the first 2 to 3 months, iron is reclaimed and stored. These stores may be sufficient for the first 6 to 9 months of life but will become depleted if iron supplementation does not occur. Ongoing iron intake is required throughout the first 15 years of life in order to reach

adult levels (American Academy of Pediatrics, 2010e).

Take Note!

Maternal iron stores are transferred to the fetus throughout the last trimester of pregnancy. Infants born prematurely miss all or at least a portion of this iron store transfer, placing them at increased risk for iron deficiency anemia compared with term infants.

FIGURE 3.3 **A.** Acrocyanosis. Note blueness of the hands. **B.** Mottling of the skin in a young infant.

Immunologic System

Newborns receive large amounts of IgG through the placenta from their mothers. This confers immunity during the first 3 to 6 months of life for antigens to which the mother was previously exposed. Infants then synthesize their own IgG, reaching approximately 60% of adult levels at age 12 months (Feigin, Cherry, Kaplan, & Demmler-Harrison, 2009). IgM is produced in significant amounts after birth, reaching adult levels by 9 months of age. IgA, IgD, and IgE production increases very gradually, maturing in early childhood (Feigin et al., 2009).

Psychosocial Development

Erik Erikson (1963) identifies the psychosocial crisis of infancy as Trust versus Mistrust. Development of a sense of trust is crucial in the first year, as it serves as the foundation for later psychosocial tasks. The parent or primary caregiver can have a significant impact on the infant's development of a sense of trust. When the infant's needs are consistently met, the infant develops this sense of trust. But if the parent or caregiver is inconsistent in meeting the infant's needs in a timely manner, then the infant develops a sense of

mistrust. Table 3.3 lists activities that promote a sense of trust in infancy.

Cognitive Development

The first stage of Jean Piaget’s theory of cognitive development is referred to as the sensorimotor stage (birth to 2 years) (Piaget, 1969). Infants learn about themselves and the world through their developing sensory and motor capacities. Infants’ development from birth to 1 year of age can be divided into four substages within the sensorimotor stage: reflexes, primary circular reaction, secondary circular reaction, and coordination of secondary schemes. Cause and effect guides most of the cognitive development seen in infancy (see Table 3.3).

The concept of **object per manence** begins to develop between 4 and 7 months of age and is solidified by about 8 months of age (Piaget, 1969). If an object is hidden from the infant’s sight, he or she will search for it in the last place it was seen, knowing it still exists. This development of object permanence is essential for the development of self-image. By age 12 months the infant knows he or she is separate from the parent or caregiver. Self-image is also promoted through the use of mirrors. By 12 months of age, infants can recognize themselves in the mirror. The 12-month-old will explore objects in different ways, such as throwing, banging, dropping, and shaking. He or she may imitate gestures and knows how to use certain objects correctly (e.g., puts phone to ear, turns up cup to drink, attempts to comb hair) (Piaget, 1969).

Motor Skill Development

Infants exhibit phenomenal increases in their gross and fine motor skills over the first 12 months of life.

Gross Motor Skills

The term “gross motor skills” refers to those that use the large muscles (e.g., head control, rolling, sitting, and walking). Gross motor skills develop in a **cephalocaudal** fashion (from the head to the tail) (Fig. 3.4). In other words, the baby learns to lift the head before learning to roll over and sit (Goldson & Reynolds, 2011). At birth, babies have poor head control and need to have their necks supported when being held. They can lift their heads only slightly while in a prone position. Over the next several months the infant’s motor skills progress at a dramatic rate. First the infant achieves head control, then the ability to roll over, sit, crawl, pull to stand, and, usually around 1 year of age, walk independently. Table 3.4 gives details on when the infant develops each specific gross motor skill. Progression of gross motor skills is illustrated in Figures 3.5 through 3.7.

| Theorist | Stage | Activities |
|----------|---|--|
| Erikson | Trust vs. Mistrust (birth to 1 year) | Caregivers respond to the infant's basic needs by feeding, changing diapers, cleaning, touching, holding, and talking to the infant. This creates a sense of trust in the infant. As the nervous system matures, infants realize they are separate beings from their caregivers. Over time the infant learns to tolerate small amounts of frustration and trusts that although gratification may be delayed, it will eventually be provided. |
| Piaget | Sensorimotor (birth to 2 years) Substage 1: use of reflexes (birth to 1 month) Substage 2: primary circular reactions (1 to 4 months) Substage 3: secondary circular reactions (4 to 8 months) Substage 4: coordination of secondary schemes (8 to 12 months) | Infant uses senses and motor skills to learn about the world. Reflexive sucking brings the pleasure of ingesting nutrition. Infant begins to gain control over reflexes and recognizes familiar objects, odors, and sounds. Thumb sucking may occur by chance; then the infant repeats it on purpose to bring pleasure. Imitation begins. Object permanence begins. Infant shows affect. Infant repeats actions to achieve wanted results (e.g., shakes rattle to hear the noise it makes). The infant's actions are purposeful but the infant does not always have an end goal in mind. Infants coordinate previously learned schemes with previously learned behaviors. They may grasp and shake a rattle intentionally or crawl across the room to reach a desired toy. Infant can anticipate events. Object permanence is fully present at about 8 months of age. The infant begins to associate symbols with events (e.g., waving goodbye means someone is leaving). |
| Freud | Oral stage (birth to 1 year) | Pleasure is focused on oral activities: feeding and sucking. |

Levin, J. M. Sondheimer, & R. R. Dieterling (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill; and Piaget, J. (1969). *The theory of stages in cognitive development*. New York: McGraw-Hill.

FIGURE 3.4 Gross motor skills develop in a cephalocaudal direction, fine motor skills in a proximodistal fashion.

Take Note!

Warning signs that may indicate problems with motor development include the following: arms and legs are stiff or floppy; child cannot support head at 3 to 4 months of age; child reaches with one hand only; child cannot sit with assistance at 6 months of age; child does not crawl by 12 months of age; child cannot stand supported by 12 months of age.

Fine Motor Skills

Fine motor development includes the maturation of hand and finger use. Fine motor skills develop in a **proximodistal** fashion (from the center to the periphery) (see Fig. 3.4). In other words, the infant first bats with the whole hand, eventually progressing to gross grasping, before being capable of fine fingertip grasping (Goldson & Reynolds, 2011) (Fig. 3.8). The newborn's hand movements are involuntary in nature, whereas the 12-month-old is capable of feeding himself or herself with a cup and spoon. By 12 months of age the infant should be able to eat with his or her fingers and assist with dressing (e.g., pushing an arm through the sleeve). Table 3.5 gives details on when the infant develops each specific fine motor skill.

TABLE 3.4

DEVELOPMENT OF GROSS MOTOR SKILLS IN INFANCY

| Age | Gross Motor Skills |
|-----------|--|
| 1 month | Lifts and turns head to side in prone position Head lag when pulled to sit Rounded back in sitting |
| 2 months | Raises head and chest, holds position Improving head control |
| 3 months | Raises head to 45 degrees in prone Slight head lag in pull-to-sit |
| 4 months | Lifts head and looks around Rolls from prone to supine Head leads body when pulled to sit |
| 5 months | Rolls from supine to prone and back again Sits with back upright when supported |
| 6 months | Tripod sits |
| 7 months | Sits alone with some use of hands for support |
| 8 months | Sits unsupported |
| 9 months | Crawls, abdomen off floor |
| 10 months | Pulls to stand Cruises |
| 12 months | Sits from standing position Walks independently |

Philadelphia: Saunders; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York: Bantam Books.

Sensory Development

Though hearing should be fully developed at birth, the other senses continue to develop as the infant matures. Though they mature at different rates, sight, smell, taste, and touch all continue to develop after birth.

Sight

The newborn is nearsighted, preferring to view objects at a distance of 8 to 15 inches. Newborns prefer the human face to other objects and may even imitate the facial expressions made by those caring for them. In addition to human faces, newborns show a preference for certain objects, particularly those with contrasts such as black-and-white stripes. The newborn's eyes wander and occasionally cross. At 1 month of age the infant can recognize by sight the people he or she knows best. The infant will study objects within his or her visual range closely. The ability to fuse two ocular images into one cerebral picture (**binocularity**) begins to develop at 6 weeks of age and is well established by 4 months of age. Full color vision develops by 7 months of age, as do distance vision and the ability to track objects.

Hearing

The newborn's hearing is intact at birth and as acute as that of an adult. Newborns prefer the sound of human voices to nonhuman sounds. By 1 month of age the infant can recognize the sounds of those he or she knows best.

FIGURE 3.5 When pulled to sit, an infant shows (A) significant head lag (newborn; 2 or 3 weeks old), (B) improving head control (2 months old), and (C) no head lag (4 months old).

Smell and Taste

The sense of smell develops rapidly: the 7-day-old infant can differentiate the smell of his or her mother’s breast milk from that of another woman and will preferentially turn toward the mother’s smell. Newborns prefer sweet tastes to all others. This persists for several months, and eventually the infant will accept nonsweet flavors.

Touch

The sense of touch is perhaps the most important of all the senses for newborn communication. Even the most immature infant responds to soothing stroking. The infant prefers soft sensations to coarse sensations. The infant dislikes rough handling and may cry. Holding, stroking, rocking, or cuddling calms infants when they are upset and makes them more alert when they are drowsy. Infants learn to understand their caregiver’s moods by the way they touch them.

Warning signs that may indicate problems with sensory development include the following: young infant does not respond to loud noises; child does not focus on a near object; infant does not start to make sounds or babble by 4 months of age; infant does not turn to locate sound at age 4 months; infant crosses eyes most of the time at age 6 months.

Communication and Language Development

For several months, crying is the only means of communication for the newborn and infant. The basic reason for crying is unmet needs. The 1- to 3-month-old baby coos, makes other vocalizations, and demonstrates differentiated crying. At 4 to 5 months of age, the infant makes simple vowel sounds, laughs aloud, performs “raspberries,” and vocalizes in response to voices. The infant also responds to his or her own name and begins to respond to “no.” Between 4 and 7 months the infant begins to distinguish emotions based on tone of voice. Squealing and yelling begin around 6 months of age; these may be used to express joy or displeasure. At age 7 to 10 months, babbling begins and progresses to strings (e.g., mamama, dadada) without meaning. The infant at this age is also able to respond to simple commands. At 9 to 12 months of age the infant begins to attach meaning to “mama” and “dada” and starts to imitate other speech sounds. The average 12-month-old uses two or three recognizable words with meaning, recognizes objects by name, and starts to imitate animal sounds. At this age, the infant pays increasing attention to speech and tries to imitate words; he or

she may also say “uh-oh.” The 12-month-old also babbles with inflection (this babbling has the rhythm and timing of spoken language, but few of the “words” make sense) (Feigelman, 2007; Goldson & Reynolds, 2011).

FIGURE 3.6 Development of sitting. **A.** At 4 months, the infant requires significant support. **B.** The 6-month-old infant sits in tripod fashion. **C.** The 8-month-old sits alone.

It is very important for the parent or caregiver to talk to the infant in order for the infant to learn communication skills. Sometimes regression in language development occurs briefly when the child is focusing energy on other skills, such as crawling or walking. As long as the infant’s hearing is normal, language acquisition should continue to progress. Infants in bilingual families may “language mix” (uses some words from each language). This is considered to be a normal progression in language development for these children, but it makes it more difficult for the physician or nurse practitioner to determine delays in communication skills (Abell & Ey, 2007).

FIGURE 3.7 Development of locomotion. **A.** At 4 months the infant pushes up from a prone position. **B.** At 8 months, the infant crawls with the abdomen off the floor. **C.** The infant pulls to stand by 10 months of age. **D.** The infant cruises along furniture or **(E)** takes steps with assistance at 10 to 11 months of age. **F.** The infant independently stands from a crouched position and walks around 12 months of age (plus or minus 3 months).

FIGURE 3.8 Development of the pincer grasp. Note the gross (whole-hand) approach to grasping a small object (**A**), compared with the fine (thumb-to-finger) ability (**B**).

 **Take Note!**

Warning signs that may indicate problems in language development are as follows: infant does not make sounds at 4 months of age; infant does not laugh or squeal by 6 months of age; infant does not babble by 8 months of age; infant does not use single words with meaning at 12 months of age (mama, dada).

Social and Emotional Development

The newborn spends much of the time sleeping, but by 2 months of age the infant is ready to start socializing. The infant exhibits a first real smile at age 2 months. He or she spends a great deal of time while awake watching and observing what is going on around him or her. By about 3 months of age the infant will start an interaction with a caregiver by smiling widely and possibly gurgling. This prompts the caregiver to smile back and talk to the infant. The infant responds with more smiling, cooing, and gurgles as well as moving the arms and legs. The 3- to 4-month-old will also mimic the parent's facial movements, such as widening the eyes and sticking out the tongue. The baby may hesitate at first, but once the other person responds pleasantly to the infant, the infant engages and gets into the interaction. The infant may cry when the pleasant interaction stops. At 6 to 8 months of age the infant may enjoy socially interactive games such as patty-cake and peek-a-boo (Feigelman, 2007; Goldson & Reynolds, 2011).

TABLE 3.5 DEVELOPMENT OF FINE MOTOR SKILLS IN INFANCY

| Age | Fine Motor Skills |
|-----------|--|
| 1 month | Fists mostly clenched Involuntary hand movements |
| 3 months | Holds hand in front of face, hands open |
| 4 months | Bats at objects |
| 5 months | Grasps rattle |
| 6 months | Releases object in hand to take another |
| 7 months | Transfers object from one hand to the other |
| 8 months | Gross pincer grasp (rakes) |
| 9 months | Bangs objects together |
| 10 months | Fine pincer grasp Puts objects into container and takes them out |
| 11 months | Offers objects to others and releases them |
| 12 months | Feeds self with cup and spoon Makes simple mark on paper Pokes with index finger |

Adapted from Feigelman, S. (2007). The first year. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York: Bantam Books.

Stranger Anxiety

Around the age of 8 months the infant may develop **stranger anxiety**. The previously happy and very friendly infant may become clingy and whiny when approached by strangers or people not well known. Stranger anxiety is an indicator that the infant is recognizing himself or herself as separate from others. As the infant becomes more aware of new people and new places, he or she may view an interaction with a stranger as threatening and may start crying, even if the parent is right there. Family members whom the child sees infrequently, as well as others the child does not spend a lot of time with, should approach the infant calmly and slowly, with the parent in sight. Sometimes this will prevent a sudden crying spell (Feigelman, 2007; Goldson & Reynolds, 2011).

Separation Anxiety

Separation anxiety may also start in the last few months of infancy. The infant becomes quite distressed when the parent leaves. The infant will eventually calm down and become engaged with the current caregiver. It is not until the infant is older that cognition and memory are sufficient for him or her to understand that the parent will come back (Feigelman, 2007; Goldson & Reynolds, 2011).

Take Note!

Warning signs of possible problems with social/emotional development include the following: child does not smile at people at 3 months of age; child refuses to cuddle;

child does not seem to enjoy people; child shows no interest in peek-a-boo at 8 months of age.

Temperament

Temperament is an individual's nature; it is referred to as the "how" of behavior (Child Development Institute, 2010). Temperament ranges from low or moderately active, regular, and predictable to highly active, more intense, and less adaptable. These are all considered normal along a continuum. An infant's innate temperament affects the way he or she responds to the environment. As parents take note of their infant's usual activity level, how intensely he or she reacts with others and the environment, and how stimulated he or she becomes with interactions, they start to learn about their infant's temperament. The parent should note how adaptable and flexible the infant is as well as how predictable and persistent the baby is.

When parents are familiar with how the baby approaches life on a routine basis, they will be better able to recognize when the baby is not acting like himself or herself. Nurses can help parents interpret observations about their infant's temperament and recommend ways to support the infant's individual behavior. Some infants are slower to warm up than others; those infants should be approached slowly and calmly. Some infants exhibit increased levels of activity compared to quieter, more passive babies; those infants generally require more direct play with the parent or caregiver and will be the type of older infant who is in constant motion. Some infants are loud and some are not. The quiet infant may become overwhelmed with excessive stimulation, whereas the very active baby may need additional stimulation to be satisfied (Child Development Institute, 2010). Becoming familiar with the infant's temperament also helps the parents describe the best approach to the infant by others (e.g., child care workers or health care professionals).

Cultural Influences on Growth and Development

Many cultural differences have an impact on growth and development. For instance, certain ethnic groups tend to be shorter than others because of their genetic makeup (Ferry, 2010). These children will not grow to be as tall as those of another ethnic background. Cultural feeding practices in some cultures may lead to overweight in some children. Some cultures and certain religions advocate vegetarianism; those children need nutritional assessment to ensure they are getting enough protein intake for adequate growth.

Parenting styles and health promotion behaviors can also be significantly influenced by culture. Parents and extended family are the most significant influences in an infant's life in most cultures. Certain cultures place a high value on independence and may encourage their infants to develop quickly, while other cultures "baby" their infants for longer periods. In most cultures the mother takes primary responsibility for caring for the child, but in some cultures, major health-related decisions may be deferred to the father or grandparents.

Health beliefs are often strongly influenced by an individual's religious or spiritual background. Sometimes this creates conflict in the health care setting when the health providers have a different value system than that of the infant's family.

In some cultures infants and children share a bed with their parents. When an infant or child is hospitalized and is accustomed to sleeping with the parents, it may be difficult and distressing for him or her to try to sleep alone.

The nurse should explore the family's cultural practices related to growth and development. Usually these practices are not harmful and can be supported by the health care team, but safety must always be considered. The nurse should not make assumptions about a family's cultural practices based on their skin color, accent, or name; rather, the nurse should perform an adequate assessment (Leininger & MacFarland, 2006).

Take Home

Many communities now include people from a variety of cultures, so it is important for nurses to practice transcultural nursing (nursing care that is directed by cultural aspects and that respects the individual's differences). Many nurse researchers are exploring the cultural aspects of health care and the impact that cultural diversity has upon health.

Refer back to Allison Johnson, who was introduced at the beginning of the chapter. What developmental milestones would you expect Allison to have reached by this age? How would this be different if Allison had been born 6 weeks premature?

THE NURSE'S ROLE IN NEWBORN AND INFANT GROWTH AND DEVELOPMENT

Growth and development affect every aspect of the infant's life. As infants progress through various stages of development, they do so in a predictable fashion. Growth and development are sequential and orderly, though some children develop at faster rates than others. It is important for the nurse to understand growth and development. Health care visits through infancy often focus primarily on anticipatory guidance (educating parents and caregivers about what to expect in the next phase of development). The purpose of anticipatory guidance is to give parents the tools they need to support their infant's development in a safe fashion.

Hospital nurses also need to use their knowledge of growth and development when caring for ill infants. Hospitalization often requires the infant to be confined to the crib or the hospital room. Nurses must support growth and development within the constraints imposed by the child's illness.

NURSING PROCESS OVERVIEW

After the infant's current growth and development status has been assessed, problems related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Ineffective breastfeeding
- Risk for disproportionate growth
- Imbalanced nutrition, less than body requirements
- Risk for impaired parent/infant attachment
- Delayed growth and development
- Risk for caregiver role strain

Nursing care planning for the infant with growth and development issues should be individualized based on the infant's and family's needs. [Nursing Care Plan 3.1](#) (p. 82) can be used as a guide in planning nursing care for the infant with a growth and development problem. The nurse may choose the appropriate nursing diagnoses from the plan and individualize them as needed. The nursing care plan is intended to serve as a guide, not as an all-inclusive growth and development care plan.

Promoting Healthy Growth and Development

Adding a new person to the family produces both excitement and anxiety. Newborns are completely reliant upon their parents or caregivers to fill every need. It is quite a burden and precious responsibility that new parents are taking on. Many parents read the latest books about caring for newborns, while others rely on information received from family and friends. Newborns and their mothers spend only a short time in the hospital after delivery, so it is very important that parents can care for their newborn and know when to call the primary care provider with concerns.

Periodic screening for adequate growth and development is recommended by the American Academy of Pediatrics (AAP) for all infants and children. The prevention of devastating disease is another priority for infants and children. The AAP and the Advisory Committee on Immunization Practices (ACIP) have made recommendations for immunization schedules. Immunizations are a very important part of the newborn and infant's health visits. Nurses caring for newborns and infants should be familiar with the recommended infant/child periodic screenings (check-ups) as well as the current immunization schedule (see [Chapter 9](#) for further information on immunizations).

NURSING CARE PLAN 3.1

Growth and Development Issues in the Newborn and Infant

NURSING DIAGNOSIS: Breastfeeding, ineffective, related to lack of exposure, misconceptions, or knowledge deficit as evidenced by first baby, mother's verbalization, or nursing observations

Outcome Identification and Evaluation

Mother/infant dyad will experience successful breastfeeding: *infant will latch on, suck and swallow at the breast; mother will not experience sore nipples.*

Interventions: Promoting Effective Breastfeeding

- Educate mother on recognition of and response to infant hunger cues to promote on-cue breastfeeding, which will establish milk supply.
- Educate mother on appropriate diet and fluid intake to *ensure ability to manufacture adequate supply of breast milk.*
- Demonstrate breastfeeding positions with infant at the breast (*appropriate positioning increases probability of successful latch*).
- Assess infant's latch technique, sucking motion, and audible swallowing (*an appropriately latched infant will take most of the areola in the mouth, suck in spurts, and demonstrate audible swallowing*).
- Assess infant voiding/stool patterns: *at least six voids per day and passage of stool ranging from one or more per day to one every several days is a normal*

pattern for breastfed infants.

- Assess infant weight gain: *gain of 15 to 30 gper day after the second week of life indicates infant is receiving appropriate nutrition.*
- Assess mother's nipples for redness or soreness; *if infant appropriately latches on, nipples will not become sore.*

NURSING DIAGNOSIS: Risk for altered growth pattern (risk factors: caregiver knowledge deficit, first infant, premature infant, or maladaptive feeding behaviors)

Outcome Identification and Evaluation

Infant will demonstrate adequate growth and appropriate feeding behaviors: *steady increases in weight, length, and head circumference; infant feeds appropriately for age.*

Interventions: Promoting Adequate Growth

- Observe mother/infant dyad breastfeeding *or bottle-feeding to determine need for further education or identify infant difficulties with feeding.*
- Educate mother about appropriate breastfeeding *or bottle-feeding so that mother is aware of what to expect in normal feeding pattern.*
- When infant is old enough, provide education about addition of solid foods, spoon and cup feeding: *after 6 months of age breast milk or formula needs to be supplemented with a variety of foods.*
- Determine need for additional caloric intake if necessary (*premature infants and infants with chronic illnesses or metabolic disorders often need adjustments in caloric intake to demonstrate adequate or catch-up growth*).
- Obtain daily weights if hospitalized (weekly if outpatient) and weekly length and head circumference *to determine whether feeding pattern is sufficient to promote adequate growth.*

NURSING DIAGNOSIS: Nutrition, altered, less than body requirements, related to possible ineffective feeding pattern or inadequate caloric intake as evidenced by failure to gain weight or by inadequate increases in weight, length, and head circumference over time

Outcome Identification and Evaluation

Infant will take in adequate nutrients using effective feeding pattern: *infant will demonstrate adequate weight gain (15 to 30 gper day) and steady increases in length and head circumference.*

Interventions: Promoting Adequate Nutritional Intake

- Assess current feeding pattern and daily intake *to determine areas of concern.*
- Increase frequency of breastfeeding or volume of bottle-feeding *if needed to meet caloric needs.*
- Introduce solid foods on age-appropriate schedule: *introducing solids at the right time improves the chances that the child will learn to take solid foods.*
- Limit juice intake or discontinue altogether (*juice has little nutritive value and displaces nutrients from breast milk or formula*).
- Use human milk fortifier (if ordered) *to increase caloric density of breast milk.*
- Increase caloric density of formula (if ordered) by mixing to a more concentrated level or with additives (fats or carbohydrates) *to provide increased calories needed to support adequate growth.*
- If infant is taking solids already, choose higher-calorie foods *to maximize nutrient intake.*

NURSING DIAGNOSIS: Parent/infant attachment, altered, risk for (risk factors: premature infant, parental knowledge deficit about normal newborn activity and care, infant with difficult temperament or medical problems)

Outcome Identification and Evaluation

Parent and infant will demonstrate appropriate attachment via *eye contact, parental response to infant cues, parental verbalization of caring for infant, infant response to parent's caretaking behaviors.*

Interventions: Encouraging Appropriate Parent-Infant Attachment

- Assess parent's response to infant cues *to determine degree of attachment and level of parent's knowledge about infant care.*
- Assess infant's response to parent's caretaking behaviors *to determine degree of attachment.*
- Determine infant's temperament *to counsel parent effectively about responses appropriate for that type of temperament.*
- Encourage en face positioning for holding or feeding the young infant *to encourage give-and-take response between infant and parent.*
- Encourage parent to meet infant's needs promptly and with affection *to promote sense of trust in the infant.*
- Reinforce parent's attempts at improving attachment with infant (*positive reinforcement naturally encourages appropriate behaviors*).

NURSING DIAGNOSIS: Growth and development, altered, related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be maximized: *infant will make continued progress toward attainment of developmental milestones.*

Interventions: Maximizing Development

- Perform developmental evaluation of the infant *to determine infant's current level of functioning.*
- Offer age-appropriate play, activities, and toys *to encourage further development.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist (*repeated exposure to the activities or exercises is needed to make developmental progress*).
- Provide support to parents of infants with developmental concerns, *as developmental progress can be slow and it is difficult for families to stay motivated and maintain hope.*

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: first baby, knowledge deficit about infant care, lack of prior exposure, fatigue if premature, ill, or developmentally delayed infant)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in new role.*

Interventions: Preventing Caregiver Role Strain

- Assess parent's knowledge of newborn/infant care and the issues that arise as a part of normal development *to determine parent's needs.*
- Provide education on normal newborn/infant care *so that parents have the knowledge they need to appropriately care for their new baby.*
- Provide anticipatory guidance related to normal infant development *to prepare parents for what to expect next and how to intervene.*
- Encourage respite for parents *(even a few hours away from the demands of an infant's care can rejuvenate the parents).*

NURSING DIAGNOSIS: Injury, risk for (risk factors: developmental age, infant curiosity, rapidly progressing motor abilities)

Outcome Identification and Evaluation

Infant safety will be maintained: *infant will remain free from injury.*

Interventions: Preventing Injury

- Encourage car seat safety *to decrease risk of injury related to motor vehicles.*
- Childproof home: *as infant becomes more mobile, he or she will want to explore everything, increasing risk of injury.*
- Parents should have the Poison Control Center phone number available: *should an accidental ingestion occur, Poison Control can give parents the best advice for appropriate intervention.*
- Never leave an infant unattended in the sink, bathtub, or swimming pool *to prevent drowning.*
- Teach parents first aid measures and infant CPR *to minimize consequences of injury should it occur.*
- Parents should watch the infant at all times *(no amount of childproofing can replace the watchful eye of a caring parent).*

Promoting Growth and Development Through Play

Experts in child development and behavior have said repeatedly that play is the work of children. Infants practice their gross and fine motor skills and language through play (Goldson & Reynolds, 2011). Play is a natural way for infants and children to learn. Play is critical to infant development, as it gives infants the opportunity to explore their environment, practice new skills, and solve problems. The newborn prefers interacting with the parent to toys. Parents can talk to and sing to their newborns while participating in the daily activities that infants need, such as feeding, bathing, and changing diapers. Newborns and young infants love to watch people's faces and often appear to mimic the expressions they see.

As infants become older, toys may be geared toward the motor skills or language skills that the child is developing. Parents can promote fine motor development in infants by providing age-appropriate toys. For example, a rattle that a young infant can hold promotes reaching and attaining. The older infant builds fine motor skills by stacking cups or placing smaller toys inside of larger ones. Gross motor skills are reinforced and practiced over and over again when the infant wants to reach something he or she is interested in.

When playing with toys, the infant usually engages in solitary play; he or she does not share with other infants or directly play with other infants (Feigelman, 2007; Goldson & Reynolds, 2011). A wide variety of toys are available for infants, but infants often enjoy the most basic ones, such as plastic containers of various shapes and sizes, soft balls, and wooden or plastic spoons.

Books are also very important toys for infants. Reading to all ages of infants is appropriate, and the older infant develops fine motor skills by learning to turn book pages.

Table 3.6 lists age-appropriate toys.

Promoting Early Learning

Research has shown that reading aloud and sharing books during early infancy are critical to the development of neural networks that are important in the later tasks of reading and word recognition. Reading books increases listening comprehension. Infants demonstrate their excitement about picture books by kicking and waving their arms and babbling when looking at them. At 6 to 12 months, the infant reaches for books and brings them to the mouth. Over time, reading leads to acquisition of language skills. Reading picture books and simple stories to infants starts a good habit that should be continued throughout childhood (Zuckerman, 2009).

Promoting Safety

Hundreds of children younger than 1 year of age die each year as a result of injury (AAP, 2010c). As infants become more mobile, they risk injury from falls down stairs and off chairs, tables, and other structures. Curiosity leads the infant to explore potentially dangerous items, such as electrical outlets, hot stove or furnace vents, mop buckets, and toilets. Since infants explore so much with their mouths, small objects or hard foods pose a choking hazard. The infant will invariably pick up any accessible object and bring it to the mouth. With increasing dexterity, poisoning from medications, household cleaning products, or other substances also becomes a problem.

Safety in the Car

Motor vehicle accidents are one source of injury, particularly if the infant is improperly restrained. Infants should never be transported in a motor vehicle without proper restraint. Infant car seats should face the rear of the car until the infant is 12 months of age and weighs 20 pounds (AAP, 2010a). The car seat should be secured tightly in the center of the back seat. The infant should never be placed in a front seat that is equipped with an airbag.

| Age | Appropriate Toys |
|----------------|---|
| Newborn to | <ul style="list-style-type: none">• Mobile with contrasting colors or patterns |
| 1 month | <ul style="list-style-type: none">• Unbreakable mirror• Soft music via tape or music box• Soft, brightly colored toys |
| 1 to 4 months | <ul style="list-style-type: none">• Bright mobile• Unbreakable mirror• Rattles• Singing by parent or caregiver, varied music• High-contrast patterns in books or images |
| 4 to 7 months | <ul style="list-style-type: none">• Fabric or board books• Different types of music• Easy-to-hold toys that do things or make noise (fancy rattles)• Floating, squirting bath toys• Soft dolls or animals |
| 8 to 12 months | <ul style="list-style-type: none">• Plastic cups, bowls, buckets• Unbreakable mirror• Large building blocks• Stacking toys• Busy boxes (with buttons or knobs that make things happen)• Balls• Dolls• Board books with large pictures• Toy telephone• Push-pull toys (older infants) |

Adapted from Schuman, A. T. (2007). The ABCs of toy safety: More than just child's play. *Contemporary Pediatrics*, 24(7), 49-57, 64; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York: Bantam Books.

Infants should never be left unattended in a motor vehicle. The temperature rises very quickly inside a closed vehicle, and an infant can suffocate from heat in a closed vehicle in the summer. Even during cooler weather, the heat generated within a closed vehicle can reach three to five times the exterior temperature. Kidnapping is also a concern if the baby is left unattended in a vehicle. Additional information on car safety can be found on [thePoint](http://thePoint.lww.com/Kyle2e) at <http://thePoint.lww.com/Kyle2e>.

Safety in the Home

The baby's crib should have a firm mattress that fits snugly in the crib on a secure support. The distance between crib slats should be 2 3/8 inches or less to prevent injury (Safe Kids Worldwide, 2009). All crib edges should be smooth. Only well-fitting crib sheets should be used, not sheets intended for large beds. Crib side rails should always be raised when the parent is not right next to the crib. Additional information about crib and playpen safety can be found on [thePoint](http://thePoint.lww.com/Kyle2e) at <http://thePoint.lww.com/Kyle2e>.

Even before the infant can roll over, he or she wiggles and pushes with the feet. The infant can easily fall from a changing table, sofa, or crib with the side rails down, so the infant should never be left unattended on any surface. If infant seats, bouncy seats, or swings are used, the infant should always be restrained in the seat with the appropriate straps.

The AAP (2010b) does not recommend the use of infant walkers, because the walker may tip over and the baby may fall out of it or the infant may fall down the stairs in it. Walkers allow infants access to things they may not otherwise be capable of reaching until they are able to walk alone, such as hot stoves and items on the edge of the countertop.

As the infant becomes more mobile, learning to crawl and walk, new safety issues arise. Safety gates should be used at the tops and bottoms of stairways. Gates may also be used to block curious infants from rooms that may pose physical danger to them.

because of sharp-edged furniture or decorative objects. Electrical outlets should be covered with approved safety covers. Cabinets and drawers should be secured with child safety latches. Medications, household cleaning supplies, and other potentially hazardous substances should be stored completely out of reach of infants (AAP, 2010c).

Choking is a risk because infants immediately bring small items to the mouth for exploration. To avoid choking, recommend the following to parents:

- Use only toys recommended for children 0 to 12 months of age.
- Avoid stuffed animals with eyes or buttons that can be dislodged by the persistent infant.
- Keep the floor free of small items (accidentally dropped coins, paper clips, straight pins).
- Avoid feeding popcorn, nuts, carrot slices, grapes, and hot dog pieces to infants.

Suffocation is also a risk for infants. Cribs should not have pillows, comforters, stuffed animals, or other soft items in them. Keep plastic bags of any size away from infants. Avoid the risk of strangulation by keeping window blind and drapery cords out of the infant's reach (AAP, 2010b, 2010c).

Though no safety measure is as effective as close supervision by a watchful parent or caregiver, the aforementioned safety measures can be critical to the infant's well-being.

Safety in the Water

Infants can drown in a very small amount of water. Never leave an infant unattended in the sink, a baby bathtub or standard bathtub, a swimming or wading pool, or any other body of water, even if it is quite shallow. The bathroom door should be kept closed and the toilet lid down. Water should be emptied from tubs, pails, or buckets immediately after use. If the family has a swimming pool, a locked fence or locked screen enclosure should surround it. Exterior doors should be kept locked to prevent the older infant from wandering out to the pool (AAP, 2010c). The AAP recommends that parents use caution when enrolling their infant in an aquatic or swim program. Research has not sufficiently demonstrated that water survival skills taught to infants are effective (AAP, 2010d). Completing an aquatic program does not decrease the risk of drowning; vigilant supervision is still always required.

Remember Allison Johnson, the infant described in the beginning of the chapter? What anticipatory guidance related to safety would you provide to Allison's parents?

Promoting Nutrition

Adequate nutrition is essential for growth and development. Breastfeeding and bottle-feeding of infant formula are both acceptable means of nutrition in the newborn and infant. Breast milk or formula supplies all of the infant's daily nutritional requirements until 4 to 6 months of age, at which time solid foods may be introduced (Shelov & Altmann, 2009).

Cultural Factors

Many dietary practices are affected by culture, both in the types of food eaten and in the approach to progression of infant feeding. Some ethnic groups tend to be lactose intolerant (particularly blacks, Native Americans, and Asians); therefore, alternative sources of calcium must be offered. Explore the cultural practices of the family related to infant feeding so that you can support the family's cultural values.

Nutritional Needs

Newborns and infants are experiencing tremendous growth and need diets that support these rapid changes. [Table 3.7](#) compares fluid and caloric needs in the newborn and infant.

TABLE 3.7

NUTRITIONAL REQUIREMENTS

| Nutritional Requirements | Newborn | Infant |
|--------------------------|---------------------|--|
| Fluid | 140–160 mL/kg/day | 100 mL/kg/day for first 10 kg 50 mL/kg/day for next 10 kg |
| Calories | 105–108 kcal/kg/day | 1 to 6 months: 108 kcal/kg 6 to 12 months: 98 kcal/kg |

Adapted from Johns Hopkins Hospital, Custer, J. W., Rau, R. E., & Lee, C. K. (2008). *The Harriett Lane handbook* (18th ed.). St. Louis: Mosby.

Breastfeeding

The NAPNAP, the AAP, the American College of Obstetrics and Gynecology, the American Dietetic Association, and the U.S. Breastfeeding Committee of the Department of Health and Human Services all recommend breast-feeding as the natural and preferred method of newborn and infant feeding (NAPNAP, 2007). In their position statement on breastfeeding (2007), NAPNAP identifies “human milk as superior to all substitute feeding methods.” Breast milk provides complete infant nutrition.

Breastfeeding or feeding of expressed human milk is recommended for all infants, including sick or premature newborns (with rare exceptions). The exceptions include infants with galactosemia, maternal use of illicit drugs and a few prescription medications, maternal untreated active tuberculosis, and maternal HIV infection in developed countries.

Data from the Centers for Disease Control and Prevention’s (CDC) *Breastfeeding Report Card – United States, 2010* indicate that in 2010 75% of US women breastfed in the early postpartum period, 43% of infants were breast-feeding at 6 months of age, and only 22.4% were still breastfeeding at 1 year of age (CDC, 2010). Even partial breastfeeding is helpful and offers some of the health benefits of breastfeeding. Pediatric nurses in the community and the hospital are in an excellent position to promote and support breastfeeding, thereby contributing to the *Healthy People 2020* goal of increasing the proportion of mothers who breastfeed their babies.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|---|
| Increase the proportion of infants who are breastfed. | <ul style="list-style-type: none"> • Encourage breastfeeding in all mothers beginning with the prenatal visit if applicable. • Provide accurate education related to breastfeeding. • Be available for questions or problems related to initiation and continuation of breastfeeding. Consult lactation consultant as needed or available. • Encourage pumping of breast milk when mother returns to work in order to continue breastfeeding. • Refer to local breastfeeding support groups such as La Leche League. |
| 2020 target: | |
| Ever 81.9% | |
| At 6 months 60.5% | |
| At 1 year 34.1% | |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

BREAST MILK COMPOSITION

Breast milk includes lactose, lipids, polyunsaturated fatty acids, and amino acids. The ratio of whey to casein protein in breast milk

makes it readily digestible. The high concentration of fats and the balance of amino acids are believed to contribute to proper myelination of the nervous system. The concentration of iron in breast milk is less than that of formula, but the iron has increased bioavailability and is sufficient to meet the infant's requirements for the first 4 to 6 months of life.

In addition to complete nutrition, immunologic protection is transferred from mother to infant via breast milk and maternal–infant bonding is promoted. The benefits of breastfeeding are listed in [Box 3.1](#).

BREAST MILK SUPPLY AND DEMAND

Frequent, on-demand breastfeeding of the newborn is necessary to establish an adequate milk supply. After delivery of the placenta, levels of progesterone drop dramatically, which stimulates the anterior pituitary to produce prolactin. Prolactin stimulates the production of milk in the acinar or alveolar cells of the breast. When the infant sucks at the breast, nervous impulses stimulate further production of breast milk.

BOX 3.1

BENEFITS OF BREASTFEEDING

Infant

- Increased bonding with mother
- Immunologic protection
- Breast milk has anti-infective properties
- Decreased incidence and severity of diarrhea
- Decreased incidence of asthma, otitis media, bacterial meningitis, botulism, urinary tract infection
- Possible enhancement of cognitive development
- Decreased incidence of obesity in later childhood

Maternal

- Increased bonding with infant
- Lessens maternal blood loss in the postpartum period
- Decreased risk of ovarian and premenopausal breast cancer
- Reduced incidence of pregnancy-induced, long-term obesity
- Possible delay of return of ovulation in some women
- Always ready; no mixing!
- Economic advantage

Adapted from Heird, W. C. (2007). The feeding of infants and young children. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders.

The first “milk” to be produced by the breasts is termed **colostrum**. It is produced for the first 2 to 4 days after birth. Colostrum is a thin, watery, yellowish fluid that is easy to digest, as it is high in protein and low in sugar and fat. Colostrum is complete nutrition and all that is needed by the newborn for the first 2 to 4 days of life (Shelov & Altmann, 2009). Transitional breast milk replaces colostrum on days 2 to 4 after birth. By day 10 after birth, mature breast milk is produced. Mature breast milk has a slightly bluish color and appears thin.

The breastfeeding mother produces milk continually. Called **for emilk**, it collects in the lactiferous sinuses, which are small tubules serving as reservoirs for milk located behind the nipples. The **let-down reflex** is responsible for the release of milk from these reservoirs. When the baby sucks at the breast, oxytocin is released from the posterior pituitary, causing the lactiferous sinuses to contract. This allows milk to “let down” into the nipples, and the infant then sucks the milk. The let-down reflex is triggered not only by suckling at the breast but also by thinking of the baby or by the sound of a baby crying. After the foremilk is let down, new, fattier milk is formed. This **hind milk** helps the breastfed infant to grow quickly (Shelov & Altmann, 2009). Mothers should be informed that the production of oxytocin during suckling may also cause uterine contractions and may cause afterpains during breastfeeding.

BREASTFEEDING TECHNIQUE

Breastfeeding mothers may not have established adequate breastfeeding prior to leaving the hospital after birth of the newborn. The pediatric nurse may encounter an infant–mother dyad experiencing difficulty with breastfeeding for a variety of reasons. Thus, the

pediatric nurse must be competent in counseling the breastfeeding mother.

Before each breastfeeding session, mothers should wash their hands. It is not necessary to wash the breast in most cases. The mother should be positioned comfortably. A number of positions are possible, and they should be varied throughout the day (Fig. 3.9). The mother may hold the breast in a “C” position if that is helpful to her. Stroke the nipple against the baby’s cheek (Fig. 3.10). This should stimulate the infant to open the mouth widely. Bring the baby’s wide-open mouth to the breast to form a seal around all of the nipple and areola (Fig. 3.11). When the infant is finished feeding, the mother can break the suction by inserting her finger into the baby’s mouth, thus releasing the mouth from the nipple (Fig. 3.12). This technique may prevent the infant from pulling on the nipple, which can lead to soreness and cracking.

FIGURE 3.9 Various positions may be used during breastfeeding: (A) cradle hold, (B) side-lying, (C) football hold.

FIGURE 3.10 Stroking the infant's cheek with the nipple will elicit the rooting reflex.

FIGURE 3.11 Bringing the infant's open mouth to the breast, rather than bringing the breast to the infant, helps the infant correctly latch on. The infant's mouth forms a seal around all of the nipple and areola. Note the "C" position for holding the breast during latching on.

FIGURE 3.12 Inserting the little finger between the areola and the infant's mouth helps to break the suction.

Watching and listening to the infant feed may assess the adequacy of the baby's latch technique. The infant who is properly latched on to the breast will suck rhythmically, taking most or all of the areola into the mouth. Audible swallowing should be heard as milk is

delivered into the infant's mouth. Assess the mother for pain related to breastfeeding. She should not be in pain if the baby is latched on properly.

Establishment of breastfeeding is best achieved if the infant is allowed to feed on demand, whenever he or she is hungry. This may be as often as every 1½ to 3 hours in the neonate. Infants may feed for 10 to 20 minutes on each breast at each feeding, or longer on just one breast, alternating the breast at each feeding. Both methods are acceptable.

The breastfeeding infant does not need supplementation with water or formula even in the first few days of life as long as the newborn continues to wet six to eight diapers per day. After several days of age, the mother's milk supply should be well established. Adequate urine output and bowel movements, as well as continued weight gain in the infant, indicate the adequacy of breastfeeding. Working mothers in particular may need additional support from the nurse in order to continue breastfeeding if they desire to do so. Common problems occurring with breastfeeding are addressed in [Teaching Guidelines 3.1](#). Additional reliable resources for mothers who desire to breastfeed may be found on the websites listed on the Point.

Teaching Guidelines 3.1

PROMOTING BREASTFEEDING

| Problem | Solutions |
|--|---|
| Sore nipples | Prevention: encourage appropriate latch-on from the beginning. Expose nipples to air between feedings. Allow breast milk to dry on nipples. Aloe vera or vitamin E may help to heal sore nipples. Medical-grade lanolin or preservative-free lanolin (Lansinoh) may be helpful. |
| Engorgement | Apply warm compresses or encourage the mother to take a warm shower prior to having the baby latch on. Warmth encourages some of the milk to be released, allowing the breast to soften and making it easier for the infant to latch on. |
| Poor sucking | Feed on cue, not on a schedule. Encourage the sleepy infant by stroking the feet, undressing, and rubbing the head. |
| Inadequate milk supply | Decrease maternal stress. Encourage adequate maternal diet and fluid intake. Mothers who return to work must pump in order to keep up milk supply when away from infant. |
| Father feels left out | Encourage father to participate in other aspects of care. |
| Mother worries about adequacy of breast milk | If infant is voiding six times per day and gaining weight, then he or she is receiving enough milk and appropriate nutrition. |

Bottle Feeding

For the mother who does not desire to, or cannot, breast-feed, commercially prepared formulas are available for bottle-feeding. These formulas are designed to imitate human milk. Standard infant formulas based on cow's milk provide 20 kcal/ounce and use lactose as a source for carbohydrates (Shelov & Altmann, 2009). Vegetable oil is used as the source of fat; whey or casein provides protein. Newer cow's milk-based formulas contain long-chain polyunsaturated fatty acids that are thought to improve brain development. Ordinary cow's milk is not recommended for the first year of life.

Take Note!

Cow's milk does not provide an adequate balance of nutrients for the growing infant, especially iron. It may also overload the infant's renal system with inappropriate amounts of protein, sodium, and minerals.

Only formulas that are fortified with iron should be used. Iron stores that the infant received prenatally are depleted by 4 to 6 months of age. To prevent iron deficiency anemia, poor growth patterns, and impaired development, iron-fortified formulas must be used. The AAP recommends that commercial formulas provide 10 to 12 mg of iron per liter (Baker, Greer, & Committee on Nutrition, 2010). Commercial formulas also provide an adequate blend of essential vitamins and minerals.

FEEDING PATTERNS

Infant feeding is an opportune time to establish good eating behaviors. The infant should always be held while being bottle-fed. Cradling in a semiupright position allows for additional bonding time, as the infant can see the caregiver's face while feeding (Fig. 3.13). Talking or singing during feeding time also increases bonding. As with breastfed infants, the bottle-fed infant should be fed on cue. Overfeeding with the bottle increases the incidence of gastroesophageal reflux, so families need to learn their baby's cues to hunger and satiety (NAPNAP, 2011a).

It is important to feed the baby when he or she displays signs of hunger. Crying is a late sign of hunger; earlier signs include making sucking motions, sucking on hands, or putting the fist to the chin. The infant should be burped two or three times per feeding, when he or she slows feeding or stops sucking. Newborns may only take a half-ounce to 1 ounce per feeding initially, working up to 2 to 3 ounces in the first few days. They need to feed about 6 to 10 times per day. The infant will gradually be able to ingest more formula per feeding. By 3 to 4 months of age, babies feed four or five times per day and take 6 to 7 ounces per feeding. Most infants will not require specific amounts per feeding; the infant should be fed until full. To prevent overfeeding, healthy bottle-fed infants should be allowed to self-regulate the amount of formula ingested per feeding. When the baby is satiated, he or she might fall asleep, spit out the nipple or formula, play with the nipple, or lie quietly, only sucking once in a while (Shelov & Altmann, 2009).

FIGURE 3.13 Technique for bottle-feeding the infant.

TYPES OF FORMULAS AND BOTTLES

Parents may choose to use commercial formulas that are ready to feed or available as a concentrate or as a powder. Parents should follow the instructions for mixing the concentrate or powder to avoid dehydration or fluid and electrolyte imbalances. Ready-to-feed formula should be used as is and never diluted (NAPNAP, 2011a).

A wide variety of baby bottle and nipple types are available for formula feeding, and the choice is purely individual. Few infants require special nipples or bottles. [Box 3.2](#) gives guidelines on preparation and storage of formula and care of bottles.

SPECIAL FORMULAS

Special formulas may be needed for the infant who is allergic to a particular component of standard formula or has a renal, hepatic, metabolic, or intestinal disorder. For example, lactose-free cow's milk formulas are available for the lactose-intolerant child. Formulas

using soy as the base ingredient instead of whey or casein are also available. Soy formulas are necessary for infants with a milk allergy, and they may be appealing to the vegetarian family.

BOX 3.2

PREPARATION AND STORAGE OF BOTTLES AND FORMULA

- Wash nipples and bottles in hot soapy water and rinse well OR
- Run nipples and bottles through the dishwasher.
- Store tightly covered ready-to-feed formula can after opening in refrigerator for up to 48 hours.
- After mixing concentrate or powdered formula, store tightly covered in refrigerator for up to 48 hours.
- Do not reheat and reuse partially used bottles. Throw away the unused portion after each feeding.
- Do not add cereal to the formula in the bottle.
- Do not sweeten formula with honey.
- Warm formula by placing bottle in a container of hot water.
- Do not microwave formula.

Adapted from Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York, NY: Bantam Books

These special formulas are designed to meet the nutritional needs of infants, depending on the disorder. Infants who fail to gain weight may be placed on standard infant formula prepared to deliver a higher caloric density per ounce. Preterm infants (those born at less than 36 weeks' gestation) need adequate nutrition to exhibit catch-up growth. Good catch-up growth (quadrupling or even quintupling the birth weight) in the first year or so of life is critical for adequate head growth and avoidance of neurodevelopmental consequences. Premature infant follow-up formulas are designed to provide additional calories, protein, and a particular calcium-to-phosphorus ratio as well as the vitamins and minerals needed for adequate catch-up growth.

Progressing to Solid Foods

After 6 months of age, infants usually require the nutrients available in solid foods in addition to their breast milk or formula. Progressing to feeding solid foods can be exciting and trying. Before solid foods are attempted, the infant should be assessed for readiness to progress. Parents need instruction in choosing appropriate solid foods and support in the progression process.

ASSESSING INFANT READINESS

Several factors contribute to the appropriate timing of solid food introduction. The tongue extrusion reflex is necessary for sucking to be an automatic reaction—that is, when a nipple or other item is placed in the mouth, the tongue extrudes and sucking begins. This reflex disappears at about 4 to 6 months of age (Shelov & Altmann, 2009). Introducing solid food with a spoon prior to 4 to 6 months of age will result in extrusion of the tongue. The parent may think that the infant does not want the food and is spitting it out intentionally, but this is not the case; the infant simply must be mature enough to eat with a spoon (absence of extrusion reflex).

The ability to swallow solid food does not become completely functional until 4 to 6 months of age. Enzymes to appropriately digest food other than breast milk and formula are also not present in sufficient quantities until the age of 4 to 6 months.

Before the introduction of solid foods and the cup, the infant should be able to sit supported in a high chair. Solids should be fed with a spoon, with the infant in an upright position.

CHOOSING APPROPRIATE SOLID FOODS

Iron-fortified rice cereal mixed with a small amount of breast milk or formula is a good choice for the first solid food. The cereal is easily digested and its taste is generally well accepted. The cereal should be quite thin at first; it can be mixed to a thicker consistency as the infant gets older. Once the feeding of cereal with a spoon is successful, other single foods may be introduced. The foods should be pureed to a smooth consistency, whether prepackaged “baby food” or pureed at home.

BOX 3.3

FOODS TO AVOID IN INFANCY

- Honey
- Egg yolks and meats (until 10 months of age)

- Excessive amounts of fruit juice
- Foods likely to cause choking
 - Peanuts
 - Popcorn
 - Other small hard foods (e.g., raw carrot chunks)
 - Grapes and hot dog slices (must be cut in smaller pieces)
- Foods likely to result in allergic reaction
 - Citrus
 - Strawberries
 - Wheat
 - Cow's milk
 - Egg whites
 - Peanut butter

Adapted from Brown, J. (2011). *Nutrition now* (6th ed.). Florence, KY: Wadsworth Publishing.

The introduction of one new food every 4 to 7 days is recommended (Hagan et al., 2008; Shelov & Altmann, 2009). This allows for identification of food allergies (Box 3.3). No salt, sugar, or other seasoning should be added to these first foods.

Generally, by 8 months of age the infant is ready for more texture in his or her foods. Soft, smashed table food without large chunks is appropriate. Finger foods such as Cheerios, soft green bean pieces, or soft peas may also be offered. Avoid hard foods that the infant may choke on. Strained, pureed, or mashed meats may be introduced at 10 to 12 months of age.

The cup should be introduced at 6 to 8 months of age. One ounce of breast milk or formula should be placed in the cup while the infant is learning. This will decrease the amount of mess should the cup be spilled. Old-fashioned sippy cups are generally acceptable for use, though older infants quickly learn to drink from an ordinary cup with assistance when they are thirsty. Newer “no-spill” sippy cups are not recommended for general home use. They require sucking much like a bottle and do not really encourage the child to learn cup drinking. They should be reserved for use on long trips in the car or other instances in which spills should be avoided (Rychnovsky, 2000).

Fruit juice is unnecessary and should not be introduced until 6 months of age. If juice is given, it should be limited to 2 to 4 ounces per day. Fruit itself is much more nutritious than fruit juice. If infants are allowed to consume larger quantities of juice, it can displace important nutrients from breast milk or formula (AAP, 2007).

PROMOTING HEALTHY EATING HABITS

Infants and children learn about food within a social context, so the family plays an important role in creating healthy eating habits. Families “model” eating behaviors; infants and children learn about eating through watching others. Lifelong eating patterns are often established in childhood, so it is important to emphasize healthy eating practices beginning in infancy. Parents should not let infants eat whatever they want (permissive feeding style); this will lead to fights over eating in the future. Infants may require as many as 20 exposures to a new food before it is accepted. On the other hand, infants should not be coerced into eating all that is provided (authoritarian feeding style). Forcing an infant to eat when he or she is full sets the child up for overeating in the future and may lead to more power struggles (Shelov & Altmann, 2009). Parents need to find a balance between the permissive and authoritarian feeding styles to establish lifelong healthy eating patterns in their children. By providing education about appropriate diet and feeding behaviors, the nurse can help the family to accomplish this goal.

Think back to Allison Johnson. What questions should you ask Allison’s parents related to her nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

Newborns sleep about 20 hours a day, waking frequently to feed and quickly returning to sleep. By 3 months of age, most infants sleep 7 to 8 hours per night without waking. They will continue to take about three naps a day. By 4 months of age the infant is more active and alert and may have more trouble going to sleep in the evening. Night waking may occur, but the infant should be capable of sleeping through the night and does not require a night feeding. By 12 months of age infants sleep 8 to 12 hours per night and take two naps per day (Feigelman, 2007).

Discuss safe sleeping practices with parents of newborns and infants; the baby should sleep on a firm mattress without pillows or

comforters. The baby's bed should be placed away from air conditioner vents, open windows, and open heaters. Sudden infant death syndrome (SIDS) has been associated with prone positioning of newborns and infants, so the infant should be placed to sleep on the back (Shelov & Altmann, 2009). See Healthy People 2020.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Increase the percentage of infants who are put down to sleep on their backs. | <ul style="list-style-type: none">• Begin teaching about "back to sleep" at prenatal or newborn visit.• Use each encounter with the young infant as an opportunity to reinforce the supine position for sleep. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Take Note!

The AAP has determined that side sleeping is not as safe as supine sleeping.

In the newborn period, the primary caregiver should try to sleep when the baby is sleeping. Since newborns need to be fed every 1½ to 3 hours around the clock, parents may become exhausted quickly and are often eager for the infant to sleep through the night. Adding rice cereal to the evening bottle has not been proven to discourage night waking and is not recommended (Hagan et al., 2008). Provide support to parents of newborns and educate them on infant sleeping patterns.

It is important to establish a bedtime routine around 4 months of age due to the infant's increased alertness and activity level. The baby who is 4 months or older needs a time of calming and relaxation before going to sleep. A consistent bedtime routine should be established, perhaps a bath followed by rocking, singing, or reading. The infant should fall asleep in his or her own crib rather than being rocked to sleep or held until sleeping and then put in the crib. After 4 months of age, infants must learn to soothe themselves back to sleep following night waking. Older infants may exhibit head banging as a form of self-soothing and use it to fall asleep at night. Night feedings are unnecessary at this age and will create a routine of further night waking that will be difficult to break (Hagan et al., 2008). Parents should minimize attention and stimulation provided during a night waking. Briefly checking on the infant to ascertain his or her safety, followed by placing the infant back in a lying position and telling him or her good night, is all that is needed. This may have to be repeated several times before the infant falls back to sleep. It is important to keep interactions brief during the night waking so that the infant learns to fall back to sleep on his or her own. Continued issues with night waking should be discussed with the infant's primary care provider.

What anticipatory guidance should you provide to Allison's parents in relation to sleep?

Promoting Healthy Teeth and Gums

Healthy teeth and gums require proper oral hygiene and appropriate fluoride supplementation. Children older than 6 months of age who are at risk for developing dental caries and whose drinking water source contains less than 0.3 parts per million may require fluoride supplementation (Rozier, 2010). Excess fluoride ingestion can result in discoloration of the teeth (fluorosis). Early childhood dental caries can result from pooling of milk or juice around teeth and gums.

Before tooth eruption, parents should clean the child's gums after feeding with a damp washcloth. After teeth have erupted, parents can continue to use a soft cloth for tooth cleaning and then eventually use a small soft-bristled toothbrush. Toothpaste is unnecessary in infancy. Infants should not be allowed to take milk or juice bottles to bed, as the high sugar content of the fluid in contact with the teeth all night leads to dental caries (see section on baby bottle mouth later in this chapter). Weaning from the bottle at age 12 to 15 months may help prevent dental caries. No-spill sippy cups have also been implicated in the development of dental caries and should be avoided. The American Academy of Pediatric Dentistry recommends that infants receive their first dental visit by the age of 1 year.

Promoting Appropriate Discipline

Parenting requires ever-changing adaptations to the developing infant's needs. Unconditional love, patience, and compassion must be balanced with the parents' needs. **Discipline** refers to the molding of a child's behavior through instruction, practice, and consistency. Discipline helps build self-esteem in children as well as sets standards for social interactions. The primary goal of discipline is to teach an infant limits. Discipline should be used to help the infant solve problems. The infant's activities are based on the basic needs of food, security, warmth, love, and comfort. Misbehavior is the result of an unmet need, and the parents should respond accordingly.

As the infant is undergoing rapid changes in motor skills, safety needs increase. Nurses should encourage the parents to "childproof" their home so that the infant can develop physical skills without being at risk. In a childproof home, fewer restrictions need to be placed on the infant's behavior, and he or she can explore.

Physical punishment or spanking should never be used in infancy. Infants are at increased risk for physical injury from spanking and cannot make the connection between the spanking and the undesirable behavior. Providing a safe environment, redirection away from undesirable behaviors, and saying "no" in appropriate instances are far more effective. For example, when the infant is in potential danger (e.g., inserting a key into an electrical outlet, attempting to ingest a poisonous substance, or reaching into the toilet), the parent must use a firm but calm and brisk approach. If the infant knows the parent is serious, he or she will usually comply more quickly (AAP, 2004).

Remaining calm, firm, and consistent is necessary. Immediacy is also an important component of appropriate discipline. The infant cannot make the connection between a subsequent punishment or discussion of behavior with the earlier event itself. Positive reinforcement should be used to support good behavior (Anderson, 2008).

Addressing Child Care Needs

Many mothers work outside the home, there are many single-parent families, and many families live a distance away from relatives. In all of these circumstances, infants may need to be cared for outside the home, often in child care settings or home day care centers.

Parents contemplating child care must consider a number of factors. Do they want a sitter to come to their home? Will they use a traditional day care center or a home care situation with fewer children? How much can they afford? If families choose to use a freestanding day care center or a home-based day care center, they should make sure that the provider is appropriately licensed. Parents should feel comfortable with the caregiver-to-child ratio. Are the caregivers trained in infant CPR and first aid? Families may need to visit or interview several facilities before finding one that meets their requirements.

When an older infant is attending a child care situation for the first time, it may be helpful to visit the center once or twice beforehand so that the infant can get used to the caregivers from the comfort and security of the parent's lap. Warn parents that separation anxiety in late infancy can cause a disturbing crying episode when the parent leaves. Reassure parents that the infant will not suffer harm due to the separation.

Addressing Common Developmental Concerns

Parents commonly have multiple concerns during normal infant growth and development. Although most of these issues are not actual disease states or behavior problems, nurses must be aware of these issues to recognize them and to intervene appropriately.

Colic

Healthy 6-week-old infants cry for a total of about 3 hours every day. Crying and fussing are more prevalent in the evenings. By age 12 weeks, the total amount of crying is about 1 hour per day, and infants are better able to soothe themselves by this age. **Colic** is defined as inconsolable crying that lasts 3 hours or longer per day and for which there is no physical cause. It typically resolves by 3 months of age, coinciding with the age at which infants are better able to soothe themselves (e.g., by finger sucking). The cause of colic is thought to be problems in the gastrointestinal or neurologic system (probably system immaturity), temperament, or parenting style of the mother or father. Some parents are overly anxious or overly attentive or, at the other extreme, may not give the infant the attention he or she needs. Any of these may contribute to a baby's fussing and crying.

Prolonged crying leads to increased stress among caregivers. Failure to stop the crying leads to frustration, and crying that prevents the parents from sleeping contributes to the exhaustion they are already experiencing.

Educate parents that normal crying increases by the time the infant is 6 weeks old and diminishes by about 12 weeks. When faced with a colicky baby, parents should develop a stepwise approach to checking that all of the infant's basic needs are met. When these needs are met, attempts at soothing the infant may be used. Reducing stimulation may decrease the length of crying. Carrying the infant more may also be helpful. Some infants respond to the motion of an infant swing or a car ride. Vibration, white noise, or swaddling

may also help to decrease fussing in some infants. Pacifiers can be soothing to babies who need additional nonnutritive sucking. Parents should try one intervention at a time, taking care not to stimulate the infant excessively in the process of searching for solutions. Nurses should provide ongoing support to the parents of a colicky infant and reassure them that this is a temporary condition that will resolve in time (Shelov & Altmann, 2009).

Spitting Up

Spitting up (regurgitating small amounts of stomach contents) occurs in all infants, and a significant number of normal infants spit up excessively. Although spitting up after feeding is normal, it can be a cause of great concern to parents. Overfed babies who feed based on a parent-designed schedule and those who burp poorly are more likely to spit up. For some infants, the amount and frequency of spitting up are significant, and it may indicate gastroesophageal reflux.

Teach parents that feeding smaller amounts on a more frequent basis may help to decrease spitting-up episodes. Always burp the baby at least two or three times per feeding. Keep the baby upright for 30 minutes after feeding and do not lay the infant prone after feeding. Avoid bouncing or excess activity immediately after feeding. Positioning in an infant seat compresses the stomach and is not recommended. When placing the baby in bed, position him or her on the side with the head of the bed slightly elevated (Shelov & Altmann, 2009).

EVIDENCE-BASED PRACTICE 3.1

BENEFITS AND RISKS OF PACIFIER USE

STUDY

The authors review the history of pacifier use and several recent research studies that attempted to determine the risks and benefits of pacifier use. The majority of the studies were performed within the early part of the 21st century.

Findings

Upon analysis of the various research studies, the authors reached several conclusions. Pacifier use has been shown to lower the risk of sudden infant death syndrome (SIDS) when used at the time of sleep. Additional benefits include assistance in development of neurologic maturity in pre-term infants and not shortening breastfeeding duration in preterm or term infants older than 1 month of age. Potential risks include shortening of breastfeeding duration if a pacifier is used before 1 month of age, increased incidence of otitis media when used after 1 year of age, and development of dental misalignment.

Nursing Implications

In light of the potential risks and benefits of pacifier use, nurses must be prepared to provide parents with accurate information related to the use of pacifiers. Educate parents to avoid introduction of the pacifier until breastfeeding is well established (4 weeks of age), to use pacifiers only during periods of sleep, and to never force a pacifier on an infant or replace a pacifier in a sleeping infant's mouth. Additionally, parents should begin to wean the infant from the pacifier in late infancy so that it is not used past 1 year of age.

Adapted from Marter, A., & Agruss, J. C. (2007). Pacifiers: An update on use and misuse. *Journal for Specialists in Pediatric Nursing, 12*(4), 278-285.

Reassure parents that if the infant is wetting at least six diapers per 24 hours and gaining weight, the spitting up is normal. If the infant vomits one third or more of most feedings, chokes when vomiting, or experiences forceful emesis, the primary care provider should be notified.

Thumb Sucking, Pacifiers, and Security Items

Infants demonstrate a clear need for nonnutritive sucking: even fetuses can be observed sucking their thumbs or fingers in utero. Thumb sucking is a healthy self-comforting activity. Infants who suck their thumbs or pacifiers often are better able to soothe themselves than those who do not. Studies have not shown that sucking either thumbs or pacifiers leads to the need for orthodontic braces unless the sucking continues well beyond the early school-age period. However, pacifier use has been associated with the increased incidence of otitis media, and hygiene is always a concern as pacifiers often fall on the floor (Marter & Agruss, 2007).

Infants may also become attached to a doll, stuffed animal, or blanket. Just like thumb sucking, the attachment item gives the infant the security to self-soothe when he or she is uncomfortable.

Families need to explore their feelings and cultural preferences about sucking habits and security items. Parents should not try to break the habit during a stressful time for the infant. When the infant is intensely trying to master a new skill such as sitting or walking,

he or she may need the sucking or security item to self-soothe. Pacifiers and security items can be physically taken away at some point, but the thumb is attached. The infant who has become attached to thumb sucking should not have additional attention drawn to the issue, as that may prolong thumb sucking.

Families of infants who use pacifiers may want to wean the infant from the pacifier when the child approaches 1 year of age (Marter & Agruss, 2007). This is the time when the need for additional sucking naturally decreases. Attempts to wean the child from a security blanket or toy should probably be reserved for after infancy (see [Evidence-Based Practice 3.1](#)).

Teething

Discomfort is common as the tooth breaks through the periodontal membrane. Infants may drool, bite on hard objects, or increase finger sucking. Some infants may become very irritable, refuse to eat, and not sleep well. Fever, vomiting, and diarrhea are generally not considered a sign of teething but rather of illness.

Teething pain results from inflammation. Teach parents that application of cold may be soothing to the gums. The infant may chew on a cold teething ring, or parents can rub an ice cube wrapped in a washcloth on the gums. Over-the-counter topical anesthetics such as baby Orajel may also be helpful. Parents should apply the ointment correctly to the gums, avoiding the lips, as these ointments cause numbing. Occasionally, oral acetaminophen or ibuprofen may be given to relieve pain (Tinanoff, 2007).

Refer back to 6-month-old Allison Johnson. List some common developmental concerns of 6-month-old infants. What anticipatory guidance related to these concerns would you provide to her parents?

KEY CONCEPTS

- Infancy encompasses the period from birth to age 12 months.
- The infant exhibits tremendous growth, doubling the birthweight by 6 months of age and tripling it by 12 months of age.
- Most organ systems are immature at birth and develop and mature over the first year of life.
- Child development is orderly, sequential, and predictable, progressing in a cephalocaudal and proximodistal fashion.
- The infant is mastering the psychosocial task of Trust versus Mistrust.
- Cognitive development in infancy is sensorimotor; infants use their senses and progressing motor skills to master their environment.
- The 12-month-old babbles expressively and uses two or three words with meaning.
- Promotion of safety is of key importance throughout infancy.
- Breastfeeding is the natural and preferred method for infant feeding.
- Breastfed and bottle-fed infants should both be fed on cue rather than on a parent-designed schedule.
- Solid foods should be introduced at age 4 to 6 months. A spoon should be used to feed the infant, and rice cereal should be the first food. New foods should be introduced no more frequently than every 4 to 7 days.
- The cup may be introduced at 6 months of age. No-spill sippy cups are generally not recommended.
- Spitting up and colic are parts of normal development in the otherwise thriving infant and do not require medical intervention.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

- The mother of a 3-month-old boy asks the nurse about starting solid foods. What is the most appropriate response by the nurse?
 - “It’s okay to start pureed solids at this age if fed via the bottle.”
 - “Infants don’t require solid food until 12 months of age.”
 - “Solid foods should be delayed until age 6 months, when the infant can handle a spoon on his own.”
 - “The tongue extrusion reflex disappears at age 4 to 6 months, making it a good time to start solid foods.”
- The father of a 2-month-old girl is expressing concern that his infant may be getting spoiled. The nurse’s best response is:
 - “She just needs love and attention. Don’t worry; she’s too young to spoil.”
 - “Consistently meeting the infant’s needs helps promote a sense of trust.”
 - “Infants need to be fed and cleaned; if you’re sure those needs are met, just let her cry.”
 - “Consistency in meeting needs is important, but you’re right, holding her too much will spoil her.”
- Parents of an 8-month-old girl express concern that she cries when left with the babysitter. How does the nurse best explain this behavior?
 - Crying when left with the sitter may indicate difficulty with building trust.
 - Stranger anxiety should not occur until toddler-hood; this concern should be investigated.
 - Separation anxiety is normal at this age; the infant recognizes parents as separate beings.
 - Perhaps the sitter doesn’t meet the infant’s needs; choose a different sitter.
- The nurse is providing anticipatory guidance to the mother of a 6-month-old infant. What is the best instruction by the nurse in relation to the infant’s oral health?
 - “Start brushing her teeth after all the baby teeth come in.”
 - “Use a washcloth with toothpaste to clean her mouth.”
 - “Clean your baby’s gums, then new teeth, with a washcloth.”
 - “Rinse your baby’s mouth with water after every feeding.”
- A 9-month-old infant’s mother is questioning why cow’s milk is not recommended in the first year of life as it is much cheaper than formula. What rationale does the nurse include in her response?
 - It is permissible to substitute cow’s milk for formula at this age as he is so close to 1 year old.
 - Cow’s milk is iron poor and does not provide the proper balance of nutrients for the infant.
 - As long as the mother provides whole milk, rather than skim, she can start cow’s milk in infancy.
 - If the mother cannot afford the infant formula, she should dilute it to make it last longer.

CRITICAL THINKING EXERCISES

- The mother of an 11-month-old boy who was born at 24 weeks’ gestation is concerned about his size and motor skills. What information should the nurse provide?
- An infant’s mother thinks there may be something wrong with him because “he spits up so much.” What further information should the nurse obtain?
- If you determine that the infant in the question above is experiencing normal spitting up associated with his developmental age, develop a brief teaching plan to review with the mother.

STUDY ACTIVITIES

1. A mother brings her 9-month-old boy to the clinic for a well-child check-up. She has questions about feeding, speech, and walking. Develop a teaching plan of anticipatory guidance for the 9-month-old infant.
2. Develop a safety plan for the 12-month-old infant.
3. In the clinical setting, observe two infants of the same age, one who is developing appropriately for his or her age and one who is delayed. Note the similarities and differences between the two infants.

Growth and Development of the Toddler

Words of Wisdom *Toddlers* will take risks *and* make many mistakes, but remember that both are an essential part of their growth.

KEY TERMS

animism
echolalia
egocentrism
expressive language
food jag
individuation
parallel play
physiologic anorexia
receptive language
regression
separation
separation anxiety
sibling rivalry
telegraphic speech

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Explain normal physiologic, psychosocial, and cognitive changes occurring in the toddler.
2. Identify the gross and fine motor milestones of the toddler.
3. Demonstrate an understanding of language development in the toddler years.
4. Discuss sensory development of the toddler.
5. Demonstrate an understanding of emotional/social development and moral/spiritual development during toddlerhood.

6. Implement a nursing care plan to address common issues related to growth and development in toddlerhood.
7. Encourage growth and learning through play.
8. Develop a teaching plan for safety promotion in the toddler period.
9. Demonstrate an understanding of toddler needs related to sleep and rest, as well as dental health.
0. Develop a nutritional plan for the toddler based on average nutritional requirements.
1. Provide appropriate anticipatory guidance for common developmental issues that arise in the toddler period.
2. Demonstrate an understanding of appropriate methods of discipline for use during the toddler years.
3. Identify the role of the parent in the toddler's life and determine ways to support, encourage, and educate the parents about toddler growth, development, and concerns during this period.

Jose Gonzales is a 2-year-old boy brought to the clinic by his mother and father for his 2-year-old check-up. During your assessment, you find that his weight is 30 pounds, height 33 inches, and head circumference 19.5 inches. As the nurse caring for him, assess Jose's growth and development, and then provide appropriate anticipatory guidance to the parents.

The toddler period encompasses the second 2 years of life, from age 1 year to age 3 years. This period is a time of significant advancement in growth and development for the child. It can also be quite a challenging time for parents. The theme during the toddler years is one of holding on and letting go. Having learned that parents are predictable and reliable, the toddler is now learning that his or her behavior has a predictable, reliable effect on others. The challenge is to encourage independence and autonomy while keeping the curious toddler safe.

Take Note!

As more grandparents are assuming the primary caregiver role for their grandchildren, nurses should be alert to the possibility of increased stress that is placed upon the older caregiver, particularly during the active and sometimes trying years of toddlerhood (Leder, Grinstead, & Torres, 2007).

Infancy is a time of intense growth and development. Both physical growth and acquisition of new motor skills slow somewhat during the toddler years. Refinement of motor skills, continued cognitive growth, and acquisition of appropriate language skills are of prime importance during toddlerhood. The nurse uses the knowledge of normal toddler development as a roadmap for behavioral assessment of the 1- to 3-year-old child.

Physical Growth

The toddler's height and weight continue to increase steadily, though the increase occurs at a slower velocity compared to infancy. Toddler gains in height and weight tend to occur in spurts, rather than in a linear fashion (Fig. 4.1). The average toddler weight gain is 3 to 5 pounds per year. Length/height increases by an average of 3 inches per year. Toddlers generally reach about half of their adult height by 2 years of age. Head circumference increases about 1 inch from when the child is between 1 and 2 years of age, then increases an average of a half-inch per year until age 5. The anterior fontanel should be closed by the time the child is 18 months old. Head size becomes more proportional to the rest of the body near the age of 3 years (Hagan, Shaw, & Duncan, 2008).

Organ System Maturation

Though not as pronounced as the changes occurring during infancy, the toddler's organ systems continue to grow and mature in their functioning. Significant functional changes occur within the neurologic, gastrointestinal, and genitourinary systems. The respiratory and cardiovascular systems undergo changes as well.

FIGURE 4.1 The typical toddler appearance is that of a rounded abdomen, a slight swayback, and a wide-based stance.

Neurologic System

Brain growth continues through toddlerhood, and the brain reaches about 80% of its adult size by 3 years of age (Zero to Three,

2011). Myelination of the brain and spinal cord continues to progress and is complete around 24 months of age. Myelination results in improved coordination and equilibrium as well as the ability to exercise sphincter control, which is important for bowel and bladder mastery. Integration of the primitive reflexes occurs in infancy, allowing for the emergence of the protective reflexes near the end of infancy or early in toddlerhood. The forward or downward parachute reflex is particularly helpful when the child starts to toddle. Rapid increase in language skills is evidence of continued progression of cognitive development.

Respiratory System

The respiratory structures continue to grow and mature throughout toddlerhood. The alveoli continue to increase in number, not reaching the adult number until about 7 years of age. The trachea and lower airways continue to grow but remain small compared with the adult. The tongue is relatively large in comparison to the size of the mouth. Tonsils and adenoids are large and the Eustachian tubes are relatively short and straight.

Cardiovascular System

The heart rate decreases and blood pressure increases in toddlerhood. Blood vessels are close to the skin surface and so are compressed easily when palpated.

Gastrointestinal System

The stomach continues to increase in size, allowing the toddler to consume three regular meals per day. Pepsin production matures by 2 years of age. The small intestine continues to grow in length, though it does not reach the maximum length of 2 to 3 meters until adulthood. Stool passage decreases in frequency to one or more per day. The color of the stool may change (yellow, orange, brown, or green) depending on the toddler's diet. Since the toddler's intestines remain somewhat immature, the toddler often passes whole pieces of difficult-to-digest food such as corn kernels. Bowel control is generally achieved by the end of the toddler period.

Genitourinary System

Bladder and kidney function reach adult levels by 16 to 24 months of age. The bladder capacity increases, allowing the toddler to retain urine for increased periods of times. Urine output should be about 1 mL/kg/hour. The urethra remains short in both the male and female toddler, making them more susceptible to urinary tract infections compared to adults.

Musculoskeletal System

During toddlerhood, the bones increase in length and the muscles mature and become stronger. The abdominal musculature is weak in early toddlerhood, resulting in a pot-bellied appearance. The toddler appears to have a swayback along with the potbelly. Around 3 years of age, the musculature strengthens and the abdomen is flatter in appearance.

Psychosocial Development

Erikson defines the toddler period as a time of autonomy versus shame and doubt. It is a time of exerting independence. Since the toddler developed a sense of trust in infancy, he or she is ready to give up dependence and to assert his or her sense of control and autonomy (Erikson, 1963). The toddler is struggling for self-mastery, to learn to do for himself or herself what others have been doing for him or her. Toddlers often experience ambivalence about the move from dependence to autonomy, and this results in emotional lability. The toddler may quickly change from happy and pleasant to crying and screaming. Exertion of independence also results in the toddler's favorite response, "no." The toddler will often answer "no" even when he or she really means "yes."

This negativism—always saying "no"—is a normal part of healthy development and is occurring as a result of the toddler's attempt to assert his or her independence. [Table 4.1](#) gives further information related to developing a sense of autonomy.

Cognitive Development

According to Jean Piaget (1969), toddlers move through the last two substages of the first stage of cognitive development, the sensorimotor stage, between 12 and 24 months of age. Young toddlers engage in tertiary circular reactions and progress to mental combinations. Rather than just repeating a behavior, the toddler is able to experiment with a behavior to see what happens. By 2 years of age, toddlers are capable of using symbols to allow for imitation. With increasing cognitive abilities, toddlers may now engage in delayed imitation. For example, they may imitate a household task that they observed a parent doing several days ago.

Piaget identified the second stage of cognitive development as the preoperational stage. It occurs in children between ages 2 and 7 years. During this stage toddlers begin to become more sophisticated with symbolic thought. The thinking of the older toddler is far more advanced than that of the infant or young toddler, who views the world as a series of objects. During the preoperational stage, objects begin to have characteristics that make them unique from one another. Objects are considered large or small, a particular color or shape, or a unique texture. This moves beyond the connection of sensory information and physical action. Words and images allow the toddler to begin this process of developing symbolic thought by providing a label for the objects' characteristics (Piaget, 1969).

Toddlers also use symbols in dramatic play. First they imitate life with appropriate toy objects, and then they are able to substitute objects in their play. A bowl may be used to pretend to eat from, but then later it can be used upside down on the head as a hat (Fig. 4.2). Human feelings and characteristics may also be attributed to objects (**animism**) (Papalia & Feldman, 2011). See Table 4.1 for further explanation of cognitive development in toddlerhood.

Take Note!

Mothers who are depressed may not be as sensitive to their children as other mothers. For this reason, maternal depression is a risk factor for poor cognitive development. Be alert to the mental status of a toddler's mother so that appropriate referrals can be made if needed (Wacha-rasin, Barnard, & Speiker, 2003).

| TABLE 4.1 DEVELOPMENTAL THEORIES | | |
|----------------------------------|--|---|
| Theorist | Stage | Activities |
| Erikson | Autonomy vs. Shame & Doubt Age: 1–3 years | Achieves autonomy and self-control Separates from parent/caregiver Withstands delayed gratification Negativism abounds Imitates adults and playmates Spontaneously shows affection Is increasingly enthusiastic about playmates Cannot take turns in games until age 3 years |
| Piaget | Sensorimotor Substage 5: Tertiary Circular Reactions Age: 12–18 months Substage 6: Mental Combinations Age: 18–24 months Preoperational Age: 2–7 years | Differentiates self from objects Increased object permanence (knows that objects that are out of sight still exist [e.g., cookies in the cabinet]) Uses ALL senses to explore environment Places items in and out of containers Imitates domestic chores (domestic mimicry) Imitation is more symbolic Starting to think before acting Understands requests and is capable of following simple directions Has a sense of ownership (my, mine) Time, space, and causality understanding is increasing Uses mental trial and error rather than physical Makes mechanical toys work Plays make-believe with dolls, animals, and people Increased use of language for mental representation Understands concept of "two" Starting to make connections between an experience in the past and a new one that is currently occurring Sorts objects by shape and color Completes puzzles with four pieces Play becomes more complex |
| Freud | Anal Stage Age: 1–3 years | Focus is on achieving anal sphincter control. Satisfaction and/or frustration may occur as the toddler learns to withhold and expel stool. |

Adapted from Erikson, E. H. (1963). *Childhood and society* (2nd ed.). New York: W.W. Norton and Company; Feigelman, S. (2007). *Preschool years*. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; Feigelman, S. (2007). *The second year*. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; and Piaget, J. (1969). *The theory of stages in cognitive development*. New York: McGraw-Hill.

Motor Skill Development

Toddlers continue to gain new motor skills as well as refine others. Walking progresses to running, climbing, and jumping. Pushing or pulling a toy, throwing a ball, and pedaling a tricycle are accomplished in toddlerhood. Fine motor skills progress from holding and pinching to the ability to manage utensils, hold a crayon, string a bead, and use a computer. Development of eye-hand coordination is necessary for the refinement of fine motor skills. These increased abilities of mobility and manipulation help the curious toddler explore and learn more about his or her environment (Fig. 4.3). As the toddler masters a new task, he or she has confidence to conquer the next challenge. Thus, mastery in motor skill development contributes to the toddler's growing sense of self-esteem. The toddler who is eager to face challenges will likely develop more quickly than one who is reluctant. The senses of sight, hearing, and touch are useful in helping to coordinate gross and fine motor movement.

Gross Motor Skills

As gross motor skills are mastered and then used repeatedly, the large muscle groups in the toddler are strengthened. The “toddler gait” is characteristic of new walkers. The toddler does not walk smoothly and maturely. Instead, the legs are planted widely apart, toes are pointed forward, and the toddler seems to sway from side to side while moving forward (Fig. 4.4). Often the toddler seems to speed along, pitching forward, appearing ready to topple over at any moment. The toddler may fall often, but will use outstretched arms to catch himself or herself (parachute reflex). After about 6 months of practice walking, the toddler’s gait is smoother and the feet are closer together. By 3 years of age, the toddler walks in a heel-to-toe fashion similar to that of adults. Toddlers often use physical actions such as running, jumping, and hitting to express their emotions because they are only just learning to express their thoughts and feelings verbally. Table 4.2 lists motor skill expectations in relation to age.

FIGURE 4.2 The toddler will (A) pretend with items in the way they are intended to be used as well as (B) find other creative uses for them.

FIGURE 4.3 The toddler’s curiosity about the world increases, as does her ability to explore it.

Fine Motor Skills

Fine motor skills in the toddler period are improved and perfected. Holding utensils requires some control and agility, but even more is needed for buttoning and zipping. Adequate vision is necessary for the refinement of fine motor skills because eye-hand coordination is crucial for directing the fingers, hand, and wrist to accomplish small muscle tasks such as fitting a puzzle piece or stringing a bead. See [Table 4.2](#) for age expectations for various motor skills.

FIGURE 4.4 The young toddler (early walker) walks with a wide-based stance, feet pointing forward and arms akimbo.

TABLE 4.2

MOTOR SKILL DEVELOPMENT

| Age | Expected Gross Motor Skill | Expected Fine Motor Skills |
|--------------|---|--|
| 12–15 months | Walks independently | Feeds self finger foods Uses index finger to point |
| 18 months | Climbs stairs with assistance Pulls toys while walking | Masters reaching, grasping, and releasing: stacks blocks, puts things in slots Turns book pages (singly with board book, multiple if paper) Removes shoes and socks Stacks four cubes |
| 24 months | Runs Kicks ball Can stand on tiptoe Carries several toys, or a large toy while walking Climbs onto and down from furniture without assistance | Builds tower of six or seven cubes Right- or left-handed Imitates circular and vertical strokes Scribbles and paints Starting to turn knobs Puts round pegs into holes |
| 36 months | Climbs well Pedals tricycle Runs easily Walks up and down stairs with alternate feet Bends over easily without falling | Undresses self Copies circle Builds tower of nine or ten cubes Holds a pencil in writing position Screws/unscrews lids, nuts, bolts Turns book pages one at a time |

Adapted from Feigelman, S. (2007). Preschool years. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; Feigelman, S. (2007). The second year. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders.

Sensory Development

Toddlers use all of their senses to explore the world around them. Toddlers examine new items by feeling them, looking at them, shaking them to hear what sound they make, smelling them, and placing them in their mouths. Toddler vision continues to progress and should be 20/50 to 20/40 in both eyes. Depth perception also continues to mature. Hearing should be at the adult level, as infants are ordinarily born with hearing intact. The sense of smell continues to mature, and toddlers may comment if they do not care for the scent of something. Though taste discrimination is not completely developed, toddlers may exhibit preferences for certain flavors of foods. The toddler is more likely to try a new food if its appearance or smell is familiar. Lack of complete taste discrimination places the toddler at risk of accidental ingestion.

Communication and Language Development

Language development occurs rapidly during the toddler years. The acquisition of language is a dynamic and complex process. The child's age and social interactions and the types of language to which he or she has been exposed influence language development. **Receptive language** development (the ability to understand what is being said or asked) is typically far more advanced than **expressive language** development (the ability to communicate one's desires and feelings) (Feigelman, 2007b; Goldson & Reynolds, 2011). In other words, the toddler understands language and is able to follow commands far sooner than he or she can actually use the words himself or herself. Language is a very important part of the toddler's ability to organize his or her world and actually make sense of it. Thoughtfully planned use of language can provide behavior guidance and contribute to the avoidance of power struggles. In regard to expressive language development, the young toddler begins to use short sentences and will progress to a vocabulary of 50 words by 2 years of age (Feigelman, 2007b; Goldson & Reynolds, 2011). **Echolalia** (repetition of words and phrases without understanding) normally occurs in toddlers younger than 30 months of age. "Why" and "what" questions dominate the older toddler's language. Telegraphic speech is common in the 3-year-old. **Telegraphic speech** refers to speech that contains only the essential words to get the point across, much like a telegram. Rather than "I want a cookie and milk," the toddler might say, "Want cookie milk." In telegraphic speech the nouns and verbs are present and are verbalized in the appropriate order (Feigelman, 2007b). [Table 4.3](#) gives an overview of receptive and expressive language development in the toddler.

TABLE 4.3

LANGUAGE DEVELOPMENT IN TODDLERS

| Age | Receptive Language | Expressive Language |
|-----------|--|--|
| 12 months | Understands common words independent of context Follows a one-step command accompanied by gesture | Uses a finger to point to things Imitates or uses gestures such as waving goodbye Communicates desires with word and gesture combinations Vocal imitation First word |
| 15 months | Looks at adult when communicating Follows a one-step command without gesture Understands 100–150 words | Repeats words that he or she hears Babbles in what sound like sentences |
| 18 months | Understands the word “no” Comprehends 200 words Sometimes answers the question, “What’s this?” | Uses at least 5–20 words Uses names of familiar object |
| 24 months | Points to named body parts Points to pictures in books Enjoys listening to simple stories Names a variety of objects in the environment Begins to use “my” or “mine” | Vocabulary of 40–50 words Sentences of two or three words (“me up,” “want cookie”) Asks questions (“what that?”) Uses simple phrases Uses descriptive words (hungry, hot) Two thirds of what child says should be understandable Repeats overheard words |
| 30 months | Follows a series of two independent commands | Vocabulary of 150–300 words |
| 36 months | Understands most sentences Understands physical relationships (on, in, under) Participates in short conversations May follow a three-part command | Speech usually understood by those who know the child, about half understood by those outside family Asks “why?” Three- to four-word sentences Talks about something that happened in the past Vocabulary of 1,000 words Can say name, age, and gender Uses pronouns and plurals |

Adapted from Feigelman, S. (2007). Preschool years. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; Feigelman, S. (2007). The second year. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; and Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Detering (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York: McGraw-Hill.

Take Note!

Stuttering usually has its onset between 2 and 4 years of age. It occurs more often in boys than in girls. About 75% of all cases of stuttering resolve within 1 to 2 years after they start (Prasse & Kikano, 2008).

Early identification and referral of children with potential speech delays is critical. If a delay is identified, early intervention may increase the child’s potential to acquire age-appropriate receptive and expressive language skills.

Take Note!

Children with preexisting conditions such as genetic syndromes that are known to have an effect on language development should be referred to a speech-language pathologist as soon as the condition is recognized rather than waiting until the child exhibits a delay.

Of special concern in the toddler years is the development of speech and language in potentially bilingual children. At the age of 1 to 2 years, the potentially bilingual child may blend two languages—that is, parts of the word in both languages are blended into one word. At age 2 to 3 years, the potentially bilingual toddler may mix languages within a sentence. Thus, the assessment of adequate language development is more complicated in bilingual children. There are websites that may be helpful to parents of potentially bilingual children, where they can find support and resources. A list of websites is included on [thePoint](http://thePoint.lww.com/Kyle2e) at <http://thePoint.lww.com/Kyle2e>.

Take Note!

Bilingual children often mix languages, and thus speech delay may be more difficult to assess in this population. The bilingual child should have command of 20 words (between both languages) by 20 months of age and should be making word combinations. If this is not the case, further investigation may be warranted (Abell & Ey,

Emotional and Social Development

Emotional development in the toddler years is focused on **separation** and **individuation** (Papalia & Feldman, 2011). Seeing oneself as separate from the parent or primary caregiver is accompanied by forming a sense of self and learning to exert control over one's environment. As this need to feel in control of his or her world emerges, the toddler displays **egocentrism** (focus on self). This need for control results in emotional lability: very happy and pleasant one moment, then overreacting to limit setting with a temper tantrum in the next moment (Brazelton & Sparrow, 2006). As toddlers identify the boundaries between themselves and the parent or primary caregiver, they learn to negotiate a balance between attachment and independence. Toddlers initially rely on the parents' communication and signals in order to initiate appropriate behavior or inhibit undesirable behavior. They have a difficult time choosing between sets of behaviors as they occur in different situations. Power struggles often occur in this age group, and it is important for parents and caregivers to thoughtfully and intentionally develop the rituals and routines that will provide stability and security for the toddler (Feigelman, 2007). Many toddlers rely on a security item (blanket, doll, or bear) to comfort themselves in stressful situations (Fig. 4.5). This ability to self-soothe is a function of autonomy and is viewed as a sign of a nurturing environment, rather than, as one might suspect, one of neglect.

FIGURE 4.5 The toddler may be able to self-soothe and produce a sense of comfort during this stage of establishing autonomy by relying upon a security item such as a doll, bear, or blanket.

Children also begin to learn about gender differences in the toddler years. They observe the differences between male and female body parts if they are exposed to them. Toddlers may question parents about these differences and may begin to explore their own genitals. Toddlers also begin to understand and mimic social gender differences. They make observations about gender-specific behavior dependent upon what they are exposed to.

Aggressive behaviors are typically displayed during the toddler years. Toddlers may hit, bite, or push other children and grab toys. Adults can assist the toddler in building empathy by pointing out when someone is hurt and explaining what happened. Toddlers should not be blamed for their impulsive behavior; rather, they should be guided toward socially acceptable actions in order to foster development of appropriate social judgment. It is particularly important for the parent or caregiver to serve as a role model for

appropriate behavior, rather than losing his or her own temper, in order for the toddler to be able to learn how to acceptably handle frustrations. Offering limited choices is one way of allowing toddlers some control over their environment and helping them to establish a sense of mastery. Since toddlers naturally have a short attention span, they tend to dawdle. As the toddlers become more self-aware, they start to develop emotions of self-consciousness such as embarrassment and shame.

Though toddlers are becoming more self-aware, they still do not have clear body boundaries. They do not clearly understand the body's functions, though they are beginning to make appropriate connections. Feces may be viewed as a part of the child, and the toddler may become upset at seeing it disappear in the toilet. The toddler will protect his or her body by resisting intrusive procedures such as temperature or blood pressure measurement (Hagan et al., 2008).

Separation Anxiety

As toddlers become increasingly skilled at mobility, they realize that if they have the capability of leaving, then so does the parent. As self-awareness develops and conflicts over closeness versus exploration occur, **separation anxiety** may reemerge in the 18- to 24-month period (Brazelton & Sparrow, 2006). Power struggles may escalate and distress at separating from the parent may increase. Again, a predictable routine with appropriate limit setting may help toddlers to feel safer and more secure during this period. From the age of 24 to 36 months, separation anxiety again eases. The older toddler begins to have a concept of object constancy: he or she has an internal representation of the parent or caregiver and is better able to tolerate separation, knowing that a reunion will occur.

Temperament

Temperament is the biological basis for personality. It is our emotional and motivational core, around which the personality develops over time (Child Development Institute, 2010). Temperament affects how the toddler interacts with the environment. The easygoing toddler may adapt more easily and not mind changes in routine as much as other toddlers. The easygoing toddler usually sleeps and eats well and has more predictable and regular behaviors. However, the toddler may still express frustration by having a temper tantrum. The "difficult" toddler is more likely to have intense reactions, negative or positive, with temper tantrums being more likely, more frequent, and more intense than in other toddlers. The structure and routine that toddlers need to feel secure are essential for the difficult toddler; otherwise, the child feels insecure and as a result is more likely to behave inappropriately. The difficult toddler is also the most active of the three temperament types. The slow-to-warm-up toddler is more of a loner and may be very shy. He or she may experience more difficulty with separation anxiety. The behavior of the slow-to-warm-up toddler is more passive; the toddler may be very watchful and withdrawn and may take longer to mature. Changes in routine usually do not result in as much upset, since the toddler's natural reaction is one of passivity (Feigelman, 2007).

Based on the toddler's temperament, make suggestions to the parents for interacting with the toddler in various situations. For example, to avoid temper tantrums in the difficult toddler, suggest that the parent should be especially diligent about maintaining structure and routine as well as avoiding tantrum triggers such as fatigue and hunger. Explain to parents that they may need to exercise additional patience with new activities to which the slow-to-warm-up toddler may need extra time becoming accustomed.

Fears

Common fears of toddlers include loss of parents (which contributes to separation anxiety) and fear of strangers. Some toddlers may be very slow to warm up to people they do not know. The nurse caring for a toddler in the outpatient or hospital setting should take the time to establish a relationship with the toddler in order to allay the toddler's fears. Toddlers may be afraid of loud noises and large or unfamiliar animals. Going to sleep may be a scary time for toddlers as they may be afraid of the dark. A nightlight in the toddler's room may be very helpful.

Moral and Spiritual Development

During the toddler years, children may feel comfort from the routine of praying, but they do not understand religious beliefs because of their limited cognitive abilities. Reading simple Bible stories can lay a foundation for later religious teachings. Kohlberg's (1984) description of moral development places the older toddler in the pre-conventional level. The toddler is only just beginning to learn right from wrong and does not understand the larger concept of morality. The toddler will base his or her actions on the avoidance of punishment and the attainment of pleasure. Older toddlers begin to feel empathy for others.

Cultural Influences on Growth and Development

Homelessness or poverty may directly influence the toddler's ability to grow adequately, as resources for the purchase and

preparation of appropriate food may be lacking. Appropriate toys (safe ones) may also not be available in those situations. Food customs continue to have an impact on the child's diet and ability to ingest appropriate nutrients. Individual families' value systems have an impact on the toddler's development as well. Some parents desire to keep their child a "baby" for a longer period, thus delaying weaning or continuing to feed the child baby food or pureed food for a longer period. Other families may highly value independence and encourage the toddler to walk everywhere on his or her own rather than carrying the child.

Culture may also affect emotional development. Some families start at a very young age to discourage crying in boys, encouraging them to "act like a big boy" or "be a man." Ridicule for crying at this age may hurt the toddler's self-concept. Educating families about normal growth and development while continuing to value and support cultural practices is important (Papalia & Feldman, 2011).

Remember Jose Gonzales, whom you met at the beginning of the chapter? What developmental milestones would you expect him to have reached at his age?

THE NURSE'S ROLE IN TODDLER GROWTH AND DEVELOPMENT

The toddler's growth and development affects his or her everyday life as well as the family's. Though some toddlers may grow more quickly or reach developmental milestones sooner than others, growth and development remains orderly and sequential. Health care visits throughout toddlerhood continue to focus on growth and development. The nurse must have a good understanding of the changes that occur during the toddler years in order to provide appropriate anticipatory guidance and support to the family.

FIGURE 4.6 The hospitalized toddler continues to enjoy developmental tasks appropriate for his or her age, such as playing with manipulative toys.

When the toddler is hospitalized, growth and development may be altered. The toddler's primary task is establishing autonomy, and the toddler's focus is mobility and language development. Hospitalization removes most opportunities for the toddler to learn through exploration of the environment. Isolation for contagious illness further constrains the toddler's ability to find some control over the environment. The nurse caring for the hospitalized toddler must use knowledge of normal growth and development to be successful in interactions with the toddler, promote continued development, and recognize delays (see [Chapter 11](#)) ([Fig. 4.6](#)).

NURSING PROCESS OVERVIEW

Upon completion of assessment of the toddler's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Nursing care planning for the toddler with growth and development issues should be individualized based on the toddler's and family's needs. The nursing care plan may be used as a guide in planning nursing care for the toddler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the Nursing Care Plan (p. 110) and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be

Promoting Healthy Growth and Development

Parents who give their toddler love and respect regardless of the child's gender, behavior, or capabilities are helping to lay the foundation for self-esteem. Self-esteem is also built through familiarity with the daily routine. Routine and ritual help toddlers develop a conscience. Making expectations known through everyday routines helps to avoid confrontations. If the toddler knows the routine, he or she knows what to expect and how he or she is expected to act. When routine and limits are absent, the toddler develops feelings of uncertainty and anxiety. Limit setting (and remaining consistent with those limits) helps toddlers master their behavior, develop self-esteem, and become successful participants in the family. Children then are able to learn about cooperation throughout the predictable flow of daily life. Nurses need to be aware of normal developmental expectations in order to determine whether the toddler is progressing appropriately. [Table 4.4](#) lists potential signs of developmental delay. Any toddler with one or more of these concerns should be referred for further developmental evaluation.

NURSING CARE PLAN 4.1

Growth and Development Issues in the Toddler

NURSING DIAGNOSIS: Risk for injury related to curiosity, increased mobility, and developmental immaturity

Outcome Identification and Evaluation

Toddler safety will be maintained: *Toddler will remain free from injury.*

Interventions: Preventing Injury

- Teach and encourage appropriate use of rear-facing car seat until 2 years of age and forward-facing car seat after 2 years of age *to decrease risk of toddler injury related to motor vehicles.*
- Teach toddlers to stay away from the street and provide constant supervision *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Childproof the home *to provide a developmentally safe environment for the curious and increasingly mobile toddler.*
- Post poison control center phone number *in case of accidental ingestion.*
- Never leave a toddler unattended in a tub or pool or near any body of water *to prevent drowning.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on crib/bed in hospital *because toddlers are at particularly high risk for falling or becoming entangled in tubing as they attempt mobility.*

NURSING DIAGNOSIS: Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

Outcome Identification and Evaluation

Toddler will consume adequate nutrients while using an appropriate feeding pattern: *Toddler will demonstrate weight gain and increases in height.*

Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine toddler's ability to drink from cup, finger feed, swallow, and consume textures *to determine if additional exposure is needed or if further interventions such as speech or occupational therapy are required.* Weigh toddler daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Wean from bottle by 15 months of age *to discourage excess milk or juice intake in toddler who can carry bottle around.*
- Limit juice to 4 to 6 ounces per day and milk to 16 to 24 ounces per day *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed toddler on a similar schedule daily, without distractions and with the family: *toddlers respond well to routine and structure and may eat better in the social context of meals, and they become distracted easily (TV should be off).*

NURSING DIAGNOSIS: Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be enhanced: *Toddler will make continued progress toward realization of expected developmental milestones.*

Interventions: Enhancing Growth and Development

- Screen for developmental capabilities *to determine toddler's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*

- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of toddlers with developmental delay (*progress in achieving developmental milestones can be slow and ongoing motivation is needed*).
- Reinforce positive attributes in the toddler *to maintain motivation.*
- Model age-appropriate communication skills *to illustrate suitable means for parenting the toddler.*

NURSING DIAGNOSIS: Risk for disproportionate growth related to excess milk or juice intake, late bottle weaning, and consumption of inappropriate foods or in excess amounts

Outcome Identification and Evaluation

Toddler will grow appropriately and not become overweight or obese: *Toddler will achieve weight and height within the 5th to 95th percentiles on standardized growth charts.*

Interventions: Promoting Proportionate Growth

- Wean from bottle and discourage use of no-spill sippy cups by 15 months of age (*will keep mobile toddler from carrying around and continually drinking from cup or bottle*).
- Provide juice (4-6 ounces per day) and milk (16-24 ounces per day) from a cup at meal and snack time *to encourage appropriate cup drinking and limit intake of nutrient-poor, high-calorie fluids.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the toddler won't eat, it is inappropriate to provide high-calorie junk food just so the toddler eats something.*
- Ensure adequate physical activity *to stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming life-long habit of appropriate physical activity.*

NURSING DIAGNOSIS: Interrupted family processes related to issues with toddler development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the toddler

Outcome Identification and Evaluation

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

Interventions: Enhancing Family Functioning

- Assess the family's level of stress and ability to cope *to determine family's ability to cope with multiple stressors.*
- Engage in family-centered care *to provide a holistic approach to care of the toddler and family.*
- Encourage the family to verbalize feelings (*verbalization is one method of decreasing anxiety levels*), and acknowledge feelings and emotions.
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the toddler (*contributes to family's sense of control of situation*).
- Involve family members in toddler's care, *giving them a feeling of control and connectedness.*

NURSING DIAGNOSIS: Readiness for enhanced parenting related to parental desire for increased skills and success with toddler as evidenced by current healthy relationships and verbalization of desire for improved skills

Outcome Identification and Evaluation

Parent will provide safe and nurturing environment for the toddler.

Interventions: Increasing Parenting Skill Set

- Use family-centered care *to provide holistic approach.*
- Educate parent about normal toddler development *to provide basis for understanding the parenting skills needed in this time period.*
- Acknowledge and encourage parent's verbalization of feelings related to chronic illness of child or difficulty with normal toddler behavior *to validate the normalcy of the parent's feelings.*
- Encourage positive parenting with respect to toddlers and their normal development (*helps parents develop approaches to toddlers that can be used in place of anger and frustration*).
- Acknowledge and admire positive parenting skills already present *to contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the toddler (*role modeling actually shows rather than just telling the parent what to do*).

TABLE 4.4

SIGNS OF DEVELOPMENTAL DELAY

| Age or Time Frame | Concern |
|--|---|
| After independent walking for several months | <ul style="list-style-type: none"> • Persistent tiptoe walking • Failure to develop a mature walking pattern |
| By 18 months | <ul style="list-style-type: none"> • Not walking • Not speaking 15 words • Does not understand function of common household items |
| By 2 years | <ul style="list-style-type: none"> • Does not use two-word sentences • Does not imitate actions • Does not follow basic instructions • Cannot push a toy with wheels |
| By 3 years | <ul style="list-style-type: none"> • Difficulty with stairs • Frequent falling • Cannot build tower of more than four blocks • Difficulty manipulating small objects • Extreme difficulty in separation from parent or caregiver • Cannot copy a circle • Does not engage in make-believe play • Cannot communicate in short phrases • Does not understand simple instructions • Little interest in other children • Unclear speech, persistent drooling |

Promoting Growth and Development Through Play

Play is the major socializing medium for toddlers. Parents should limit television viewing and encourage creative and physical play instead. Toddlers typically play alongside another child (**parallel play**) rather than cooperatively (Fig. 4.7). The short attention span of the toddler will make him or her often change toys and types of play. It is important to provide a variety of safe toys to allow the toddler many different opportunities for exploring the environment. Toddlers do not need expensive toys; in fact, regular household items sometimes make the most enjoyable toys. Toddlers are egocentric, a normal part of their development (Piaget, 1969). This makes it difficult for them to share. As they are developing a sense of self (who they are as a person), they may see their toys as an extension of themselves. Learning to share occurs in later toddlerhood. Toddlers also like dramatic play and play that recreates familiar activities in the home. Toddlers like to listen to music of all kinds and will often dance to whatever they hear on the radio. Toddlers enjoy drums, xylophones, cymbals, and toy pianos. Musical instruments made at home are also enjoyed. A few pebbles or coins inside an empty water bottle with the top tightly secured is a great music maker; an empty butter tub with a lid and a pair of wooden spoons makes a nice drum.

FIGURE 4.7 Parallel play. The toddler usually plays alongside another child rather than cooperatively.

FIGURE 4.8 Toddlers love outdoor physical play, such as climbing on playground equipment. An adult should always supervise toddlers when they are playing outdoors.

Adequate physical activity is necessary for the development and refinement of movement skills. Toddlers need at least 30 minutes of structured physical activity and anywhere from 1 to several hours of unstructured physical activity per day (National Association for Sport & Physical Education, 2011). Indoor and outdoor play areas should encourage play activities that use the large muscle groups. The activity must occur within a safe environment. Outdoor play structures should be positioned over surfaces that are soft enough to absorb a fall, such as sand, wood chips, or sawdust (Fig. 4.8). Box 4.1 lists recommended age-appropriate toys.

Promoting Early Learning

The parent-child relationship and the interactions between parent and child form the context for the toddler's early learning.

Promoting Language Development

Talking and singing to the toddler during routine activities such as feeding and dressing provides an environment that encourages conversation. Frequent, repetitive naming helps the toddler learn appropriate words for objects. The parent or caregiver should be attentive to what the toddler is saying as well as to his or her moods. Using clarification validates the toddler's emotions and ideas. Parents should listen to and answer the toddler's questions. They should sit down quietly with the toddler and gently repeat what the toddler is saying. Encouragement and elaboration convey confidence and interest to the toddler. The toddler needs time to complete his or her thoughts without being interrupted or rushed because he or she is just starting to be able to make the connections necessary to transfer thoughts and feelings into language.

BOX 4.1

APPROPRIATE TOYS FOR TODDLERS

- Familiar household items such as plastic bowls and cups of various sizes, large plastic serving utensils, pots and pans, wooden spoons, cardboard boxes and tubes (from paper towel rolls), old magazines, baskets, purses, hats
- Child-size household item toys (kitchen, broom, vacuum cleaner, lawnmower, telephone, and so on)
- Blocks, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), simple dolls, stuffed animals, balls, doll beds and carriages
- Manipulative toys with knobs, wind-ups, and buttons that make things happen; putting large pegs or shapes into matching holes; stringing large beads on shoelaces; blocks and containers that stack; jigsaw puzzles with large pieces; toys that can be taken apart and put back together again
- Gross motor toys: play gym, push and pull toys, wagons, tricycle or other ride-on toys, tunnels
- Tape or CD players for music, various musical instruments
- Chalk, large crayons, finger paint, Play-Doh, washable markers
- Bucket, plastic shovel, and other containers for sand and water play
- Squeaking, floating, and squirting toys for the bath

Adapted from Schuman, A. T. (2007). *The ABCs of toy safety: More than just child's play*. *Contemporary Pediatrics*, 24(7), 49-57, 64; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York: Bantam Books.

Parents should not overreact to the child's use of the word "no." They can give the toddler opportunities to use the word "no" appropriately by asking silly questions such as, "Can a cat drive a car?" or "Is a banana purple?" When promoting language development, the parent or primary caregiver should teach the toddler appropriate words for body parts and objects and should help the toddler choose appropriate words to label feelings and emotions. Toddlers' receptive language and interpretation of body language and subtle signs far surpass their expressive language, especially at a younger age (Feigelman, 2007b; Goldson & Reynolds, 2011).

Parents should avoid discussing scary or serious topics in the presence of the toddler, since the toddler is very adept at reading emotions.

If the parents speak a foreign language in addition to English, both languages should be used in the home.

FIGURE 4.9 Reading to a toddler daily is one of the best ways to promote language development and school readiness.

Encouraging Reading

Reading to the toddler every day is one of the best ways to promote language and cognitive development (Fig. 4.9). Toddlers particularly enjoy homemade or purchased books about feelings, family, friends, everyday life, animals and nature, and fun and fantasy. Board books have thick pages that are easier for young toddlers to turn; older toddlers can turn paper pages one at a time. The toddler may also enjoy “reading” the story to the parent. Reach Out and Read, a program designed to promote early literacy, offers tips for reading with young children (see [Teaching Guidelines 4.1](#)).

Teaching Guidelines 4.1

TIPS FOR READING WITH YOUNG CHILDREN

- Make reading part of every day: Read at bedtime or on the bus.
- Have fun: Children who love books learn to read. Books can be part of special time with your child.
- A few minutes is OK: Young children can sit for only a few minutes for a story, but as they grow they will sit longer.
- Talk about the pictures: You do not have to read the book to tell a story.
- Let your child turn the pages: Babies need board books and help to turn pages, but your 3-year-old can do it alone.
- Show your child the cover page: Explain what the story is about.
- Show your child the words: Run your finger along the words as you read them.
- Make the story come alive: Create voices for the story characters and use your body to tell the story.
- Ask questions about the story: What do you think will happen next? What is this?
- Let your child ask questions about the story: Use the story as an opportunity to engage in conversation and to talk about familiar activities and objects.
- Let your child tell the story: Children as young as 3 years old can memorize a story, and many children love an opportunity to express their creativity.

Choosing a Preschool

The older toddler may benefit from the structure and socialization provided by attending preschool. Attending preschool will help the toddler become more mature and independent and give the toddler a different source for a sense of accomplishment. At this age, toddlers need supervised play with some direction that fosters their cognitive development. A strict curriculum is not necessary in this age group. When choosing a preschool, the parent or caregiver should look for an environment that has the following qualities:

- Goals and an overall philosophy with which the parents agree (promotion of independence and self-confidence through structured and free play)
- Teachers and assistants trained in early childhood development as well as child cardiopulmonary resuscitation (CPR)
- Small class sizes and an adult-to-child ratio with which the parent feels comfortable
- Disciplinary procedures consistent with the parents' values
- Parents can visit at any time
- School is childproofed inside and out
- Appropriate hygiene procedures, including prohibiting sick children from attending

Teach the parents how to ease the toddler's transition to attending preschool. Encourage parents to talk about going to preschool and visit the school a couple of times. On the first day, parents should calmly and in a matter-of-fact tone tell the toddler that they will return to pick him or her up. If the toddler expresses separation anxiety, the parent should remain calm and follow through with the plan for school attendance. After a few days of attendance, the toddler will be accustomed to the new routine and crying when parting from the parent should be minimal.

Promoting Safety

Safety is of prime concern throughout the toddler period. Curiosity, mobility, and lack of impulse control all contribute to the incidence of unintentional injury in toddlerhood. Even the most watchful and caring parents have toddlers who run into the street, otherwise disappear from parents, and fall down the stairs. Toddlers require direct observation and cannot be trusted to be left alone. A childproof environment provides a safe place for the toddler to explore and learn. Motor vehicle accidents, drowning, choking, burns, falls, and poisoning are the most common injuries suffered by toddlers. Safety and injury prevention focuses on these categories.

Safety in the Car

The safest place for the toddler to ride is in the back seat of the car. Parents should use the appropriate size and style of car seat for the child's weight and age as required by the state. At a minimum, toddlers should be in a rear-facing car seat with harness straps and a clip until 2 years of age (American Academy of Pediatrics [AAP], 2011a). After age 2 years, a forward-facing seat may be used. A toddler riding in a pickup truck should never ride in the cargo area or truck bed. A full rear seat in the truck is the preferred placement for the toddler car seat. If an appropriate rear seat is unavailable, the air bag should be disarmed and the forward-facing car seat should be secured appropriately in the truck seat. The lower anchor and top tether are additionally required for all forward-facing car seats manufactured since 2002 and are accommodated by motor vehicles manufactured since that time (Fig. 4.10). In older vehicles or car seats, seat belts are utilized for installation. Drivers should avoid using the cell phone or attempting to intervene with the children while they are driving. Excellent resources about car seat safety appropriate for both parents and professionals can be found on [thePoint](#).

Safety in the Home

Key areas of concern for keeping toddlers safe in the home include avoiding exposure to tobacco smoke, preventing injury, and preventing poisoning.

AVOIDING EXPOSURE TO TOBACCO SMOKE

Environmental exposure to tobacco smoke has been associated with increased risk of respiratory disease and infection, decreased lung function, and increased incidence of middle ear effusion and recurrent otitis media. It may also hinder neurodevelopment and may be associated with behavior problems (World Health Organization, 2011). Parents should avoid cigarette smoking entirely to best protect their children. Even smoking outside of the home is suboptimal because smoke lingers on parents' clothing and children who are often carried (such as younger toddlers) face more exposure. Counsel parents to stop smoking (optimal), but if they continue smoking never to smoke inside the home or car with children present.

PREVENTING INJURY

The toddler is able to open drawers and doors, unlock deadbolts, and climb anywhere he or she wants to go. Toddlers have a limited concept of body boundaries and essentially no fear of danger. Toddlers may fall from any height to which they can climb (e.g., play structures, tables, counters). They may also fall from wheeled toys such as tricycles. As toddlers gain additional height and hand dexterity they are able to reach potentially dangerous items on the counter or stove, leading to an accidental ingestion, burn, or cut.

To prevent injury in the home, stress the following to parents:

- Never leave a toddler unsupervised out of doors.
- Lock doors to dangerous rooms.

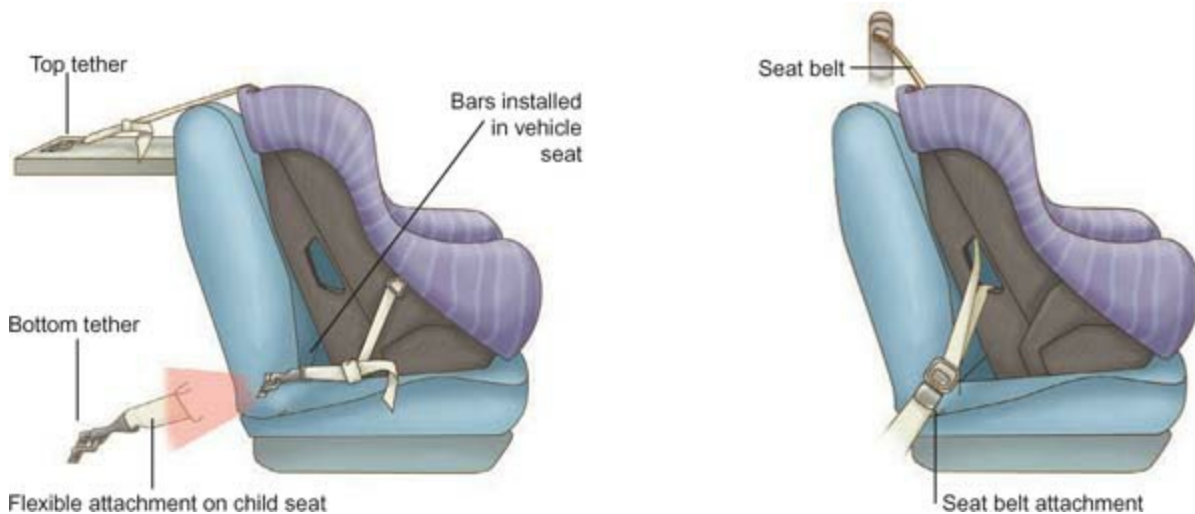

FIGURE 4.10 A lower anchor and top tether secure the forward-facing car seat. (Adapted from U.S. Department of Transportation, National Highway Traffic Safety Administration, 2008.)

- Install safety gates at the top and bottom of staircases.
- Ensure that window locks are operable; if windows are left opened, then secure all window screens.
- Keep pot handles on the stove turned inward, out of an inquisitive toddler’s reach.
- Teach the toddler to avoid the oven, stove, and iron.
- Keep electrical equipment, cords, and matches out of reach.
- Remove firearms from the home, or keep them in a locked cabinet out of the toddler’s reach.
- Always require the child to wear a helmet approved by the Consumer Products Safety Commission (CPSC) when riding a wheeled toy. This starts the habit of helmet wearing early, so it can be more easily carried over to the bicycle-riding years of the future.
- Begin teaching the toddler about watching for cars when crossing the street, but always carry or hold the hand of the toddler when crossing the street.
- Teach the toddler to avoid unknown animals (AAP, 2010b, 2010c).

Take Note!

”Bernie Burn’,” by Sarah Cruz, RN, is a book *designed* to educate parents and their toddlers about burn prevention while entertaining them. It is endorsed by the American Journal of Nursing, a link to which can be found on [thePoint](#)

PREVENTING POISONING

As toddlers become more mobile, they are increasingly able to explore their environment and more easily and efficiently gain access to materials that may be unsafe for them to handle. Their natural curiosity leads them into situations that may place them in danger. Poor taste discrimination in this age group allows for ingestion of chemicals or other materials that older children would find too unpleasant to swallow. **Box 4.2** lists most potentially dangerous ingested poisons. Discuss poison prevention in the home at each well-child visit (see Healthy People 2020). The American Academy of Pediatrics (2010c) recommends that potentially poisonous substances (e.g., medications, cleaners, hair care products, car care products) be stored out of the toddler’s reach, out of the toddler’s sight, and in a childproof, locked cabinet.

| Objective | Nursing Significance |
|--|---|
| Prevent an increase in the rate of non-fatal poisonings. | <ul style="list-style-type: none"> Use every encounter with the toddler's family as an opportunity to educate about preventing poisonings. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

BOX 4.2

MOST DANGEROUS POTENTIAL POISONS

- Medicines (especially iron)
- Cleaning products
- Antifreeze, windshield washer solution
- Alcohol
- Pesticides
- Gasoline, kerosene, lamp oil, furniture polish
- Wild mushrooms

Adapted from American Association of Poison Control Centers. (2011). *Poisoning prevention FAQ*. Retrieved March 7, 2011, from <http://www.aapcc.org/dnn/PoisoningPrevention/FAQ.aspx>

Encourage all families to take the following safety measures:

- Store all substances in original containers only.
- Never store any liquid other than soda in a soda pop bottle.
- Do not allow toddlers access to baby powder, lotion, cream, or other toddler hygiene products.
- Ensure all medications have child-safety caps.
- Do not leave within the toddler's reach medications such as lozenges or samples that are not packaged in safety bottles.
- Be very careful with medications that are provided in transdermal patch form.
- Do not refer to medicines as candy, as the toddler may mistake pills for candy and ingest them.
- Do not expose toddlers to hazardous vapors such as paints, cleaners, tobacco smoke, and especially street drugs such as crack and marijuana.
- Keep "button" batteries secured and away from a toddler's reach.
- Keep house plants off the floor, remove them from the home, or hang them or place them on a high shelf (American Association of Poison Control Centers, 2011; Hagan et al., 2008).

Take Note!

The American Academy of Pediatrics (2003) recommends that all families post the Poison Control Center number in a readily accessible place in the home: (800) 222-1222. The AAP discourages the use of syrup of ipecac in the home to induce vomiting after an accidental ingestion.

Safety in the Water

Drowning is the leading cause of unintentional injury and death in US children, with the highest rate of drowning occurring in 1- to 2-year-olds (AAP, 2010a). Drowning may occur in very small volumes of water such as a toilet, bucket, or bathtub, as well as the obvious sites such as swimming pools and other bodies of water. Toddlers' large heads in relation to their body size place them at risk for toppling over into a body of water that they are inquisitive about. Toddlers should be supervised at all times when in or around the water. In general, most children do not have the physical and cognitive capabilities necessary to truly learn how to swim until 4 years of age (AAP, 2010a). Parents who want to enroll a toddler in a swimming class should be aware that a water safety skills class would be most appropriate. However, even toddlers who have completed a swimming program still need *constant* supervision in the water (AAP, 2010a). [Box 4.3](#) gives recommendations for the prevention of drowning.

BOX 4.3

PREVENTING DROWNING

- Pools should be fenced with locked gates or screened with locked doors.
- Interior doors should be kept locked.
- Young children should never be left unattended in or near water.
- Water wings or “floaties” are not a substitute for adult supervision or for personal flotation devices.
- U.S. Coast Guard-approved life preservers or personal flotation devices should be available when a young child is in or near a body of water.
- Parents and caregivers should be trained in child cardiopulmonary resuscitation (CPR).

Adapted from American Academy of Pediatrics, Committee on Injury, Violence, and Poison Prevention. (2010). Prevention of drowning. *Pediatrics*, 126, 178-185.

Remember Jose Gonzales, the 2-year-old introduced at the beginning of the chapter? What anticipatory guidance related to safety should you provide to his parents?

Promoting Nutrition

The toddler’s ability to chew and swallow is improving, and he or she learns to use utensils effectively to feed himself or herself. The early years lay a foundation for the future, and a great deal of parental and societal interest is focused on nutrition and eating. Forming healthy eating habits has its foundation early in life, and diet has significant influence upon the child’s future health status. By establishing healthier food choice patterns early in life, the child is better able to continue these healthy choices later in life. The child younger than 2 years of age should not have his or her fat intake restricted, but this does not mean that unhealthy foods such as sweets should be eaten liberally. A diet high in nutrient-rich foods and low in nutrient-poor high-calorie foods such as sweets is appropriate for children of all ages. See Healthy People 2020.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Eliminate very low food security among children. | <ul style="list-style-type: none">• Counsel families about the appropriate toddler diet.• Refer eligible families to WIC for grocery supplementation and nutritional counseling. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Weaning

The timing of weaning from breastfeeding is influenced by a number of factors such as cultural beliefs, local and regional ethnic beliefs, the mother’s work schedule, desired child spacing, or societal feelings about the nature of the mother-infant relationship. The extent and duration of breastfeeding are inversely related to the development of obesity later in life: children who breastfeed longer are less likely to become obese than those who breastfeed for shorter periods of time (AAP, 2007b). Thus, extending breastfeeding into toddlerhood is believed to be beneficial to the child. Extended breastfeeding provides nutritional, immunologic, and emotional benefits to the child. Contrary to popular belief, it is biologically possible to become pregnant while breastfeeding. Breastfeeding a newborn appropriately can occur while continuing to nurse the older sibling.

Weaning from breastfeeding tends to occur earlier in the United States than in countries around the world, despite recommendations on length of breastfeeding by a number of organizations. Most professional organizations recommend breastfeeding for at least 1 year (National Association of Pediatric Nurse Practitioners [NAPNAP], 2007).

Weaning is a highly individualized decision. Educate the mother about the benefits of extended breastfeeding and support her in her decision to wean at a given time.

Weaning from the bottle should occur by 12 to 15 months of age. Prolonged bottle-feeding is associated with the development of dental caries. No-spill “sippy cups” contain a valve that requires sucking by the toddler in order to obtain fluid, thus functioning similar to a baby bottle. Hence, no-spill sippy cups can also be associated with dental caries and are not recommended (Rychnovsky, 2000). Cups with spouts that do not contain valves are acceptable. The 12- to 15-month-old is developmentally capable of consuming

adequate fluid amounts using a cup.

Teaching About Nutritional Needs

Adequate calcium intake and appropriate exercise lay the foundation for proper bone mineralization. The toddler requires an average intake of 500 mg calcium per day (Heird, 2007a). Dairy products are considered the primary sources of dietary calcium. One cup of low-fat or whole milk, 8 ounces of low-fat yogurt, and 1 ounce of cheddar cheese each provide 300 mg of calcium. Broccoli, oranges, sweet potatoes, tofu, and dried beans or legumes are also good sources of calcium (35 to 120 mg calcium per serving).

Take Note!

Though a half-cup of cooked spinach contains 120 mg of calcium, it is essentially nonbioavailable, making spinach a poor source of calcium.

Iron-deficiency anemia in the first 2 years of life may be associated with developmental and psychomotor delays (Baker, Greer, & the Committee on Nutrition, 2010). Although it is important for toddlers to consume adequate amounts of iron, they tend to have the lowest daily iron intake of any age group. When breastfeeding or formula feeding ends (most often at 1 year of age), it is often replaced with iron-poor cow's milk. Limiting milk intake to 16 ounces per day, as well as limiting juice intake, can be helpful. Encourage the parents to provide iron-fortified cereals and other foods rich in iron and vitamin C.

Take Note!

Toddlers who consume a strictly vegan diet (no food from animal sources) are at risk for deficiencies in vitamin D, vitamin B₁₂, and iron. Supplementation with these nutrients should occur to promote adequate nutrition and growth (Heird, 2007b).

Fat or cholesterol intake should not be restricted in children younger than age 2 years. The first 2 years of life require high energy intake because they are a time of very rapid growth and development. To promote healthy cholesterol levels, children older than age 2 years should consume a diet with a total fat content between 20% and 30% of total calories. Saturated fats should account for less than 10% of total calories (Heird, 2007b). Due to daily variations and the pickiness of the toddler, fat intake should be evaluated over a period of several days. The daily recommended intake of fiber for a 1- to 3-year-old is 19 grams. Generally, toddler serving sizes should be about two-thirds that of an older child. [Box 4.4](#) lists common sources of several nutrients.

BOX 4.4

KEY NUTRIENTS PROVIDED BY FRUITS AND VEGETABLES

Dietary fiber: applesauce, carrots, corn, green beans, mangos, pears

Folate: avocados, broccoli, green peas, oranges, spinach and dark greens, strawberries

Vitamin A: apricots, cantaloupe, carrots, mangos, spinach and dark greens, sweet potatoes

Vitamin C: broccoli, cantaloupe, green peas, oranges, potatoes, strawberries, tomatoes

Adapted from Brown, J. (2011). *Nutrition now* (6th ed.). Florence, KY: Wadsworth Publishing.

Parents should encourage toddlers to drink water. Juice intake should be limited to 4 to 6 ounces per day. Milk intake should be limited to 16 to 24 ounces per day. Juice and milk should be served along with meals or snacks. Water should be offered for between-meal drinking. Toddlers should drink from a cup.

Advancing Solid Foods

Parents should offer three full meals and two snacks daily. Portion sizes for toddlers are about one-quarter the size of adult portions. Large portions of a new or different food on the toddler's plate may intimidate the toddler. Normal toddler behaviors of mouthing, handling, tasting, extruding the food from the mouth, and then resampling the food often occur. These behaviors are distasteful to some parents but are a normal part of toddler development. Parents need to understand and tolerate these behaviors rather than scolding the toddler for them (Brazelton & Sparrow, 2006). Toddlers are often afraid to try new things anyway, so the parent or care-giver should be flexible with the toddler's acceptance or rejection of new foods. If the toddler refuses healthy food choices at meal or snack time, parents should not substitute high-fat, high-sugar, processed food "just to make sure he's eating something" (Weaver, More, & Harris, 2008). This sets the stage for future power struggles. The parent decides which foods will be served or

offered. The toddler decides how much will be eaten. The toddler self-regulates the amount of food needed to sustain and allow further growth and development. The toddler may not eat well every day but generally, over the course of several days, will consume the foods he or she needs (Heird, 2007b).

Foods should be served near room temperature. Some of the food on the plate should be soft and moist. Food should always be cut into bite-size pieces. [Teaching Guidelines 4.2](#) gives recommendations on ways to prevent choking.

Teaching Guidelines 4.2

AVOIDING CHOKING

- Slowly add foods that are more difficult to chew as the toddler becomes more adept at chewing.
- Cut all foods into bite-sized pieces.
- Avoid foods that are hard to chew and may become lodged in the airway, such as:
 - Nuts
 - Gumdrops or other chewy candies
 - Raw carrots
 - Peanut butter (by itself)
 - Popcorn
- Cut hotdogs and grapes into quarters. Cook carrots until soft; if serving raw, then grate them.
- Always supervise the toddler while he or she is eating.

Adapted from Brown, J. (2011). *Nutrition now* (6th ed.). Florence, KY: Wadsworth Publishing

Promoting Self-Feeding

Toddlers most often eat with their fingers, but they do need to learn to use utensils properly. The following are suggestions for parents:

- Use a child-sized spoon and fork with dull tines.
- Seat the toddler in a high chair or at a comfortable height in a secure chair. The toddler should have his or her feet supported rather than dangling ([Fig. 4.11](#)).
- Never leave the toddler unattended while eating.
- Minimize distractions during mealtime. Turn off the television and serve food to the toddler along with the other members of the family (NAPNAP, 2011).

Promoting Healthy Eating Habits

Since the toddler's rate of growth has slowed somewhat compared to that in infancy, the toddler requires less caloric intake for his or her size compared to the infant. This results in **physiologic anorexia**: toddlers simply do not require as much food intake for their size as they did in infancy. The toddler will also exhibit **food jags**. During a food jag, the toddler may prefer only one particular food for several days, then not want it for weeks. Again, it is important for the parent to continue to offer healthy food choices during a food jag and not give in by allowing the toddler to eat junk food (NAPNAP, 2011).

The normal developmental issue of testing limits will also occur for the toddler at mealtime. Since toddlers still have limited ability to express their emotions with words, they use nonverbal behaviors to do so. While eating, the toddler may dislike the taste of a particular food or experience a feeling of fullness but will communicate that feeling by screaming or throwing food. When the child exhibits these behaviors, the parent must remain calm and remove the toddler from the situation. Meals should be eaten in a calm and pleasant environment. Parents should serve as role models for appropriate eating habits, but toddlers may also be willing to try more foods if they are exposed to other children who eat those foods. Praise the child for trying a new food, and never punish the toddler for refusing to try something new. A new food may need to be offered many times in a row before the toddler chooses to try it. Parents should be sure to include foods the child is familiar with and likes to eat at the same meal that the new food is being introduced (Cathey & Gaylord, 2004). [Teaching Guidelines 4.3](#) lists alternative foods that meet nutritional needs and a list of books for parents of the picky eater.

FIGURE 4.11 The toddler should be appropriately and safely seated in the high chair. The safety strap is secure, the toddler's feet are supported, and the tray table is locked in place.

Teaching Guidelines 4.3

MEETING NUTRITIONAL NEEDS OF THE PICKY EATER

Alternative Food Choices for the Picky Eater

- Won't drink milk? Obtain calcium through yogurt (frozen or regular), cheese, pudding, and hot cocoa.
- Poor meat intake? Obtain iron through unsweetened iron-fortified cereals or breakfast bars, or raisins; cook with an iron skillet.
- Loves processed white bread? Encourage fiber intake with fresh fruits and vegetables, bran muffins, beans, or peas (can be in soup).
- Refuses vegetables? Encourage vitamin A intake with apricots, sweet potatoes, and vegetable juices.

Preventing Overweight and Obesity

In the child younger than 3 years of age, the greatest risk factor for the development of overweight or obesity is having an obese parent (AAP, 2007b). The nurse can screen for overweight in the child older than 2 years of age by calculating the body mass index (BMI) and plotting the BMI on the standardized age- and gender-appropriate growth charts (see Appendix A for growth charts, and

refer to [Chapter 10](#) for BMI calculation instructions). Trends over time may be predictive of the development of overweight or obesity.

Another factor in development of obesity in young children is juice intake (AAP, 2007a). Since most young children like the sweet taste of juice, they may drink excessive amounts of it. Toddlers who drink excess fruit juice and eat well may develop overweight or obesity because of the high sugar content in the juice. On the other end of the spectrum, some children may actually feel full from juice consumption and decrease their intake of solid foods. These children are at risk for malnutrition. Fruit juice intake should be limited to 4 to 6 ounces per day.

Take Note!

Young children should consume only pasteurized juice, as unpasteurized juice consumption places the toddler at increased risk of *Escherichia coli*, *Salmonella*, and *Cryptosporidium* infection.

Refer back to Jose Gonzales. What questions should you ask his parents related to his nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The 18-month-old requires 13.5 hours of sleep per day, the 24-month-old 13 hours, and the 3-year-old 12 hours (Feigelman, 2007a, 2007b). A typical toddler should sleep through the night and take one daytime nap. Most children discontinue daytime napping at around 3 years of age. The toddler who slept in a crib as an infant will need to move to a youth or toddler bed or even a full-size bed usually sometime in the toddler period. When the crib becomes unsafe (i.e., when the toddler becomes physically capable of climbing over the rails), then he or she must make the transition to a bed.

Consistent bedtime rituals help the toddler prepare for sleep. Choose a bedtime and stick to it as much as possible. The nightly routine might include a bath followed by reading a story. The routine should be a calm period with minimal outside distractions. Toddlers often require a security item to help them get to sleep. Older toddlers may be afraid of the dark, so a nightlight is often helpful.

Night waking is a problem for some toddlers. This may occur as a result of change in routine or as a desire for nighttime attention. Attention during night waking should be minimized so that the toddler receives no reward for being awake at night. The book *Solve Your Child's Sleep Problems*, by Dr. Richard Ferber (2006, New York: Fireside Publishing), is an excellent resource for the family with a toddler who resists bedtime or is a persistent night waker. For some toddlers, night waking is caused by nightmares. As the imagination and capacity for make-believe grow, the toddler may not be able to distinguish between reality and pretend. The parent should hold and comfort the toddler after a nightmare. Limiting television viewing (especially shortly before bedtime) may be helpful in limiting nightmares.

Some families practice “co-sleeping” (when children sleep in the parents’ bed). Although some professionals believe that co-sleeping may interfere with the toddler’s struggle for independence, this theory has not been proven. The nurse should support the family’s choice for sleep arrangements unless the co-sleeping is unsafe either physically or psychologically ([SafeBedSharing.org](http://www.safebedsharing.org), 2011). Refer to <http://www.safebedsharing.org> for bed-sharing safety guidelines.

Provide anticipatory guidance to Jose Gonzales’ parents in relation to his sleep.

Promoting Healthy Teeth and Gums

By 30 months of age, the toddler should have a full set of primary (“baby”) teeth. Parents may not be aware of the importance of preventing cavities in primary teeth since they will eventually be replaced by the permanent teeth. Poor oral hygiene, prolonged use of a bottle or no-spill sippy cup, lack of fluoride intake, and delayed or absent professional dental care may all contribute to the development of dental caries (Wagner & Oskouian, 2008). Cleaning of the toddler’s teeth should progress from brushing with simply water to using a very small amount (pea-sized) of fluoridated toothpaste with brushing beginning at 2 years of age ([Fig. 4.12](#)). Weaning from the bottle no later than 15 months of age and severely restricting use of a no-spill sippy cup (the kind that requires sucking for fluid delivery) is recommended.

FIGURE 4.12 The parent should brush the toddler’s teeth to ensure proper cleaning of the teeth, gums, and tongue. Use only water for brushing before 2 years of age and a pea-sized amount of fluoride-containing toothpaste after age 2 years.

At age 1 year, the toddler should have his or her first dentist visit to establish current health of the teeth and gums. Eating should be limited to meal and snack times, as “grazing” throughout the day exposes the teeth to food throughout the day. Carbohydrate-containing foods combined with oral bacteria create a decreased oral pH level that is optimal for the development of dental caries (cavities). See Healthy People 2020.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Reduce the proportion of children with untreated dental decay. | <ul style="list-style-type: none"> • Encourage weaning from bottle by 15 months of age. • Discourage use of no-spill sippy cups. • Refer any toddler with potential or existing caries to pediatric dentist. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Public water fluoridation is a public health initiative that ensures that most children receive adequate fluoride intake to prevent dental caries. Table 4.5 gives recommendations regarding fluoride supplementation. If the water supply contains adequate fluoride, no other supplementation is necessary other than brushing with a small amount of fluoride-containing toothpaste after age 2 years. Excess fluoride ingestion should be avoided, as it contributes to the development of fluorosis (mottling of the enamel). Fluorosis occurs most often in the toddler years (AAP, 2011b). Risk factors for fluorosis development include:

- High fluoride levels in the local water supply

- Use of fluoride-containing toothpaste prior to age 2 years
- Excessive ingestion of fluoride either in toothpaste or foods
 - Fluoride-containing foods: tea, ready-to-eat infant foods containing chicken, white or purple grape juice, and beverages, processed foods, and cereals that were manufactured with fluoride-containing water

TABLE 4.5 RECOMMENDATIONS FOR FLUORIDE SUPPLEMENTATION

| Age | Fluoride Ion Level in Drinking Water (ppm) | | |
|---------------------|--|-------------|----------|
| | <0.3 ppm | 0.3–0.6 ppm | >0.6 ppm |
| Birth to 6 months | None | None | None |
| 6 months to 3 years | 0.25 mg/day | None | None |
| 3–6 years | 0.50 mg/day | 0.25 mg/day | None |
| 6–16 years | 1.0 mg/day | 0.50 mg/day | None |

ppm, parts per million is equivalent to 1 mg/liter.
 These recommendations are public domain at www.ada.org and were approved by the American Dental Association, the American Academy of Pediatrics, and the American Academy of Pediatric Dentistry.

Promoting Appropriate Discipline

Discipline is a common concern during toddlerhood. The toddler’s intense personality and extreme emotional reactions can be difficult for parents to understand and cope with. The toddler needs firm, gentle guidance to learn what the expectations are and how to meet them. The parent’s love and respect for the toddler teach the toddler to care about himself or herself and for others. Affection is as important as the guidance aspect of discipline. Having realistic expectations of what the toddler is capable of learning and understanding can help the parent in the disciplinary process. The toddler’s intense push for autonomy can often test a parent’s limits. The easygoing infant usually becomes more challenging in toddlerhood. The toddler’s continual quest for new experiences often places the toddler at risk, and his or her negativism very often taxes the parent’s patience.

In an effort to prevent the toddler from experiencing harm and in response to his or her continual testing of limits, parents often resort to spanking. Though commonly accepted, the American Academy of Pediatrics and the National Association of Pediatric Nurse Practitioners recommend against corporal or physical punishment (AAP, 2004; NAPNAP, 2006). Recent research points out the dangers inherent in the use of corporal punishment as well as the possibilities for negative effects on the child’s future behavior (Box 4.5). Spanking or other forms of corporal punishment lead to a proviolence attitude, create resentment and anger in some children, and contribute to the cycle of violence (NAPNAP, 2006). See [Evidence-Based Practice 4.1](#).

Take Note!

Toddlers younger than 18 months of age should NEVER be spanked, as there is an increased possibility of physical injury in this age group. Also, the infant/young toddler is not capable of linking the spanking with the undesired behavior (AAP, 2004).

Normal toddler development includes natural curiosity, and this curiosity often results in dangerous or problematic activities for the toddler (Anderson, 2008). Toddlers have a difficult time learning the rules and in general do not behave badly intentionally. Providing a childproof environment will allow the toddler to participate in safe exploration, which will meet his or her developmental needs and decrease the frequency of intervention needed on the part of the parents.

Discipline should focus on limit setting, negotiation, and techniques to assist the toddler to learn problem solving. Parents should provide consistency and commit to the limits that are set.

Offering realistic choices helps give the toddler a sense of mastery. Rules should be simple and limited in number. Maintaining the toddler’s schedule of meals and rest/sleep will help to prevent conflicts that occur as a result of hunger or fatigue. Toddlers should not be made to share, as this is a concept they do not understand. Parents should encourage simple activities enjoyed by the children involved and avoid confrontation over toys. Parents should offer toddlers appropriate choices to help them develop autonomy, but should not offer a choice when none exists.

NEGATIVE IMPACT OF PHYSICAL PUNISHMENT

- Spanking is less effective than time-out or other discipline measures to reduce undesired behavior in children.
- The toddler younger than 18 months of age:
 - Is not capable of making the appropriate connections between spanking and the undesired behavior
 - Is at increased risk for physical injury from spanking than older children
- Physical punishment:
 - May lead to a proviolence attitude
 - May create resentment in the toddler
 - Is a poor model for learning effective problem solving
 - May be correlated with antisocial and criminal behavior later in life
 - Leads to increased aggression in preschoolers, school-age children, and adults
 - When used frequently, may weaken the parent-child relationship
- Childhood corporal punishment increases the probability of depression and substance abuse in adulthood.
- Spanking may lead to more severe forms of punishment and to actual child abuse and maltreatment.
- The more frequently children are hit or spanked, the more likely they are to hit their own children and to be involved in spouse abuse as adults.

Adapted from American Academy of Pediatrics. (2004). *Guidance for effective discipline*. Retrieved March 11, 2011, from <http://aappolicy.aappublications.org/cgi/content/full/pediatrics;101/4/723>; and National Association of Pediatric Nurse Practitioners. (2006). NAPNAP position statement on corporal punishment. *Journal of Pediatric Health Care*, 20(6), A43-A44.

Positive reinforcement should be used as much as possible. “Catching” a child being good helps to reinforce appropriate or desirable behaviors. When the toddler is displaying appropriate behavior, the parent should reward the child consistently with praise and physical affection.

“Time-out” can be used effectively at around 2.5 to 3 years of age (refer to [Chapter 5](#) for details). “Extinction” is a particularly useful technique with 2- and 3-year-olds. Extinction involves systematic ignoring of the undesired behavior. Parents sometimes unknowingly contribute to the occurrence of an unwanted behavior simply by the attention they give the toddler (even if it is negative in nature, it is still attention). Parents who want to extinguish an annoying (nondangerous) behavior should resolve to ignore it every time it occurs. When the child withholds the behavior or performs the opposite (appropriate) behavior, they should use compliments and praise. It may be difficult to ignore a difficult behavior, but the results are well worth the effort. [Teaching Guidelines 4.4](#) provides tips on avoiding power struggles and offering appropriate guidance to toddlers.

EVIDENCE-BASED PRACTICE 4.1

CORPORAL PUNISHMENT AND BEHAVIOR PROBLEMS IN EARLY CHILDHOOD

STUDY

A large volume of research indicates that there are few, if any, positive developmental outcomes associated with the use of corporal punishment (spanking). In order to determine if negative consequences resulted, the authors used data from a large longitudinal ongoing multicenter study, the National Institute of Child Health and Human Development Study of Early Child Care and Youth Development. They reviewed the data from over 100 children, performing analyses that specifically controlled for contextual and parenting variables as well as for partial child effects. The Home Observation for the Measurement of the Environment (HOME) was administered when the children were 15, 36, and 54 months of age. The HOME measurement determined the use of corporal punishment. To determine the presence of behavior problems, the Child Behavior Checklist was administered at 36 months of age and again when the child was in the first grade.

Findings

Multiple regression analysis was performed on the data sets, controlling for variables such as the child’s gender, ethnicity, and temperament as well as maternal sensitivity and depression. The results established a causal link between the use of corporal punishment and child adjustment, particularly an increase in behavior problems during toddlerhood.

Nursing Implications

Targeted interventions may have a positive impact on decreasing the use of corporal punishment in young children. Advise parents about the risks associated with corporal punishment. Provide them with education about appropriate alternative methods

of discipline, including limit setting with consistent follow-through, extinction, and time-out. Support parents' efforts to use alternative methods of discipline.

Adapted from Mulvaney, M. K., & Mebert, C. J. (2007). Parental corporal punishment predicts behavior problems in early childhood. *Journal of Family Psychology*, 21(3), 389-397.

Teaching Guidelines 4.4

PROVIDING TODDLERS WITH GUIDANCE

- When giving the toddler instructions, tell the child what to do, NOT what not to do. This allows for a positive focus. If you must say “no,” “don’t,” or “stop,” then follow with a direction of what to do instead.
- Offer limited choices, when a choice is truly available. Say, “Do you want to wear your blue hat or your red hat?” NOT “Do you want to put on your hat?” This gives the toddler some, but not all, control.
- Role model appropriate communication, but don’t feel like you have to speak nicely all the time. If the situation warrants, use a firm and even tone to get the point across. Avoid yelling.
- Pay attention to the inflection in your voice. A statement or direction should not end in a questioning tone or with “Okay?” Be clear. Statements should sound like statements, and only questions should end in a questioning tone.
- When a toddler behaves aggressively, label the child’s feelings calmly, but be firm and consistent with the expectation. For example, “I know you’re mad at your friend, but it is not okay to hit.”

Adapted from American Academy of Pediatrics. (2004). *Guidance for effective discipline*. Retrieved March 11, 2011,

Addressing Common Developmental Concerns

Common developmental concerns of the toddler period are toilet teaching, temper tantrums, thumb sucking or pacifier use, sibling rivalry, and regression. An understanding of the normalcy of negativism, temper tantrums, and sibling rivalry will help the family cope with these issues. Prepare parents for these developmental events by giving appropriate anticipatory guidance.

Toilet Teaching

When myelination of the spinal cord is achieved around age 2 years, the toddler is capable of exercising voluntary control over the sphincters. Girls may be ready for toilet teaching earlier than boys. Toddlers are ready for toilet teaching when:

- Bowel movements occur on a fairly regular schedule.
- The toddler expresses knowledge of the need to defecate or urinate. This may be through verbalization, change in activity, or gestures such as:
 - Looks into or grabs diaper
 - Squats
 - Crosses legs
 - Grimaces and/or grunts
 - Hides behind a door or the couch when defecating
- The diaper is not always wet (this indicates the ability to hold the urine for a period of time).
- The toddler is willing to follow instructions.
- The toddler walks well alone and is able to pull down his or her pants.
- The toddler follows caregivers to the bathroom.
- The toddler climbs onto the potty chair or toilet (AAP, 2011c).

Parents should approach toilet teaching with a calm, positive, and nonthreatening manner. Initially it may be helpful to allow the toddler to observe a same-sex family member using the toilet. Start with the toddler fully clothed on the potty chair or toilet while the parent or caregiver talks about what the toilet is used for and when. The toddler will feel most comfortable with a toddler potty chair that sits on the floor (Fig. 4.13). If a potty chair is unavailable, facing toward the toilet tank may make the toddler feel more secure, as the buttocks remain on the front of the seat rather than sinking through the toilet seat opening. After a week or longer, remove a dirty

diaper and place the contents in the toilet. Next try having the toddler sit on the potty chair or toilet without pants or diaper on. The toddler may benefit from watching a caregiver or friend use the toilet. It may also be beneficial to demonstrate using the potty chair with a baby doll that wets.

FIGURE 4.13 The toddler will feel most comfortable with a potty chair that sits on the floor.

Parents should always use gentle praise and no reproaches. Usually the best time to achieve success with defecation on the toilet is following a meal. When the toddler has achieved success with bowel control, bladder control will come next. It may be many months before nighttime bladder control is achieved, and the toddler may still require a diaper at night. Parents should use appropriate words for body parts, urination, and defecation, then use those words consistently so the toddler understands what to say and do (AAP, 2011c).

After a couple of weeks of successful toileting, the toddler may start wearing training pants. When toddlers have an accident and don't make it to the toilet, gently remind them about toileting and let them help clean up. Toddlers should never be punished for bowel or bladder "accidents."

With so much attention focused on the genitalia during toilet teaching and the frequency of being without a diaper, it is natural for toddlers to become more focused on their own genitalia. Boys and girls both will explore their genitalia and discover the resulting pleasurable sensation. Masturbation in the toddler often causes a great deal of discomfort in the parent. The parent should not draw attention to the activity, as that may increase its frequency. The parent should calmly explain to the toddler that this is an activity that may only be done in private (Feigelman, 2007b). If the toddler is masturbating excessively or refuses to stop when in public, then there may be additional stressors in the toddler's life that should be explored.

Negativism

Negativism is common in the toddler period (Brazelton & Sparrow, 2006). As the toddler separates from the parent, recognizes his or her own individuality, and exerts autonomy, negativism abounds. Parents should understand that this negativism is a normal developmental occurrence and not necessarily deliberate defiance (though that also occurs). Avoid asking yes-or-no questions, as the toddler's usual response will be "no," whether he or she means it or not. Offering the child simple choices will give the toddler a sense of control. The parent should not ask the toddler if he or she "wants" to do something, if there is actually no choice. "Do you want to use the red cup or the blue cup?" is more appropriate than "Do you want your milk now?" When it is time to go outside, don't ask, "Do you want to put your shoes on?" Instead, state in a matter-of-fact tone that shoes must be worn outside, and give the toddler a choice of type of shoe or color of socks. If the child continues with negative answers, then the parent should remain calm and make

the decision for the child.

FIGURE 4.14 Tantrums are a normal component of toddler development.

Temper Tantrums

Even children who displayed an easygoing personality as infants may lose their temper frequently during the toddler years (Fig. 4.14). A toddler who was more intense as an infant may have more temper tantrums. Temper tantrums are a natural result of the frustration that toddlers experience. Toddlers are eager to explore new things, but their efforts are often thwarted (usually for safety reasons). Toddlers do not behave badly on purpose. They need time and maturity to learn the rules and regulations. Some of their frustration may come from lack of language skills to express themselves. Toddlers are just starting to learn how to verbalize feelings and to use alternative actions rather than just “pitching a fit.” The temper tantrum may be manifested as a screaming and crying fit or a full-blown episode in which the toddler throws himself or herself on the floor kicking, screaming, and pounding, perhaps even holding the breath. Fatigue or hunger may limit the toddler’s coping abilities and promote negative behavior and temper tantrums (Lyness, 2008).

Although tantrums are annoying to parents and caregivers, they are a normal part of the toddler’s quest for independence. As toddlers mature, they become better able to express themselves and to understand their environment.

Parents need to learn their toddler’s behavioral cues in order to limit activity that is frustrating. When the parent notes the beginnings of frustration, a friendly warning might be given. Intervening early with an activity change might prevent a tantrum. Use distraction, refocusing, or removal from the situation.

When a temper tantrum does occur, the best course of action is to ignore the behavior and ensure that the child is safe during the tantrum. Physical punishment will probably just prolong the tantrum and in fact produce more intense negative behavior. If the tantrum occurs in public, it may be necessary for the parent to immobilize the child with a big bear hug and use a calm voice to soothe the toddler. It is very important for parents to model self-control. Since toddlers’ tantrums most often result from frustration, the role-modeled behavior of self-control helps to teach toddlers to control their temper when they can’t get what they want (Lyness, 2008).

Thumb Sucking and Pacifiers

Infants bring their hands to their mouths and begin thumb sucking as a form of self-soothing (Brazelton & Sparrow, 2006). This habit may continue into the toddler years and beyond. The pacifier is used for the same reason. Toddlers may calm themselves in a stressful

situation by thumb sucking or sucking on a pacifier. Opinions about thumb and finger sucking and pacifier use are significantly affected by family history and culture. For most children there is no need to worry about a sucking habit until it is time for the permanent teeth to erupt. Prolonged and frequent sucking in the withdrawn child is more likely to yield changes to the tooth and jaw structure than sucking that is primarily used for self-soothing. Parents must sort through their own feelings about thumb sucking and pacifier use and then decide how they want to handle the habit.

To ensure safety with pacifier use:

- Use only one-piece pacifiers.
- Replace worn pacifiers with new ones.
- Never tie a pacifier around a toddler’s neck.

Parents may want to limit thumb sucking and pacifier use to bedtime, in the car, and in stressful situations. The parent should calmly discuss these limits with the toddler and then remain consistent about enforcing them (Marter & Agruss, 2007).

Sibling Rivalry

Many families have subsequent children when their first child is a toddler. The toddler has been accustomed to being the baby and receiving a great deal of attention, both at home and with the extended family. Since toddlers are normally egocentric, bringing a new baby into the home may be quite disruptive. To minimize issues with sibling rivalry, parents should attempt to keep the toddler’s routine as close to normal as possible. Spend individual time with the toddler on a daily basis. Involve the toddler in the care of the baby. The toddler is capable of fetching a diaper or T-shirt, entertaining the baby with a toy, or helping sing a song to calm the baby (Brazelton & Sparrow, 2006). “Helping” the parent care for the baby gives the toddler a sense of importance (Fig 4.15). The toddler will need significant support while holding the baby.

FIGURE 4.15 The toddler may be more likely to accept the new baby in a positive manner if she feels that this is “our baby,” not just “mommy’s baby.” This toddler is meeting her new brother for the first time.

Regression

Some toddlers experience **regression** during a stressful event (e.g., the birth of a sibling, hospitalization). Stress in a toddler's life affects his or her ability to master new developmental tasks. During regression, the toddler may want to go back to an earlier stage. He or she may desire a bottle or pacifier long ago forgotten. The toddler may stop displaying previously achieved language or motor skills. A significant stress in the toddler's life may also disrupt the toilet teaching process (toilet teaching may not be achieved near the time a sibling is born). When regression occurs, parents should ignore the regressive behavior and offer praise for age-appropriate behavior or attainment of skills (Brazelton & Sparrow, 2006).

Refer to Jose Gonzales, the 2-year-old in the case study. List common developmental concerns of the toddler. What anticipatory guidance related to these concerns would the nurse provide to Jose's parents?

KEY CONCEPTS

- The toddler's organ systems are continuing to mature, and growth slows during this period as compared with infancy.
- The psychosocial task of the toddler years is to attain a sense of autonomy and to experience separation and individuation.
- Cognitive development in toddlerhood progresses from sensorimotor in nature to preoperational.
- The toddler refines gross motor skills after learning to walk and builds fine motor skills through the use of utensils and various manipulative toys.
- The toddler progresses from limited expressive language capabilities to a vocabulary of 900 words by age 3 years.
- Toddlers use all of their senses to explore and learn about their environment.
- Visual acuity progresses to at least 20/50 in the toddler period.
- Negativism abounds in toddlers as they attempt to exert their independence.
- Very ritualistic, toddlers feel safer and more secure when clear limits are enforced and a structured routine is followed.
- The toddler is starting to learn right from wrong and bases actions on punishment avoidance.
- Toddler development may be promoted through active gross motor play, books, music, and block building.
- Safety is a primary concern in the toddler years as the child is more mobile, very curious, and experimenting with autonomy.
- Poisoning in the toddler period may be prevented through proper storage of medications and other potentially poisonous substances and appropriate supervision.
- Consistent bedtime rituals help ease the toddler's transition to sleep.
- All primary teeth are erupted by 30 months of age and may be kept healthy with appropriate tooth brushing and fluoride supplementation.
- The toddler may experience a decrease in appetite as growth slows, yet he or she still needs appropriate nutritional intake for continued development.
- Toilet teaching can be achieved after myelination of the spinal cord is complete, usually around 2 years of age.
- Thumb sucking, pacifier use, security items, and temper tantrums are expected issues in the toddler years.
- Toddler discipline should focus on clear limits and consistency. It should not involve spanking. It should be balanced with a caring and nurturing environment along with frequent praise for appropriate behavior.
- Parental role modeling of appropriate behavior, especially related to dealing with frustration, is beneficial to toddlers.
- Parents play an important role in toddler development, not only by providing a loving environment but also by role modeling appropriate behavior in most areas of daily life.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a hospitalized 30-month-old who is resistant to care, is angry, and yells “no” all the time. The nurse identifies this toddler's behavior as
 - a. Problematic, as it interferes with needed nursing care.
 - b. Normal for this stage of growth and development.
 - c. Normal because the child is hospitalized and out of his routine.
2. The mother of a 15-month-old is concerned about a speech delay. She describes her toddler as being able to understand what she says, sometimes following commands, but using only one or two words with any consistency. What is the nurse's best response to this information?
 - a. The toddler should have a developmental evaluation as soon as possible.
 - b. If the mother would read to the child, then speech would develop faster.
 - c. Receptive language normally develops earlier than expressive language.
 - d. The mother should ask her child's physician for a speech therapy evaluation.
3. A 2-year-old is having a temper tantrum. What advice should the nurse give the mother?
 - a. For safety reasons, the toddler should be restrained during the tantrum.
 - b. Punishment should be initiated, as tantrums should be controlled.
 - c. The mother should promise the toddler a reward if the tantrum stops.
 - d. The tantrum should be ignored as long as the toddler is safe.
4. What is the best advice about nutrition for the toddler?
 - a. Encourage cup drinking and give water between meals and snacks.
 - b. Encourage unlimited milk intake, because toddlers need the protein for growth.
 - c. Avoid sugar-sweetened fruit drinks and allow as much natural fruit juice as desired.
 - d. Allow the toddler unlimited access to the sippy cup to ensure adequate hydration.

5. To gain cooperation from a toddler, what is the best approach by the nurse?
 - a. Immediately pick the toddler up from the mother's lap.
 - b. Kneel in front of the toddler while he or she is on the mother's lap.
 - c. Do the nursing tasks quickly so the toddler can play.
 - d. Ask the toddler if it is okay if you begin the needed task.

CRITICAL THINKING EXERCISES

1. Develop a teaching plan about safety to present to a toddler-age preschool class.
2. Construct a 3-day menu for a 2-year-old, one that is realistic and will provide the nutrients needed.
3. Develop a plan for educating the parent of a 34-month-old who has been resistant to toilet teaching. Include assessments the nurse will make as well as the plan for teaching.

STUDY ACTIVITIES

1. Visit a preschool that provides care for special-needs toddlers as well as typical toddlers. Perform a developmental assessment on a typical toddler and one with special needs (both the same age). Compare and contrast your findings.
2. Care for two average 2-year-olds in the clinical setting. Describe each toddler's behavior, response to the parent, and response to the nurse and list strategies used to gain compliance and minimize stress to the toddler.
3. Observe in the toddler classroom of a typical preschool. Choose two toddlers the same age with different temperaments. Record the toddlers' differences and similarities in response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

Growth and Development of the Preschooler

Words of Wisdom Quality parenting is achieved only by example.

KEY TERMS

animism

 imaginary friend
 magical thinking
 preoperational thought
 school readiness
 telegraphic speech
 transduction

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify normal physiologic, cognitive, and psychosocial changes occurring in the preschool-age child.
2. Express an understanding of language development in the preschool years.
3. Implement a nursing care plan that addresses common concerns or delays in the preschooler's development.
4. Integrate knowledge of preschool growth and development with nursing care and health promotion of the preschool-age child.
5. Develop a nutrition plan for the preschool-age child.
6. Identify common issues related to growth and development during the preschool years.
7. Demonstrate knowledge of appropriate anticipatory guidance for common developmental issues that arise in the preschool period.

Nila Patel is a 4-year-old girl brought to the clinic by her mother and father for her school check-up. During your assessment you measure her weight to be 44 pounds and her height 40 inches. As the nurse caring for her, assess Nila's growth and development, and then provide appropriate anticipatory guidance to her parents.

The preschool period is the period between 3 and 6 years of age. This is a time of continued growth and development. Physical growth continues much more slowly compared to earlier years. Gains in cognitive, language, and psychosocial development are substantial throughout the preschool period. Many tasks that began during the toddler years are mastered and perfected during the preschool years. The child has learned to tolerate separation from parents, has a longer attention span, and continues to learn skills that will lead to later success in the school-age period. Preparation for success in school continues during the preschool period because most children enter elementary school by the end of the preschool period.

The healthy preschooler is slender and agile, with an upright posture. The formerly clumsy toddler becomes more graceful, demonstrating the ability to run more smoothly. Athletic abilities may begin to develop. Major development occurs in the area of fine motor coordination. Psychosocial development is focused on the accomplishment of initiative. Preconceptual thought and intuitiveness dominate cognitive development. The preschooler is an inquisitive learner and absorbs new concepts like a sponge absorbs water.

Physical Growth

The average preschool-age child will grow 2.5 to 3 inches (6.5 to 7.8 cm) per year. The average 3-year-old is 37 inches tall (96.2 cm), the average 4-year-old is 40.5 inches tall (103.7 cm), and the average 5-year-old is 43 inches tall (118.5 cm). Average weight gain during this time period is about 4 to 5 pounds (2.3 kg) per year (Feigelman, 2007). The average weight of a 3-year-old is 32 pounds (14.5 kg), increasing to an average weight of 41 pounds (18.6 kg) by age 5. The loss of baby fat and the growth of muscle during the preschool years give the child a stronger and more mature appearance (Fig. 5.1). The length of the skull also increases slightly, with the lower jaw becoming more pronounced. The upper jaw widens through the preschool years in preparation for the emergence of permanent teeth, usually starting around age 6.

Organ System Maturation

Most of the body systems have matured by the preschool years. Myelination of the spinal cord allows for bowel and bladder control to be complete in most children by age 3 years. The respiratory structures are continuing to grow in size, and the number of alveoli continues to increase, reaching the adult number at about 7 years of age. The Eustachian tubes remain relatively short and straight. Heart rate decreases and blood pressure increases slightly during the preschool years. An innocent heart murmur may be heard upon auscultation, and splitting of the second heart sound may become evident. The preschooler should have 20 deciduous teeth present.

FIGURE 5.1 The preschool child has a more slender appearance and erect posture than the toddler.

The small intestine is continuing to grow in length. Stool passage usually occurs once or twice per day in the average preschooler. The 4-year-old generally has adequate bowel control. The urethra remains short in both boys and girls, making them more susceptible to urinary tract infections than adults. Bladder control is usually present in the 4- and 5-year-old child, but an occasional accident may occur, particularly in stressful situations or when the child is absorbed in an interesting activity.

The bones continue to increase in length and the muscles continue to strengthen and mature. However, the musculoskeletal system is still not fully mature, making the preschooler susceptible to injury, particularly with overexertion or excess activity.

Psychosocial Development

According to Erik Erikson, the psychosocial task of the preschool years is establishing a sense of initiative versus guilt (Erikson, 1963). The preschooler is an inquisitive learner, very enthusiastic about learning new things. Preschoolers feel a sense of accomplishment when succeeding in activities (Fig. 5.2), and feeling pride in one's accomplishment helps the child to use initiative. However, when the child extends himself or herself further than current capabilities allow, he or she may feel a sense of guilt. The superego or conscience development is completed during the preschool period, and this is the basis for moral development (understanding right and wrong). Table 5.1 gives examples illustrating the stage of initiative versus guilt.

FIGURE 5.2 Allowing the preschooler to assist with simple household tasks such as preparing a sandwich encourages the development of initiative.

Cognitive Development

According to Jean Piaget's theory (1969), the preschool-age child continues in the preoperational stage. **Preoperational thought** dominates during this stage and is based on a self-centered understanding of the world. In the preconceptual phase of preoperational thought, the child remains egocentric and is able to approach a problem from a single point of view only. The young preschooler may understand the concept of counting and begins to engage in fantasy play (Papalia & Felman, 2011).

Magical thinking is a normal part of preschool development. The preschooler believes that his or her thoughts are all-powerful. The fantasy experienced through magical thinking allows the preschooler to make room in his or her world for the actual or the real. Through make-believe and magical thinking, preschool children satisfy their curiosity about differences in the world around them (Papalia & Felman, 2011).

The preschooler often has an **imaginary friend** as well. This friend serves as a creative way for the preschooler to sample different activities and behaviors and practice conversational skills (Brazelton & Sparrow, 2002). Despite this imagination, the preschooler is able to switch easily between fantasy and reality throughout the day.

The child in the intuitive phase can count 10 or more objects, correctly name at least four colors, and better understand the concept of time, and he or she knows about things that are used in everyday life, such as appliances, money, and food. The preschooler uses **transduction** when reasoning: he or she extrapolates from a particular situation to another, even though the events may be unrelated. The preschooler also attributes lifelike qualities to inanimate objects (**animism**) (Papalia & Felman, 2011). Table

5.1 gives further examples illustrating this developmental stage.

The acquisition of language skills in the toddler period is enhanced in the preschool period. The expansion of vocabulary enables the preschooler to progress further with symbolic thought. At this age, children do not completely understand the concept of death or its permanence: they may ask when their grandparent or pet who died is returning.

Moral and Spiritual Development

The preschool child can understand the concepts of right and wrong and is developing a conscience. That inner voice that warns or threatens is developing in the preschool years. Kohlberg identified this stage (between 2 and 7 years) as the preconventional stage, which is characterized by a punishment-and-obedience orientation (Kohlberg, 1984). Preschool children see morality as external to themselves; they defer to power (that of the adult). The child's moral standards are those of their parents or other adults who influence them, not necessarily their own. Preschoolers adhere to those standards to gain rewards or avoid punishment. Since the preschool child is facing the psychosocial task of initiative versus guilt, it is natural for the child to experience guilt when something goes wrong. The child may have a strong belief that if someone is ill or dying, then he or she may be at fault and the illness or death is punishment (Ford, 2007).

As the child's moral development progresses, he or she learns how to deal with angry feelings. Sometimes the way the child chooses to deal with those feelings may be inappropriate, such as fighting and biting. Preschoolers are so involved in imagination and fantasy that lying begins to occur at this age (Brazelton & Sparrow, 2002). Preschoolers also use their limited life experiences to make sense of and help them cope with crises. They need to learn the socially acceptable limits of behavior and are also learning the rewards of manners. The preschool child begins to help out in the family and begins to understand the concept of give-and-take in relationships.

During the preoperational phase of cognitive development, the preschooler's concept of faith is intuitive and projective in nature (Ford, 2007). The preschool child's imagination allows for anything to be possible, so he or she does not have a logical view of the world (as adults do). Preschool children have limited life experiences, so they may project a feeling onto a new person or situation. They may use this projection to help them understand what is going on around them. Preschoolers may project their parents' or caregiver's feelings or characteristics onto "God": if mommy gets angry, then God is probably also angry.

TABLE 5.1

DEVELOPMENTAL THEORIES

| Theorist | Stage | Activities |
|----------|---|---|
| Erikson | Initiative vs. Guilt Age 3–6 years | Likes to please parents Begins to plan activities, make up games Initiates activities with others Acts out the roles of other people (real and imaginary) Develops sexual identity Develops conscience May take frustrations out on siblings Likes exploring new things Enjoys sports, shopping, cooking, working Feels remorse when makes wrong choice or behaves badly Cooperates with other children Negotiates solutions to conflicts |
| Piaget | Preoperational substage: Preconceptual phase Age: 2–4 years Preoperational substage: Intuitive phase Age 4–7 years | Exhibits egocentric thinking, which lessens as the child approaches age 4 Has short attention span Learns through observing and imitating Displays animism Forms concepts that are not as complete or as logical as the adult's Is able to make simple classifications By age 4 understands the concept of opposites (hot/cold, soft/hard) Reasoning is that of specific to specific Has an active imagination Is able to classify and relate objects Has intuitive thought processes; knows if something is right or wrong, though cannot state why Tolerates others' differences but doesn't understand them Is very curious about facts Knows acceptable cultural rules Uses words appropriately but often without true understanding of their meaning Has a more realistic sense of causality May begin to question parents' values |
| Kohlberg | Punishment–obedience orientation Age 2–7 years (preconventional morality) | Determines good vs. bad dependent upon associated punishment Children may learn inappropriate behavior at this stage if parental intervention does not occur (if the child hits, bites, or is verbally disrespectful but is not punished for these activities, the child will view those behaviors as good and continue to participate in them) |
| Freud | Phallic stage Age 3–7 years | Child's pleasure centers on genitalia and masturbation. Superego is developing and conscience is emerging. Oedipal stage occurs: jealousy and rivalry toward same-sex parent, with love of the opposite-sex parent. This usually resolves by the end of the preschool years, when the child develops a strong identification with the same-sex parent. |

Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; Kohlberg, L. (1984). *Moral development*. New York, NY: Harper & Row; and Piaget, J. (1969). *The theory of stages in cognitive development*. New York, NY: McGraw-Hill.

FIGURE 5.3 The preschool child may participate in religious rituals without having full understanding of their meaning.

The family's religious beliefs may affect the child's diet, the mode of discipline that parents use, and even how the parents view their children. Knowing about a family's practices of prayer or meditation is helpful to the pediatric nurse, who can help continue the ritual when the child is ill or hospitalized (Ford, 2007) (Fig. 5.3).

Motor Skill Development

As the preschooler's musculoskeletal system continues to mature, existing motor skills become refined and new ones develop. The preschooler has more voluntary control over his or her movements and is less clumsy than the toddler. Significant refinement in fine motor skills occurs during the preschool period (Table 5.2).

Gross Motor Skills

The preschooler is agile while standing, walking, running, and jumping (Fig. 5.4). He or she can go up and down stairs and walk forward and backward easily. Standing on tiptoes or on one foot still requires extra concentration. The preschooler seems to be in constant motion. He or she also uses the body to understand new concepts (such as using the arms in a "chug-chug" motion when describing how the train wheels work).

| TABLE 5.2 MOTOR SKILL DEVELOPMENT | | |
|-----------------------------------|--|---|
| Age | Expected Gross Motor Skills | Expected Fine Motor Skills |
| 4 years | <ul style="list-style-type: none"> • Throws ball overhand • Kicks ball forward • Catches bounced ball • Hops on one foot • Stands on one foot up to 5 seconds • Alternates feet going up and down steps • Moves backward and forward with agility | <ul style="list-style-type: none"> • Uses scissors successfully • Copies capital letters • Draws circles and squares • Traces a cross or diamond • Draws a person with two to four body parts • Laces shoes |
| 5 years | <ul style="list-style-type: none"> • Stands on one foot 10 seconds or longer • Swings and climbs well • May skip • Somersaults • May learn to skate and swim | <ul style="list-style-type: none"> • Prints some letters • Draws person with body and at least six parts • Dresses/undresses without assistance • Can learn to tie laces • Uses fork, spoon, and knife (supervised) well • Copies triangle and other geometric patterns • Mostly cares for own toileting needs |

Adapted from Feigelman, S. (2007). Preschool years. In R. M. Kliegman, R. E. Behman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia, PA: Saunders; Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Detering (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill; and Papalia, D., & Felman, R. (2011). *A child's world: Infancy through adolescence* (12th ed.). New York, NY: McGraw-Hill.

FIGURE 5.4 The preschooler runs well, navigate stairs, and can balance on one foot.

Fine Motor Skills

The 3-year-old can move each finger independently and is capable of grasping utensils and crayons in adult fashion, with the thumb on one side and the fingers on the other. He or she can also scribble freely, copy a circle, trace a square, and feed himself or herself without spilling much. These skills become refined over the next 2 years, and by 5 years of age the child can write letters, cut with

scissors more accurately, and tie shoelaces (Fig. 5.5).

Sensory Development

Hearing is intact at birth and should remain so throughout the preschool years. The senses of smell and touch continue to develop throughout the preschool years. The young preschooler may have a less discriminating sense of taste than the older child, putting him or her at increased risk for accidental ingestion. Visual acuity continues to progress and should be equal bilaterally. The typical 5-year-old has visual acuity of 20/40 or 20/30. Color vision is intact at this age.

FIGURE 5.5 The 5-year-old has the fine motor dexterity to cut well with scissors.

Communication and Language Development

The acquisition of language allows the preschool child to express thoughts and creativity. The preschool years are a time of refinement of language skills. The 3-year-old exhibits **telegraphic speech**, using short sentences that contain only the essential information. Vocabulary at 3 years is composed of about 900 words. The preschool child may acquire as many as 10 to 20 new words per day and at age 5 usually has a vocabulary of 2,100 words (Taylor, 2008). By the end of the preschool period, the child is using sentences that are adultlike in structure (Table 5.3).

The 3- to 6-year-old is starting to develop fluency (the ability to smoothly link sounds, syllables, and words when speaking). Initially, the child may exhibit dysfluency or stuttering. Speech may sound choppy, or the child may say repeated consonants or “um.” Stuttering usually has its onset between 2 and 4 years of age, and about 75% of children will recover from it without therapy (Prasse & Kikano, 2008). Parents should slow down their speech and should give the child time to speak without rushing or interrupting. Some sounds remain difficult for the preschooler to enunciate properly: “f,” “v,” “s,” and “z” sounds are usually mastered by age 5 years, but some children do not master the sounds of “sh,” “l,” “th,” and “r” until age 6 or later.

Communication in preschool children is concrete in nature, as they are not yet capable of abstract thought. Despite its concrete nature, the preschooler’s communication can be quite elaborate and involved; he or she may talk about dreams and fantasies. In addition to acquiring vocabulary and learning the correct use of grammar, the preschool child’s receptive language skills are also becoming refined.

TABLE 5.3

COMMUNICATION SKILLS IN THE PRESCHOOL CHILD

| Age | Communication Abilities |
|---------|--|
| 4 years | <ul style="list-style-type: none"> Speaks in complete sentences using adultlike grammar Tells a story that is easy to follow 75% of speech understood by others outside of family Asks questions with "who," "how," "how many" Stays on topic in a conversation Understands the concepts of "same" and "different" Asks many questions Knows names of familiar animals Names common objects in books and magazines Knows at least one color Uses language to engage in make-believe Follows a three-part command Can count a few numbers Vocabulary of 1,500 words |
| 5 years | <ul style="list-style-type: none"> Persons outside of the family can understand most of the child's speech Explains how an item is used Participates in long, detailed conversations Talks about past, future, and imaginary events Answers questions that use "why" and "when" Can count to 10 Recalls part of a story Speech should be completely intelligible, even if the child has articulation difficulties Speech is generally grammatically correct Vocabulary of 2,100 words Says name and address |

Adapted from Felgelman, S. (2007). Preschool years. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed.). Philadelphia, PA: Saunders; Papalia, D., & Felman, R. (2011). *A child's move: infancy through adolescence* (12th ed.). New York, NY: McGraw-Hill; and Taylor, E. (2008). Providing developmentally based care for preschoolers. *ACRN Journal*, 88(2), 267-273.

The preschooler is very much in tune with the parent's moods and easily picks up on negative emotions in conversations. If the preschooler hears parents discussing things that are frightening to the child, the preschooler's imagination may fuel the development of fears and lead to misinterpretation of what the child has heard.

In the potentially bilingual child, by 4 years of age the child will cease the language mixing exhibited during the toddler years and should be able to use each language as a separate system (Abell & Ey, 2007).

Emotional and Social Development

By the time a child enters kindergarten, he or she should have developed a useful set of social skills that will help him or her have successful experiences in the school setting as well as in life in general. These skills include cooperation, sharing (of things and feelings), kindness, generosity, affection display, conversation, expression of feelings, helping others, and making friends.

Preschoolers tend to have strong emotions. They can be very excited, happy, and giddy in one moment, then extremely disappointed in the next. The preschool child has a vivid imagination, and fears are very real to preschoolers. Most children this age have learned to control their behaviors. They should be able to name the feelings they are having rather than acting on them. Strong feelings may be expressed through outlets such as clay or Play-Doh, water play, drawing or painting, or dramatic play such as with puppets.

Preschoolers are developing a sense of identity. They recognize that they are boys or girls. They know that they belong to a particular family, community, or culture. They take pride in using self-control rather than giving in to their impulses. The preschool child is capable of helping others and being involved in routines and transitions.

Parents can encourage and assist preschool children with developing the social and emotional skills that will be needed when the child enters school. Preschool children thrive on one-to-one communication with a parent. During interactive communication, children learn to express their feelings and ideas. Interactive communication fosters not only emotional and moral development but also self-esteem and cognitive development. Asking the preschool child questions requires the child to think out his or her own intention or motivation and encourages vocabulary development. Parents may use individual communication as a time to explore right and wrong, thus further contributing to moral development. Being listened to while answering parents' questions gives preschoolers a sense that they are valued, that what they think and have to say matters.

Establishing a few simple rules and enforcing them consistently gives preschoolers the structure and security they need while promoting moral development. Parents or caregivers can help the child give a name to the emotion that is being experienced. Fears are very real to preschoolers because of their active imaginations and may result in a variety of emotions. Parents should validate the feeling or emotion, then discuss with the child alternatives for dealing with the emotion.

Preschoolers are developing their sense of identity, and parents should encourage preschoolers to do simple things for themselves, like dressing and washing their hands and face (Fig. 5.6). Parents should give the child the time he or she needs to complete the task. This helps to establish a sense of accomplishment.

At this age, the child may begin to show an interest in basic sexuality (Papalia & Felman, 2011). The preschooler may want to know why boys' and girls' bodies are different, how the reproductive organs function, and where babies come from. The parent

should answer the child honestly and directly, using the correct anatomic terms. Long explanations are not necessary, just simple answers. This curiosity is a normal function of the preschool years, and the curiosity may also involve playing with the genitals (see the section on masturbation later in this chapter).

FIGURE 5.6 Encouraging the preschooler to complete simple tasks by himself or herself helps to build self-esteem.

FIGURE 5.7 The preschool child begins to develop friendships.

Friendships

Preschoolers need interactions with friends as well. Learning how to make and keep a friend is an important part of social development. Friends may be other children in the neighborhood or those at preschool or day care. A special friend is someone the preschooler can care about, talk to, and play with (Fig. 5.7). The preschooler is more likely to agree to rules and wants to please friends and be like them. The preschooler loves to sing, dance, and act and will enjoy these activities with friends. Disagreements may occur, but the parent can encourage the children to express their views, discuss and resolve conflicts, and continue being friends.

Temperament

By the time children are 3 years old, they recognize that what they do actually matters. It is helpful for the parent to view the child as an active participant in the parent-child relationship. The child's temperament has become a reliable indicator of how a parent might expect the child to react in a certain situation. When the parent is in tune with the preschooler's temperament, it is easier to find ways to ease transitions and changes for that child. In the area of task orientation, temperament may range from the highly attentive and persistent to the more distractible and active (Child Development Institute, 2010).

A child's social flexibility is also evident by this age. A child who is quite adaptable will handle stimuli from the outside world in an approaching rather than a withdrawing manner. Temperament also determines the extent of reactivity (the child's sensory threshold of responsiveness, high versus low). This determines the quality of the child's mood and the intensity of reactions to stimuli, change, or situations. When the parents are familiar with the child's task orientation, social flexibility, and reactivity, they can better structure activities and situations for the child.

The 4-year-old is better at learning self-control and can use setbacks in appropriate behavior as opportunities for growth. Temper tantrums should ease off by this age, as the child's language skills are more capable of keeping up with complex ideas. The 4-year-old is able to see the rewards of growing up. This awareness of self-power may, however, lead to additional fears. The 5-year-old who has a more vulnerable type of temperament, as opposed to a confident temperament, may be more apt to experience fears.

Fears

With their vivid imaginations, preschoolers experience a variety of fears. Preschoolers may be scared of loud noises such as fire engine sirens or barking dogs. Imaginary monsters may scare the child. Preschoolers are often afraid of people they do not know as well as strange people (Santa Claus or people who look or dress very differently from what they are accustomed to). Many preschoolers are afraid of the dark. Preschoolers may also fear insects as well as animals they are not familiar with. The preschooler's memory is long enough that he or she may fear returning to the doctor's office when a painful procedure occurred during the prior visit.

Parents should acknowledge fears rather than minimizing them. They can then collaborate with the child on strategies for dealing with the fear.

Cultural Influences on Growth and Development

Children may learn prejudice or bias at home before entering school or day care. The ways that families view other races or cultures may be subtly or overtly demonstrated in routine daily activities. The preschool child is developing a conscience, so attitudes of tolerance or bias may influence the child's values. As in the toddler period, the value that the family places on independence will affect the child's development of a healthy self-concept.

Some cultures value reading and education more than others. If reading is not valued in the home, the preschool child's first experience with books may not occur until he or she is in school.

Food served in the home is often very specific to the family's ethnic background. As the preschool child is exposed to persons of other cultures in school, he or she may or may not like the food that is served. Exploring customs or cultural practices that the family participates in is important so that these practices may be safely incorporated into the child's plan of care.

Refer back to Nila, who was introduced in the beginning of the chapter. What developmental milestones would you expect Nila to have reached at this age? Nila's mother expresses concerns about her child's imaginary friend, Sasha. How would you respond?

THE NURSE'S ROLE IN PRESCHOOL GROWTH AND DEVELOPMENT

Growth and development in the preschool child remains orderly and sequential. Some preschoolers grow faster than others or reach various developmental milestones sooner than others. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess preschool children appropriately and provide guidance to their families. The changes that the preschool child is experiencing affect not only the child but also the family. Health care visits throughout the preschool period continue to focus on expected growth and development and anticipatory guidance. An additional concern is the preparation for school entry (**school readiness**).

If the preschooler is hospitalized, growth and development may be altered. Hospitalization hinders the preschool child's ability to explore the environment and engage in make-believe play and thus presents a challenge for the curious and inquisitive child. If the child must be isolated for a contagious illness, the opportunities for exploration and experimentation are further restricted. In addition, a sick preschooler may feel a sense of guilt, worrying that maybe he or she caused the illness by negative thoughts or behaviors.

When caring for the hospitalized preschooler, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the preschooler.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the preschool child's growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including but not limited to:

- Delayed growth and development
- Imbalanced nutrition, less than body requirements
- Interrupted family processes
- Readiness for enhanced parenting
- Risk for caregiver role strain
- Risk for delayed development
- Risk for disproportionate growth
- Risk for injury

Planning nursing care for the preschool child with growth and development issues should take into account the preschooler's and family's individual needs. The nursing care plan may be used as a guide in planning nursing care for the preschooler with a growth or developmental concern. The nurse may choose the appropriate nursing diagnoses from the [Nursing Care Plan 5.1](#) and individualize them as needed. The nursing care plan is intended to serve as a guide only and is not intended to be an inclusive growth and development plan.

Promoting Healthy Growth and Development

The building of self-esteem continues throughout the preschool period. It is of particular importance during these years, as the preschooler's developmental task is focused on the development of initiative rather than guilt. A sense of guilt will contribute to low self-esteem, whereas a child who is rewarded for his or her initiative will have increased self-confidence. The parent who provides a loving and nurturing environment for the preschooler builds upon the earlier foundation.

Routine and ritual continue to be important throughout the preschool years, as they help the child to develop a sense of time as well as provide the structure for the child to feel safe and secure. Daily routine continues to assist with the development of conscience in the preschooler. As in toddlerhood, making expectations known through everyday routines helps to avoid confrontations. The preschooler is developing the maturity to know how to behave in various situations and is capable of learning manners.

Setting limits (and remaining consistent with those limits) continues to be important in the preschool period. Consistent limits provide the preschooler with expectation and guidance. As the preschooler increasingly participates in fantasy and imagination, the limits of routine and structure help guide his or her behavior and ability to distinguish reality.

TABLE 5.4

SIGNS OF DEVELOPMENTAL DELAY

| Age | Concern |
|------------|--|
| 4 years | <ul style="list-style-type: none"> • Cannot jump in place or ride a tricycle • Cannot stack four blocks • Cannot throw ball overhand • Does not grasp crayon with thumb and fingers • Has difficulty with scribbling • Cannot copy a circle • Does not use sentences with three or more words • Cannot use the words “me” and “you” appropriately • Ignores other children or does not show interest in interactive games • Will not respond to people outside the family; still clings or cries if parents leave • Resists using toilet, dressing, sleeping • Does not engage in fantasy play |
| By 5 years | <ul style="list-style-type: none"> • Is unhappy or sad often • Has little interest in playing with other children • Is unable to separate from parent without major protest • Is extremely aggressive • Is extremely fearful or timid, or unusually passive • Cannot build tower of six to eight blocks • Is easily distracted; cannot concentrate on single activity for 5 minutes • Rarely engages in fantasy play • Has trouble with eating, sleeping, or using the toilet • Cannot use plurals or past tense • Cannot brush teeth, wash and dry hands, or undress efficiently |

Nurses caring for preschoolers should have knowledge of normal developmental expectations so they can determine whether the preschool child is progressing appropriately. Table 5.4 lists potential signs of developmental delay. A preschool child with one or more of these concerns should be referred for further developmental evaluation.

NURSING CARE PLAN 5.1

Growth and Development Issues in the Preschool Child

NURSING DIAGNOSIS: Risk for injury related to developmental age, environment, and motor vehicle travel

Outcome Identification and Evaluation

Child's safety will be maintained: *Child will remain free from injury.*

Interventions: Preventing Injury

- Teach and encourage appropriate use of forward-facing car seat or booster seat *to decrease risk of injury related to motor vehicles.*
- Teach preschoolers to stay away from street and to cross the street only when holding the hand of an adult *to prevent pedestrian injury.*
- Require bicycle helmet use while riding any wheeled toy *to prevent head injury and form habit of helmet use.*
- Teach the preschooler appropriate safety rules in the home (avoiding electric outlets, etc.): *the preschooler is able to follow simple directions and carry out directives. Limits help him or her to organize the environment.*
- Post Poison Control Center phone number *(in case of accidental ingestion; the preschool child is very curious).*
- Never leave a preschool child unattended in a tub or pool or near any body of water *to prevent drowning.*
- Provide swimming lessons for children age 4 or 5 *to encourage water safety, but not as a replacement for adult supervision.*
- Teach parents first-aid measures and child CPR *to minimize consequences of injury should it occur.*
- Provide close observation and keep side rails up on bed in hospital *because the preschool child continues to be at risk for falling or injuring self on equipment or*

tubing (because of curiosity).

NURSINGDIAGNOSIS: Imbalanced nutrition, less than body requirements, related to inappropriate nutritional intake to sustain growth needs (excess juice or milk intake, inadequate food variety intake) as evidenced by failure to attain adequate increases in height and weight over time

Outcome Identification and Evaluation

Child will consume adequate nutrients: *Child will demonstrate weight gain and increases in height.*

Interventions: Promoting Appropriate Nutrition

- Assess current feeding schedule and usual intake, as well as methods used to feed, *to determine areas of adequacy versus inadequacy.*
- Determine if the preschooler is unable to drink from a cup or does not finger feed or use utensils properly, or if the child has difficulty swallowing or tolerating certain textures of foods *to determine if further interventions such as speech or occupational therapy are required.*
- Weigh child daily on same scale if hospitalized, weekly on same scale if at home, and plot growth patterns weekly or monthly as appropriate on standardized growth charts *to determine if growth is improving.*
- Limit juice to 4 to 6 ounces per day, milk to 16 to 24 ounces per day, *to discourage sense of fullness achieved with excess milk or juice intake, thereby increasing appetite for appropriate solid foods.*
- Provide three nutrient-dense meals and at least two healthy snacks per day *to encourage adequate nutrient consumption.*
- Feed child on a similar schedule daily, without distractions and with the family: *preschool children continue to respond well to routine and structure. They are more interested in the social context of meals and are still apt to become distracted easily, so the TV should be off at mealtimes.*

NURSINGDIAGNOSIS: Delayed growth and development related to motor, cognitive, language, or psychosocial concerns as evidenced by delay in meeting expected milestones

Outcome Identification and Evaluation

Development will be enhanced: *Child will make continued progress toward realization of expected developmental milestones.*

Interventions: Enhancing Growth and Development

- Screen for developmental capabilities *to determine child's current level of functioning.*
- Offer age-appropriate toys, play, and activities (including gross motor) *to encourage further development.*
- Perform interventions as prescribed by physical, occupational, or speech therapist: *participation in those activities helps to promote function and accomplish acquisition of developmental skills.*
- Provide support to families of preschoolers with developmental delay *(progress in achieving developmental milestones can be slow and ongoing motivation is needed).*
- Reinforce positive attributes in the child *to maintain motivation.*
- Model age-appropriate communication skills *to illustrate suitable means for parenting the preschooler.*

NURSINGDIAGNOSIS: Risk for disproportionate growth related to excess milk or juice intake, consumption of inappropriate foods or in excess amounts

Outcome Identification and Evaluation

Child will grow appropriately and not become overweight or obese: *Child will achieve weight and height within the 5th to 85th percentiles on standardized growth charts.*

Interventions: Promoting Appropriate Growth

- Discourage use of no-spill sippy cups *(they contribute to dental caries and allow unlimited access to fluids, possibly decreasing appetite for appropriate solid foods).*
- Provide juice (4-6 ounces per day) and milk (16-24 ounces per day) from a cup at meal and snack time and water in between *to avoid having the child drink excessive juice or milk.*
- Provide only nutrient-rich foods without high sugar content for meals and snacks; *even if the preschooler is a picky eater, it is inappropriate to provide high-calorie junk food just so the child eats something.*
- Teach parents to role model appropriate eating (nutrient-rich, varied diet) *to encourage child to try/accept new foods, as well as become familiar with a variety of food.*
- Severely limit the intake of fast foods and foods with high sugar and fat content *to decrease intake of nutrient-poor, high-calorie foods.*
- Ensure adequate physical activity *to stimulate development of motor skills and provide appropriate caloric expenditure. This also sets the stage for forming lifelong habit of appropriate physical activity.*
- Teach parents to limit television viewing to 1 to 2 hours per day *to encourage participation in physical activities.*

NURSING DIAGNOSIS: Interrupted family processes related to issues with preschool child's development, hospitalization, or situational crisis as evidenced by decreased parental visitation in hospital, parental verbalization of difficulty with current situation, possible crisis related to health of family member other than the preschool child

Outcome Identification and Evaluation

Family will demonstrate adequate functioning: *Family will display coping and psychosocial adjustment.*

Interventions: Enhancing Family Functioning

- Assess the family's level of stress and ability to cope *to determine family's ability to cope with multiple stressors.*
- Engage in family-centered care *to provide a holistic approach to care of the preschooler and family.*
- Encourage the family to verbalize feelings *(verbalization is one method of decreasing anxiety levels)* and acknowledge feelings and emotions.
- Use puppets or dramatic play with the child *to elicit the preschooler's feelings about the current situation.*
- Encourage family visitation and provide for sleeping arrangements for a parent or caregiver to stay in the hospital with the preschooler; *this contributes to family's*

sense of control in situation.

- Involve family members in preschooler's care, *giving them a feeling of control and connectedness.*

NURSING DIAGNOSIS: Readiness for enhanced parenting related to parental desire for increased skill level and success with preschool child as evidenced by current healthy relationships and verbalization of desire for improved skills

Outcome Identification and Evaluation

Parent will provide safe and nurturing environment for the preschool child: *Parents will verbalize new skills they will employ in the family.*

Interventions: Increasing Parenting Skill Set

- Use family-centered care *to provide holistic approach.*
- Educate parent about normal preschool development *to provide basis of understanding for parenting skills needed in this time period.*
- Acknowledge and encourage parents' verbalization of feelings related to chronic illness of child or difficulty with normal preschool behavior; *this validates the normalcy of parents' feelings.*
- Encourage positive parenting and respect for preschooler and his or her normal development (*helps parents develop approaches to preschoolers that can be used in place of anger and frustration*).
- Acknowledge and admire positive parenting skills already present *to contribute to parents' confidence in their abilities to parent.*
- Role model appropriate parenting behaviors related to communicating with and disciplining the child (*role modeling actually demonstrates rather than just verbalizes what the parent should strive for*).

Promoting Growth and Development Through Play

Providing sincere encouragement for the preschool child's efforts and accomplishments helps him or her develop a sense of initiative. Giving children opportunities to decide how and with whom they want to play also helps them develop initiative. Preschool children like to write, color, draw, paint with a brush or their fingers, and trace or copy patterns (Fig. 5.8). They may start small collections that may be sorted. They like using toys for their intended purpose as well as for whatever invented purpose they can imagine.

Preschoolers begin to play cooperatively with one another. Play may be focused around a distinct theme. They define roles, make up rules, and assign jobs. They are able to work together toward a common goal such as building a house or fort with discarded boxes. Cooperative play encourages the preschool child to learn to share, take turns and compromise, listen to others' opinions, consider the feelings of others, and use self-control and overcome fears.

FIGURE 5.8 The preschool child loves to create things, so coloring and molding clay are ideal activities for children this age.

FIGURE 5.9 Preschool children enjoy imitative play.

Preschoolers have incredible imaginations and love to play “make-believe” (Fig. 5.9). Encouraging pretend play and providing props for dress-up stimulates curiosity and creativity. Fantasy play is usually cooperative in nature. It encourages the preschooler to develop social skills such as taking turns, communication, paying attention, and responding to one another’s words and actions. Fantasy play also allows preschoolers to explore complex social ideas such as power, compassion, and cruelty. Through role playing, children begin to develop their sexual identity as well.

Since preschool children have vivid imaginations, it is important to be careful about what television they watch. The preschooler should be limited to 1 to 2 hours per day of quality television (Christakis & Zimmerman, 2007). The violence in some television programs may scare the preschool child or inspire him or her to act out violent behavior.

Most preschoolers also engage in dramatic play, fueled by their innate curiosity and vivid imaginations. Three-year-olds may not realize that they are pretending. They run from scary creatures, make plans, and pack their backpacks (never intending to actually leave). Four-year-olds are more sophisticated with dramatic or pretend play: they know they are pretending, and they use dress-up clothes and props to act out more complex roles and scenarios (Fig. 5.10). Five-year-olds are capable of quite complex scenarios. They pretend they are real or fantasy characters. They often use dramatic play to express anxiety, try out negative feelings, or conquer their fears. For example, a child who is afraid of getting a shot at the doctor’s office may work through that feeling with pretend play.

FIGURE 5.10 Preschool children love to dress up and pretend.

Parents should encourage physical activity in the preschool child. Regular physical activity improves gross motor skills, may enhance the child's self-confidence, and allows the child to expend excess energy. Establishing the habit of daily physical activity in the early years is important in the long-term goal of avoiding obesity. The main goal of organized sports at this age should be fun and enjoyment, although of course safety must remain a priority.

Expensive toys that claim to teach the young child are not necessary. Toys that require interactive rather than passive play, and that may include the involvement of the parent, are recommended (Schuman, 2007; Shelov & Altmann, 2009). [Box 5.1](#) lists appropriate playthings for the preschool child.

Promoting Early Learning

The family is the foundation for the child's early growth and development. Parents serve as role models for behavior related to education and learning, as well as instilling values in their children. School readiness is a topic that has received a significant amount of national attention in recent years (High, 2008). To succeed in school, children need a safe, responsive home environment that allows them to learn and explore, as well as structure and limits that allow them to learn the socially acceptable behaviors that they will need in school. Language development is critical to the ability to succeed in school and can be encouraged through books and reading. Each of these components is important in readying the child for education in a more formal setting. Promoting language development, choosing a preschool, and making the transition to kindergarten are discussed in more detail below.

BOX 5.1

APPROPRIATE TOYS FOR PRESCHOOLERS

- Blocks, simple jigsaw puzzles (four to six large pieces), pegboards, wooden bead with string
- Supplies for creativity: chalk, large crayons, finger paint, Play-Doh or clay, washable markers, paper, paint and paintbrush, scissors, paste, or glue
- Puppets, dress-up clothes and props for dramatic play
- Bucket, plastic shovel, and other containers for sand and water play
- Play kitchen with accessories and pretend food (empty food boxes can be recycled for kitchen play)
- Squeaking, floating, squirting toys for the bath
- Sandbox with shovel and various toys for building
- Dolls that can be dressed and undressed (large buttons, zippers, and snaps), doll care accessories (diapers, bottles, carriage, crib)
- Gross motor toys: tricycle or big wheel (with helmet), jungle gym or swing set (with supervision), hula hoop, tunnel, wagon
- Blocks, Legos, cars and trucks, plastic animals, trains, plastic figures (family, community helpers), stuffed animals, balls, sewing

cards

- Tape or CD players for music, various musical instruments
- Simple card and board games (older preschooler)
- Dollhouse with furniture and accessories, people, and animals

Adapted from Schuman, A. T. (2007). The ABCs of toy safety: More than just child's play. *Contemporary Pediatrics*, 24(7), 49-57, 64; and Shelov, S. P., & Altmann, T. R. (Eds.). (2009). *Caring for your baby and young child: Birth to age 5* (5th ed.). New York, NY: Bantam Books.

Promoting Language Development

The parent serves as the child's first teacher. The interactions between parent and child in relation to books and other play activities model the types of interactions that the child will later have in school. Asking open-ended questions stimulates the development of thinking as well as language in the preschool child. The preschooler is a great imitator, so the parent should serve as a role model for appropriate language. Parents should avoid swearing, as the child is sure to repeat "bad words" even if he or she does not understand what they mean. Allowing children to pursue interests at their own pace will help them to develop the literacy and numeric skills that will enable them to later focus on academic skills.

Preschoolers enjoy books with pictures that tell stories (Fig. 5.11). Stories with repeated phrases help to keep the child's attention. Children like stories that describe experiences similar to their own. The preschool child demonstrates early literacy skills by reciting stories or portions of books. He or she also may retell the story from the book, pretend to read books, and ask questions about the story. The preschool child has enough focus and expanded attention to notice when a page is skipped during reading and will call it to the parent's attention.

FIGURE 5.11 Preschool children enjoy being read to and looking at the pictures that go along with the story.

Take Note!

Risk factors for lack of social and emotional readiness for school include insecure attachment in the early years, maternal depression, parental substance abuse, and low socioeconomic status. Nurses should screen for these factors and make referrals if appropriate.

Choosing a Preschool/Starting Kindergarten

Many parents choose to enroll their child in preschool. Preschool should be used primarily as an opportunity to foster the child's social skills and accustom him or her to the group environment. When selecting a preschool, the parent may want to consider the accreditation of the school, the teachers' qualifications, and recommendations of other parents. The focus of the school environment is also important: What is the daily schedule of activities? Is the school very structured, or does it have a looser environment? The parents must decide how focused on curriculum they want the school to be. The parent should observe the classroom, evaluating the environment, noise level, and sanitary practices as well as how the children interact with each other and how the teachers interact with the children.

The type of discipline used in the school is also an important factor. Parents should not choose a preschool that uses corporal punishment. The American Academy of Pediatrics (AAP) discourages the use of corporal punishment in the school setting (AAP, 2006). Corporal punishment may hurt a child's self-esteem as well as his or her ability to achieve in school (Mulvaney & Mebert, 2007). It may also lead to disruptive and violent behavior in the classroom. As preschool is the foundation for later education, the child should have the opportunity to build self-esteem and the skills needed for the more formal setting of elementary school.

Whether or not the child attended preschool, kindergarten will be the next big step. Kindergarten hours may be longer than preschool hours, and kindergarten is usually held 5 days per week. This may be a significant change for some children. For most children, the setting and personnel in kindergarten will be new to the child. Rules and expectations are often very different as well. When discussing starting kindergarten with the preschool child, parents should do so in an enthusiastic fashion, keeping the conversation light and positive. Parents should meet with the child's teacher prior to the start of school, if possible, to discuss particular needs or concerns. Parents may want to schedule a tour of the school for the preschooler or attend the school's open house with the child to ease the transition. Practicing the new daily routine prior to the start of school will also be helpful.

Most states require up-to-date immunizations and a health screening of the child before he or she enters kindergarten, so advise parents to plan ahead and schedule these in a timely fashion so that school entrance is not delayed (Centers for Disease Control and Prevention, 2010).

Promoting Safety

In the United States, accidental injury remains the leading cause of death for children between the ages of 1 and 14 years (National Center for Injury Prevention and Control, 2006). Preschoolers are at an ideal age to be taught about safety and safe behaviors. They are cognitively able to absorb concrete information and they desire to master the situations they are in, but they continue to display poor judgment related to safety issues. Their engagement in fantasy is so strong that it makes it difficult for them to master complicated cause-and-effect relationships. The preschool child is capable of learning safe behaviors but may not always be able to transfer those behaviors to a different situation. Parents must continue to closely supervise preschool children to avoid accidental injury during this period.

FIGURE 5.12 The older preschool child should be appropriately secured in an approved booster seat.

Safety in the Car

The preschooler up until 4 years of age whose height meets the car seat size requirement should use a forward-facing car seat with harness and top tether. All preschoolers after reaching the car seat height restriction should ride in a booster seat that uses both the lap and shoulder belts (Fig. 5.12). It is recommended that the booster seat continue to be used until a height of 4 feet 9 inches and age of 8 to 12 years are reached (AAP, 2011a). The back seat of the car is always the safest place for a child to ride. If a child younger than 12 years of age must sit in the front seat because there are not enough rear seats available, then the front passenger seat air bag should be deactivated. Children should never ride in the cargo area of a pickup truck (AAP, 2007). See Healthy People 2020 and Evidence-Based Practice 5.1.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Increase age-appropriate vehicle restraint system use in children. | <ul style="list-style-type: none">Encourage car seat and booster seat use until the child is of the appropriate size and age to progress to seat belts. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

EVIDENCE-BASED PRACTICE 5.1

INTERVENTIONS DIRECTED TOWARD ACQUIRING AND USING BOOSTER SEATS FOR CHILDREN 4 TO 8 YEARS OLD

STUDY

Children outgrow toddler car seats around the age of 4 years or when they weigh 40 pounds. Regular seat belts do not fit children properly. The purpose of booster seats for the 4- to 8-year-old child is to raise him or her higher on the seat of the car, in order for the adult seat belt to secure the child properly. Booster seats provide increased comfort and safety for this age group. Booster seat use in this age group has been shown to decrease injury and death via motor vehicle accident by nearly 60%. The authors reviewed five studies involving 3,070 subjects and performed a meta-analysis of the study results. Each of the randomized controlled trials reviewed assessed the efficacy of interventions directed toward increasing booster seat use.

Findings

The authors' meta-analysis of the studies revealed that interventions directed toward improving booster seat use can make a difference. Enforcement of booster seat law was the weakest intervention. More successful interventions all included education of parents about the importance and appropriate use of booster seats. Providing a free booster seat upon completion of the training or an incentive coupon to receive a discount upon purchase were the most helpful interventions.

Nursing Implications

Parents want to protect their children from injury when riding in motor vehicles, but many may lack the knowledge or financial resources to do so. Nurses are in a unique position to provide ongoing, repeated education about the importance of booster seat use for the preschooler to families wherever they encounter them. Nurses can also seek out resources in their individual communities to provide financial incentives to assist families with obtaining a booster seat. Nurses should always praise preschoolers for complying with booster seat use while riding in vehicles.

Adapted from Ehiri, J. E., Ejere, H. O. D., Magnussen, L., Emusu, D., King, W., & Osberg, J. S. (2007). Interventions for promoting booster seat use in four to eight year olds traveling in motor vehicles. *The Cochrane Library* 2007, 4.

Take Note!

Although motor vehicle accidents remain a major cause of injury and death in the preschool age group, many families do not use appropriate car seat/seat belt safety with their children. Child passenger safety technicians are available to provide proper installation of car seats. To find one in your area, visit <http://www.nhtsa.dot.gov/people/injury/childps/contacts> or <http://www.seatcheck.org>. The National Highway Traffic Safety Administration (NHTSA) Auto Safety Hot Line may be reached at (888) 327-4236.

Safety in the Home

Handguns, matches, bodies of water, bicycle riding, and poisons continue to be sources of potential injury during the preschool years. Falls account for the highest percentage of nonfatal injuries among preschoolers. In this age group, motor vehicle accidents are responsible for the most fatal injuries, followed by drowning. A significant number of injuries also occur in or around the home, including burns and poisoning (National Center for Injury Prevention and Control, 2006).

PREVENTING EXPOSURE TO TOBACCO SMOKE

Parents should protect their preschoolers from secondhand tobacco smoke. Exposure to tobacco smoke is associated with an increased incidence of otitis media and respiratory infections, as well as increased symptoms and medication use in children with asthma. Other effects include decreased lung function and behavioral difficulties (World Health Organization, 2011). The preschool child should never be in an enclosed space (such as a car) where tobacco smoke is present.

PREVENTING INJURY

The preschool child who runs out into the street is at risk for being struck by a car. Teach preschoolers to stop at the curb and never go into the street without a grown-up. The preschooler may learn to ride a bicycle (with or without training wheels). The child must wear an approved bicycle helmet any time he or she rides the bicycle, even if it is just in the driveway. Requiring helmet use in the early years may lead to the habit of helmet use as the child gets older. Allowing the preschooler to choose his or her own helmet may encourage the child to use the helmet.

Bicycles should be safe for this age group. The size must be correct; the balls of the feet should reach both pedals while the child is sitting on the seat and has both hands on the handlebars. Children younger than 5 years of age have difficulty learning to use hand-operated brakes, so traditional pedal-back brakes are recommended in this age group. Preschoolers are not mature enough to ride a bicycle in the street even if they are riding with adults, so they should always ride on the sidewalk (AAP, 2010c).

It is important to make the inside of the home safe for the preschool child. Parents should install and maintain smoke alarms in the home. Increased physical dexterity and refinement of motor skills enable the preschooler to strike matches or use a lighter and start a fire. The preschool child is capable of washing his or her hands independently, so the water heater should be set at 120°F or below to prevent scalding (AAP, 2010b).

The preschooler's active imagination and desire to play make-believe may result in a firearm injury. The average preschooler is physically capable of handling and firing a gun, particularly a handgun, which is smaller and lighter. If present in the home, firearms should be kept in a locked cabinet with the ammunition stored elsewhere (AAP, 2010b, 2010c).

PREVENTING POISONING

Though it is continuing to develop, preschoolers still have unrefined taste discrimination, placing them at risk for accidental ingestion. Parents should never try to coax a child to take a vitamin supplement, tablet, or pill by calling it "candy." Dangerous fluids should be stored in their original containers and should be kept out of reach of preschoolers; they should not be poured into containers that look like ordinary drinking glasses or cups. Potentially dangerous cleaning or personal health and beauty products, gardening and pool chemicals, and automotive materials should be kept out of reach of preschoolers and in a locked cabinet if possible. Medications should have childproof caps and should be kept in a locked cabinet. The Poison Control Center telephone number should be posted on or near the home phone (1-800-222-1222) (American Association of Poison Control Centers, 2011).

Safety in the Water

Five years of age is an appropriate time for a child to learn to swim (AAP, 2010a). Children at this age are physically capable of this activity and have the cognitive maturity to accomplish the task of swimming and basic water safety. Swimming programs should focus on appropriate swim techniques as well as safety measures. Parents and caregivers should be trained in infant/child cardiopulmonary resuscitation (CPR). Homes with swimming pools should have lifesaving devices readily accessible. Preschoolers should be taught never to dive into water until an adult has verified its depth. Preschoolers are still too young to be left unattended around any body of water, even if they know how to swim. Preschoolers should never be allowed to swim in a canal or any fast-moving water. Preschoolers who are riding in boats or fishing off riverbanks should wear a personal flotation device. Parents should also be cautioned about close supervision of young children walking, skating, or riding near thin or weak ice. See Healthy People 2020.

| Objective | Nursing Significance |
|-------------------------|---|
| Reduce drowning deaths. | <ul style="list-style-type: none"> • Never leave a young child unattended in or near the water. • Educate families about water safety. • Remind families that the preschooler's ability to swim does not replace the need for constant supervision while in the pool or other body of water. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

The American Academy of Pediatrics recommends that all swimming pools be secured by a fence that is at least 5 feet high and has a self-latching gate to protect young children from entering a pool area unattended (AAP 2010a).

Recall Nila Patel, the 4-year-old presented at the beginning of the chapter. What anticipatory guidance related to safety should you provide to her parents?

Promoting Nutrition

The preschool child has a full set of primary teeth, is able to chew and swallow competently, and has learned to use utensils fairly effectively to feed himself or herself (Fig. 5.13). As in the toddler years, it is important for the preschool child to continue to learn and build upon healthy eating habits. These habits will last throughout the child's life. A diet high in nutrient-rich foods such as whole grains, vegetables, fruits, appropriate dairy foods, and lean meats is appropriate for the preschooler. Nutrient-poor, high-calorie foods such as sweets and typical fast foods should be offered only in limited amounts.

FIGURE 5.13 The preschool child has the manual dexterity to handle utensils appropriately and feed himself or herself independently.

Nutritional Needs

The 3- to 5-year-old requires 500 to 800 mg calcium and 10 mg iron daily (Krebs, Primark, & Haemer, 2011). Box 5.2 lists good calcium and iron sources. Preschoolers should consume a minimum of 19 mg dietary fiber daily (Brown, 2011). The typical preschooler requires about 85 kcal/kg of body weight. Saturated fats should account for less than 10% of total calories. Preschool

children's diets should include a daily total fat intake of no less than 20% and not more than 35% of total calories to promote and maintain healthy cholesterol levels (Krebs et al., 2011).

Take Note!

Drinking excess amounts of milk may lead to iron deficiency, as the calcium in milk blocks iron absorption.

Promoting Healthy Eating Habits

Preschool children may be picky eaters. They may eat only a limited variety of foods or foods prepared in certain ways and may not be very willing to try new things. The 3- or 4-year-old may exhibit “food fads,” eating only certain foods over a several-day period. As the child gets older, pickiness lessens. By 5 years of age the child is more focused on the social context of eating: table conversation and manners. The 5-year-old is generally more willing to at least try new foods and may like to help with meal preparation and clean-up as appropriate.

If the preschooler is growing well, then the pickiness is not a cause for concern. A larger concern may be the negative relationship that can develop between the parent and child relating to mealtime. The more the parent coaxes, cajoles, bribes, and threatens, the less likely the child is to try new foods or even eat the ones he or she likes that are served. The parent must maintain a positive and patient demeanor at mealtime. The child should be offered a healthy diet, with foods from all groups over the course of the day as recommended by the U.S. Department of Agriculture (USDA). “MyPyramid for Preschoolers” (from the USDA) may be used to plan the preschool child’s daily diet (Fig. 5.14).

The parent should maintain a matter-of-fact approach, offer the meal or snack, and then allow the child to decide how much of the food, if any, he or she is going to eat. High-fat, nutrient-poor snacks should not be substituted for healthy foods just to coax the child to “eat something.” See Healthy People 2020.

BOX 5.2

DAILY CALCIUM AND IRON RECOMMENDATIONS FOR PRESCHOOL CHILDREN

Calcium: 500 mg
(3-year-old), 800 mg
(4- to 8-year-old)

Calcium in Foods

- 8 oz low-fat or whole milk: 300 mg
- 8 oz low-fat yogurt: 300 mg
- 1 1/2 oz cheddar cheese: 300 mg
- 1 oz dried white beans (cooked): 160 mg
- 1/4 cup tofu: 125 mg
- 1 medium orange: 50 mg
- 1/2 cup mashed sweet potatoes: 44 mg
- 1/2 cup cooked or 1 1/2 cup raw broccoli: 35 mg

Iron: 10 mg

Iron in Foods

- 3/4 cup 100% fortified prepared cereal: 18 mg
- 3/4 cup 50% fortified prepared cereal: 9 mg
- 3 oz beef: 3 mg
- 3 oz chicken leg: 3 mg
- 1/2 cup cooked lentils: 3 mg
- 3 oz chicken breast: 2 mg
- 1/4 cup fresh cooked spinach: 1.6 mg
- 1/4 cup tofu: 0.9 mg
- 1 slice enriched bread: 0.8 to 0.9 mg
- 1/4 cup frozen spinach, cooked: 0.7 mg

FIGURE 5.14 The preschool food pyramid. (From U.S. Department of Agriculture. [2008]. *MyPyramid for preschoolers*. Retrieved March 21, 2011, from <http://www.mypyramid.gov/downloads/PreschoolerMiniPoster.pdf>.)

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|--|
| Increase consumption of calcium in the population aged 2 years and older. | <ul style="list-style-type: none"> • Screen preschoolers for appropriate dietary intake of calcium. • Educate families about calcium content in foods. • Assist families with choosing a diet that meets calcium needs and is appealing to the young child. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Preventing the Development of Overweight and Obesity

Worldwide, over 22 million children younger than 5 years old are obese. In the past 30 years, the number of US children and adolescents who are overweight has doubled. According to the National Health and Nutrition Examination Survey, 21% of all 2- to 5-year-olds are either overweight or at risk of overweight (National Association of Pediatric Nurse Practitioners [NAPNAP], 2006a). Overweight and obese children are at risk for hypertension, hyperlipidemia, and the development of insulin resistance. Obese preschoolers have a 20% chance of being obese as adults. This risk increases to 80% if they are obese as adolescents (AAP, 2007c). The risk is increased if one or both parents are overweight.

Parents are in an opportune position to exert a positive influence on their preschooler’s nutritional intake and activity level. The habits learned in early childhood will likely carry over into the school-age, adolescent, and adult years. Children whose parents take an authoritarian approach to mealtime may learn to overeat, as they are encouraged to finish the entire meal (“Clean your plate!”). If they are offered appropriate, healthy food choices and access to high-calorie, nutrient-poor food is limited, preschoolers will learn to self-regulate (eat only until full). Food should not be used as either reward or punishment.

Parents should remain positive and patient at mealtime. Mealtimes should continue to be structured. Unstructured meals lead to an increase in fat and calorie consumption. Children who eat nutrient-dense and lower-fat foods are less likely to become overweight

(Institute of Medicine, 2011). To limit the chance that overeating will occur, preschoolers should be offered a variety of healthy foods at each meal. This may include one each of a protein source, grain, vegetable, and fruit. The preschool child's serving size is usually one third to one half of the recommended size of an adult serving. The preschool child may imitate the other eaters at the table. Parents have a prime chance to be good role models, setting an example of eating vegetables and fruits.

As with toddlers, fruit juice should be limited to 4 to 6 ounces per day, as excess consumption can lead to excess weight gain (AAP, 2007b). Preschoolers should be encouraged to drink water.

Limiting television viewing and encouraging physical activity are also important strategies for the prevention of overweight and obesity.

Refer back to Nila Patel, the 4-year-old introduced at the beginning of the chapter. What questions should you ask Nila's parents related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate? Nila's mother expresses concerns regarding obesity. How would you address these?

Promoting Healthy Sleep and Rest

The preschool child needs about 11 to 12 hours of sleep each day (Feigelman, 2007). Some preschool children continue to take a nap during the day. Unless very tired, many preschool children will resist going to bed from time to time. Bedtime rituals continue to be reassuring to children, and it is important to continue them in the preschool years. Having a time of relaxation with a decrease in stimulation will allow the child to fall asleep more easily. Some children continue to need a security item at bedtime or naptime. A nightlight in the bedroom may be necessary, as many children this age are afraid of the dark. [Teaching Guidelines 5.1](#) gives information about assisting parents to establish a bedtime routine.

Teaching Guidelines 5.1

BEDTIME ROUTINES

- Establish a bedtime as well as morning wake-up time, and enforce them consistently.
- Avoid sugar or caffeine consumption in the evening.
- Avoid stimulating activities such as roughhousing before bedtime.
- Do not allow television watching in bed.
- Make the child's bedroom an inviting and comfortable area of the home.
- Provide a nightlight in the child's bedroom if he or she is afraid of the dark.
- Conform to a nightly routine:
 - Television off at a certain time
 - Bath
 - Quiet game or story reading/telling
 - Bedtime prayer or song
- Maintain quiet in the bedroom and nearby to increase the child's ability to fall asleep.

Adapted from Dowshen, S. (2008). *Sleep and your preschooler*. Retrieved March 21, 2011, from http://kidshealth.org/parent/general/sleep/sleep_preschool.html; and Goldson, E., & Reynolds, A. (2011). Child development and behavior. In W. W. Hay, M. J. Levin, J. M. Sondheimer, & R. R. Deterding (Eds.), *Current pediatric diagnosis and treatment* (20th ed.). New York, NY: McGraw-Hill.

Nightmares often occur in preschool children as a result of the child's struggle to distinguish what is real from what is not. When a child awakens from a nightmare, he or she is often crying and may be able to recount what the dream was about. Parents should validate the child's fear rather than discounting it (Goldson & Reynolds, 2011). Saying, "Yes, I agree, monsters are scary; it's a good thing they aren't real" is more appropriate than, "Don't be silly: monsters aren't real." Sometimes children benefit from reading stories about dreams. Recommended books include:

- *Bedtime for Frances* by Russell Hoban
- *Ben's Dream* by Chris van Allsberg
- *In the Night Kitchen* by Maurice Sendak
- *There's a Nightmare in My Closet* by Mercer Mayer

Nightmares should not be confused with night terrors. After a nightmare, the child is aroused and interactive, but night terrors are different: a short time after falling asleep, the child seems to awaken and is screaming. The child usually does not respond much to the parent's soothing, but he or she eventually stops screaming and goes back to sleep. Night terrors are often frightening for parents because the child does not seem to be responding to them. One technique that may help to decrease the incidence of night terrors is to wake the child about 30 to 45 minutes into the sleep cycle. If continued nightly for about a week, the cycle of night terrors may be broken (Hopkins & Glaze, 2008). See [Comparison Chart 5.1](#).

Think back to Nila Patel. What anticipatory guidance would you provide to her parents in relation to sleep during the preschool years?

Promoting Healthy Teeth and Gums

Dental caries prevention continues to be important and can be achieved through daily brushing and flossing. Parents should use only a pea-sized amount of toothpaste to prevent excess fluoride consumption, which can contribute to fluorosis (AAP, 2011b). The preschooler may brush his or her own teeth, but the parent must continue to supervise to ensure adequate brushing. Parents must perform flossing because the preschool child cannot perform this task adequately.

Cariogenic foods should be avoided. If sugary foods are consumed, the mouth should be rinsed with water if it is not possible to brush the teeth immediately (Wagner & Oskouian, 2008). The preschool child should visit the dentist every 6 months.

Dental caries prevention is important in the primary teeth, because loss of these teeth to caries may affect the proper formation of permanent teeth as well as the width of the dental arch.

Promoting Appropriate Discipline

Successful discipline results from a loving and nurturing environment in which the preschooler's self-esteem is fostered and where limits are well chosen and enforced consistently. Spanking (striking with the open hand) is the least effective discipline practice and is discouraged by the American Academy of Pediatrics (2004) and the National Association of Pediatric Nurse Practitioners (2006b). Belts, switches, paddles, or other items should never be used to strike a child. The use of physical punishment has been associated with a number of additional problems in adulthood, such as antisocial and criminal behaviors (AAP, 2004) (see [Chapter 4](#)).

COMPARISON CHART 5.1 NIGHTMARES VERSUS NIGHT TERRORS

| | Nightmare | Night Terror |
|----------------------------------|--|--|
| <i>Definition</i> | Scary or bad dream followed by awakening | Partial arousal from deep sleep |
| <i>When parents become aware</i> | Child awakens parent after episode is over | Screaming and thrashing during the episode awakens the parent |
| <i>Timing</i> | Usually in the second half of the night | Usually about an hour after falling asleep |
| <i>Behavior</i> | Crying, may be scared after awakening | Sits up, thrashes, cries, screams, talks, looks wild-eyed. Sweats, may have racing heartbeat |
| <i>Responsiveness</i> | Responsive to parent's soothing and reassurances | Child unaware of parent's presence, may scream and thrash more if restrained |
| <i>Return to sleep</i> | Difficulty going back to sleep if afraid | Rapidly returns to sleep without full awakening |
| <i>Memory of occurrence</i> | May remember the dream and talk about it later | No memory of event |

Adapted from Hopkins, B., & Glaze, D. (2008). Disorders of arousal in children. *Pediatric Annals*, 37(7), 481-487.

If parents are consistent with discipline while encouraging the preschooler's normal growth and development of imagination and make-believe, the child will learn to accept that certain things are not allowed. The sense of initiative can be preserved and guilt avoided if the rules are clear and enforced consistently (AAP, 2004).

The more frequently children are hit in the preschool years, the more anger they report as adults (AAP, 2004).

Minimize the occurrence of misbehavior by anticipating conditions likely to lead to the undesired or risky action. When the situation becomes difficult, parents should use distraction to change the preschooler's focus. When discussing the misbehavior, be certain to label the behavior and not the child. This helps to preserve the preschooler's self-esteem. When teaching preschoolers about undesired behavior, be sure they also understand the reason why it is wrong or unacceptable to do it. This helps to encourage the child to use internal controls over behavior. Parents should serve as role models for self-control, including choice of words, the tone they are delivered in, and the actions that accompany them.

Children work harder to obtain praise than to receive punishment, so always reward positive behaviors. Preschool children are becoming capable of understanding the concept of right and wrong. They start to understand each other's feelings (**empathy**) and are cognitively capable of remembering basic rules (AAP, 2004).

Time-out or time away from the situation can be very effective in this age group. The punishment should be used only for intentional misbehavior (knowing something is forbidden but doing it anyway). It is particularly helpful with dangerous or destructive behavior. The preschooler is given a warning that time-out will occur if the behavior does not stop. The preschooler is removed from the situation and must stay in time-out for a specified period of time. A particular time-out area is helpful; a boring corner of the room without distractions available is a good location. The generally recommended period of time is to require 1 minute of time-out per year of age; thus, a 4-year-old would be in time-out for 4 minutes (Shelov & Altmann, 2009). Set the timer so the child will know when the time-out is over. If the child gets up before the prescribed time, replace the child in time-out and restart the timer. Time-out works best if used each and every time the undesirable behavior occurs. Also, praise the child when he or she follows the rules and behaves appropriately.

A simple and clear explanation of the misbehavior should be given to the child; parents should also talk about acceptable alternative strategies that the child can use in the future instead of the undesired behavior. Removal of a privilege such as playing with a favorite toy can be as effective as time-out.

Books and other media that are available to help educate parents about appropriate discipline and to help the child learn self-control are listed in [Box 5.3](#).

BOX 5.3

SELECTED RESOURCES FOR PARENTS AND PRESCHOOLERS

Books for Parents (about discipline)

- *How to Talk so Kids Will Listen and Listen so Kids Will Talk* by A. Faber & E. Mazlish (Harper Resource)
- *Kids Are Worth It: Giving Your Children the Gift of Inner Discipline* by B. Colorosos (Harper Collins Publishers)
- *Positive Discipline A to Z: 1001 Solutions to Everyday Parenting Problems* by J. Nelson, L. Lott, & S. G. Glenn (Three Rivers Press)
- *Setting Limits With Your Strong-Willed Child: Eliminating Conflict by Establishing Clear, Firm and Respectful Boundaries* by R. MacKenzie (Three Rivers Press)
- *The Case Against Spanking: How to Discipline Children Without Hitting* by I. A. Hyman (Jossey-Bass)
- *The Nurturing Parent: How to Raise Creative, Loving, Responsible Children* by J. S. Dacey & A. J. Packer (Fireside)
- *Without Spanking or Spoiling: A Practical Approach to Toddler and Preschool Guidance* by E. Crary (Parenting Press)

Books for Preschoolers (about dealing with feelings and learning how to behave)

- *Hands Are Not for Hitting* by M. Agassi (Free Spirit Publishing)
- *I Can't Wait* by E. Crary (Parenting Press)
- *I Want It* by E. Crary (Parenting Press)
- *I Want to Play* by E. Crary (Parenting Press)
- *I Was so Mad* by M. Mayer (Golden Books)
- *I Was so Mad* by N. Simon & D. Leder (Albert Whitman & Company)
- *I'm Excited* by E. Crary (Parenting Press)
- *I'm Frustrated* by E. Crary (Parenting Press)
- *I'm Mad* by E. Crary (Parenting Press)
- *I'm Scared* by E. Crary (Parenting Press)
- *Feet Are Not for Kicking* by E. Verdick (Free Spirit Publishing)
- *Teeth Are Not for Biting* by E. Verdick (Free Spirit Publishing)
- *When Sophie Gets Angry ... Really, Really Angry* by M. Bang (Blue Sky Press)

Addressing Common Developmental Concerns

Common developmental concerns of the preschool period include lying, sex education, and masturbation (Shelov & Altmann, 2009). Parents often express difficulty in dealing with these issues with their preschool children. Offering appropriate anticipatory guidance may give the parents the support and confidence they need to deal with these issues.

Lying

Lying is common in preschool children. It may occur because the child fears punishment, has gotten carried away with imagination, or is imitating what he or she sees the parent do. The parent should ascertain the reason for the lie before punishing the child. If the child has broken a rule and fears punishment, then the parent must determine the truth. The child needs to learn that lying is usually far worse than the misbehavior itself. The punishment for the misbehavior should be lessened if the child admits the truth. The parent should remain calm and serve as a role model of an even temper. The next time the misbehavior occurs, the child will be more apt to simply tell the truth.

If the child's lying is really just his or her imagination getting carried away, then the parent should guide the child in distinguishing between myth and reality (Brazelton & Sparrow, 2002). The preschooler's imagination is very vivid, and the child needs direction in the use of that faculty. Parents should serve as role models of appropriate behavior for their children to learn it. Children who lie because they hear their parents lying simply must not see or hear their parents do it.

Sex Education

Preschoolers are keen observers but are still not able to interpret all that they see correctly. The child may recognize, but not understand, sexual activity. Preschoolers are very inquisitive and want to learn about everything around them; therefore, they are very likely to ask questions about sex and where babies come from. Before attempting to answer questions, parents should try to find out first what the child is really asking and what the child already thinks about that subject. Then they should provide a simple, direct, and honest answer. The child needs only the information that he or she is requesting. Additional questions will occur in the future and should be addressed as they arise.

Masturbation

The normal curiosity of the preschool years often leads children to explore their own genitals (Shelov & Altmann, 2009). This behavior may be upsetting to some parents, but masturbation is a healthy and natural part of normal preschool development if it occurs in moderation. If the parent overreacts to this behavior, then it may occur more frequently. Masturbation should be treated in a matter-of-fact way by the parent. The child needs to learn certain rules about this activity: nudity and masturbation are not acceptable in public. The child should also be taught safety: no other person can touch the private parts unless it is the parent, doctor, or nurse checking to see when something is wrong.

Think back to Nila Patel. What are some developmental concerns that are common during the preschool years? What anticipatory guidance related to these concerns would you provide to Nila's parents?

KEY CONCEPTS

- The preschool child grows at a slower rate and takes on a more slender and upright appearance than the toddler.
- The primary psychosocial task of the preschool period is developing a sense of initiative.
- Cognitive development moves from an egocentric approach to the world toward a more empathetic understanding of what happens outside of the self.
- The preschooler gains additional motor skills and displays significant refinement of fine motor abilities.
- Cognitive and language skills that develop in the preschool years help prepare the child for success in school.
- Dysfluency or hesitancy in speech is a normal finding in the preschool period and occurs as a result of the fast pace with which the preschooler is gaining language skills and vocabulary.
- The vocabulary of a preschooler increases to about 2,100 words, and the child speaks in full sentences with appropriate use of tense and prepositions.

- Appropriate growth and development should be maintained in the ill or hospitalized child.
- Recognizing concerns or delays in growth and development is essential so that the appropriate referrals may be made and intervention can begin.
- The preschool child requires a well-balanced diet with fat content between 20% and 30% of calories consumed.
- Adequate physical activity and provision of a nutrient-dense diet (rather than foods high in fat and sugar) are the foundation for obesity prevention in the preschool child.
- Adequate dental care is important for the health of the primary teeth.
- Preschoolers need about 12 hours of sleep per day and benefit from a structured bedtime routine.
- Due to the active imagination of the preschooler, nightmares and night terrors may begin during this period.
- Safety and injury prevention remain a focus in the preschool years.
- Structure, appropriate limit setting, and consistency are the keys for effective discipline in the preschool period.
- Time-out is an effective disciplinary measure for preschoolers.
- Masturbation may occur as the preschooler discovers his or her body. If not excessive, it is considered a normal part of growth and development.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is caring for a hospitalized 4-year-old who insists on having the nurse perform every assessment and intervention on her imaginary friend first. She then agrees to have the assessment or intervention done to herself. The nurse identifies this preschooler's behavior as
 - a. Problematic; the child is old enough to begin to have a basis in reality.

b. Normal, because the child is hospitalized and out of her routine.

c. Normal for this stage of growth and development.

d. Problematic, as it interferes with needed nursing care.

2. The mother of a 3-year-old is concerned about her child's speech. She describes her preschooler as hesitating at the beginning of sentences and repeating consonant sounds. What is the nurse's best response?

a. Hesitancy and dysfluency are normal during this period of development.

b. Reading to the child will help model appropriate speech.

c. Expressive language concerns warrant a developmental evaluation.

d. The mother should ask her child's physician for a speech therapy evaluation.

3. The mother of a 4-year-old asks for advice on using time-out for discipline with her child. What advice should the nurse give the mother?

a. If spanking is not working, then time-out is not likely to be helpful either.

b. Place the child in time-out for 4 minutes.

c. Use time-out only if removing privileges is unsuccessful.

d. The child should stay in time-out until crying ceases.

4. A 5-year-old child is not gaining weight appropriately. Organic problems have been ruled out. What is the priority action by the nurse?

a. Allow the child unlimited access to the sippy cup to ensure adequate hydration.

b. Encourage sweets for the extra caloric content.

c. Teach the mother about nutritional needs of the preschooler.

d. Assess the child's usual intake pattern at home.

CRITICAL THINKING EXERCISES

1. Teach a preschool class about bicycle and street safety. Be certain to design the content at an appropriate developmental level.

2. Construct a 3-day menu for a picky 4-year-old. Include three daily meals and two snacks. Follow the nutritional guidelines recommended by the USDA.

3. Color or draw with a preschool child. Analyze the drawings and interactions or discussions you have with the child, relating them to psychosocial and cognitive development expected at this age.

STUDY ACTIVITIES

1. Care for two average 3-, 4-, or 5-year-old children in the clinical setting (make sure both are the same age). Describe each child's development level, response to hospitalization, and family dynamics.

2. Visit a preschool that provides care for special needs children as well as typically developing children. Perform a development assessment on a typical child and one with special needs (both the same age). Compare and contrast your findings.

3. Observe in a 3-, 4- or 5-year-old classroom of a typical preschool. Choose two children who are the same age with different temperaments. Record the differences and similarities in their response to structure and authority, interactions with classmates, attention levels, and language and activity levels.

Growth and Development of the School-Age Child

Words of Wisdom Always give a *hundred percent*, and you will never *doubt your* ability to succeed.

KEY TERMS

bruxism
 caries
 industry
 inferiority
 malocclusion
 prepubescence
 principle of conservation
 school-age child
 school refusal
 secondary sexual characteristics
 self-esteem

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify normal physiologic, cognitive, and moral changes occurring in the school-age child.
2. Describe the role of peers and schools in the development and socialization of the school-age child.
3. Identify the developmental milestones of the school-age child.
4. Identify the role of the nurse in promoting safety for the school-age child.
5. Demonstrate knowledge of the nutritional requirements of the school-age child.
6. Identify common developmental concerns in the school-age child.
7. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

Lawrence Jones is a 10-year-old boy brought to the clinic by his mother for his annual school check-up. During your assessment you measure his weight at 62 pounds and his height at 54 inches. As the nurse caring for him, assess Lawrence's growth and development, and then provide appropriate anticipatory guidance to his mother.

School-age children, between the ages of 6 and 12 years, are experiencing a time of slow progressive physical growth, while their social and developmental growth accelerates and increases in complexity. The focus of their world expands from family to teachers, peers, and other outside influences (e.g., coaches, media). The child at this stage becomes increasingly more independent while participating in activities outside the home.

The school-age years are a time of continued maturation of the child's physical, social, and psychological characteristics. It is during this time that children move toward abstract thinking and seek approval of peers, teachers, and parents. Their eye-hand-muscle coordination allows them to participate in organized sports in school or the community. The **school-age child** typically values school attendance and school activities. The nurse uses knowledge of normal growth and development of the school-age child to assist the child with coping with disruptions and changes during this time period.

Physical Growth

From 6 to 12 years of age, children grow an average of 2.5 inches (6 to 7 centimeters) per year, increasing their height by at least 1 foot. An increase of 7 pounds (3 to 3.5 kilograms) per year in weight is expected (Feigelman, 2007a). In the early school-age years, girls and boys are similar in height and weight and appear thinner and more graceful than in previous years. In later school-age years, most girls begin to surpass boys in both height and weight. (See [Appendix A](#) for growth charts.)

Preadolescent boys and girls do not want to be different from peers of the same sex or the opposite sex, although there are differences in physical and physiologic growth during the school-age years. These differences, especially **secondary sexual characteristics**, are concerning and often a source of embarrassment for both sexes.

The differences between girls and boys are more apparent at the end of the middle-school years and may become extreme and a source of emotional problems. These differences in height and weight relationships, and changes in growth patterns, should be explained to parents and children ([Fig. 6.1](#)). Physical maturity is not necessarily associated with emotional and social maturity. An 8-year-old who is the size of an 11-year-old will think and act like an 8-year-old. Many times, the expectations placed on these children are unrealistic and can impact the self-esteem and competence of the child. This can work in reverse, to similar effect, for an 11-year-old who is the size of an 8-year-old and is therefore treated as such.

Organ Systems Maturation

Maturation of organs may differ with age or gender. Maturation of organs remains fairly consistent until late school age. In the late school-age years (10- to 12-year-olds), boys experience a slowed growth in height and increased weight gain, which may lead to obesity. During this time, girls may begin to have changes in the body that soften body lines. Preadolescence is a period of rapid growth, especially for girls.

FIGURE 6.1 The different growth rates of school-age children are depicted by these same-age school-age children.

Neurologic System

The brain and skull grow very slowly during the school-age years. Brain growth is complete by the time the child is 10 years of age. The shape of the head is longer and the growth of the facial bones changes facial proportions.

Respiratory System

The respiratory system continues to mature with the development of the lungs and alveoli, resulting in fewer respiratory infections. Respiratory rates decrease, abdominal breathing disappears, and respirations become diaphragmatic in nature. The frontal sinuses are developed by 7 years of age. Tonsils decrease in size from the preschool years, but they remain larger than adolescents'. The adenoids and tonsils may appear large normally, even in the absence of infection.

Cardiovascular System

The school-age child's blood pressure increases and the pulse rate decreases. The heart grows more slowly during the middle years and is smaller in size in relation to the rest of the body than at any other development stage.

Gastrointestinal System

During the school-age years, all 20 primary deciduous teeth are lost, replaced by 28 of 32 permanent teeth, with the exception of the third molars (commonly known as wisdom teeth). The school-age child experiences fewer gastrointestinal upsets compared with earlier years. Stomach capacity increases, which permits retention of food for longer periods of time. In addition, the caloric needs of the school-age child are lower than in the earlier years.

Genitourinary System

Bladder capacity increases, but varies among individual children. Girls generally have a greater bladder capacity than boys. Urination patterns vary with the amount of fluids ingested, the time they were ingested, and the stress level of the child. The formula for bladder capacity is age in years plus 2 ounces. Therefore, the bladder capacity of the 7-year-old would be 9 ounces. The larger capacity of the bladder allows for the child to experience longer periods between voiding.

Prepubescence

The late school-age years are also referred to as *preadolescence* (the time between middle childhood and the 13th birthday). During preadolescence, **prepubescence** occurs. Prepubescence typically occurs in the 2 years before the beginning of puberty and is characterized by the development of secondary sexual characteristics, a period of rapid growth for girls, and a period of continued growth for boys. There is approximately 2 years' difference in the onset of prepubescence between boys and girls. Sexual development in both boys and girls can lead to a negative perception of physical appearance and lowered self-esteem. Early development in girls can lead to embarrassment, concern over physical appearance, and low self-esteem. Delayed development in boys can lead to a negative self-concept, resulting in substance abuse or reckless use of nonautomobile vehicles. Early development may lead to risk-taking behaviors in both boys and girls. It is important for the nurse and parents to educate the late school-age child about body changes to decrease anxiety and promote comfort with these body changes.

Musculoskeletal System

Musculoskeletal growth leads to greater coordination and strength, yet the muscles are still immature and can be injured easily. Bones continue to ossify throughout childhood, but mineralization is not complete until maturity.

Immune System

Lymphatic tissues continue to grow until the child is 9 years old; immunoglobulins A and G (IgA and IgG) reach adult levels at around 10 years of age. Due to the lymphatic system becoming more competent in localizing infections and producing antibody-antigen responses, school-age children may have fewer infections. They may experience more infections during the first 1 to 2 years of school due to exposure to other children who may have infections.

Psychosocial Development

Erikson (1963) describes the task of the school-age years to be a sense of **industry** versus **inferiority** (Feigelman, 2007a). During this time, the child is developing his or her sense of self-worth by becoming involved in multiple activities at home, at school, and in the community, which develops his or her cognitive and social skills. The child is very interested in learning how things are made and work. The school-age child's satisfaction from achieving success in developing new skills leads him or her to an increased sense of self-worth and level of competence. It is the role of the parents, teachers, coaches, and nurses of the school-age child to identify areas of competency and to build on the child's successful experiences to promote mastery, success, and self-esteem. If the expectations of adults are set too high, the child will develop a sense of inferiority and incompetence that can affect all aspects of his or her life. See [Table 6.1](#) for a further explanation of psychosocial development in school-age children.

| TABLE 6.1 DEVELOPMENTAL THEORIES | | |
|---|---|---|
| Theorist | Stage | Activities |
| Erikson | Industry vs. inferiority | Interested in how things are made and run Success in personal and social tasks Increased activities outside home—clubs, sports Increased interactions with peers Increased interest in knowledge Needs support and encouragement from important people in child's life Needs support when child is not successful Inferiority occurs with repeated failures with little support or trust from those who are important to the child |
| Piaget | Concrete operational | Learns by manipulating concrete objects Lacks ability to think abstractly Learns that certain characteristics of objects remain constant Understands concepts of time Engages in serial ordering, addition, subtraction Classifies or groups objects by their common elements Understands relationships among objects Starts collections of items Can reverse thought process |
| Kohlberg | Conventional Stage 3: interpersonal conforming, "good child, bad child" Age 7–10 years Stage 4: "law and order" Age 10–12 years | An act is wrong because it brings punishment Behavior is completely wrong or right Does not understand the reason behind rules If child and adult differ in opinions, the adult is right Can put self in another person's position Begins to exercise the "golden rule" Acts are judged in terms of intention, not just punishment |
| Freud | Latency | A time of tranquility between the Oedipal phase of early childhood and adolescence—focuses on activities that develop social and cognitive skills Develops social skills in relating to same-sex friends through joining clubs like Brownies, Girl Scouts, Boy Scouts |

Cognitive Development

Piaget's stage of cognitive development for the 7- to 11-year-old is the period of concrete operational thoughts (Feigelman, 2007a). In developing concrete operations, the child is able to assimilate and coordinate information about his or her world from different dimensions. The child is able to see things from another person's point of view and think through an action, anticipating its consequences and the possibility of having to rethink the action. He or she is able to use stored memories of past experiences to evaluate and interpret present situations. The school-age child also develops the ability to classify or divide things into different sets and to identify their relationships to each other. The school-age child is able to classify members of four generations on a family tree vertically and horizontally, and at the same time see that one person can be a father, son, uncle, and grandson. It is at this time that the school-age child develops an interest in collecting objects. The child starts out collecting multiple objects and becomes more selective as he or she gets older. Also, during concrete operational thinking, the school-age child develops an understanding of the **principle of conservation**—that matter does not change when its form changes. For example, if the child pours a half-cup of water into a short, wide glass and into a tall, thin glass, she still only has a half-cup of water despite the fact that it looks like the tall, thin glass has more (Fig. 6.2). She learns about conserving matter in a sequence ranging from the simplest to the more complex. See [Table 6.1](#) for further information about cognitive development of school-age children.

FIGURE 6.2 School-age children understand the theory of conservation (A). If you pour an equal amount of liquid into two glasses of unequal shape (B), the amount of water you have remains the same despite the unequal appearance in the two glasses (C).

Moral and Spiritual Development

During the school-age years, the child's sense of morality is constantly being developed. According to Kohlberg, the school-age child is at the conventional stage of moral development (Kohlberg, 1984). The 7- to 10-year-old usually follows rules out of a sense of being a "good" person. He or she wants to be a good person to parents, friends, and teachers and to himself or herself. The adult is viewed as being right. This is stage 3: interpersonal conformity (good child, bad child), according to Kohlberg. Ten- to 12-year-olds progress to stage 4: the "law and order" stage. At this stage, the child can determine if an action is good or bad based on the reason for the action, not just on the possible consequences of the action. The older school-age child's behavior is guided by his or her desire to cooperate and by his or her respect for others. This leads to the school-age child's ability to understand and incorporate into his or her behavior the concept of the "golden rule" (Feigelman, 2007a). See [Table 6.1](#) for additional information about the moral development of school-age children.

It is during school age that children may develop a desire to understand more about their religion (Ford, 2007). They are still concrete thinkers and are guided by their family's religious and cultural beliefs. They are comforted by the rituals of their religion, but are just beginning to understand the differences between natural and supernatural. Incorporating religious practices in their lives can assist school-age children in coping with different stressors.

Motor Skill Development

Gross and fine motor skills continue to mature throughout the school-age years. Refinement of motor skills occurs, and speed and accuracy increase. To assess the motor skills of school-age children, ask questions about participation in sports and after-school activities, band membership, constructing models, and writing skills.

Gross Motor Skills

During the school-age years, coordination, balance, and rhythm improve, facilitating the opportunity to ride a two-wheel bike, jump rope, dance, and participate in a variety of other sports ([Fig. 6.3](#)). Older school-age children may become awkward due to their bodies growing faster than their ability to compensate.

School-age children between the ages of 6 and 8 enjoy gross motor activities such as bicycling, skating, and swimming. They are enthralled with the world and are in constant motion. Sometimes fear is limited due to the strong impulses of exploration. Children between 8 and 10 years of age are less restless, but their energy level continues to be high with activities more subdued and directed. These children exhibit greater rhythm and gracefulness of muscular movements, allowing them to participate in physical activities that require longer and more concentrated attention and effort, such as baseball or soccer.

FIGURE 6.3 Jumping rope is an example of the increased development of gross motor skills of the school-age child.

Between the ages of 10 and 12 years (the pubescent years for girls), energy levels remain high but are more controlled and focused. Physical skills in this age group are similar to adults', with strength and endurance increasing during adolescence.

All school-age children should be encouraged to engage in physical activities and learn physical skills that contribute to their health for the rest of their lives. Cardiovascular fitness, weight control, emotional tension release, and development of leadership and following skills are enhanced through physical activity and team sports.

Fine Motor Skills

Myelination of the central nervous system is reflected by refinement of fine motor skills. Eye-hand coordination and balance improve with maturity and practice. Hand usage improves, becoming steadier and independent and granting an ease and precision that allows these children to write, print words, sew, or build models or other crafts. The child between 10 and 12 years of age begins to exhibit manipulative skills comparable to adults. School-age children take pride in activities that require dexterity and fine motor skills such as playing musical instruments (Fig. 6.4). Talent and practice become the keys to proficiency.

Sensory Development

All senses are mature early in the school-age years. The typical school-age child has 20/20 visual acuity (Jarvis, 2008). In addition, ocular muscular control, peripheral vision, and color discrimination are fully developed by the time the child is 7 years of age. Good vision is essential to the physical development and educational progression of school-age children. Vision screening programs conducted by school nurses identify problems with vision and result in appropriate referrals when warranted. Some problems frequently identified include amblyopia (lazy eye), uncorrected refractive errors or other eye defects, and malalignment of the eyes (called *strabismus*). Amblyopia is reduced vision in an eye that has not been adequately used during early development. Inadequate

use can result from conditions such as strabismus, one eye being more nearsighted, farsighted, or astigmatic than the other eye. Amblyopia is the leading cause of visual impairment in children (National Eye Institute, 2008). If untreated by age 9 years, amblyopia can cause irreversible visual loss. This condition is correctable prior to this time with glasses or patching. Recent studies have suggested that older children (7 to 17 years) may benefit from these treatments, which are more commonly used on younger children (National Eye Institute, 2008). Proper screening and referral, as well as notification to parents of the existing condition, are essential to the education and socialization of the school-age child.

FIGURE 6.4 School-age children improve their fine motor skills so they can play musical instruments well.

Hearing deficits that are severe are usually diagnosed in infancy, but the less severe may not be diagnosed until the child enters school and has difficulty learning or with speech. It is important to screen children for hearing deficits to ensure proper educational and social progression.

Take Note!

With loud music heard over long periods of time each day, there are concerns about these environmental noises affecting hearing in the school-age and adolescent populations.

The sense of smell is mature and can be tested in the school-age child by using scents that children are familiar with, such as chocolate or other familiar odors. In addition, the school-age child may be tested for the sense of touch with objects to discriminate cold from hot, soft from hard, and blunt from sharp.

Communication and Language Development

Language skills continue to accelerate during the school-age years and vocabulary expands. Culturally specific words are used, with bilingual children speaking English in school and a second language at home. The school-age child learns to read and reading efficiency improves language skills. Reading skills are improved with increased reading exposure. School-age children begin to use more complex grammatical forms such as plurals and pronouns. Also, they develop metalinguistic awareness—an ability to think about language and comment on its properties. This enables them to enjoy jokes and riddles due to their understanding of double meanings and play on words and sounds. They are also beginning to understand metaphors such as “a stitch in time saves nine.” School-age children may experiment with profanity and dirty jokes if exposed. This age group tends to imitate parents, family members, or others. Therefore, role modeling is very important.

Emotional and Social Development

Patterns of temperamental traits identified in infancy may continue to influence behavior in the school-age child. Analyzing past situations may provide clues to the way a child may react to new or different situations. Children may react differently over time due to

their experiences and abilities. **Self-esteem** is the child's view of his or her individual worth. This view is impacted by feedback from family, teachers, and other authority figures.

Temperament

Temperament has been described as the way individuals behave. Some descriptions of temperament are that the child is *easy*, *slow to warm*, or *difficult* (Feigelman, 2007b). These behaviors vary from the child who is easy (even-tempered and predictable) to the child labeled as difficult (due to high activity levels, irritability, and moodiness) (Alba-Fisch, 2007). The child who is easy may adapt to school entry and other experiences smoothly and with little or no stress. The slow-to-warm child may be slow to adapt to changes. The slow-to-warm school-age child may exhibit discomfort when placed in different or new situations such as school. This child may need time to adjust to the new place or situation, and may demonstrate frustration with tears or somatic complaints. The slow-to-warm child should be allowed time to adjust to new situations and people (such as teachers) within his or her own time frame. All of these factors may impact the younger school-age child upon entering the school environment, with changes in authority and the introduction of many peers. The difficult or easily distracted child may benefit from an introduction to the new experience and people by role-playing, by visiting the site and being introduced to the teachers, and by hearing stories or participating in conversations about the upcoming school experience. These children require patience, firmness, and understanding to make the transition into a new situation or experience such as school. The Behavioral Style Questionnaire (BSQ) (McDevitt & Carey, 1978) is a temperament questionnaire for children 3 to 7 years old; the Middle Childhood Temperament Questionnaire is another tool for children 8 to 12 years of age (Hegvik, McDevitt, & Carey, 1982). These tools may be useful for determining type of temperament and guiding interventions.

Self-Esteem Development

Self-esteem mirrors the child's individual self-worth and consists of both positive and negative qualities. Children strive to achieve internalized goals of attainment, although they continually receive feedback from individuals they perceive as authorities (parent or teacher). By the school-age years, children have received feedback related to their performance or tasks. The direction of this feedback influences the child's opinion of self-worth, which influences self-esteem and self-evaluation.

Children face the process of self-evaluation from a framework of either self-confidence or self-doubt. Children who have mastered the earlier developmental task of autonomy and initiative face the world with feelings of pride rather than shame (Erikson, 1963).

If school-age children regard themselves as worthwhile, they have a positive self-concept and high self-esteem. Significant adults in school-age children's lives can manipulate the environment to facilitate success. This success impacts the self-esteem of the child.

Body Image

Body image is how the school-ager perceives his or her body. School-age children are knowledgeable about the human body but may have different perceptions about body parts. School-age children are very interested in peers' views and acceptances of their body, body changes, and clothing. This age group may model themselves after parents, peers, and persons in movies or on television. It is important for late school-agers to feel accepted by peers. If they feel different and are teased, there may be lifelong effects.

School-Age Fears

School-age children are less fearful of harm to their body than in their preschool years, but fear being kidnapped or undergoing surgery. They continue to fear the dark and worry about their past behaviors. They fear death and are fascinated by death and dying. They are less fearful of animals, such as dogs and noises. The school-age child needs reassurance that his or her fears are normal for this developmental age. Parents, teachers, and other caretakers should discuss the fears and answer questions posed by the child (Child Development Institute, 2007).

Peer Relationships

The school-age child's concept of self is shaped not only by his or her parents but also by relationships with others. Peer relationships influence children's independence from parents. Peers play an important role in the approval and critiquing of skills of school-age children. Previously, only adults such as parents and teachers have been authorities; now, peers influence school-age children's perceptions of themselves. Peer relationships help to support the school-age child by providing enough security to risk the parental conflict brought about when establishing independence. School-age children associate with peers of the same sex most of the time. Although games and other activities are shared by both boys and girls, the child's concept of the appropriate sex role is influenced by

his or her relationship with peers.

Continuous peer relationships provide the most important social interaction for school-age children. Valuable lessons are learned from interactions with children their own age. Children learn to respect differing points of view that are represented in their groups (Fig. 6.5). Peer groups establish norms and standards that signify acceptance or rejection. Children may modify behavior to gain acceptance. A characteristic of school-age children is their formation of groups with rules and values. Peer and peer-group identification are important to the socialization of the school-age child (Feigelman, 2007a).

Teacher and School Influences

School serves as a means to transmit values of society and to establish peer relationships. Secondary only to the family, school exerts a profound influence on the social development of the child. Often school requires changes for the child and parent. The child enters an environment that requires conforming to group activities that are structured and directed by an adult other than the parent. The parent's attitude and support influences the child's transition into the school setting. Parents that are positive and supportive promote a smooth entry into school. Parents that encourage clinging behaviors may delay a successful transition into school.

FIGURE 6.5 School-age children like to join clubs. These children, in the acting club at school, are rehearsing for a play.

To facilitate the transition from home to school, the teacher must have the personality and knowledge of development that will allow him or her to meet the needs of young children. Even though the teacher's responsibilities are primarily to stimulate and guide intellectual development, they must share in shaping the child's attitudes and values. The system of awards and punishment administered by teachers affects the self-concept of children and influences their response to school. Teachers and school are important in shaping the socialization, self-concept, and intellectual development of children.

Family Influences

The school-age years are a time for peer relationships, questioning of parents, and the potential for parental conflict but continued respect for family values. School-age years are the beginning of the time of peer-group influence, with testing of parental and family values. Although the peer group is influential, the family's values usually predominate when parental and peer-group values come into conflict. Even though the school-age child may question the parents' values, the child will usually incorporate the values from parents into his or her values.

Many times in the late school-age and preadolescent period, the child may prefer to be in the company of peers and show a decreased interest in family functions. This may require an adjustment for parents. Parents' awareness of this developmental trend and their continuing support for the child are important while they continue to enforce restrictions and control of behaviors. The school-age child is beginning to strive for independence, but parental authority and controls continue to impact choices and values.

School-age children continue to need parenting. They do not need parents as pals.

Cultural Influences on Growth and Development

Culture influences habits, beliefs, language, and values. School-age children thrive on learning the music, language, traditions, holidays, games, values, gender roles, and other aspects of culture. Nurses must be aware of the effects on children of various groups' family structures and traditional values. The school-age child's cultural and ethnic backgrounds must be considered when assessing growth and development, including differences in growth in children of different racial and cultural backgrounds. Cultural implications must be considered for all children and families in order to provide appropriate care.

Refer back to Lawrence Jones, who was introduced at the beginning of this chapter. What developmental milestones would you expect him to have reached by this age?

THE NURSE'S ROLE IN SCHOOL-AGE GROWTH AND DEVELOPMENT

Growth and development in the school-age child occurs in irregular spurts with a wide variation of sizes, shapes, and abilities seen. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess school-age children appropriately and provide guidance to the child and his or her family. This is a time when children compare themselves to peers and self-esteem is a central issue. The school-age child is separating from his or her parents and seeks acceptance from peers and adults outside of his or her family. Health care visits throughout the school-age period continue to focus on expected growth and development and anticipatory guidance. Visits are more infrequent during the school-age years; therefore, the nurse needs to assess the child's functioning not only at home but also at school and within the community.

If the school-age child is hospitalized, growth and development may be altered. The school-age child is able to understand the reason for hospitalization and what will happen. He or she is often worried about pain or changes that may occur to his or her body. It is important for physicians and family members to be honest and open with the school-age child. The school-age child may miss school and the interactions with his or her peers. The school-age child may regress and exhibit behaviors of a younger child, such as needing special comfort toys or demanding attention from his or her parents. Hospitalization for the school-age child can bring with it a loss of control. The school-age child is used to controlling his or her self-care and making choices about his or her meals and activities.

When caring for the hospitalized school-age child, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the school-age child. Provide opportunities for the school-age child to maintain independence, gain control, and increase self-esteem.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the school-age child's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development
- Risk for caregiver role strain
- Risk for injury

Nursing care planning for the school-age child with growth and development issues should be individualized based on the school-age child's and family's needs. The nursing care plan can be used as a guide in planning nursing care for the school-age child with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from [Nursing Care Plan 6.1](#) and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

Promoting Healthy Growth and Development

The family plays a critical role in promoting healthy growth and development of the school-age child. Respectful interchange of communication between the parent and child will foster self-esteem and self-confidence. This respect will give the child confidence in achieving personal, educational, and social goals appropriate for his or her age. The nurse should study interactions between parents and school-age children to observe for this respect or lack of respect ("putting the child down"). The nurse can model appropriate behaviors by listening to the child and making appropriate responses. The nurse can be a resource for parents and an advocate for the child in promoting healthy growth and development.

Promoting Growth and Development Through Play

Cooperative play is exhibited by the school-age child. Play for the school-age child includes both organized cooperative activities (such as team sports) and solitary activities. School-age children have the coordination and intellect to participate with other children their age in sports such as soccer, baseball, football, and tennis. The school-age child comprehends that his or her cooperation with others will lead to a unified whole for the team. Additionally, the child learns rules and the value of playing by the rules.

NURSING CARE PLAN 6.1

Growth and Development Issues of the School-Age Child

NURSING DIAGNOSIS: Risk for disproportionate growth (risk factors: caregiver knowledge deficit, frequent illnesses)

Outcome Identification and Evaluation

School-age child will demonstrate adequate growth: *appropriate weight gain and increases in height for age and gender*

Interventions: Promoting Proportionate Growth

- Assess parent’s knowledge of nutritional needs of school-age children *to determine need for further education.*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Educate mother about appropriate serving sizes and foods *so that mother is aware of what to expect for school-age children.*

NURSING DIAGNOSIS: Ineffective Health Maintenance related to lack of exercise, increased caloric intake, poor food choices

Outcome Identification and Evaluation

School-age child will engage in health maintenance behaviors and lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and gender*

Interventions: Promoting Appropriate Health Maintenance Behaviors

- Assess knowledge of parents and child about nutritional needs of school-age children *to determine deficits in knowledge.*
- Plot out height, weight, and BMI *to detect weight loss or weight gain.*
- Have child keep food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview parents in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Analyze preceding data, and base recommendations for changes on these data.
- Discuss ways to decrease temptation to overeat and to make good meal choices (see [Teaching Guideline 6.2](#)).
- Have child assist in meal planning and grocery shopping *to allow him or her some sense of control in process.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement, *to increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight-loss program for school-age children *to increase self-esteem and to increase awareness that other children have the same problem.*

NURSING DIAGNOSIS: Growth and development, delayed related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

Outcome Identification and Evaluation

Development will be maximized: School-age child will make continued progress toward attainment of expected school performances.

Interventions: Promoting Growth and Development

- Perform scheduled evaluation of the school-age child by school and physician *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.*
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings *to be able to adapt interventions as soon as possible.*

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: new sibling in household, knowledge deficit about school-age issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for a school-age child*

Interventions: Preventing Caregiver Role Strain

- Assess parents’ knowledge of school-age children and the issues that arise as a part of normal development *to determine parents’ needs.*
- Provide education on normal issues of school-age children so that parents are armed with the knowledge they need *to appropriately care for their school-age child.*
- Provide anticipatory guidance related to upcoming expected issues related to school-age development *to prepare parents for what to expect next and how to intervene.*

NURSING DIAGNOSIS: Injury, risk for (risk factors: curiosity, increasing cognitive skills and motor abilities)

Outcome Identification and Evaluation

School-age child’s safety will be maintained: *will remain free from injury*

Interventions: Preventing Injury

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, water, and play ground *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending on age, sex, and maturity of child *to prevent possible injury and to promote child’s self-esteem.*
- Instruct parents to post the Poison Control Center phone number *(in the event of accidental ingestion, Poison Control can give parents the best advice for appropriate intervention).*
- Teach parents and child first-aid measures and child cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers on actions of school-age children *to prevent possible injury due to mimicking behavior.*

FIGURE 6.6 This school-age girl enjoys solitary play with her dollhouse and dolls.

School-age children also enjoy solitary activities including board, card, video, and computer games, and dollhouse and other small-figure play (Fig. 6.6). Many school-agers start collections of stamps, cars, or other valuable or not-so-valuable items. During the school-age years, children may also begin a scrapbook or keep a diary. They may participate in activities such as dance or karate. Girls and boys may join clubs, gangs, or special interest groups.

Active play has decreased in recent years as television viewing and computer games have increased. This trend has resulted in health risks such as obesity, type 2 diabetes, and cardiovascular problems.

Promoting Learning

School attendance and learning are very important to the school-age child. Parent-child, child-teacher, and child-peer relationships and activities influence the school-age child's learning.

Formal Education

Most children are excited about starting school and making new friends. They like the notion of getting books, having book bags, and having homework assignments. The reality of the work involved with school and homework may decrease the enthusiasm about school.

Peers are very important within this age group. Both peers and teachers influence children. Attending school may be their first experience interacting with a large number of children their own age. Through this interaction, children learn cooperation, competition, and the importance of following the rules. Peer approval and influences grow as the child matures. Teachers have significant influences on children. They help to guide the child's intellectual development by rewarding successes and helping the child deal with failures. The student-teacher relationship is a key to success. Teachers play a role in fostering feelings of industry and preventing feelings of inferiority (Fig. 6.7). School-age children also learn skills, rules, values, and other ways to work with peers and other authority figures.

FIGURE 6.7 School is important to the school-age child.

Parental support is important for school adjustment and achievement. Parents must collaborate with teachers and school personnel to ensure that the child is fulfilling the expectations and requirements for this age group in school. Parents must monitor the child's homework assignments and friends, and observe for any changes in behavior that would indicate school or behavioral problems.

Reading

Encouraging reading is an excellent way to promote learning in the school-age child. Trips to the library and purchasing books help to promote a love of reading. School-age children enjoy being read to as well as reading on their own. Younger school-age children (6 to 8 years) enjoy books that are simple to read with few words on a page, such as the Dr. Seuss books. They enjoy books about animals and trains and simple mysteries. Children 8 to 10 years of age have more advanced reading skills and enjoy those books from early childhood, plus more classic novels and adventures such as the Harry Potter series. Older children enjoy horror stories, mysteries, romances, and adventure stories as well as classic novels. School-age children of all ages benefit from books on topics related to things they may be experiencing, such as a visit to the hospital for a surgical procedure. See [Box 6.1](#) for ideas for parents to promote reading in the school-age child.

Promoting Safety

School-age children become more independent with age. This independence leads to an increased self-confidence and decreased fears, which may contribute to accidents and injuries. School age is a time that the child may walk to school with peers who may influence his or her behavior. Increased independence may also increase exposure to dangerous situations such as the approach of strangers or unsafe streets. Promotion of safe habits during the school-age years is important for parents and nurses. See [Teaching Guidelines 6.1](#) for additional information on safety education for nurses and parents.

BOX 6.1

PROMOTION OF READING IN SCHOOL-AGE CHILDREN

- Parents, read to and with your children.
- Ask teachers and librarians for advice on books appropriate for your child.
- Choose stories that the child can relate to if the child has difficulty reading.
- Choose books with movement if the child has a short attention span.
- Take advantage of all reading opportunities (cereal boxes, road signs).
- Provide choices for the child to select a book of interest.
- Talk about the text and ask questions to improve understanding.
- Keep a record of what the child is reading.

- Visit a library, get a library card, and check out books.
- Parents, demonstrate role modeling through reading books.

Teaching Guidelines 6.1

SAFETY ISSUES AND INTERVENTIONS OF THE SCHOOL-AGE CHILD

Safety Issue Interventions

- | | |
|---|---|
| Car safety | <ul style="list-style-type: none"> • Seat belt or age- and weight-appropriate booster seat should be used at all times. • Seat belts should be fastened before car is started. • Children under 12 years must sit in back seat. • Childproof locks should be used in back seat. • Rules of conduct for car rides must be established. |
| Pedestrian safety | <ul style="list-style-type: none"> • Child should be instructed on looking right, left, then right again before crossing the street; and crossing only at safe crossings. • Older children and adults should provide supervision of younger children. • Walking should only be done on sidewalks. • In parking lots, children should know to watch for cars backing up and not dart out between parked cars. • If children are playing outside, drivers should be aware of their presence before backing up. |
| Bike safety: general | <ul style="list-style-type: none"> • Bikes should be well-maintained and appropriately sized. • Child should be oriented to bike and demonstrate ability to ride bike safely before being allowed to ride on street. • Safe areas for bike riding should be established as well as routes to and from area of activities. • Riding bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike should be prohibited. • Child should know to wear sturdy, well-fitting shoes. • Child should know to wear ANSI-approved helmets. • Bike should be inspected often to ensure it is in proper working order. • A basket should be used to carry heavy objects. |
| Bike safety in traffic | <ul style="list-style-type: none"> • All traffic signs and signals must be observed. • If riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes. • Child should know to ride on the side of the road traveling with traffic, and keep close to the side of the road in single file. • Child should learn to watch and listen for cars. • Headphones should not be used while riding a bike. • Never hitch a ride on any vehicles. |
| Sports safety | <ul style="list-style-type: none"> • Sports should be matched to child's ability and desire. • Sports program should have warm-up procedure. • Coaches should be trained in car-diopulmonary resuscitation (CPR) and first aid. • Appropriate protection devices should be used for individual sport. |
| Skateboarding and inline skating safety | <ul style="list-style-type: none"> • Child should wear helmet, and protective padding on knees, elbows, and wrists • Child should know not skate in traffic or on streets or highways. Homemade ramps should be assessed for hazards before skating. |
| All-terrain vehicle safety | <ul style="list-style-type: none"> • Child should be at least 16 years of age to operate vehicle. • Helmets must be worn in addition to protective coverings. • No nighttime riding. • Use should be avoided on public roads. • Never stand up in the vehicle or ride in a person's lap. • All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year. • Have a fire-escape plan. |

- Practice fire-escape plan routinely.
- Fire safety
 - Nobody should smoke in bed. Teach what to do in case of a fire: use fire extinguisher, call 911, and how to put out clothing fire. Use stove and other cooking facilities under adult supervision. All flammable materials and liquids should be stored safely. Fireplaces should have protective gratings.
 - Teach children to avoid touching wires they might encounter while playing.
- Teach children how to swim.
- If swimming skill is limited, child must wear life preserver at all times.
- Child should know never swim alone—if at all possible, swim only where there is a life guard.
- Water safety
 - Understand basic CPR.
 - Teach child to never run or fool around at edge of pool.
 - Drains in pool should be covered with appropriate cover.
 - Life jackets should be worn when on boat.
 - Make sure water is deep enough to support diving.
 - Teach child never to touch gun—tell adult.
- Firearm safety
 - If have guns in household, need to secure them in safe place, use gun safety locks, store bullets in separate place.
 - Never point a gun at a person.
- Toxin safety
 - Teach child the hazards of accepting illegal drugs, alcohol, or dangerous drugs.
 - Store potential dangerous material in safe place.

Retrieved March 23, 2011, from <http://www.cdc.gov/HomeandRecreationalSafety/Water-Safety/waterinjuries-factsheet.html>; and Hagan, J. F., Shaw, J. S., & Duncan, P. (2008). *Bright futures guidelines for health supervision of infants, children, and adolescents* (3rd ed.). Elk Grove Village, IL: American Academy of Pediatrics.

Unintentional injuries are the leading cause of death in children between 1 and 21 years of age (Centers for Disease Control and Prevention [CDC], 2009). Each year, 20 million children sustain an injury sufficiently severe to seek medical attention (Borse et al., 2008; CDC, 2008c). School-age children are very active at home, in the community, and at school. This increased mobility, activity, and time away from parents increases the risk for unintentional injuries. School-age children continue to need supervision and guidance. They need information and rules about car safety, pedestrian safety, bicycle and other sport safety, fire safety, and water safety.

Car Safety

Motor vehicle accidents are a common cause of injury in the school-age child. While traveling in the car, school-age children should always sit in the rear seat. The front seat is dangerous because of passenger-side airbags in most new-model cars. The school-age child should use a three-point restraint system in the rear seat of the car with the shoulder strap and lap belt fitted snugly. In addition, a school-age child over 40 pounds (generally 4 to 8 years of age) should use a belt-positioning, forward-facing booster seat using both lap and shoulder belts (National Highway Traffic Safety Administration [NHTSA], 2008). School-age children who outgrow the convertible restraint can sit in a booster seat until their head is higher than the vehicle seat back (usually 4'9" and taller) (NHTSA, 2008). Children younger than 12 years of age should not ride in the front seat of a vehicle with an airbag (NHTSA, 2008).

Pedestrian Safety

Twenty percent of fatal crashes in children between the ages of 5 and 9 involve pedestrian-related fatalities (Percer, 2009). Children younger than 10 years of age should not cross the street alone (Percer, 2009). Young school-age children therefore should walk to school or the bus with an older friend, sibling, or parent. Darting out into the street without looking both ways or from between cars is a common occurrence in the school-age years. Teach children safe street and pedestrian practices.

Bicycle and Sport Safety

Bicycling, riding scooters, skateboarding, and inline skating or rollerskating are common activities of school-age children. Laws in

most states require helmets for riding bicycles and scooters. In addition, when skating or skateboarding, school-age children should wear a helmet, kneepads, and elbow pads.

Research has shown that head injuries due to bicycle accidents have been reduced by 85% by wearing a well-fitting helmet (Bicycle Helmet Safety Institute, 2009). National estimates of bicycle helmet ownership and use varies greatly among different areas and sectors of the U.S., but overall it is estimated at about 25% (Bicycle Helmet Safety Institute, 2009) (see Healthy People 2020). It is important for children to wear helmets that fit and that do not obstruct their vision or hearing. Because school-age children have completed most of their skull growth, a helmet can be worn into adolescence. It is important for the child to have a bicycle that is appropriate for his or her size and age. The child should be able to plant both feet on the ground when sitting on the seat of the bike (Fig. 6.8). It is important to stress to parents the importance of appropriate size and not to get a bike for the child to “grow into.” If older school-agers are using the bike for transportation on busy streets, they should be taught to use bike lanes and to give appropriate hand signals for turning. Nonmotorized and motorized scooters also place children at risk for injury, so counsel families about the use of protective gear, including helmets, elbow pads, and kneepads.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|---|
| Reduce fatal and nonfatal traumatic brain injuries. | <ul style="list-style-type: none">• Provide education to children and their parents about avoiding head injury through helmet use.• Encourage child to choose a helmet that appeals to him or her (one that looks “cool”). |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

FIGURE 6.8 Wearing the appropriate safety equipment and having an appropriately sized bicycle are important to prevent injuries in school-age children.

Fire Safety

School-age children are eager to help parents with cooking and ironing. They are curious about fire and are drawn to play with fire, matches, and fireworks. Serious burns can occur from any exposure to fire. Educate children about the hazards of fire. In addition, teach children proper behavior around fires at home and outdoors. Always supervise children in the use of matches. In the home setting, parents should develop a fire safety plan with their children, teach children what to do if their clothes catch on fire, and practice evacuating the house in the event of a fire. In the school setting, children should be aware of the appropriate response to fire drills and fire drills should be conducted on a regular basis.

Water Safety

Teach school-age children swim and water safety. An adult should always supervise children when they are swimming to prevent water-related accidents.

Abuse in Children

Child abuse, including physical abuse and sexual abuse, is a common crime of violence against children. An estimated 6 million reports of child abuse are made annually to child protective services in the United States (CDC, 2008a). Over 900,000 cases were substantiated in 2006, with 64% being victims of neglect, 16% victims of physical abuse, 9% victims of sexual abuse, and 7% victims of emotional or psychological abuse (CDC, 2008b). The abusers of children are family, friends, and strangers. It is important for parents to teach children the concept of “good touch” versus “bad touch” prior to school-age years. Whenever the school-age child’s behavior yields suspicion of physical or sexual abuse, the nurse should report to the appropriate authorities in his or her state. These topics will be discussed in more depth in [Chapter 30](#).

Remember Lawrence Jones, the 10-year-old presented in the case study? What anticipatory guidance related to safety should you provide to his mother?

Promoting Nutrition

Growth, body composition, and body shape remain constant during late school-age years. Needed calories decrease while the appetite increases. In preparation for adolescence, the body fat composition of school-age children increases. This tendency toward increased body fat occurs earlier in girls than in boys, with the amount of increase greater in girls. Boys have more lean body mass per inch of height than girls.

BOX 6.2

DIETARY QUESTIONS

Questions for the Child

- How often do you eat together as a family?
- What are the usual mealtimes?
- How often does the family eat out?
- Do you eat breakfast regularly?
- Where do you eat lunch?
- What do you drink/how much?
- What foods do you eat most often?
- What is your favorite food?
- How often do you eat fast foods?
- What type of exercise do you do?

Questions for the Parents

How would you describe your child's usual appetite?

- Do you have any special cultural/religious practices regarding food?
- Has your child gained or lost weight recently?
- Do you have any concerns about his or her eating behaviors?
- How does your child exercise? Your family?
- Is there a family history of cancer, hypertension, diabetes, obesity, or heart disease?

Diet preferences established in the preschool years continue during the school-age period. As the child grows older, influences of family, media, and peers can impact the eating habits of this age group. Some of these influences are parents' work schedule, outside activities, and exercise level of the child. Decreased exercise levels and poor nutritional choices lead to the mounting problem of obesity seen in this age group. See [Box 6.2](#) for appropriate questions to ask the child and parent regarding nutritional status. Healthy People 2020 provides objectives and actions to improve the nutritional health of children.

| Objective | Nursing Significance |
|---|--|
| Increase the contribution of fruits to the diets of the population aged 2 years and older. | <ul style="list-style-type: none"> Educate families about the importance of whole grains, fruits, and vegetables in the diet. Encourage the child to choose fruits and vegetables that appeal to him or her. |
| Increase the contribution of total vegetables to the diets of the population aged 2 years and older. | |
| Increase the contribution of dark green vegetables, orange vegetables, and legumes to the diets of the population aged 2 years and older. | <ul style="list-style-type: none"> Provide creative suggestions for vegetable preparation to make them more appealing to children. Educate families about saturated fat-containing foods. |
| Increase the contribution of whole grains to the diets of the population aged 2 years and older. | |
| Reduce consumption of calories from solid fats. | <ul style="list-style-type: none"> Offer suggestions for alternate sources of proteins and fats (chicken or fish, olive oil). |
| Reduce consumption of calories from added sugars. | |
| Reduce consumption of calories from solid fats and added sugars. | |
| Reduce consumption of saturated fat in the population aged 2 years and older. | |
| Reduce consumption of sodium in the population aged 2 years and older. | |
| Increase consumption of calcium in the population aged 2 years and older. | |

Nutritional Needs

The school-age child's calorie needs vary based on age, gender, and activity level. In general, children with higher activity levels and male gender have higher calorie needs (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Boys and girls 4 to 8 years old who are moderately active will need about 1,400 to 1,600 calories a day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Boys 9 to 13 years old who are moderately active need about 1,800 to 2,000 calories a day, while girls this age who are moderately active need about 1,600 to 2,000 calories a day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Of these calories, 45% to 65% should come from carbohydrates, 10% to 30% from protein, and 25% to 35% from fat (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). The 4- to 8-year-old child needs 800 to 1,000 mg of calcium, while the 9- to 13-year-old needs 1,300 mg of calcium for maintenance of growth and good nutrition (Krebs, Primark, & Haemer, 2011). Calcium is needed for the development of strong bones and teeth. Milk, yogurt, and cheese provide protein, vitamins, and minerals and are an excellent source of calcium. Meats, poultry, fish, and eggs provide protein, vitamins, and minerals.

Promoting Healthy Eating Habits

School-age children should choose culturally appropriate foods and snacks from the U.S. Department of Agriculture's MyPyramid (Fig. 6.9). MyPyramid.gov offers many tools for the child to use including development of personalized goals and menus, online dieting and physical activity assessment tools, games, activities, and tips for parents. School-age children need to limit intake of fat and processed sugars. A prudent diet limits the use of fatty meats, high-fat dairy products, eggs, and hydrogenated shortenings and promotes the consumption of fish and the substitution of polyunsaturated vegetable oils and margarines. The American Heart Association has endorsed a diet for school-age children that includes the recommendations listed in Box 6.3.

Preventing the Development of Overweight and Obesity

The National Health and Nutrition Examination Survey (NHANES) found that more and more children are overweight. Over the past three decades the number of overweight children and adolescents more than tripled. Thirty percent of 6- to 11-year-olds are overweight or at risk for overweight (National Association of Pediatric Nurse Practitioners, 2006). Overweight is classified as a body mass index (BMI) greater than 85% and obese is classified as a BMI greater than 95% (Krebs et al., 2011; U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010) (see Healthy People 2020).

AMERICAN HEART ASSOCIATION'S DIET RECOMMENDATIONS FOR SCHOOL-AGE CHILDREN

- A high-quality protein with every meal
- Milk with added vitamin D and other low-fat dairy products
- Vegetables high in vitamin A
- Fruits high in vitamin C
- Whole-grain or enriched breads or cereals
- Vegetable oils high in polyunsaturated fats
- Meats (4 servings per week of 4 ounces each)
- Fish (1-2 times per week)
- Poultry (1-2 times per week)
- Dark green, leafy, or deep yellow vegetables (at least 4 times per week)
- Eggs (4 times per week)

Adapted from American Heart Association, Gidding, S. S., Dennison, B. A., Birch, L. L., Daniels, S. R., Gilman, M. W., et al. (2006). Dietary recommendations for children and adolescents: A guide for practitioners. *Pediatrics*, 7 77(2), 544-559.

HEALTHY PEOPLE 2020

Objective

Reduce the proportion of children and adolescents who are considered obese.

Prevent inappropriate weight gain in youth.

Nursing Significance

- Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age.
- Provide accurate diet counseling.
- Encourage daily physical activity.
- Counsel parents to limit television/computer time daily.

Obesity occurs when the intake of calories and food exceeds the expenditures. Some factors linked to causing obesity include family role modeling, lack of exercise, unstructured meals, consumption of sugar-sweetened beverages, large portion sizes, television viewing, and video gaming as well as cultural, genetic, environmental, and socioeconomic factors. Some factors that influence lack of exercise include the decreased number of days that school systems offer physical education programs and recess. Also, some children live in unsafe neighborhoods or in a community that lacks sidewalks or parks and have no safe place to play outside; therefore, they spend time doing sedentary activities such as watching TV or playing video or computer games (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Obese children are at risk for cardiovascular diseases such as high cholesterol and hypertension, type 2 (non-insulin-dependent) diabetes, respiratory complications such as obstructive sleep apnea, mental health issues such as depression, anxiety and eating disorders, and orthopedic problems (Krebs et al., 2011; U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). When parents do not have knowledge of nutrition, do not monitor snacks or meals, and have unstructured meals, habits are established that lead to obesity.

FIGURE 6.9 MyPyramid for kids. Eat foods from each color every day; choose more foods from the food groups with the wider stripes. (From U.S. Department of Agriculture [2005]. *My pyramid for kids*. Retrieved March 21, 2011, from http://teamnutrition.usda.gov/Resources/mpk_poster2.pdf)

Preventing obesity in childhood is important because the fat cells of childhood are carried into adulthood obesity and contribute to disease. Due to the risk of obesity, encourage parents to never use food as a reward. To prevent obesity, establish regular mealtimes and offer healthy foods and snacks. Encourage parents to praise their child's good food choices and to role model appropriate eating and exercise.

Regarding Lawrence Jones, what questions should you ask Lawrence's mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The number of hours of sleep required for growth and development decreases with age. Children between the ages of 6 and 8 years require about 12 hours of sleep per night, children between 8 and 10 years of age require 10 to 12 hours of sleep per night, and children between 10 and 12 years of age need 9 to 10 hours of sleep per night. Young school-age children may need an occasional brief nap for an energy boost after being in school for most of the day. Bedtime rituals and consistent schedules continue to be important throughout the school-age years. Parents must facilitate the bedtime schedule and quiet time before bed. Bedtime is a special time for parents and children to read together, listen to stories or soothing music, share events of the day, and exchange expressions of affection (American Academy of Pediatrics, 2007a). Children should have bedtime expectations as well as wake-up times and methods for waking up (alarm, calling by parent, and so forth).

Night terrors or sleepwalking may occur in 6- to 8-year-olds but should be resolved between the ages of 8 and 10 years. In the

older school-age child (11 to 12 years), encourage parents to allow a variation in the sleep schedule on the weekends and a regular schedule on weekdays.

Provide anticipatory guidance to Lawrence Jones's mother in relation to proper sleep for her 10-year-old son.

Promoting Healthy Teeth and Gums

Dental caries remains a leading chronic disease in the United States (CDC, 2010a; Peterson-Sweeney & Stevens, 2010). The incidence declined from the 1970s to the early 1990s, mostly due to the introduction of fluoride (National Institutes of Dental and Craniofacial Research, National Institutes of Health, 2008). Since then there has been a small but significant increase in the incidence of dental caries. Recent statistics show that 51% of children between the ages of 6 and 11 have dental caries in their primary teeth and 21% have dental caries in their permanent teeth (National Institutes of Dental and Craniofacial Research, National Institutes of Health, 2008).

Dental care with emphasis on prevention of caries is important in this age group. School-age children need to brush their teeth two to three times per day for 2 to 3 minutes each time with fluorinated toothpaste (Nield, Stenger, & Kamat, 2007) (Fig. 6.10). Parents should replace the toothbrush (soft) every 3 to 4 months (Peterson-Sweeney & Stevens, 2010). Flossing the teeth at least once daily is recommended along with limiting the intake of sugar to aid in the prevention of cavities and improved oral health (Nield et al., 2007). Parents must monitor teeth brushing, observe for abnormal alignment of their child's teeth, and schedule regular dental examinations every 6 months to ensure good dental health and prevent dental problems. Children may need help with brushing teeth until they are between 7 and 10 years of age.

FIGURE 6.10 Using correct technique to brush the teeth is important in the prevention of cavities.

Dental sealants are recommended for all school-age children (CDC, 2010a). The sealant is a plastic coating applied to biting

surfaces to seal out tooth decay on permanent back teeth. In addition, parents should give a fluoride supplement (as directed by the dentist) to their children if fluoride is not in the town's water supply (American Academy of Pediatric Dentistry, 2008). The school-age child should have an established dental home; if not, provide appropriate resources to establish one (Hagan, Shaw, & Duncan, 2008).

Sometimes dental care is not considered to be important by parents of young children because the primary teeth will be replaced by permanent teeth. This perception leads to complications of permanent teeth such as **malocclusion**, a condition in which the teeth are crowded, crooked, or misaligned (see Healthy People 2020).

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|--|
| Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth. | <ul style="list-style-type: none"> • Encourage appropriate tooth-brushing and flossing. • Educate child and family about fluoride use. |
| Reduce the proportion of children and adolescents with untreated dental decay. | <ul style="list-style-type: none"> • Refer school-age children to dentist for regular check-ups and interventions such as molar sealants. |
| Increase the proportion of children who have received dental sealants to their molar teeth. | <ul style="list-style-type: none"> • Assist families lacking dental insurance to find resources for the provision of dental care. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Proper alignment of teeth is important to tooth formation, speech development, and physical appearance. Many school-age children need braces or other orthodontic devices to correct malocclusion, a condition in which the teeth are crowded, crooked, or misaligned. **Bruxism** or teeth grinding while asleep may continue in the school-age years. Bruxism may result in grinding away of tooth enamel. Teeth grinding may be due to malalignment. A dental evaluation should be scheduled if consistent teeth grinding occurs.

Children wearing braces are more prone to cavities; encourage them to brush their teeth after meals and snacks. School nurses can assist these children with brushing after lunch. In addition, the school nurse should promote dental health through education on dental care and gum problems that result from lack of proper dental care. Diet can play a part in dental health. Limiting sticky, high-sugar, and high-carbohydrate foods will decrease the possibility of cavities.

Promoting Appropriate Discipline

Because of the increasing ability of the school-age child to view situations from different angles, the school-age child should be able to see how his or her actions affect others. The school-age child is aware of the cause and effect of his or her behaviors and realizes that his or her behaviors have consequences. School-age children should be able to express emotions without using violence. Discipline techniques with consequences have both *natural* and *logical* consequences (Barakat & Clark, 2007). Natural consequences allow the child to learn the results of his or her actions. For example, if the child throws a toy out of the window, then he or she cannot play with the toy anymore. In logical consequences, if the child does not put away his or her bike, he or she does not get to ride the bike for the rest of the day.

In disciplining children, parents should teach children the rules established by the family, values, and social rules of conduct. Rules should provide the school-age child with guidelines about behavior that is acceptable and unacceptable. School-age children look to their parents for guidance and as role models. Parents should role model appropriate expressions of feelings and emotions and allow the child to express emotions and feelings. Discuss the effects of the child's temperament on his or her behavior, as well as what constitutes age-appropriate behavior. Include how the parents' temperament can influence the child's temperament.

Effective guidance and discipline focus on the development of the child. They can preserve the child's self-esteem and dignity. Discuss with parents guidelines regarding discipline. Explain to parents that they should never belittle the child. Children may view parents and caretakers negatively if they are consistently belittled or insulted. These negative actions can inhibit learning and teach the child to react unkindly to others. Instead, parents should discipline with praise. Positive acknowledgements of progress are likely to

encourage healthy development and appropriate behavior (American Academy of Pediatrics, 2004). Discuss with parents how to be realistic when planning activities so as to not overwhelm the child, resulting in misbehavior. Encourage parents to say “no” only when they mean it, to avoid a negative atmosphere in the home, and to avoid inconsistency.

When misbehaviors occur, the type and amount of discipline are based on different factors:

- Developmental level of both the child and the parents
- Severity of the misbehavior
- Established rules of the family
- Temperament of the child
- Response of the child to rewards

Keep in mind that school-age children should participate in developing a plan of action for their misbehavior. Whatever methods of discipline are chosen, it is important that parents are consistent in providing discipline in a nurturing environment.

Addressing Common Developmental Concerns

The developmental task (according to Erikson) of the school-age child is industry (Erikson, 1963; Feigelman, 2007a). The school-age child is busy learning, achieving, and exploring. As the school-age child becomes more independent, forces other than the family such as television, video games, and peers influence him or her. Some of these influences are positive and others are negative. Some of the common developmental concerns for the school-age child are discussed in the following sections. Guidelines to assist the parents and nurses when encountering these concerns are included in [Teaching Guidelines 6.2](#).

Teaching Guidelines 6.2

ADDRESSING COMMON DEVELOPMENTAL CONCERNS

Television and Video Games

- Limit television watching and video-game playing to 2 hours per day.
- Monitor television programs.
- Prohibit television or video games with violence.
- Do not put television or video games in children’s bedrooms.
- Provide a schedule of accepted television programs for viewing each week.
- Co-view television and video games with the child.
- Encourage sports, interactive play, and reading.

Obesity

- Provide healthy meals and snacks.
- Schedule and encourage daily exercise.
- Encourage involvement in sports.
- Restrict TV and computer-game use.
- Limit the amount of fast-food intake.
- Provide education about healthy nutrition.
- Never use food as a reward.
- Be a good role model.

School Phobia

- Return child to school.
- Investigate cause of the fear.
- Support child.
- Collaborate with teachers.
- Praise success in school attendance.

Latchkey Kids

- Provide rules to follow and expectations, such as:
 - Not answering the door or phone

- No friends in the house when parents are not home
- No playing with fire
- Teach child to call a trusted neighbor when help is needed and 911 in the event of emergency.
- Post all resource numbers (even numbers you think your child may have memorized), including after-school help lines if available, in a clearly viewable spot.
- Purchase caller ID for the phone system.
- Enroll the child in an after-school program if available.
- Discuss limitations of outside play.
- Discuss limitations of television viewing and videogame use.
- Make sure the child knows how to contact the parent.
- Set clear homework expectations.
- DO NOT keep guns in the home.

Stealing

- Educate parents about possibility of stealing.
- Discuss ways to teach concept of ownership and property rights.
- Handle situation openly.
- Assist child in developing and enacting a plan to return what was stolen.
- Make sure the punishment is appropriate for the action.

Lying

- Help parents in understanding why the child is lying.
- When the child lies, calmly confront the child and explain why the behavior is not acceptable.
- Educate parents that their behavior should reflect what they teach and expect from their child.
- Educate parents that too-rigid or severe punishments can decrease the child's sense of worth.
- Seek professional help if lying persists in the older school-age child, to rule out underlying problems.

Cheating

- Educate parents that the child must be mature enough to understand the concept of rules.
- Handle cheating situations openly.
- Help parents to understand why their child is cheating and to modify the trigger.
- Develop appropriate punishment; inappropriate punishment could undermine the child.
- Educate parents that their behavior should reflect what they expect from their child.
- Seek professional help if cheating persists in the older school-age child, to rule out underlying problems.

Bullying

The Bullied Child

- Educate parents whose children are at risk for being bullied, such as:
 - Children who appear different from the majority
 - Children who act different from the majority
 - Children who have low self-esteem
 - Children with a mental or psychological problem
- Teach parents to role-play different scenarios the child may face at school; show the child different ways to react to being bullied.
- Impress upon the child that he or she did not cause the bullying.
- Develop ways to increase the child's self-esteem at home.
- Discuss the situation with the teacher and develop a plan of care.

The Bullying Child

- Educate parents on reasons why it is important to correct the behavior.
- Discuss ways the child can appropriately show his or her anger and feelings.
- Have parents help the child to see how it feels to be bullied.
- Do not allow fighting at home.
- Reward settling of conflicts without violence.

Tobacco and Alcohol Education

- Inquire about tobacco and alcohol use.
- Discuss the physical and social dangers of tobacco and alcohol use.
- Urge parents to be good role models.
- Limit reading and media materials about alcohol and tobacco use.
- Discuss the influences of tobacco and alcohol use by peers.
- Educate the child on spit tobacco. Let them know it is just as dangerous as smoking tobacco.
- Advocate for a smoke-free environment in the home and other places frequented.
- Avoid having tobacco and alcohol products readily available in the home.

Television and Video Games

The influence of television and video games upon the school-age child is a growing concern for parents and child specialists. Children, 8 to 18 years of age, in the United States spend about 4 hours a day either watching TV or playing video games and another 2 hours on the computer outside of school work (Gavin, 2008). During that time, a child by the age of 18 will see 200,000 violent acts (Gavin, 2008). Although a school-age child can determine what is real from what is fantasy, research has shown that this amount of time in front of the TV—watching it or playing video games—can lead to aggressive behavior, less physical activity, and obesity (Gavin, 2008) (see Healthy People 2020).

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|--|
| Increase the proportion of children and adolescents who do not exceed recommended limits for screen time. | <ul style="list-style-type: none"> • Assist families to identify activities other than television or video games for the child to participate in. |
| Increase the proportion of children and adolescents aged 2 years through 12th grade who view television or videos or play video games for no more than 2 hours a day. | <ul style="list-style-type: none"> • Praise craft, music, and sports participation. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Although some television shows and video games can have positive influences on children, teach parents guidelines on the use of TV and video games. Parents should set limits on how much TV watching the child can have. The American Academy of Pediatrics recommends 2 hours or less of television viewing per day (Gavin, 2008). The parent should establish guidelines on when the child can watch TV, for example, after homework or when chores are completed (Gavin, 2008). Television watching should not be used as a reward. The parents should be aware of what the child is watching. Watch the programs together and use that opportunity to discuss the subject matter with the child. There should be no TV during dinner and no TV in the child's room. The parents need to set an example for the child. Read instead of watching TV or do a physical activity together as a family. If the TV causes fights or arguments, it should be turned off for a period of time.

School Phobia

School refusal (also called *school phobia* or *school avoidance*) has been defined as a refusal to attend school or difficulty remaining in school for an entire day. Behaviors include frequent absences, skipping classes, chronically late for school, severe misbehavior before school, or attending school with great fear. School phobia needs to be defined both symptomatically and operationally as the cause for the anxiety. School avoidance occurs in approximately 8.2% of children and adolescents (Kearney & Chapman, 2008).

Some of the fears expressed by school-refusing children include separating from parents, riding the bus, tests, bullying, teacher reprimands, anxieties over toileting in a public bathroom, physical harm, or undressing in the locker room. Due to the emotional

distress caused in these children when attending school, they are frequently classified as having school phobia. Young children may complain of stomachache or headache and older children may complain of palpitations or feeling faint.

It is important to investigate specific causes of school refusal/school phobia and take appropriate actions. Many times school phobia is a symptom of deeper problems. Children with extensive school refusal are at risk for dropping out of school, delinquency, and social and occupational problems in adulthood (Kearney & Chapman, 2008). The physician or nurse practitioner should conduct a physical examination of the child to rule out any physical illness. After these measures are taken, the parent, teacher, school counselor, and school administrator may devise a plan to assist the student to overcome a specific fear. In uncomplicated cases, parents must return the child to school as soon as possible. There may be altered schedules (partial days or decreased hours) to help promote a successful transition back to school. Another idea to help desensitize the child may be to have him or her spend part of the day in the counselor's or school nurse's office.

Latchkey Children

With the increasing incidence of both parents in the workforce and many children living with just one parent, often times children return home alone without adult supervision for a number of hours. Most young children are not capable of handling stress or making decisions on their own before 11 or 12 years of age. However, some school-age children are more mature and can be left alone by 8 to 10 years of age; maturity is the key, not the age. Parents not only need to consider their child's maturity and readiness to be home alone but also must comply with legal requirements if present. Laws regarding the age at which it is legal to leave a child home alone vary by state; therefore, the nurse needs to be familiar with the state and local laws in order to assist parents in making decisions about when it is appropriate for their child to be home alone (Kroll & Nield, 2010). The American Academy of Pediatrics recommends that a school-age child come home to a parent or another responsible adult (American Academy of Pediatrics, 2009a).

Despite the level of maturity, children who are unsupervised are more likely to participate in risky behaviors such as smoking, drinking, and doing drugs (Kroll & Nield, 2010). Children left alone have a higher incidence of injuries such as burns, falls, and poisoning than children who are supervised (Kroll & Nield, 2010). In addition, latchkey children may feel anxiety, fear, boredom, or loneliness (Kroll & Nield, 2010).

If children come home to no supervision, they should know the names, addresses, and phone numbers of parents and a neighbor, as well as emergency numbers. They should be given rules about answering the door and the phone. They should tell anyone who comes to the door or who calls that mom is home but busy at this time. Directions as to the handling of the house key and fire safety should be taught and demonstrated (see [Teaching Guidelines 6.2](#)).

Stealing, Lying, and Cheating

It is during the school-age years that antisocial behaviors can emerge. Children who were previously well behaved may now exhibit behaviors such as stealing, lying, and cheating (Mannheim & Zieve, 2010). Parents are usually disturbed by this change in behavior. In turn, they have difficulty in addressing these issues and need help in providing appropriate interventions.

Children between 6 and 8 years old do not fully understand the concept of ownership and property rights. These children may steal things because they like the look of the item. By the age of 9, the child should respect others' possessions and property and understand that stealing is wrong (Children's Hospital of Boston, 2010). The school-age child may steal because he or she desires the item, feels peer pressure and is trying to impress his or her peers, or has a sense of low self-esteem (Children's Hospital of Boston, 2010). Stealing becomes a concern if the child steals and does not have remorse or continuously steals, or if stealing is accompanied by other behavior problems (Children's Hospital of Boston, 2010).

Lying is more common in boys and in children between 5 and 8 years old (Children's Hospital of Boston, 2010). It is acceptable for these children to tell tall tales, but they should know what truth is and what make-believe is. These younger children typically lie to avoid punishment. However, they do not like others to lie and will tell on them if they lie. Children between 8 and 12 years old typically lie because they are unable to meet expectations of family and peers, they are testing the rules and limits placed on them, or they are unable to explain bad behavior (Children's Hospital of Boston, 2010). If lying persists in older school-age children, parents should discuss the matter with a physician because the lying may be evidence of underlying problems.

The concept of cheating is not well understood until the child is 7 years old. Before this age, the desire to "win" is most important and rigid rules are hard to understand. In children between 8 and 12 years old, the concept of cheating is fully understood and following of rules becomes more important (Children's Hospital of Boston, 2010). Cheating is usually done because of competition and strong pressure placed on the child to succeed (American Academy of Pediatrics, 2010). If cheating persists in older school-age children, parents should discuss the matter with a physician because the behavior may indicate underlying problems.

In dealing with children who exhibit stealing, lying, or cheating behaviors, parents must first realize the importance of their own

behaviors in those areas. Parents are role models to the school-age child. Therefore, when the child sees or hears that parents lie, steal, or cheat (e.g., parents bragging about cheating on their taxes), they think it is all right to mimic those behaviors. Secondly, parents must directly confront any stealing, lying, or cheating behaviors and discuss (and follow through consistently with) the consequences of such behaviors (see [Teaching Guideline 6.2](#)).

Bullying

Bullying, which is inflicting repeated verbal, emotional, or physical abuse upon others, is on the rise (Schoen & Schoen, 2010). Utilizing email, text messages, social networking, and instant messaging, often referred to as cyberbullying, is a growing concern. Bullies often look for victims who appear shy, weak, and defenseless. Children with disabilities are at an increased risk of being bullied (Schoen & Schoen, 2010).

In general, about 10% of all children attending school are frightened and afraid most of the day (American Academy of Child and Adolescent Psychiatry, 2008). Thirty percent of children in 6th to 10th grades bully or have been bullied (American Academy of Pediatrics, 2009b). Most of the bullying occurs at school (Augustyn & Zuckerman, 2007). Both boys and girls are bullied and can bully others; however, boys are twice as likely to be bullies and victims of bullying (Augustyn & Zuckerman, 2007). Boys usually bully other boys and use force more often, while girls can be bullied by both sexes using mainly verbal bullying, like social alienation and intimidation (Schoen & Schoen, 2010). Being bullied can have negative results on children throughout life. These children often have increased episodes of headaches, stomachaches, sleep problems, anxiety, loneliness, depression, and suicidal tendencies (Schoen & Schoen, 2010). After the problem of either being bullied or being the bully has been identified, parents must work with the child, the school, and the physician to solve the problem (see [Teaching Guidelines 6.2](#) and [Evidence-Based Practice 6.1](#)).

Tobacco and Alcohol Education

School-age children are eager to grow up and be independent. Peers and acceptance are very important at this time. School-age children may be exposed to messages that are in conflict with their parents' values regarding smoking and alcohol. Peers often exert pressure for children to experiment with tobacco and alcohol (see Healthy People 2020).

HEALTHY PEOPLE 2020

Objective

Reduce initiation of tobacco use among children and adolescents.

Nursing Significance

- Educate children and families about the dangers of tobacco use.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

School-age children are ready to absorb information that deals with drugs and alcohol. Information from parents or other adults who are major influences in the child's life is essential at this time to set clear rules and model behaviors for children to embrace. Discussions with children need to be based on facts and focused on the present. Some topics for discussion include:

EVIDENCE-BASED PRACTICE 6.1

BENEFITS OF BULLY-PREVENTION EDUCATION

STUDY

Child conduct problems continue to pose a problem in elementary schools. In addition to the behavioral disruption that occurs as a result of bullying and victimization, prior research has demonstrated that child bullies and victims are at increased risk for mental health problems and antisocial behavior. This study was performed over a 2-year period utilizing fourth-grade classrooms at 28 public elementary schools. The group-randomized trial assigned classrooms to receive a program aimed at bullying and aggression prevention or to receive no treatment at all. Self-reported bullying and victimization were then analyzed after the 2-year trial.

Findings

Upon analysis of the findings, the researchers reported a mild decrease in bullying and a greater decrease in bullying

victimization. It appears that bullying-prevention programs in elementary schools may be effective in decreasing aggression and violence in the school-age group.

Nursing Implications

Nurses should continue to educate parents and teachers about bullying. Encourage children to be involved in peer groups. Become actively involved in the local elementary school bullying-prevention program. When bullies are identified, refer them for education in alternative means of emotional expression such as social skills training.

Adapted from Jensen, J. M., & Dieterich, W. A. (2007). Effects of a skills-based prevention program on bullying and bully victimization among elementary school children. *Prevention Science*, 8, 285-296.

- What alcohol and drugs are like and how they harm you
 - Differences in medical use versus illegal use of drugs
 - How to think critically to interpret messages seen in advertising, media, sports, and entertainment personalities
- See [Teaching Guidelines 6.2](#).

Recall Lawrence Jones, the 10-year-old presented at the beginning of the chapter. List potential developmental problems he may experience. What anticipatory guidance related to these concerns should you provide to his mother?

KEY CONCEPTS

- Physical growth is slow and steady, with social and cognitive development progressing rapidly, during the school-age years of 6 to 12. Height increases approximately 2.5 inches (6 to 7 centimeters) per year and weight gain is 3 to 3.5 kilograms (7 pounds) per year. Boys are taller and heavier than girls during this time period (Feigelman, 2007a).
- With entrance into the school system, school-age children have the influences of peers and teachers.
- With the development of gross motor skills and involvement in sports at school and in the community, safety education and practices are required. Also, with the participation in cooperative sports, injuries occur.
- Visual acuity is reaching maturation and 20/20 vision is expected by 7 years of age (Jarvis, 2008).
- Increased independence leads to increased exposure to safety hazards.
- The school-age child develops the cognitive ability to classify objects and to identify relationships among objects.
- Dental care is very important to prevent dental caries, malocclusion, and other problems. In early school age, the first primary teeth will be lost.
- The onset of puberty may occur by the later school-age years.
- Erikson's (1963) developmental task for the age group is the development of a sense of industry.
- Peers are very important, especially peers of the same sex. School-age children usually have a best friend and belong to clubs. They have collections of nonvaluable items such as rocks, clips, and so forth.
- School-age children are capable of concrete operations, solving problems, and making decisions. They continue to need guidance, rules, and direction from parents.
- The school-age child develops a conscience and knows cultural and social values. He or she can understand and obey rules.
- The school-age child incorporates religious practices into his or her life, which may be a source of comfort during stressful times.
- The nurse's role includes educating parents and school-age children in promoting health and safety.
- Nurses should inform the school-age child about expected developmental changes in the body to promote self-esteem and self-confidence.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

- The successful resolution of developmental tasks for the school-age child, according to Erikson, would be identified by:
 - Learning from repeating tasks
 - Developing a sense of worth and competence
 - Using fantasy and magical thinking to cope with problems
 - Developing a sense of trust
- Which of the following are reasons that stealing occurs in school-age children? (Choose all that apply.)
 - To escape punishment
 - High self-esteem
 - Low expectations of family/peers
 - Lack of sense of propriety
 - Strong desire to own something
- Which activities will promote weight loss in an obese school-age child? (Choose all that apply.)
 - Unlimited computer and TV time
 - Role modeling by family
 - Becoming active in sports
 - Eating unstructured meals
 - Involving child in meal planning and grocery shopping
 - Drinking three glasses of water per day
- As the school nurse conducting screening for vision in a 6-year-old child, you would refer the child to a specialist if the visual acuity in both eyes is:
 - 20/20
 - 20/25
 - 20/30
 - 20/50
- The mother of two sons, ages 6 and 9, states they want to play on the same baseball team. As the school nurse, what advice would you give their mother?
 - Having the boys on the same team will make it more convenient for the mother.
 - Levels of coordination and concentration differ, so the boys need to be on different teams.
 - Put the boys on the same team because they are both school-age children.
 - It is best to avoid putting the boys on the same team to prevent sibling rivalry.

CRITICAL THINKING EXERCISES

- Ms. Sams brings her 8-year-old son, Frank, to the physician's office for his annual exam. She states that she is concerned about his

recent behavior. He went to the grocery store with his friend and his friend's mother and he came home with a Matchbox car. The friend's mother stated she had not purchased the car.

- a. What would be your response to Ms. Sams?
- b. Ms. Sams said she still has the car. What would you advise Ms. Sams to do to make Frank aware of the consequences of his actions?

2. Sally's mother is asking the nurse for advice about purchasing a two-wheeled bike for her 7-year-old. What guidance should the nurse offer this parent?
3. Ms. Shaw brings in her 11-year-old daughter for a well-child check-up. The school-ager says to the nurse, "I look different from my friends. I do not wear bras and my friends are already wearing bras." What would be an appropriate response to this school-ager?
4. Johnny is a 9-year-old whose mother and father both work during the day. He returns home after school. How should the parents prepare Johnny for this experience? What safety rules would be included in the education for Johnny?

STUDY ACTIVITIES

1. Attend a sporting event (such as soccer or baseball) with school-age teams. Describe the coordination and gross motor functioning of this group.
2. Attend a first-grade class. Observe the behaviors exhibited by the school-age children in this class. How do these behaviors compare with normal values for this age group?

Growth and Development of the Adolescent

Words of Wisdom The only way to grow is to let go ...

KEY TERMS

adolescence

menarche

peer groups

puberty

risk-taking behaviors

sexuality

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify normal physiologic changes, including puberty, occurring in the adolescent.
2. Discuss psychosocial, cognitive, and moral changes occurring in the adolescent.
3. Identify changes in relationships with peers, family, teachers, and community during adolescence.
4. Describe interventions to promote safety during adolescence.
5. Demonstrate knowledge of the nutritional requirements of the adolescent.
6. Demonstrate knowledge of the development of sexuality and its influence on dating during adolescence.
7. Identify common developmental concerns of the adolescent.
8. Demonstrate knowledge of the appropriate nursing guidance for common developmental concerns.

Cho Chung is a 15-year-old girl brought to the clinic by her mother for her annual school check-up. During your assessment you measure Cho's weight at 110 pounds and her height at 60 inches. As the nurse caring for her, assess Cho's growth and development, and then provide appropriate anticipatory guidance to her and her mother.

Adolescence spans the years of transition from childhood to adulthood, which is usually between the ages of 11 and 20 years. There is some overlap between late school age and adolescence. The adolescent experiences drastic changes in the physical, cognitive, psychosocial, and psychosexual areas. With this rapid growth during adolescence, the development of secondary sexual characteristics, and interest in the opposite sex, the adolescent needs the support and guidance of parents and nurses to facilitate healthy lifestyles and to reduce **risk-taking behaviors**.

Adolescence is a time of rapid growth with dramatic changes in body size and proportions. The magnitude of these changes is second only to the growth in infancy. During this time sexual characteristics develop and reproductive maturity is achieved. The age of onset and the duration of the physiologic changes vary from individual to individual. Generally girls enter **puberty** earlier (at 9 to 10 years of age) than boys (at 10 to 11 years). Adolescents will represent varying levels of identity formation and will offer unique challenges to the nurse (Table 7.1).

Physiologic Changes Associated with Puberty

The secretion of estrogen in girls and testosterone in boys stimulates the development of breast tissue in girls, pubic hair in both sexes, and changes in male genitalia. These biological changes that occur during adolescence are known as *puberty*. Puberty is the result of triggers among the environment, the central nervous system, the hypothalamus, the pituitary gland, the gonads, and the adrenal glands. Gonadotropin-releasing hormone (GnRH), produced by the hypothalamus, travels to the anterior pituitary gland to stimulate the production and secretion of follicle-stimulating hormone (FSH) and luteinizing hormone (LH). The increased levels of FSH and LH stimulate the gonadal response. LH stimulates ovulation in girls and acts on testicular Leydig cells in boys, prompting maturation of the testicles and testosterone production. FSH with LH stimulates sperm production. Estrogen, progesterone, and testosterone and other androgens are released from the gonads and affect biological changes and changes in various organs, including alterations in muscles, bones, skin, and hair follicles.

Adolescents experience physical development, hormonal changes, and sexual maturation during puberty that correlate to Freud's genital stage of psychosexual development. The genital stage begins with the production of sex hormones and maturation of the reproductive system.

| Stage of Adolescence | Changes in Females | Changes in Males |
|-------------------------------------|--|---|
| Early adolescence (10–13 years) | Pubic hair begins to curl and spread over mons pubis; genitalia pigmentation increases. Breast bud and areola continue to enlarge; no separation of breasts First menstrual period (average 12 years, normal range 9–16 years) | Pubic hair spreads laterally, begins to curl; pigmentation increases. Growth and enlargement of testes in scrotum (scrotum reddish in color) and continued lengthening of penis Leggy look due to extremities growing faster than the trunk |
| Middle adolescence (14–16 years) | Pubic hair becomes coarse in texture and continues to curl; amount of hair increases. Areola and papilla separate from the contour of the breast to form a secondary mound. | Pubic hair becomes coarser in texture and takes on adult distribution. Testes and scrotum continue to grow; scrotal skin darkens; penis grows in width, and glans penis develops. May experience breast enlargement Voice changes; more masculine due to rapid enlargement of the larynx and pharynx as well as lung changes |
| Late adolescence (17–20 years) | Mature pubic hair distribution and coarseness | Mature pubic hair distribution and coarseness Breast enlargement disappears. Adult size and shape of testes, scrotum, and penis; scrotal skin darkening |

Adapted from Marcell, A. V. (2007). Adolescence. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed., pp. 60–65). Philadelphia: Saunders.

Girls reach physical maturity before boys and **menarche**, the first menstrual period, usually begins between the ages of 9 and 15 years (average 12.8 years). Breast budding (thelarche) occurs at approximately age 9 to 11 years and is followed by the growth of pubic hair.

Take Note!
African-American girls on average reach menarche slightly earlier than Caucasian girls (Hirsch, 2008).

The first sign of pubertal changes in boys is testicular enlargement in response to testosterone secretion, usually occurring in Tanner stage 2. As testosterone levels increase, the penis and scrotum enlarge, hair distribution increases, and scrotal skin texture changes.

During late puberty, boys will typically experience their first ejaculation, which may occur while they are sleeping (nocturnal emissions). Nurses should provide anticipatory guidance to adolescent males regarding involuntary nocturnal emissions (wet dreams) to assure them that this is a normal occurrence.

Tanner stages 3 to 5 usually occur during adolescence. Refer to [Figures 10.28, 10.34, and 10.36](#) for an illustration of the increase in breast tissue and pubic hair distribution in girls, and scrotal and penile changes as well as hair distribution changes in boys. The nurse should provide guidance to adolescents about the normalcy of the sexual feelings and evolving body changes that occur during puberty.

Physical Growth

Diet, exercise, and hereditary factors influence the height, weight, and body build of the adolescent. Over the past three decades, adolescents have become taller and heavier than their ancestors and the beginning of puberty is earlier. During the early adolescent period, there is an increase in the percentage of body fat and the head, neck, and hands reach adult proportions.

The rapid growth during adolescence is secondary only to that of the infant years and is a direct result of the hormonal changes of puberty. Both girls and boys experience changes in appearance and size. Height in girls increases rapidly after menarche and usually ceases 2 to 2½ years after menarche. Boys' growth spurt occurs later than girls' and usually begins between the ages of 10½ and 16 years and ends sometime between the ages of 13½ and 17½ years. Peak height velocity (PHV) occurs at approximately 12 years of age in girls or at about 6 to 12 months after menarche. Boys reach PHV at about 14 years of age. Peak weight velocity (PWV) occurs about 6 months after menarche in girls and at about 14 years of age in boys. Muscle mass increases in boys and fat deposits increase in girls ([Fig. 7.1](#)).

During early adolescence growth is rapid, but it decreases in middle and late adolescence. Height for adolescent boys who are between the 50th and 95th percentile ranges from 52½ inches (132 centimeters) to 69½ inches (176.8 centimeters). Weight of boys in these percentiles ranges from 77½ pounds (35.3 kilograms) to 211 pounds (95.76 kilograms). On average, boys will gain 10 to 30 centimeters (4 to 12 inches) in height and 7 to 30 kilograms (15 to 65 pounds) in weight.

FIGURE 7.1 These adolescents reflect the differences in sizes and shapes seen in adolescents of the same age.

Height for girls who are between the 50th and 95th percentile ranges from 57 inches (144.8 centimeters) to 68½ inches (173.6 centimeters), with weight ranging from 60 pounds (27.24 kilograms) to 181 pounds (82.47 kilograms). On average, girls will gain 5 to 20 centimeters (2 to 8 inches) in height and 7 to 25 kilograms (15 to 55 pounds) in weight during adolescence. See [Appendix A](#) for growth charts for this age group. Refer to [Chapter 10, Box 10.1](#), for instructions for calculating body mass index (BMI).

Organ System Maturation

Adolescence is a time of metabolic slowing and of increasing size of some organs. The basal metabolic rate (BMR) reaches the adult level during late adolescence.

Neurologic System

During adolescence there is continued brain growth, although the size of the brain does not increase significantly. Neurons do not increase in number, but growth of the myelin sheath enables faster neural processing.

Respiratory System

The adolescent years see an increase in diameter and length of the lungs. Respiratory rate decreases and reaches the adult rate of 15 to 20 breaths per minute. Respiratory volume and vital capacity increase. Volume and capacity are greater in boys than girls, which may be associated with increased chest and shoulder size in boys. The growth of the laryngeal cartilage, larynx, pharynx, vocal cords, and lungs produces the voice changes experienced in adolescence. These changes in the quality of the child's voice are often preceded with some voice instability where voice cracking is heard. Deepening of both male and female voices occurs but is more pronounced in boys.

Cardiovascular System

There is an increase in size and strength of the heart. Systolic blood pressure increases and heart rate decreases. Blood volume reaches higher levels in boys than girls, which may be due to boys' greater muscle mass.

Gastrointestinal System

The adolescent has a full set of permanent teeth with the exception of the last four molars (wisdom teeth), which may erupt between the ages of 17 and 20 years. The liver, spleen, kidneys, and digestive tract enlarge during the growth spurt in early adolescence, but do not change in function. These systems are mature in early school age.

Musculoskeletal System

The ossification of the skeletal system is incomplete until late adolescence in boys. Ossification is more advanced in girls and occurs at an earlier age. During the growth spurt, muscle mass and strength increase. At similar stages of development, muscle development is generally greater in boys. Estrogen, progesterone, and testosterone (sex steroids) and other androgens are released from the gonads and affect changes in the muscles and bones. Low estrogen levels tend to stimulate skeletal growth, while higher levels inhibit growth. During middle adolescence, shoulder, chest, and hip breadth increase.

Integumentary System

During adolescence the skin becomes thick and tough. Under the influence of androgens, the sebaceous glands become more active, particularly on the face, back, and genitals. Due to the increased levels of testosterone during Tanner stages 4 and 5 in both boys and girls, both sexes may have increased sebum production, which may lead to the development of acne and oily hair.

The exocrine and apocrine sweat glands function at adult levels during adolescence. The exocrine glands are all over the body and they produce sweat that helps to eliminate body heat through evaporation. The apocrine glands are found in the axillae, genital, and anal areas and around the breasts. The apocrine sweat glands produce sweat in response to hair follicles. This sweat is produced continuously and is stored and released in response to emotional stimuli.

Psychosocial Development

According to Erikson, it is during adolescence that teenagers achieve a sense of identity (Erikson, 1963). As the adolescent is trying out many different roles in regard to his or her relationships with peers, family, community, and society, he or she is developing his or her own individual sense of self. If the adolescent is not successful in forming his or her own sense of self, he or she develops a sense of role confusion or diffusion. The adolescent culture becomes very important to the teenager. It is through his or her involvement with teenage groups that the adolescent finds support and help with developing his or her own identity.

Erikson (1963) believed that during the task of developing his or her own sense of identity, the adolescent revisits each of the previous stages of development. The sense of trust is encountered as the adolescent strives to find out whom and what ideals he or

she can have faith in. In revisiting the stage of autonomy, the adolescent is seeking out ways to express his or her individuality in an effective manner. The adolescent would avoid behaviors that would “shame” or ridicule him or her in front of his or her peers. The sense of initiative is revisited as the adolescent develops his or her vision for what he or she might become. And the sense of industry is again encountered as the adolescent makes his or her choice to participate in different activities at school, in the community, at church, and in the workforce.

The ability of the adolescent to successfully form a sense of self is dependent upon how well the adolescent successfully completed the former stages of development. Erikson (1963) believed that if the adolescent has been successful, he or she can develop resources during adolescence to overcome any gaps in previous developmental stages. If the adolescent believes that he or she cannot express himself or herself in any manner due to societal restrictions, he or she will develop role confusion. See [Table 7.2](#) for additional information.

Cognitive Development

According to Piaget, the adolescent progresses from a concrete framework of thinking to an abstract one (Piaget, 1969). It is the formal operational period. During this period, the adolescent develops the ability to think outside of the present; that is, he or she can incorporate into thinking concepts that do exist as well as concepts that might exist. The adolescent’s thinking becomes logical, organized, and consistent. He or she is able to think about a problem from all points of view, ranking the possible solutions while solving the problem. Not all adolescents achieve formal operational reasoning at the same time.

In the early stages of formal operational reasoning, the adolescent’s thinking is egocentric. The adolescent is very idealistic, constantly challenging the way things are and wondering why things cannot change. These activities lead to the adolescent’s feeling of being omnipotent. The adolescent must undergo this way of thinking, even though it can frustrate adults, in his or her quest to reach formal operational reasoning. As the teenager progresses toward middle adolescence, his or her thinking becomes very introspective. He or she assumes others are just as interested in what interests him or her, which leads him or her to feel unique, special, and exceptional. That feeling of “being exceptional” leads to the risk-taking behaviors of which teenagers are well known. Also, the teenager feels very committed to his or her viewpoints. He or she tries very hard to convince others of his or her viewpoints and embraces strongly those causes that support his or her opinions. This idealism can cause the adolescent to reject his or her family, culture, church, and community beliefs, which can cause conflict with his or her family, culture, church, and community. See [Table 7.2](#) for additional information.

Moral and Spiritual Development

It is during the adolescent years that teenagers develop their own set of values and morals. According to Kohlberg, adolescents are experiencing the postconventional stage of moral development (Kohlberg, 1984). It is only because adolescents are developing their formal operational way of thinking that they can experience the postconventional stage of moral development. At the beginning of this stage, teenagers begin to question the status quo. The majority of their choices are based on emotions while they are questioning societal standards. As they progress to developing their own set of morals, adolescents realize that moral decisions are based on rights, values, and principles that are agreeable to a given society. They also realize that those rights, values, and principles can be in conflict with the laws of the given society, but they are able to reconcile the differences. Because adolescents undergo the process of developing their own set of morals at different rates, they might find that their friends view a situation differently. This difference can lead to conflicts and the forming of different friendships. See [Table 7.2](#) for additional information.

Adolescents also may begin to question their formal religious practices or in some cases cling to them (Ford, 2007). As they progress through adolescence, teenagers become more interested in the spiritualism of their religion than in the actual practices of their religion. Adolescents are searching for ideals and may exhibit intense emotions along with introspection (Ford, 2007). Increased spirituality and religious activities are related to increased healthy behaviors and decreased high-risk behaviors (Ford, 2007).

Referring back to Cho Chung, identify the stage of psychosocial development that she should be in according to Erikson. What approaches for assessment and teaching would be most effective based on the stage you identified?

Motor Skill Development

During adolescence, the teenager refines and continues to develop his or her gross and fine motor skills. Because of this period of rapid growth spurts, teenagers may experience times of decreased coordination and have a diminished ability to perform previously learned skills, which can be worrisome for the teenager.

Gross Motor Skills

It is usually during early adolescence that teenagers begin to develop endurance. Their concentration has increased so they can follow complicated instructions. Coordination can be a problem because of the uneven growth spurts. During middle adolescence, speed and accuracy increase while coordination also improves. Teenagers become more competitive with each other (Fig. 7.2). During late adolescence, the teenager usually narrows his or her areas of interest and concentrates on the needed relevant skills.

| Theories | Stages | Activities |
|------------------------|---|--|
| Erikson (psychosocial) | Identity vs. role confusion or diffusion Early (11–14 years) | Focuses on bodily changes Experiences frequent mood changes Importance placed on conformity to peer norms and peer acceptance Strives to master skills within peer groups Defining boundaries with parents and authority figures Early stage of emancipation—struggles to separate from parents while still desiring dependence upon them Identifies with same-sex peers |
| | Middle (14–16 years) | Takes more responsibility for own behaviors Continues to adjust to changed body image Tries out different roles within peer groups Need for acceptance by peer group at the highest level Interested in attracting opposite gender |
| | Late (17–20 years) | Time of greatest conflict with parents/authority figures Able to understand implications of behavior and decisions Roles within peer groups established Feels secure with body image Has matured sexual identity Has idealistic career goals Importance of individual friendships emerges Process of emancipation from family almost complete |
| Piaget (cognitive) | Formal operations Early (11–14 years) | Limited abstract thought process Egocentrically thinking Eager to apply limited abstract process to different situations and to peer groups |
| | Middle (14–17 years) | Increased ability to think abstractly or in more idealistic terms Able to solve verbal and mental problems using scientific methods Thinks he or she is invincible—risky behaviors increase Likes making independent decisions |
| | Late (17–20 years) | Becomes involved/concerned with society, politics Abstract thinking is established Develops critical thinking skills—tests different solutions to problems Less risky behaviors Develops realistic goals and career plans |
| Kohlberg | Postconventional level III Early (11–14 years) Middle (14–17 years) | Morals based on peer, family, church, and societal morals Asks broad, usually unanswerable questions about life Developing own set of morals—evaluates individual morals in relation to peer, family, and societal morals |
| | Late (17–20 years) | Internalizes own morals and values Continues to compare own morals and values to those of society Evaluates morals of others |
| | | |

FIGURE 7.2 Adolescents become involved in competitive sports, which draw upon their gross motor skills.

Fine Motor Skills

The use of computers has greatly increased the fine motor skills of teenagers (Fig. 7.3). In the early adolescent years, the teenager increases his or her ability to manipulate objects. The adolescent's handwriting is neat and he or she increases his or her finger dexterity. The middle adolescent years see the teenager refining his or her dexterity skills. By late adolescence, the teenager has developed precise eye-hand coordination and finger dexterity.

FIGURE 7.3 Using computers has increased the fine motor skills of adolescents.

Communication and Language Development

Language skills continue to develop and be refined during adolescence. Adolescents have improved communication skills, using correct grammar and parts of speech. Vocabulary and communication skills continue to develop during middle adolescence.

However, the usage of colloquial speech (slang) increases, causing communication with people other than peers to be difficult at times. By late adolescence, language skills are comparable to those of adults.

Emotional and Social Development

Adolescents undergo a great deal of change in the areas of emotional and social development as they grow and mature into adults. Areas that are affected include the adolescent's relationship with parents; self-concept and body image; importance of peers; and sexuality and dating.

Relationship With Parents

Families and parents of adolescents experience changes and conflict that require adjustments and the understanding of adolescent development. The adolescent is striving for self-identity and increased independence. He or she spends more time with peers and less time with family and attending family functions. Parents sense that they have less influence on the adolescent as the teen questions family values and becomes more mobile. This may lead to a family crisis, and the parents may respond by setting stricter limits or asking questions about the teen's activities and friends. Other parents may drop all rules and assume that the adolescent can manage himself or herself. Both of these responses increase tension in the family.

With the adolescent attempting to establish some level of independence—and the family learning to let go while focusing on aging parents, their marriage, and other children—a state of disequilibrium occurs. The family may experience more stress than at any other time.

Some families have better outcomes with their adolescents than others. Families who listen to and continue to demonstrate affection for and acceptance of their adolescent have a more positive outcome. This does not mean that the family accepts all of the teen's ideas or actions, but they are willing to listen and attempt to negotiate some limits. For tips to improve communication with teenagers, see [Box 7.1](#).

Siblings experience changes in the relationship with the adolescent brother or sister; the older sibling may attempt to parent and the younger sibling may regress in an attempt to avoid the family conflict. Understanding the status of the adolescent-family relationship is essential for the nurse.

BOX 7.1

WAYS TO IMPROVE COMMUNICATION WITH TEENS

- Set aside appropriate amount of time to discuss subject matter without interruptions.
- Talk face to face. Be aware of body language. Ask questions to see why he or she feels that way.
- Ask him or her to be patient as you tell your thoughts.
- Choose words carefully so he or she understands you.
- Tell him or her exactly what you mean.
- Give praise and approval to your teenager often.
- Speak to your teenager as an equal—don't talk down to him or her.
- Be aware of your tone of voice and body language.
- Don't pretend you know all the answers.
- Admit that you do make mistakes.
- Set rules and limits fairly.

Self-Concept and Body Image

Self-concept and self-esteem are often tied to body image. Adolescents who perceive their body as being different than peers or as less than ideal may view themselves negatively. Adolescent girls often are influenced by peers and the media and want to weigh less and have smaller hips, waist, or thighs. Boys tend to view themselves as being too thin or not muscular enough.

Sexual characteristics are important to the adolescent's self-concept and body image. Boys are concerned about the size of their penis and facial hair while girls are concerned about breast size and the onset of menstruation. Larger breasts are considered more feminine and menstruation is considered the right of passage into adulthood. All of these body changes are important to the adolescent's self-concept.

Importance of Peers

Peer groups play an essential role in the identity of the adolescent (Marcell, 2007). Adolescent peer relationships are very important in providing opportunities to learn about negotiating differences; for recreation, companionship, and someone to share problems with; for learning peer loyalty; and for creating stability during transitions or times of stress. Learning to work out differences with peers is a skill that is important throughout life. Peers serve as someone safe to discuss family issues with, as the teen emotionally moves away from the family while trying to find his or her identity. Due to changes that have taken place within family systems in society, peer groups play a significant role in the socialization of adolescents (Fig. 7.4).

FIGURE 7.4 Peers play an important role in shaping the adolescent's identity.

Peers serve as credible sources of information, role model social behaviors, and act as sources of social reinforcement. Friends provide an opportunity for fun and excitement. Peers impact teens' appearance, dress, social behavior, and language. Peers also can have positive influences on each other, such as promoting college attendance, or negative influences, such as involvement with alcohol, drugs, or gangs. Early and middle adolescence are periods when teens are prone to join gangs. Peer role modeling and peer acceptance may lead to the formation of a gang that provides a collective identity and gives a sense of belonging. Peer pressure, companionship, and protection are the most frequent reasons given for joining gangs, particularly those associated with criminal activity.

Parents must know their teen's friends and continue to be aware of potential problems while allowing the teen the independence to become his or her own person. Nurses must remind parents of the importance of peers and the impact they have on the teen's decisions and life choices. The transition to greater peer involvement requires guidance and support. Adolescents who do not have parental or adult supervision and opportunities for conversation with adults may be more susceptible to peer influences and at higher risk for poor peer selections.

Sexuality and Dating

Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors related to the adolescent's sexual identity. Adolescents usually begin experimentation with heterosexual and homosexual behaviors, although these behaviors may occur earlier in some cultures.

FIGURE 7.5 Dating becomes an important aspect of the teenager's life.

An interest in the opposite sex occurs during adolescence (Fig. 7.5). Some of the reasons cited for this developing interest are physical development and body changes, peer-group pressure, and curiosity. During the past couple of decades, the percentage of 8th through 12th graders that have dated has declined. Twenty-seven percent of 12th graders have never dated, while 24% reported going on a date one or more times a week (Child Trends, 2008). Teen dating can range from group dating to single dating to serious relationships. Most early adolescents spend more time in activities with mixed-sex groups, such as dances and parties, than they do dating as a couple. Popular dating activities today include going out to dinner or the movies, "hanging out" at the mall, or visiting each other's home. During early adolescence, teens tend to date for fun and recreation. Also, they may see dating as a way to upgrade social standing by being seen with a popular boy or an attractive girl.

Middle and late adolescents have group and single dates. Romantic relationships are central to the social life of this age group. Most teens have been involved in at least one romantic relationship by middle adolescence (O'Sullivan, Cheng, Harris, & Brooks-Gunn, 2007). Dating or spending time with a potential romantic partner is viewed as a major developmental marker for teens and is one of the most challenging adjustments. Teens that date frequently report slightly higher levels of self-esteem and increased autonomy and perceive themselves as more popular. However, they frequently have lower academic success and motivation, have higher depression rates, and experience a higher level of parental conflict.

Trends in dating are changing, but dating remains a developmental milestone for the adolescent. Adolescents may experiment with homosexual behavior, though homosexual behavior as a teen does not necessarily indicate that the adolescent will maintain a homosexual orientation (Sass & Kaplan, 2011). Gay and lesbian adolescents face many challenges due to society's nonacceptance and peer insensitivity. Teens who self-declare as homosexual during high school are at increased risk for such problems as depression, suicide, victimization, school avoidance, risky sexual behaviors, and substance abuse (Friedman, 2008; Sass & Kaplan, 2011).

Early romantic relationships play a critical role in the development capacity for long-term committed relationships in adulthood (Sorensen, 2007). Healthy romantic relationships in adolescence can assist the teen in developing a strong sense of self-identity and developing interpersonal skills, such as empathy. The emotional ups and downs that accompany dating can help develop emotional resilience and coping skills. Romantic relationships at this stage are a great source of emotional support. Risks of being involved in unhealthy romantic relationships include dating violence and risky sexual activity such as sexually transmitted infections (STIs) and

premature pregnancy. Adolescents do not automatically know what makes for a healthy relationship. They need to be educated on the right and wrong behaviors of dating and what behaviors make up a healthy relationship, such as open communication, honesty, and trust. They need to know the signs of an unhealthy relationship and how to seek help if needed.

Cho Chung's mother states that she is concerned about the changes that have occurred in her and Cho's relationship over the past year. Cho seems much more self-centered, always wants to be with her friends, is very critical of her mother and father, and seems to be constantly in conflict with them. Based on what you know about this stage of development, what guidance, including approaches and techniques, can you discuss with Mrs. Chung to address her concerns?

Cultural Influences on Growth and Development

Although the adolescent's culture continues to influence him or her, the desire to be in harmony with peers becomes paramount. That desire can cause conflict with the adolescent's family and culture. Today's adolescents live in a rapidly changing, increasingly culturally diverse world. They are exposed to many different cultures and ethnic groups. In 2007, over 40% of children and adolescents in the United States were minorities (Federal Inter-agency Forum on Child and Family Statistics, 2008).

Attitudes regarding adolescence vary among different cultures. Certain cultures may have more permissive attitudes toward issues facing adolescents, while others are more conservative (e.g., toward sexuality). Experiencing a rite-of-passage ceremony to signal the adolescent's movement to adult status varies among cultures. The American culture does not universally have a rite of passage for teenagers. Some religious and social groups do have ceremonies that signal a movement toward the maturity of adulthood (e.g., the Jewish bar or bat mitzvah, the Catholic confirmation, and social debuts). In many parts of the world, separate "youth cultures" have developed in an attempt to blend traditional and modern worlds for the adolescent.

It is important for the nurse to recognize the ethnic background of each adolescent. Research has shown that certain ethnic groups are at higher risk for certain diseases. For example, adolescent African Americans are at higher risk for developing hypertension (American Heart Association, 2011). But the major barrier to the adolescent's health and successful achievement of the tasks of adolescence is socioeconomic status. Adolescents at a lower socioeconomic level are at higher risk for developing health care problems and risk-taking behaviors; this may be due to their inability to access health care and to obtain needed services (National Institute for Health Care Management [NIHCM], 2007). In caring for adolescents, recognize the influence of their culture, ethnicity, and socioeconomic level upon them.

THE NURSE'S ROLE IN ADOLESCENT GROWTH AND DEVELOPMENT

Growth and development in the adolescent is rapid. Nurses must be aware of the usual growth and development patterns for this age group so that they can assess the adolescent appropriately and provide guidance to the adolescent and his or her family. During adolescence, the teenager faces many challenges. His or her fluctuating relationships with parents and other adult figures may limit the teen from seeking assistance in dealing with the common issues of adolescence. In dealing with adolescents, be aware that they behave unpredictably, are inconsistent with their need for independence, have sensitive feelings, may interpret situations differently from what they are, think friends are extremely important, and have a strong desire to belong. During health care visits the adolescent or parent may have concerns that they are hesitant or uncomfortable talking about in front of each other. Try to provide an opportunity for them to have private time with a health care provider to discuss issues. The adolescent may greatly appreciate the opportunity for time to discuss concerns with a nonjudgmental informed adult.

If the adolescent is hospitalized, growth and development may be altered. The adolescent is concerned about how the illness or injury will affect his or her body and body image. He or she fears pain and loss of privacy. The adolescent may experience anxiety about being separated from friends and loss of control.

When caring for the hospitalized adolescent, the nurse must use knowledge of normal growth and development to recognize potential delays, promote continued appropriate growth and development, and interact successfully with the teen. Provide opportunities for them to maintain independence, participate in decisions, and encourage socialization with friends through phone, e-mail, and visits when possible. The following Nursing Process Overview will address promoting healthy growth and development and dealing with common developmental concerns.

NURSING PROCESS OVERVIEW

Upon completion of assessment of the adolescent's current growth and development status, problems or issues related to growth and development may be identified. The nurse may then identify one or more nursing diagnoses, including:

- Risk for disproportionate growth
- Imbalanced nutrition: more than body requirements
- Delayed growth and development
- Risk for caregiver role strain
- Risk for injury
- Ineffective coping

Nursing care planning for the adolescent with growth and development issues should be individualized based on the adolescent's and family's needs. [Nursing Care Plan 7.1](#) can be used as a guide in planning nursing care for the adolescent with a growth and development concern. The nurse may choose the appropriate nursing diagnoses from this plan and individualize them as needed. The nursing care plan is intended to serve as a guide, not to be an all-inclusive growth and development care plan.

Promoting Healthy Growth and Development

It takes multiple groups who address multiple issues to promote healthy growth and development in the adolescent. Some of these groups include sports teams in the school or the community, peers, teachers, band and choir members, and so forth. Also, the family's support and love will influence growth and development.

NURSING CARE PLAN 7.1

Growth and Development of the Adolescent

NURSING DIAGNOSIS: Risk for disproportionate growth (risk factors: caregiver and adolescent knowledge deficit, low self-esteem, frequent illnesses)

Outcome Identification and Evaluation

Adolescent will demonstrate adequate growth: *appropriate weight gain and increase in height for age and sex*

Intervention: *Promoting Appropriate Physical Growth*

- Assess parents' and adolescent's knowledge of nutritional needs of adolescents *to determine need for further education.*
- Educate parents and adolescent about appropriate serving sizes and foods *so that they are aware of what to expect for adolescents.*
- Determine need for additional caloric intake if necessary *(if very active in sports, if have a chronic illness).*
- Plot out height, weight, and body mass index (BMI) *to detect possible pattern.*
- Assess for risk factors for developing eating disorder *to refer to if needed and plan interventions.*

NURSING DIAGNOSIS: Ineffective health maintenance related to lack of exercise, increased caloric intake, poor food choices, and stresses of adolescence

Outcome Identification and Evaluation

Adolescent will engage in health maintenance behaviors and lose weight at an appropriate rate: *increase amount of exercise, make appropriate eating choices, decrease caloric intake to appropriate amount for age and sex*

Intervention: Promoting Appropriate Health Maintenance Behaviors

- Assess knowledge of parents and adolescent about nutritional needs of teenagers *to determine deficits in knowledge.*
- Have adolescent keep a detailed food and exercise diary for 1 week *to determine current patterns of eating and exercise.*
- Interview family in relationship to their eating habits and exercise habits *to determine where adjustments might need to be made.*
- Discuss changes in a positive manner—talk about developing healthy eating habits instead of dieting *to promote compliance.*
- Analyze preceding data, and base recommendations for changes on these data *to promote compliance and to prioritize recommendations.*
- Discuss ways to decrease temptation to overeat, for example, eat slowly, put down the fork between bites, serve food on smaller plates, and count mouthfuls, *to allow time to realize that you are full.*
- Have adolescent create meal plans and grocery shop *to allow him or her some sense of control and decision making.*
- Incorporate increase in daily exercise, which will stress sense of self-improvement *to increase caloric expenditure and self-esteem.*
- Decrease TV/computer time *to increase caloric expenditure.*
- Encourage peer exercise activities *to increase peer interactions and to help teen to realize that others are like him or her.*
- Develop reward system *to increase self-esteem.*
- Investigate joining weight loss program for adolescents *to increase self-esteem and encourage weight loss.*

NURSING DIAGNOSIS: Growth and development, delayed, related to speech, motor, psychosocial, or cognitive concerns as evidenced by delay in meeting expected school performances

Outcome Identification and Evaluation

Development will be maximized: Adolescent will make attainment of expected school performance.

Interventions: Promoting Growth and Development

- Perform scheduled evaluation of the adolescent by school and health care provider *to determine current functioning.*
- Develop realistic multidisciplinary plan *to ensure maximizing resources.* continued progress toward
- Carry out interventions as prescribed by developmental specialist, physical therapist, occupational therapist, or speech therapist at home and at school *to maximize benefit of interventions.*
- Have scheduled evaluation meetings *to be able to adapt interventions as soon as possible.*

NURSING DIAGNOSIS: Caregiver role strain, risk for (risk factors: knowledge deficit about adolescent issues, lack of prior exposure, fatigue, ill or developmentally delayed child)

Outcome Identification and Evaluation

Parent will experience competence in role: *will demonstrate appropriate caretaking behaviors and verbalize comfort in caring for an adolescent*

Interventions: Preventing Caregiver Role Strain

- Assess parents' knowledge of adolescents and the issues that arise as a part of normal development *to determine parents' needs.*
- Provide education on normal issues of adolescence *so that parents are armed with the knowledge they need to appropriately care for their adolescents.*
- Provide anticipatory guidance related to upcoming expected issues related to adolescent development *to prepare parents for what to expect next and how to intervene in an appropriate manner.*

NURSING DIAGNOSIS: Injury, risk for (risk factors: increased motor and cognitive skills and feeling of invincibility)

Outcome Identification and Evaluation

Adolescent's safety will be maintained: *will remain free from injury*

Interventions: Preventing Injury

- Discuss safety measures needed for the following: bikes, scooters, guns, skateboards, cars, and water *to decrease risk of injury related to those areas.*
- Discuss and develop a fire safety plan *to decrease risk of injury related to fire.*
- Discuss appropriate safety equipment needed for each sport *to decrease risk of injury.*
- Discuss appropriate sports to participate in depending on age, sex, and maturity of adolescent *to prevent possible injury.*
- Teach parents and adolescent first-aid measures and cardiopulmonary resuscitation (CPR) *to minimize consequences of injury should it occur.*
- Discuss influence of peers upon actions of adolescents *to prevent possible injury due to mimicking behavior.*

NURSING DIAGNOSIS: Coping, ineffective (risk factors: low self-esteem, poor relationship with parents and peers, participating in risk-taking behaviors)

Outcome Identification and Evaluation

Adolescent will demonstrate adequate coping abilities *as evidenced by management of stress of adolescence and no evidence of participating in risk-taking behaviors.*

Interventions: Promoting Effective Coping

- Assess adolescent's knowledge of normal stress facing teenagers *to determine current knowledge.*
- Assess adolescent's present coping skills *to determine areas for improvement/support.*
- Encourage parents to accept teenager as a unique individual *to improve self-esteem.*

- Discuss with parents and adolescent normal developmental issues facing teens *to give them knowledge needed to cope*.
- Provide different situations the teen might be faced with and encourage teen to develop different solutions.
- Allow for increasing independence and opportunities to solve own problems *to improve coping skills*.
- Encourage parents to provide unconditional love *to improve self-esteem*.
- Assess for any evidence of any risk-taking behaviors (drugs, smoking, suicide) *to identify need for early interventions*.

Promoting Growth and Development Through Sports and Physical Fitness

Many adolescents are involved in team sports that provide avenues for exercise. High levels of physical activity may reduce cardiovascular disease risk factors and provide disease prevention against cancer, obesity, osteoporosis, and depression (Kelly, 2010). Also, physical activity may contribute to higher academic performance and achievement (National Center for Chronic Disease Prevention and Health Promotion, Division of Adolescent and School Health, 2010). Adolescents probably spend more time and energy participating in sports than any other age group. Participation in sports contributes to the adolescent's development, educational process, and better health. Sports and games provide an opportunity to interact with peers while enjoying socially accepted stimulation and conflict. Competition in sports activities helps the teenager in processing self-appraisal and in developing self-respect and concern for others.

Every sport has some potential for injury. Rapidly growing bones, muscles, joints, and tendons are more vulnerable to unusual strains and fractures (see [Evidence-Based Practice 7.1](#)). The American Academy of Pediatrics (2007) encourages participation in regular physical activity by young persons and encourages parents and coaches to be aware of early warning signs of fatigue, dehydration, and injury. See [Chapter 23](#) for a discussion of sports injuries.

In relation to youth sports, the role of the nurse is to educate to prevent injuries ([Fig. 7.6](#)). This education should include discouraging participation when the teen is tired or has an existing injury.

Additionally, adolescence is a good time to develop an exercise program. The U.S. Department of Health and Human Services (2008) recommends that adolescents participate in 60 minutes of moderate to vigorous physical activity each day. Nurses should encourage all adolescents to be physically active daily.

FIGURE 7.6 Stretching before exercise is an important part of exercise.

EVIDENCE-BASED PRACTICE 7.1

INTERVENTIONS DIRECTED TOWARD PREVENTION OF ANKLE LIGAMENT INJURY OR SPRAIN

STUDY

Adolescents are increasingly involved in organized sports that put them at risk for injury. Soccer and basketball, in particular, result in a very high incidence of ankle injuries, and ankle sprains are very commonly treated in acute care. Inversion of the

plantar-flexed foot is the most common mechanism of ankle injury resulting in damage to the lateral ligament complex. The authors analyzed 14 randomized or quasi-randomized trials that included data for a total of 8,279 participants. The intervention evaluated included use of modified footwear (high-top athletic shoes), external ankle supports, coordination training, and health education. The study evaluated the occurrence as well as the recurrence of ankle sprains.

Findings

Ankle coordination and strength training may be beneficial in the prevention of ankle sprains, but the results from the included studies were not powerful. However, the review provided sufficient evidence that the use of semirigid orthoses reduces the risk of ankle sprain in the young athlete and adult. Use of these devices was shown to be particularly helpful in preventing reinjury of the ankle.

Nursing Implications

Nurses should recommend the use of semirigid ankle orthoses to adolescent athletes participating in sports such as soccer and basketball. Although physical conditioning of the ankle was not decisively proved to decrease the risk of ankle injury, it was not proved to be harmful, so it should still be encouraged in student athletes. Exercises designed to improve coordination and proprioception should be included. At a minimum, adolescent athletes participating in high-risk sports should wear high-top athletic shoes in order to provide some protection against the occurrence of ankle injury.

Adapted from Handoll, H. H. G., Rowe, B. H., Quinn, K. M., & de Bie, R. (2007). Interventions for preventing ankle ligament injuries. *The Cochrane Library* 2007, 4.

Promoting Learning

School, teachers, family, and peers influence education and learning for the adolescent. Also, activities such as athletics and club membership enhance learning through interactions with peers, coaches, club leaders, and others.

School

School plays an essential part in preparing adolescents for the future. Completing school prepares the adolescent for college or employment to make an adequate income. Schools in the United States may not meet the developmental needs of all adolescents. Minority students may not be at the appropriate grade level and the dropout rate may be higher than in nonminority students. Dropout rates have declined since the 1970s but still remain a concern. Dropout rates are highest among Hispanic students (Child Trends Data Bank, 2008). Those who drop out of school may lack skills needed to function in today's society. They are more likely to be unemployed and have lower income levels and occupational status than those with a high school diploma (Child Trends Data Bank, 2008) (see Healthy People 2020). Another influencing factor is a lack of parental involvement. Due to single-parent families and both parents being in the workforce, parents have less time to devote to involvement in their child's school activities.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Increase educational achievement of adolescents. | <ul style="list-style-type: none">• Encourage school attendance and completion when encountering teens for well-child or sick visits.• Refer children who have difficulty concentrating or learning for further evaluation.• Praise school accomplishments. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

There is evidence that the transition from elementary school to middle school at age 12 or 13, and then the transition to high school, both of which occur at the time of physical changes, may have a negative effect on teens. It is important to observe for transition problems into middle or high school, which may be exhibited by failing grades or behavior problems. Also, students who experience difficulties in school, resulting in negative evaluations and failing grades, may feel alienated from school. Students with failing grades and those repeating grades exhibit more emotional behavior such as violence and are more likely to engage in risky

behaviors such as tobacco and alcohol use (National Center for Chronic Disease Prevention and Health Promotion, Division of Adolescent and School Health, 2010). Schools that support peer-group relationships, promote health and fitness, encourage parental involvement, and strengthen community relationships have better student outcomes. Parents, teachers, and health care providers should provide guidance and support.

FIGURE 7.7 Wearing appropriate safety equipment can prevent injuries.

Other Activities

Adolescents are involved in many other activities that influence learning. Some of these activities include (1) school activities such as band, choir, or clubs requiring high achievement; (2) athletic activities in the school and community and sometimes in the state or region; (3) art, sewing, and building classes; and (4) work activities when the late adolescent has a part-time job. These activities all contribute to the growth, development, and education of the adolescent.

Promoting Safety

Unintentional injuries are the leading causes of death in adolescents (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2008). Injuries kill more adolescents than all diseases combined with 46% of injury related deaths due to motor vehicle accidents (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2008). Unintentional injury accounts for about 48%, violence for 15.2%, and homicide and suicide for 11.8% of adolescent injury deaths (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2008). Males are more likely than females to die of any type of injury (Centers for Disease Control and Prevention [CDC], 2008d).

Influencing factors related to the prevalence of adolescent injuries include increased physical growth, insufficient psychomotor coordination for the task, abundance of energy, impulsivity, peer pressure, and inexperience. Impulsivity, inexperience, and peer pressure may place the teen in a vulnerable situation between knowing what is right and wanting to impress peers. On the other hand,

teens have a feeling of invulnerability, which may contribute to negative outcomes. Alcohol and other drugs are contributing factors in automobile and firearm accidents among adolescents. Most of the serious or fatal injuries in adolescents are preventable (Fig. 7.7). Nurses must educate parents and adolescents on car, gun, and water safety to prevent unintentional injuries. See [Teaching Guidelines 7.1](#) for information on promoting safety.

Teaching Guidelines 7.1

PROMOTING SAFETY

| Safety Issue | Activity |
|----------------------|---|
| Motor vehicle | <ul style="list-style-type: none"> • Wear seat belt at all times. • Do not drive with someone who is impaired. • Take driver-education course. • Establish driving rules between parent and adolescent prior to getting license. • Have all passengers wear seat belts. • Do not use cell phone while driving, drink and drive, or drive when tired. • Maintain car in good condition. • Drive with adult supervision for period of time after receiving license. |
| Bike: General | <ul style="list-style-type: none"> • Have a well-maintained and appropriate-size bike for adolescent. • Adolescent should demonstrate his or her ability to ride bike safely before being allowed to ride on street. • Safe areas for bike riding should be established as well as routes to and from area of activities. • Should not ride bike barefoot, with someone else on bike, or with clothing that might get entangled in the bike. • Should wear sturdy, well-fitting shoes and American National Standards Institute (ANSI)-approved helmets. • Bike should be inspected often to ensure it is in proper working order. • A basket should be used to carry heavy objects. |
| Bike: In traffic | <ul style="list-style-type: none"> • All traffic signs and signals must be observed. • If adolescent is riding at night, the bike should have lights and reflectors and the rider should wear light-colored clothes. • Should ride on the side of the road traveling with traffic and keep close to the side of the road in single file. • Should watch and listen for cars and never hitch a ride on any vehicle. • Should not wear headphones while riding a bike. |
| All-terrain vehicles | <ul style="list-style-type: none"> • Should not be operated by adolescent younger than 16 years of age. • Helmet and protective coverings required. • No nighttime riding. • Not for use on public roads or if teen has been drinking or using drugs. • Do not stand up in the vehicle or ride in a person's lap. |
| Skateboards/skates | <ul style="list-style-type: none"> • Wear helmet, and protective padding on knees, elbows, and wrists. • Do not skate in traffic or on streets or highways. • Skating on homemade ramps could be dangerous—assess ramps for any hazards before skating. |
| Water safety | <ul style="list-style-type: none"> • Learn how to swim; if swimming skill is limited, must wear life preserver at all times. • Never swim alone—should, if at all possible, swim only where there is a life guard. • Learn basic cardiopulmonary resuscitation (CPR). • Do not run or fool around at edge of pool. • Drains in pool should be covered with appropriate cover. • Wear life jacket when on boat. • Make sure there is enough water to support diving. • Do not swim if drinking alcohol or using drugs. |
| Firearms | <ul style="list-style-type: none"> • If guns are in household, should take firearm safety class, secure guns in safe place, use gun safety locks, and store bullets in separate place. |

- Never point a gun at a person.
- All homes should have working smoke detectors and fire extinguishers. Change the batteries at least twice a year.
- Have fire-escape plan and practice the plan routinely.
- No smoking in bed.
- Teach what to do in case of a fire—use fire extinguisher, call 911, how to put out clothing fire.
- All flammable materials and liquids should be stored safely.
- Fireplaces should have protective gratings.
- Avoid touching any downed power lines. Machinery
- Use safety devices.
- Receive training on how to use equipment.
- Do not use when alone. Sports
- Match sport to adolescent’s ability and desire.
- Sports program should have warm-up procedure and hydration policy.
- Undergo sports physical before start of activity.
- Coaches should be trained in CPR and first aid.
- Wear appropriate protection devices for individual sport. Sun
- Use sunscreen with both ultraviolet A (UVA) and ultraviolet B (UVB) protection.
- Apply sunscreen prior to going out and reapply sunscreen often.
- Limit sun exposure, especially between 10 a.m. and 2 p.m.
- Wear hat and sunglasses while outside. Personal
- Never go with a stranger. safety
- Do not enter a car when the driver has been drinking.
- Notify adult where you are when out after dark.
- Keep cell phone fully charged.
- Never give out personal information over the Internet.
- Say “no” to drugs, alcohol, or smoking, or to being touched when you do not want to be touched. Toxins
- Teach the hazards of accepting illegal drugs, alcohol, dangerous drugs.
- Store potential dangerous material in safe place.

Elk Grove Village, IL: American Academy of Pediatrics; American Academy of Pediatrics, Council on Environmental Health and Section on Dermatology. (2011). Policy statement—Ultraviolet radiation: A hazard to children and adolescents. *Pediatrics*, online. Retrieved March 26, 2011, from <http://pediatrics.aappublications.org/cgi/content/abstract/peds.2010-3501v1>

FIGURE 7.8 The use of seat belts has led to fewer fatal injuries in car accidents.

Motor Vehicle Safety

The largest numbers of adolescent injuries are due to motor vehicle crashes. When the adolescent passes his or her driving test, he or she is able to drive legally. However, driving is complex and requires judgments that the teen is often incapable of making. Also, the typical adolescent is opposed to authority and is interested in showing peers and others his or her independence. Teenagers are the least likely age group to wear a seat belt, with males less likely than females and African American and Hispanic teens less likely than Caucasian teens (CDC, 2007). Crashes involving adolescents are more likely to involve speeding or driving too fast for conditions (National Highway Traffic Safety Association [NHTSA], 2008). More accidents occur when passengers, mostly other teenagers, are present in the car, during driving at night or driving under the influence of alcohol (NHTSA, 2008).

It is essential to promote driver education, to teach about the importance of wearing seat belts, and to explain laws about teen driving and curfews (Fig. 7.8). See [Teaching Guidelines 7.1](#) for additional information.

Take Note!

Many states have enacted a Graduated Driving License (GDL) program, which allows teens to gain driving experience and limits risky circumstances (such as nighttime driving and driving with passengers) by providing a license in three stages (learners permit, provisional license, and full license) (NHTSA, 2008). Studies have shown this program to be highly effective in reducing teen driver crashes (NHTSA, 2008).

Firearm Safety

The risk of dying from a firearm injury among 15- to 19-year-olds has been rising. In 2005, 84% of homicides and 46% of suicides in children and adolescents were caused by a firearm (CDC, 2008a). Provide education about gun safety. Guns in the home must be kept and locked in a safe location, with ammunition kept separately. Parents must teach adolescents about the dangers of playing with

firearms. See [Teaching Guidelines 7.1](#) for additional information on gun safety.

Water Safety

Drowning is a needless cause of death in adolescents. Many drownings are a result of risk-taking behaviors. With the independence of the adolescent, many times adult supervision is not prevalent and the teen takes a dare that results in drowning. Provide water safety education and proper supervision to decrease the incidence of risk taking. Teach about swimming lessons for nonswimmers. See [Teaching Guidelines 7.1](#) for additional information.

Remember Cho Chung, the 15-year-old presented at the beginning of the chapter? What anticipatory guidance related to safety should you provide to Cho and her mother?

Promoting Nutrition

Nutritional needs are increased during adolescence due to accelerated growth and sexual maturation. Adolescents may appear to be hungry constantly and need regular meals and snacks with adequate nutrients to meet the body's anaerobic requirements. Multiple factors influence the adolescent's diet and eating habits ([Box 7.2](#)).

According to CDC data, in 12- to 19-year-olds, the obesity rate has more than tripled (CDC, 2008c). Poor diet and physical inactivity have led to the mounting problem of obesity in this age group. Obesity in adolescence is associated with obesity in adulthood along with numerous adverse health conditions such as diabetes, hypertension, high cholesterol, and overall poorer health (CDC, 2008c).

BOX 7.2

FACTORS INFLUENCING THE ADOLESCENT'S DIET

- Peer pressure
- Busy schedules
- Concern about weight control
- Convenience of fast food

BOX 7.3

FOODS HIGH IN IRON

- Beef, chicken, fish
- Liver
- Peanut butter
- Nuts and seeds
- Green peas, lima beans
- Spinach
- Strawberries
- Tomato juice
- Whole-grain bread
- Raisins
- Watermelon

Nutritional Needs

Teenagers have a need for increased calories, zinc, calcium, and iron for growth. However, the number of calories needed for adolescence depends on the teen's age and activity level as well as growth patterns. Teenage girls who are moderately active require about 2,000 calories per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Teenage boys who are moderately active require between 2,400 and 2,800 calories per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Of these calories, 45% to 65% should come from carbohydrates, 10% to 30%

from protein, and 25% to 35% from fat (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Adolescents require about 1,300 milligrams of calcium each day (Krebs, Primark, & Haemer, 2011). Adolescents should be made aware of foods high in calcium, including milk, white beans, broccoli, cheese, and yogurt. Adolescent males require 11 milligrams of iron each day and females require 15 milligrams each day (Krebs et al., 2011). Advise adolescents about foods high in iron (**Box 7.3**; see Healthy People 2020). Protein requirements for adolescent girls, 14 to 18 years of age, are 46 grams per day, and for adolescent boys, 14 to 18 years of age, 52 grams per day (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Some foods high in protein are meats, fish, poultry, beans, and dairy products.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|---|
| Reduce iron deficiency among young children and females of child-bearing age. | <ul style="list-style-type: none"> • Educate parents and teens about iron-containing foods. • Encourage adolescent females to consume a diet high in iron-rich foods. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Promoting Healthy Eating Habits

The nurse must understand normal growth and development of the adolescent in order to provide guidance that fits the quest for independence and the need for teens to make their own choices. Assess the eating habits and diet preferences of the adolescent. The assessment should include an evaluation of foods from the different food groups that the adolescent eats each day. Also, assess the number of times that fast foods, snacks, and other junk food are eaten per week. This assessment will help the nurse to guide the adolescent in making better food choices at home and in fast-food establishments. Many fast-food restaurants offer baked chicken sandwiches and salads with fewer calories and less fat. Adolescents may be guided in alternating hamburgers and fries with more nutritious choices. Remember that planning should always include the adolescent.

The U.S. Department of Agriculture provides a personalized food pyramid called MyPyramid Plan based on an individual’s age, sex, weight, height, and amount of physical activity. Refer to **Figure 7.9** for an example. At <http://www.mypyramid.gov>, the adolescent can create his or her customized food pyramid plan. **Table 7.3** outlines daily serving recommendations based on caloric requirements (lower, moderate, or higher). Nurses may use the information in **Table 7.3** to help teens plan a healthy diet for themselves. Active teenage girls should eat the number of servings recommended in the “Moderate” column of **Table 7.3**. Active teenage boys should eat the number of servings recommended in the “Higher” column. Adolescents who are overweight and dieting should base their daily intake on the serving recommendations in the “Lower” column.

Preventing the Development of Overweight and Obesity

Over the past 20 years, the number of overweight adolescents has more than tripled from 5% to 17.6% (CDC, 2008c). Although obesity has increased in all segments of the US population, there are differences specific to race, ethnicity, and socioeconomic status. The prevalence of obesity is highest in Hispanic and African American teens between the ages of 12 and 19 years (Ogden & Carroll, 2010).

This increase in obesity in adolescents has led to increases in hypertension, heart disease, and type 2 diabetes. Influential factors causing obesity include food choices, eating practices, and lack of exercise. One study indicated that only 75% to 78% of adolescents ages 11 to 19 years eat breakfast (National Association of Pediatric Nurse Practitioners, 2006). Also, fewer than 40% of adolescents ages 12 to 19 years meet the daily dietary requirement of vegetables and fruits while exceeding the recommendation for saturated fats (National Association of Pediatric Nurse Practitioners, 2006). Adolescents are busy and eat on the run, with many meals from fast-food facilities. In addition, many schools have decreased or discontinued physical education, which has resulted in a more sedentary lifestyle, leading to weight gain. Interest in computer games and television watching at home has decreased physical activity and exercise and further contributed to weight gain and obesity (see Healthy People 2020).

Based on the information you provided, this is your daily recommended amount from each food group.

| GRAINS 10 ounces | VEGETABLES 3 1/2 cups | FRUITS 2 1/2 cups | MILK 3 cups | MEAT & BEANS 7 ounces |
|--|---|---|---|--|
| <p>Make half your grains whole</p> <p>Aim for at least 5 ounces of whole grains a day</p> | <p>Vary your veggies Aim for these amounts each week:</p> <p>Dark green veggies = 3 cups</p> <p>Orange veggies = 2 1/2 cups</p> <p>Dry beans & peas = 3 1/2 cups</p> <p>Starchy veggies = 7 cups</p> <p>Other veggies = 8 1/2 cups</p> | <p>Focus on fruits</p> <p>Eat a variety of fruit</p> <p>Go easy on fruit juices</p> | <p>Get your calcium-rich foods</p> <p>Go low-fat or fat-free when you choose milk, yogurt, or cheese</p> | <p>Go lean with protein</p> <p>Choose low-fat or lean meats and poultry</p> <p>Vary your protein routine—choose more fish, beans, peas, nuts, and seeds</p> |
| <p>Find your balance between food and physical activity</p> <p>Be physically active for at least 60 minutes every day, or most days.</p> | | <p>Know your limits on fats, sugars, and sodium</p> <p>Your allowance for oils is 8 teaspoons a day.</p> <p>Limit extra-solid fats and sugars—to 425 calories a day.</p> | | |

Your results are based on a 2800 calorie pattern.

Name: _____

This calorie level is only an estimate of your needs. Monitor your body weight to see if you need to adjust your calorie intake.

FIGURE 7.9 MyPyramid Plan for a 15-year-old boy, 140 pounds, 5 feet 4 inches, 30 to 60 minutes of exercise daily. Retrieved March 21, 2011, from http://mypyramid.gov/downloads/results/results_2800_under18.pdf

| Objective | Nursing Significance |
|---|--|
| Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity. | <ul style="list-style-type: none"> • For the nonexercising teen, advise to start slowly by walking. • Work with the teen to identify physical activities that interest the teen. • Praise efforts to participate in a routine exercise plan. • Identify an athletic individual that the teen identifies with and encourage similar activities in the teen. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Nurses must make parents and adolescents aware of factors leading to obesity. Nurses should recommend:

- Proper nutrition and healthy food choices
- Good eating habits
- Decreased fast-food intake
- Exercising for 30 minutes at least four times per week
- Parents/adolescents exercising more at home
- Decreased computer use and television watching

What questions should you ask Cho Chung and her mother related to nutritional intake? What anticipatory guidance related to nutrition would be appropriate?

Promoting Healthy Sleep and Rest

The average number of hours of sleep that teens require per night is 8.5 to 9.5 (Gavin, 2011). The adolescent often experiences a change in sleep patterns that leads to feeling more awake at night and the desire to sleep later in the morning (Gavin, 2011). Also, in this independence-seeking phase of adolescence, the teen may stay up later to do homework or to complete projects and may have difficulty awakening in the morning. Due to early school schedules and activities the teen will often try to make up for needed sleep by sleeping longer hours on the weekend. Rapid growth and increased activities may produce fatigue and the need for more rest. Parents may relate that the teen sleeps all the time and never has the time or energy to help with household chores. Explain to parents the need to discourage late hours on school nights because they may affect school performance. Encourage the teen to go to bed at the same time at night and awaken at the same time in the morning, even on weekends (Gavin, 2011). Provide advice to teens and parents about having realistic expectations; encourage them to agree on a level of normalcy and adequate rest for the teen so that he or she can still fulfill responsibilities in the home.

Provide anticipatory guidance to Cho Chung and her mother in relation to sleep during the adolescent years.

Promoting Healthy Teeth and Gums

Most permanent teeth have erupted with the possible exception of the third molars (wisdom teeth). These molars may become impacted and require surgical removal. The rate of cavities decreases but the need for routine dental visits every 6 months and brushing two to three times per day is very important. Some of the conditions that occur during adolescence include malocclusion, gingivitis, and tooth avulsion. Malocclusion occurs in approximately 45% of adolescents, resulting from facial and mandibular bone growth (Tinanoff, 2007). It is the most common reason for referral to an orthodontist. The treatment includes braces and other dental devices. Teach the adolescent to brush the teeth more frequently if he or she has braces or other dental devices. Gingivitis is inflammation of the gums and breakdown of gingival epithelium due to diet and hormonal changes. The use of dental devices/braces makes cleaning more difficult and contributes to gingivitis. Tooth avulsion (knocked-out teeth) may occur during sports and other activities such as falls. The avulsed tooth should be reimplanted as soon as possible. The nurse may see the teen first so it is important

that nurses know the proper procedure, which is to reinsert the tooth into its socket if possible or to store it in cool milk or normal saline for transport to the dentist.

Promoting Personal Care

Promotion of personal care during adolescence is an important topic to cover with the adolescent and his or her parents. Topics to discuss include general hygiene tips, caring for body piercings and tattoos, preventing suntanning, and promoting a healthy sexual identity.

General Hygiene Tips

Adolescents find that frequent baths and deodorant use are important due to apocrine sweat gland secretory activity. Also, to decrease oily skin due to sexual steroids and hormones, teach the adolescent to wash his or her face two to three times per day with plain unscented soap. Vigorous scrubbing should be discouraged because it could irritate the skin and lead to follicular rupture. The hair should be shampooed daily to remove excess oil from the hair and scalp. Many over-the-counter medications are available for beginning acne or acne with a few lesions. These preparations may cause drying or redness. Discourage adolescents from squeezing acne lesions to prevent further irritation and permanent scarring. If the adolescent has severe acne, encourage him or her to ask a parent to make an appointment with a dermatologist.

Caring for Body Piercings and Tattoos

It is not uncommon for a teen to experiment with body piercing on areas such as the tongue, lip, eyebrow, navel, and nipple (Fig. 7.10). Other sites such as the genitals, chin cleft, knuckles, and even the uvula have been used. Generally, body piercing is harmless, but nurses should caution teens about performing these procedures under nonsterile conditions and should educate them about complications. Qualified personnel using sterile needles should perform the procedure. Teach the adolescent to cleanse the pierced area twice a day and more often at some sites.

The complications of body piercing vary by site. Infections from body piercing usually result from unclean tools of the trade. Some of the infections that may occur as a result of unclean tools include hepatitis, tetanus, tuberculosis, and HIV. Also, keloid formation and allergies to metal may occur. The navel is an area prone to infection because it is a moist area that endures friction from clothing. After a navel infection occurs, it may take up to a year to heal. Pierced ear cartilage also heals slowly and is prone to infection. Tongue piercings heal very quickly, usually within 4 weeks, probably due to the antiseptic effects of saliva. Other concerns with tongue piercing include tooth damage from biting on the jewelry or partial paralysis if the jewelry pierces a nerve.

Tattoos are continuing to grow in popularity among adolescents (U.S. Food and Drug Administration, 2009). Tattoos serve to define one's identity and are a form of self-expression (see Fig. 7.10). Because of the invasiveness of the tattooing procedure, it should be considered a health-risk situation. Like piercings, tattoos are open wounds predisposing to infection.

FIGURE 7.10 Having multiple piercings and tattoos can lead to certain health risks.

Nurses should educate adolescents about the risk of bloodborne infections, such as hepatitis B and C, HIV, skin infections, scarring, and allergic reactions to dyes used in the tattoo process (U.S. Food and Drug Administration, 2009). They need to encourage the teen to go to a licensed facility and to double check that needles are new and sterilized (American Academy of Pediatrics, 2010). Teach teens to cleanse tattoos with an antibacterial soap and water several times a day and to keep the area moist with an ointment to prevent scab formation. Refer to [Box 7.4](#) for additional information about tattoos.

Preventing Suntanning

Suntanning is popular among adolescents and is influenced by the media, which promotes a link between tan skin and beauty. There is no such thing as a good tan (American Academy of Pediatrics, 2011). Most exposure to ultraviolet rays occurs during childhood and adolescence, thereby putting people at risk for the development of skin cancer. However, it is difficult to convince adolescents that tanning is harmful to their skin and puts them at risk for skin cancer later in life (see Healthy People 2020).

BOX 7.4

WHAT ADOLESCENTS NEED TO KNOW ABOUT TATTOOING

- Infections occur as a result of nonsterile equipment used in the procedure.
- Tattoos are open wounds predisposing to infection; sites require proper care with antibacterial soap and water several times per day and application of ointment.
- For most people a tattoo is permanent; new procedures for removal are painful and expensive.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|--|
| Increase the proportion of persons who participate in behaviors that reduce their exposure to harmful ultraviolet (UV) irradiation and avoid sunburn. | <ul style="list-style-type: none"> • Encourage female teens to use sunscreen-containing makeup. • Discourage teen use of tanning beds. • Remind students to use sunscreen during outdoor organized-sports practice. |
| Reduce the proportion of adolescents in grades 9 through 12 who report using artificial sources of UV light for tanning. | <ul style="list-style-type: none"> • Educate teens and families about the risks associated with sun exposure. |
| Increase the proportion of adolescents in grades 9 through 12 who follow protective measures that may reduce the risk of skin cancer. | <ul style="list-style-type: none"> • Educate teens and their families to avoid the sun between 10 a.m. and 4 p.m., wear sun-protective clothing when exposed to sunlight, use sunscreen with a sun protection factor (SPF) of 15 or higher, and avoid artificial sources of UV light. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Educate teens about the benefits and effects of different sun protection products. Explain to them that sun damage and skin cancers can be prevented if sunscreens are used as directed on a regular basis. Encourage sunscreen or sunblock use for water sports, beach activities, and participation in outdoor sports. Also, make adolescents aware of allergies to some sunscreen products. See [Teaching Guidelines 7.1](#) for additional information.

Promoting a Healthy Sexual Identity

Encourage parents and teens to have discussions about sexuality. In addition, nurses should ensure that adolescents have the knowledge, skills, and opportunities that enable them to make responsible decisions regarding sexual behaviors and sexual orientation. Education for the adolescent should include a discussion about media influences and the use of sexuality to promote products. This discussion should make the adolescent aware of the motives of the media and the need to be an individual and not be influenced by television, magazines, and other forms of advertisement. Encourage parents to be aware of who their adolescents are dating and where they go on their dates. Refer to [Teaching Guidelines 7.2](#) for information on counseling related to adolescent sexuality.

Teaching Guidelines 7.2

ADOLESCENT SEXUALITY

- It should be your choice to engage in sexual relations. Do not be influenced by peers. When you say “no,” be firm and clear about your position.
- Pregnancy, sexually transmitted infections, and HIV infection can occur with any sexual encounter without the use of barrier methods of contraception. Use appropriate contraception if sexually active. Discuss abstinence as a contraceptive method.
- Sexual activity in a mature relationship should be pleasurable to both parties. If your sexual partner is not interested in your pleasure, you need to reconsider the relationship.

Promoting Appropriate Discipline

Adolescents naturally misbehave or do not follow the rules of the house, and parents must determine how to respond. Adolescents need to know the rules and expectations. After rules are established, parents must explain to the adolescent the consequences of breaking the rules.

Offer guidance to parents related to disciplining teens. The parent and the teen should collaborate on what the consequences will be if the rules are broken. Parents must acknowledge and offer reinforcement and support when the teen follows the rules. Consistency and predictability are the cornerstones of discipline, and praise is the most powerful reinforcer of learning.

Addressing Common Developmental Concerns

Adolescence is a time of rapid growth and development with maturation of sexuality. The adolescent period begins with a child and ends with the expectation of adulthood. There are many developmental concerns that present during this period, including violence, suicide, homicide, and substance use. The following is an overview of some of these concerns.

Violence

The CDC’s Injury Center defines violence as threatened or actual physical force or power initiated by an individual that results in or has a high likelihood of resulting in physical or psychological injury or death (Centers for Disease Control and Prevention [CDC], 2010b). More than 656,000 adolescents and young adults between 10 and 24 years of age were injured and treated in an emergency department as a result of violence in 2008 (Centers for Disease Control and Prevention [CDC], 2010a). The issue of youth violence is a growing concern in America’s communities. The health and well-being of adolescents and society are threatened by this violence. See [Box 7.5](#) for factors contributing to adolescent violence. Health care providers need to provide education on the effects and ways to prevent youth violence along with supporting programs developed to curb youth violence.

BOX 7.5

FACTORS CONTRIBUTING TO ADOLESCENT VIOLENCE

- Crowded conditions/housing
- Low socioeconomic status
- Limited parental supervision
- Single-parent families/both parents in workforce
- Access to guns or cars
- Drug or alcohol use
- Low self-esteem

- Racism
- Peer or gang pressure
- Aggression

Adapted from Centers for Disease Control and Prevention (2011). Youth Violence: Risk and Protective Factors. Risk Factors for the Perpetration of Youth Violence. Retrieved from <http://www.cdc.gov/ViolencePrevention/youthviolence/riskprotectivefactors.html>.

Homicide

Homicide is the second leading cause of death in children between 10 and 24 years old, with the majority of victims being male and killed by firearms (CDC, 2010a). It is the leading cause of death in African Americans 10 to 24 years old (CDC, 2010a). Refer to [Box 7.5](#) for factors that contribute to violence among adolescents. In a nationwide survey conducted in 2009, 17.5% of youth reported carrying a weapon (gun, club, or knife) on one or more days within the past 30 days (CDC, 2010a) (see Healthy People 2020).

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Reduce homicides, physical fighting, and bullying among adolescents and weapon carrying by adolescents on school property. | <ul style="list-style-type: none"> • Screen teens at all encounters for indications of violent behaviors. • Provide education related to decreasing school violence at middle and high schools. • Encourage alternate, appropriate methods for dispelling anger. |
| Reduce suicide attempts by adolescents. | <ul style="list-style-type: none"> • Screen teens at all encounters for indications of depression. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

BOX 7.6

RISK FACTORS FOR SUICIDE IN ADOLESCENTS

- Depression or other mental illness
- Mental health changes
- History of previous suicide attempt
- Family history of suicide
- Poor school performance
- Family disorganization
- Substance abuse
- Homosexuality
- Giving away valued possessions
- Being a loner/having no close friends
- Changes in behavior
- Incarceration

Suicide

Suicide is the third leading cause of death in adolescents 15 to 19 years old (CDC, 2008b). In a nationwide CDC study, 15% of adolescents surveyed reported that they had seriously considered suicide within the past 12 months, with 11% creating a plan and 7% attempting to take their own life (CDC, 2008b). Certain factors can put youth at risk for suicide, but having these risk factors does not mean suicide will occur. Refer to [Box 7.6](#) for risk factors for suicide in adolescents (see Healthy People 2020). Most people are not comfortable discussing the topic of suicide and therefore do not communicate openly about it. It is important that health care

providers address this important health problem and work to prevent suicide. The National Center for Injury Prevention and Control (NCIPC) is working to create awareness of suicide as a serious public health problem and is developing strategies to reduce injuries and deaths due to suicide.

Dating Violence

Violent behavior that takes place in a context of dating or courtship is not a rare event. It is estimated that more than one third of teens are victims of dating violence (Betz, 2007). Females are victims of dating violence more often than males and suffer more injuries than males. Dating violence in the teen years is a risk factor for continued violence exposure in adulthood. Risk factors for dating violence include living in a broken home or rural area, inadequate parental supervision, condoning violence, substance use, prior victimization, dropping out of high school, and risky sexual practices (Mars & Valdez, 2007). Nurses need to assess for and provide interventions to those teens experiencing dating violence or those at risk for being a victim or perpetrator.

Gangs

Much of youth violence is a result of the behavior of adolescent gangs. Nationwide there are an estimated 27,000 gangs with 788,000 members, with more males joining gangs than females (Egley, Jr., & O'Donnell, 2009). The risk factors for gang involvement relate to the adolescent, family, school, community, and peers See [Box 7.7](#) for risk factors for adolescent gang involvement. Gang membership occurs in cities and in suburban areas, but may differ in composition. All socioeconomic groups are represented in gang membership. Gang membership may aid in the formation of identity by providing status and a sense of belonging. However, adolescents who are gang members are more likely to commit serious and violent crimes.

Nursing Interventions to Decrease Youth Violence

Nurses working with adolescents should include violence prevention in anticipatory guidance. Violence is a learned behavior. It is often reinforced by the media, television, music, and personal example. Explain to parents, teachers, and peers the importance of being good role models. Parents should monitor video games, music, television, and other media to decrease exposure to violence. Parents need to know who their adolescent's friends are and monitor for negative behaviors and actions. Pediatric nurses play a key role in identifying at-risk youth and developing, planning, implementing, and evaluating interventions to prevent youth violence.

Substance Use

Agents commonly abused by children and adolescents include alcohol, prescribed medications such as Ritalin and OxyContin, hallucinogens, sedatives, analgesics, anxiolytics, steroids, inhalants (inhaling fumes of common household products), stimulants, opiates, and various club drugs such as ecstasy, gamma-hydroxybutyrate (GHB), and lysergic acid diethylamide (LSD). The substance abused is related to its availability and cost. Two common substances that are more accessible and have the highest incidence of use are tobacco and alcohol. A national survey found that 80% of high school students and 44% of middle school students have personally witnessed on school grounds illegal drugs used or sold, or students high on drugs or drunk (National Center on Addiction and Substance Abuse at Columbia University, 2007). Drug use progresses from beer or wine to cigarettes or hard liquor and then to marijuana, followed by illicit drugs.

Some of the long-term effects and consequences of drug and alcohol use include possibility of overdose and death, unintentional injuries, irrational behaviors, inability to think clearly, unsafe driving and legal consequences, problems with relationships with family and friends, sexual activity and STIs, and health problems such as liver problems (hepatitis) and cardiac problems (sudden death with cocaine). Refer to [Table 7.4](#) for commonly abused drugs and behaviors exhibited (see Healthy People 2020).

BOX 7.7

RISK FACTORS FOR GANG INVOLVEMENT

Individual

- Few social ties
- Delinquency involvement
- Drug dealing
- Physical violence or aggression
- Mental health problems, including depression
- Authority conflicts, rebellion, conduct problems

- Illegal gun ownership
- Precocious sexual activity
- Alcohol and drug use
- Increased life stressors, such as failing at school, fights with friends, or death of someone close

Family

- Poor family relationship
- Antisocial parents
- Broken home
- Poverty/low socioeconomic status
- Family with criminal history, drug or alcohol problems
- Young mother
- Poor parental supervision or involvement
- Low parental education
- Child maltreatment

School

- Academic failure
- Low academic motivation
- Truancy and dropping out of school
- Frequent school transitions
- Negative labeling by teachers (as disturbed, disruptive)

Community

- Poverty
- Poor housing conditions
- High availability and use of drugs in neighborhood
- Exposure to violence and racial prejudice High crime area
- Availability of guns

Peer

- Antisocial peers
- Association with delinquent, aggressive peers
- Peer drug use
- Peer gang membership

Adapted from Howell, J.C. (2010). Gang Prevention: An Overview of Research and Programs, *Office of juvenile Justice and Delinquency Prevention, juvenile justice Bulletin*. Retrieved August 25, 2011 from <https://www.nqys.gov/pdfFiles1/ojdp/231116.pdf>

| Objective | Nursing Significance |
|---|---|
| Reduce the proportion of adolescents who report that they rode, during the previous 30 days, with a driver who had been drinking alcohol. | <ul style="list-style-type: none"> • Provide education in the office, hospital, or school related to adverse effects of tobacco, alcohol, and illicit substance use. • Educate families, teens, and coaches about the negative effects of anabolic steroids. • Praise teens for abstaining from the above substances and rising above peer pressure. |
| Reduce steroid use among adolescents. | |
| Increase the proportion of adolescents who disapprove of substance abuse. | |
| Increase the proportion of adolescents never using substances. | |
| Reduce the past-year nonmedical use of prescription drugs. | |
| Reduce the proportion of adolescents who use inhalants. | |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Take Note!

African Americans have lower rates of most licit and illicit drug use than Caucasians (Johnston, O'Malley, Bachman, & Schulenberg, 2011)

Tobacco

Tobacco use remains the leading preventable cause of death in the United States, causing more than 440,000 deaths each year (CDC, 2011b). Long-term consequences of youth smoking are reinforced by the fact that most young people who smoke regularly continue to smoke throughout adulthood. Each day in the United States, approximately 3,900 children less than 8-year-olds try their first cigarette, with 950 becoming regular smokers; 90% of adult smokers started smoking before age 19 (American Cancer Society, 2008; American Lung Association, 2010). Half of these smokers will die from the effects of smoking (American Lung Association, 2010). An estimated 6.4 million people will die prematurely because of smoking as adolescents (American Lung Association, 2010). Although the overall rate of smoking has declined since 1999, rates over the past several years have remained stable but still are high, with 19% of high school students reporting current cigarette use (CDC, 2010c). Approximately 8% of high school students use smokeless tobacco (American Lung Association, 2010). Teens who smoke are 3 times more likely than non-smokers to use alcohol, 8 times more likely to use marijuana, and 22 times more likely to use cocaine (Focus Adolescent Services, 2008b). Smoking is associated with other risky behaviors, including fighting and engaging in unprotected sex. The short-term health effects of smoking include damage to the respiratory system, addiction to nicotine, and the associated risk of other drug use. Smoking negatively impacts physical fitness and lung growth and increases the potential for addiction in adolescents. Smokeless tobacco may also cause many problems. It can lead to bleeding gums and sores in the mouth that never heal. Smokeless tobacco use leads to discoloration of the teeth and eventually may lead to cancer.

Alcohol

In the United States alcohol is one of the most abused drugs, though many do not consider it a drug at all. It is estimated that 80% of adolescents have tried alcohol by the time they reach adulthood (Dowshen, 2009). A national survey on drug use found that nearly three quarters of students have consumed alcohol by the end of high school, with 36% consuming alcohol by the end of 8th grade (Johnston et al., 2011). More than half of 12th graders and 16% of 8th graders reported having been drunk at least once (Johnston et al., 2011). The findings revealed that there were no substantial differences among various sociodemographic subgroups with respect to drinking rates, although alcohol use is lowest in African Americans and highest in Caucasians. The incidence of alcohol use increases throughout adolescence. Adolescents who begin drinking before the age of 15 are five times more likely to develop alcohol dependence than those who begin drinking at the age of 21 (Focus Adolescent Services, 2008a). Alcohol use in adolescence can lead to prevailing alcohol use in adulthood and contribute to physical health problems. It may also precede other drug abuse.

Illicit Drugs

Adolescents may also experiment with or abuse illicit drugs. Substance abuse remains a widespread problem among American adolescents. Although experimentation with marijuana has decreased between 1991 and 2003 among the adolescent population, it still remains the most widely used illicit drug (Martin & Milot, 2007). A national survey on drug use showed the prevalence rate for 12th graders for marijuana use to be 34.8%, amphetamines 7.4%, ecstasy 4.5%, Salvia 5.5%, cocaine 2.9%, LSD 2.6%, inhalants 3.6%, over-the-counter medications (such as cold medicines) 5.8%, Vicodin 8%, OxyContin 5.1%, and steroids 1.5% (Johnston et al., 2011).

Factors that primarily affect drug use include the psychoactive potential and benefits reported, how risky the drug is to use, how acceptable it is to peer groups, and the accessibility and availability of the drug. The more risky or less accepted a drug is by peers, the less likely the adolescent will use it.

| Drug | Manifestations | Considerations |
|-----------------------------------|---|--|
| Marijuana | Red eyes, dry mouth, euphoria, relaxation, decreased motivation, loss of inhibition, appetite stimulation | Considered a gateway drug |
| Cocaine | Weight loss, euphoria, elation, agitation, increased motor activity, pressured speech, tachycardia, hypertension, anorexia, insomnia | Psychotic behavior with large doses; if combined with other drugs can be fatal |
| Opiates | Elation, euphoria, detachment, drowsiness, constricted pupils, slurred speech, impaired judgment | Self-neglect with malnutrition and dehydration; criminal behaviors to get drugs; infections at injection sites |
| Amphetamines | Euphoria, agitation, weight loss, insomnia, tachycardia, hypertension | Possible paradoxical effect of depression in children |
| Hallucinogens | Hallucinations, illusions, depersonalization, heightened awareness, dilated pupils, hypertension, increased salivation, distorted perceptions | Panic flashbacks long after use of drugs; psychotic behaviors |
| Phencyclidine hydrochloride (PCP) | Euphoria, distorted perceptions, agitation, violence, antisocial behaviors, hypertension, increased salivation, increased pain response | Irrational behaviors, panic, psychosis |
| Barbiturates | Euphoria followed by depression or hostility; impaired judgment; decreased inhibitions; slurred speech; incoordination | Often used with stimulants; may have a paradoxical effect of hyperactivity in children |

Adapted from Jenkins, R. R., & Adger, A. (2007). Substance abuse. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson textbook of pediatrics* (18th ed., pp. 824–834). Philadelphia: Saunders.

Nursing Interventions to Decrease Substance Use Among Teens

Substance use in adolescence is related to poorer health outcomes; therefore, it is important that nurses are aware of interventions to decrease these behaviors. Based on reviews of programs and interventions, it has been found that certain methods work. Programs that reach children and adolescents through a variety of sources such as school, family, community, and media campaigns are more successful. Programs that address all forms of drug use (alcohol, tobacco, and illicit drugs) tend to work well. Programs that focus on increasing awareness of the risks and health consequences of substance use are important. Initial research suggests that peer teaching with adult facilitation is successful (Bandy & Moore, 2008). Programs that focus on antidrug attitudes and drug resistance along with enhancing self-esteem, social support, and stress-specific coping skills are beneficial. Topics that should be discussed include:

- Short- and long-term effects of alcohol, tobacco, and drugs on health
- Risk factors and implications for unintentional injuries and sexual activity
- Short- and long-term effects of alcohol, tobacco, and drugs on relationships and school performance and progression
- The how and why of chemical dependency
- Impact of substance abuse on society
- Importance of maintaining a healthy lifestyle
- Importance of resisting peer pressure to use drugs and alcohol
- Importance of having confidence in one's own judgment

Think back to Cho, who was introduced at the beginning of the chapter. List common developmental concerns of the adolescent. What anticipatory guidance related to these concerns would you provide?

KEY CONCEPTS

- Adolescence is a period of rapid and variable growth in the areas of physical, psychosocial, cognitive, and moral development.
- The adolescent is developing his or her own identity, becoming an abstract thinker, and developing his or her own set of morals and values. Inability to successfully develop an individual identity leads to poor preparation for the challenges of adulthood.
- Relationships with parents fluctuate widely during adolescence. The teenager eventually becomes emancipated from his or her parents.
- Peers become most important—guiding mainly the early and middle adolescent in his or her decisions, while the late adolescent can usually formulate his or her own decisions.
- Adolescence is a critical time in the development of sexuality. Sexuality includes the thoughts, feelings, and behaviors surrounding the adolescent's sexual identity.
- The egocentric and invincible thought processes of the adolescent can lead to injuries. Health care providers must emphasize safety regarding cars, bikes, water, firearms, and fire.
- Motor vehicle accidents are the number one cause of death in adolescents (CDC, 2010d).
- Nutritional habits of the adolescent lead to deficiency in vitamins and minerals needed for the rapid growth during this period.
- Obesity in adolescents is a growing health concern. Health care providers are facing increased numbers of adolescents with hypertension, type 2 diabetes, and hyperlipidemia.
- Substance abuse and experimentation is common during adolescence; it is associated with other risk-taking behaviors such as injuries and sexual activity.
- Health care providers must work collaboratively with the adolescent in the development of interventions to promote health.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. When giving parents guidance for the adolescent years, the nurse would advise the parents to: (Choose all that apply.)
 - a. Accept the adolescent as a unique individual
 - b. Provide strict, inflexible rules
 - c. Listen and try to be open to the adolescent's views
 - d. Screen all of his or her friends
 - e. Respect the adolescent's privacy
 - f. Provide unconditional love
2. In developing a weight-loss plan for an adolescent, which would the nurse include? (Choose all that apply.)
 - a. Have parents make all of the meal plans.
 - b. Eat slowly and place the fork down between each bite.
 - c. Have the family exercise together.
 - d. Refer to an adolescent weight-loss program.
 - e. Keep a food and exercise diary.
3. Which is associated with early adolescence? (Choose all that apply.)
 - a. Uses scientific reasoning to solve problems
 - b. Still at times wants to be dependent upon parents
 - c. Incorporates own set of morals and values
 - d. Is influenced by peers and values memberships in cliques
4. What has the most influence in deterring an adolescent from beginning to drink alcohol?

- a. Drinking habits of parents
- b. Drinking habits of peers
- c. Drinking philosophy of adolescent's culture
- d. Drinking philosophy of adolescent's religion

CRITICAL THINKING EXERCISES

1. During a sports physical examination, Susan, a 16-year-old, tells her physician that she is overweight. What additional information would the physician obtain?
2. The parents of Joe, a 14-year-old, talk to the school nurse about Joe's behavior at home. He is moody, fights with his younger siblings, only wants to be on his computer, and does not want to go on the family vacation. What advice would the nurse give the parents?
3. Jane tells the school nurse that she might be homosexual. What additional information would the nurse obtain?
4. Alicia's parents are worried because all of Alicia's friends wear heavy makeup and have multiple piercings and hair colors. What advice would the nurse give Alicia's parents?

STUDY ACTIVITIES

1. Talk to an early, middle, and late adolescent. Compare and contrast their interactions with you. Identify what psychosocial, cognitive, and moral stage they are in, using examples from their conversations with you.
2. Have an adolescent keep a food and exercise diary for 1 week. Analyze the information. Develop with the adolescent any interventions needed to promote healthy eating and exercise habits.
3. Plan a class on the dangers of smoking for 15-year-olds.
4. Plan a class for parents on how to keep the lines of communication open for adolescents.
5. Go to <http://www.mypyramid.gov> and create and compare a customized meal plan for a healthy adolescent versus an obese adolescent.

Working With Children and Families

Atraumatic Care of Children and Families

Words of Wisdom Children need to be seen for who they really are.

KEY TERMS

atraumatic care

child life specialist

family-centered care

health literacy

nonverbal communication

therapeutic hugging

verbal communication

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Describe the major principles and concepts of atraumatic care.
2. Incorporate atraumatic care to prevent and minimize physical stress for children and families.
3. Discuss the major components and concepts of family-centered care.
4. Utilize excellent therapeutic communication skills when interacting with children and their families.
5. Use culturally competent communication when working with children and their families.
6. Describe the process of health teaching as it relates to children and their families.

Emma Moore, 4 years old, is admitted to the pediatric unit with a suspected head injury from a fall. She was playing at a playground with her babysitter and fell from the top of the slide.

Atraumatic care is defined as therapeutic care that minimizes or eliminates the psychological and physical distress experienced by children and their families in the health care system (Hockenberry & Wilson, 2009; Wong, n.d.). This concept is based on the underlying premise of “do no harm.” **Box 8.1** highlights the major principles of atraumatic care.

Pediatric nurses must be vigilant for any situation that may cause distress and must be able to identify potential stressors. It is important to provide nursing care that decreases the child’s exposure to stressful situations and prevents or minimizes pain and bodily injury; take steps to minimize separation of the child from the family; and utilize techniques of communication and provide teaching that promotes a sense of control. Atraumatic care involves guiding children and their families through the health care experience using a

family-centered approach by promoting family roles, fostering family support of the child, and providing appropriate information. Help children cope with this experience by using age-appropriate and child-specific interventions. Preparation can help children and their families to adjust to illness and hospitalization. Use appropriate techniques for therapeutic communication (goal-directed, focused, purposeful communication), therapeutic play (type of play that provides an emotional outlet or improves the child's ability to cope with the stress of illness and hospitalization), and education to help the child and family understand the reason for the hospitalization and the necessary tests and procedures. In addition, help the family and other health care personnel to obtain the resources and relationships they need for optimal care.

BOX 8.1

PRINCIPLES OF ATRAUMATIC CARE

- Prevent or minimize physical stressors, including pain, discomfort, immobility, sleep deprivation, inability to eat or drink, and changes in elimination.
 - Avoid or reduce intrusive and painful procedures, such as injections, multiple punctures, and urethral catheterization.
 - Avoid or reduce other kinds of physical distress, such as noise, smells, shivering, nausea and vomiting, sleeplessness, restraints, and skin trauma.
 - Control pain via frequent assessments and use of pharmacologic and nonpharmacologic interventions.
- Prevent or minimize parent-child separation.
 - Promote family-centered care, treating the family as the patient.
 - Use core primary nursing.
 - Consider research findings related to preferences of parents and children and whether or not to be together.
- Promote a sense of control.
 - Elicit the family's knowledge about the child and his or her health condition, promoting partnerships, empowerment, and enabling.
 - Reduce fear of the unknown through education, familiar articles, and decreasing the threat of the environment.
 - Provide opportunities for control, such as participating in care, attempting to normalize daily schedule, and providing direct suggestions.

Adapted from Wong, D. L. (n.d.). *Innovative approaches for atraumatic cancer care*. Retrieved May 3, 2009, from <http://www.authorstream.com/presentation/Carolina-48857-op077-INNOVATIVE-APPROACHES-ATRAUMATIC-CANCER-CARE-DEFINITION-SOURCES-PATIENT-FAMILY-STRESSORS-as-Entertainment-ppt-powerpoint/>

The best pediatric nursing care encompasses the concepts of atraumatic care. Minimizing physical stressors during procedures, providing family-centered care, and utilizing excellent communication skills on the part of the nurse enhance the health care experience for the child and family. Having an informed and educated family is the best way to provide optimal health care for children.

Table 8.1 gives suggestions for incorporating the principles of atraumatic care into nursing care for the child and family. Look for tips on atraumatic care as it relates to specific topics throughout the text.

PREVENTING/MINIMIZING PHYSICAL STRESSORS

The health care facility or hospital is an unfamiliar environment for children and parents and may upset or intimidate them. They may feel anxiety, fear, helplessness, anger, or loss of control. Even health care procedures performed in the home or school may be perceived as threatening to children. To prevent and minimize the physical stress experienced by children and their families in relation to health care, pediatric nurses, child life specialists, and other health care professionals recommend the use of atraumatic care.

Utilizing the Child Life Specialist

The child life specialist (CLS) is a specially trained individual who provides programs that prepare children for hospitalization, surgery, and other procedures that could be painful (Child Life Council, 2010a). The CLS is a member of the multidisciplinary team and works in conjunction with the health care provider and parents to foster an atmosphere that promotes the child's well-being. Services provided by a CLS include:

- Nonmedical preparation for tests, surgeries, and other medical procedures
- Support during medical procedures
- Therapeutic play

| Principle | Suggestions for Nursing Care |
|--|--|
| Preventing or minimizing physical stressors | <ul style="list-style-type: none">• For painful injections, blood draws, or IV insertion, use numbing techniques (see Chapter 14).• During painful or invasive procedures, avoid traditional restraint or "holding down" of the child. Use alternative positioning such as "therapeutic hugging."• If the above-mentioned positions are not an option, have the parent stand near the child's head to provide comfort.• Insert a saline lock if the child will require multiple doses of parenteral medications.• Advocate for minimal laboratory blood draws.• Minimize intramuscular or subcutaneous injections.• Provide appropriate pain management (refer to Chapter 14). |
| Preventing or minimizing child and family separation | <ul style="list-style-type: none">• Promote family-centered care.• In the hospital, provide comfortable accommodations for the parent.• Allow the family the choice about whether to stay for an invasive procedure, and support them in their decision. |
| Promoting a sense of control | <ul style="list-style-type: none">• Maintain the child's home routine related to activities of daily living.• In the hospital, use primary nursing.• Encourage the child to have a security item present if desired.• Involve the child and family in planning care from the moment of the first encounter.• Empower the family and child by providing knowledge.• Allow the child and family choices when they are available.• Make the environment more inviting and less intimidating. |

- Activities to support normal growth and development
- Sibling support
- Advocacy for the child and family
- Grief and bereavement support
- Emergency room interventions for children and families
- Hospital preadmission tours and information programs
- Outpatient consultation with families (Child Life Council, 2010b)

The goal of the CLS is to decrease the child's anxiety and fear while improving and encouraging the child's understanding and cooperation. The CLS considers the needs of siblings or other children who may be affected by the child's illness or trauma. The CLS provides engaging and uplifting events by coordinating special entertainment and activities. The CLS is an excellent resource and provides education to health care providers and families. The American Academy of Pediatrics recommends child life services because they are "an essential component of quality pediatric health care and are integral to family-centered care and best practice models of health care delivery for children" (American Academy of Pediatrics, 2006, p. 1760).

Minimizing Physical Stress During Procedures

Children undergo numerous diagnostic and therapeutic procedures in a wide range of settings during their development. These procedures may be performed in the community or outpatient setting or in a care facility. Regardless of the procedure to be

performed and the setting, children, like adults, need thorough preparation before the procedure and support during and after the procedure, to promote the best outcome and to ensure atraumatic care.

Using positions that are comforting to the child during painful procedures is an important aspect of atraumatic care (Fig. 8.1). **Therapeutic hugging** (a holding position that promotes close physical contact between the child and a parent or caregiver) may be used for certain procedures or treatments where the child must remain still. For example, the parent can hold the child in his or her lap snugly to prevent the child from moving during an injection or venipuncture. When using this technique, make sure the parent understands his or her role and knows which body parts to hold still in a safe manner. Alternatively, distraction or stimulation (such as with a toy) can help to gain the child's cooperation. Refer to [Box 8.2](#) for distraction methods.

Before the Procedure

Appropriate preparation for procedures helps to decrease the child's and family's anxiety level, promote the child's cooperation, support the child's and family's coping skills, improve recovery, and increase trust between the child, his or her family, and the physicians (LeRoy et al., 2003). Adequate preparation also helps to foster the child's feeling of mastery over a potentially stressful event (e.g., undergoing invasive procedures in particular is extremely distressing for children) (LeRoy et al., 2003).

FIGURE 8.1 Positioning a child for comfort during a painful procedure. **A.** Sitting on the parent's lap while undergoing allergy testing provides this toddler with a sense of comfort. **B.** Position the infant cuddled over the parent's (preferable) or the nurse's shoulder when obtaining a heelstick. **C.** Use "therapeutic hugging" to maintain a child's position when the child is receiving an intramuscular injection. **D.** Use "therapeutic hugging" to position a child while the child is having an IV line inserted.

BOX 8.2

DISTRACTION METHODS

- Have the child point toes inward and wiggle them.
- Ask the child to squeeze your hand.
- Encourage the child to count aloud.
- Sing a song and have the child sing along.
- Point out the pictures on the ceiling.
- Have the child blow bubbles.
- Play music appealing to the child.

Preparation may include preparing the child psychologically (including explanation and education) as well as physically. It is very important to employ the concepts of atraumatic care when preparing children for a procedure. General guidelines for preparation include the following:

- Provide a description of and the reason for the procedure using age-appropriate language (“the doctor will look at your blood to see why you are sick”).
- Describe where the procedure will occur (“the x-ray department has big machines that won’t hurt you; it’s a little cold there too”).
- Introduce strange equipment the child may see (“you will lie on a special bed that moves in the big machine, but you can still see out”).
- Describe how long the procedure will last (“you will be in the x-ray department until lunchtime”).
- Identify unusual sensations that may occur during the procedure (“you may smell something different” [e.g., alcohol smell]; “the MRI machine makes loud noises”).
- Inform the child if any pain is involved.
- Tell the child it is okay to cry or yell.
- Identify any special care required after the procedure (“you will need to lie quietly for 15 minutes afterward”).
- Discuss ways that may help the child stay calm, such as using distraction methods or relaxation techniques (“during the procedure you may want to count from 1 to 100 or sing your favorite song”) (Justus et al., 2006).

Take Note!

In the hospital, perform all *invasive procedures in the treatment room or a room other than the child’s room. The child’s room should remain a safe and secure area* (Leahy et al., 2008).

A major aspect of preparation involves play. In general, young children respond better to play materials and older children benefit more from viewing peer modeling films (LeRoy et al., 2003). However, consider the child’s temperament, coping strategies, and previous experiences as well as developmental needs and cognitive abilities. First, gain trust and provide support. Include the child’s parents, because parents are usually the greatest source of comfort for the child. Be short, simple, and appropriate in explaining situations at the child’s level of development. Explain what is to be done and what is expected of the child. Avoid terms that have double meanings or might be confusing. [Table 8.2](#) lists alternative words or phrases to use for terms that may be confusing or misunderstood.

During the Procedure

Use a firm, positive, confident approach that provides the child with a sense of security. Encourage cooperation by involving the child in decision making and allowing the child to select from a list or group of appropriate choices. Allow the child to express feelings of anger, anxiety, fear, frustration, or any other emotions. Often this is how a child communicates and copes with the situation. Remind the child that it is okay to scream or cry, but that it is very important to hold still. Use distraction methods such as those listed in [Box 8.2](#).

Toddlers and preschoolers often resist procedures despite preparation for them. Being held down or restrained is often more traumatizing to the young child than the procedure itself. Use alternative methods (positions that provide comfort for the child) to keep the child still during the procedure (refer back to [Fig. 8.1](#)). The older child can be held while using a book or story for distraction.

After the Procedure

After the procedure, hold and comfort the child. Cuddle and soothe infants. Encourage children to express their feelings through play, such as dramatic play or use of puppets. Gross motor activities such as pounding or throwing are also helpful for children to discharge pent-up feelings and energy. School-age children and adolescents may not outwardly demonstrate behavior indicating the need for

comforting; however, provide them with opportunities to express their feelings and be comforted. Remember to praise children for appropriate behavior during the procedure and after all interventions are completed.

Take Note!

Remember to utilize child life specialists when available.

The physician's orders for Emma include starting intravenous (IV) fluids and obtaining blood work upon arrival to the unit. As the admitting nurse, how will you provide atraumatic care?

PREVENTING OR MINIMIZING CHILD AND FAMILY SEPARATION: PROVIDING CHILD- AND FAMILY-CENTERED CARE

Family-centered care involves a partnership between the child, family, and health care providers in planning, providing, and evaluating care (O'Malley, Brown, & Krug, 2008). It works well for children of any age and in all arenas of health care, from preventive care of the healthy child to long-term care of the chronically or terminally ill child. Family-centered care enhances parents' and care-givers' confidence in their own skills and also prepares children and young adults for assuming responsibility for their own health care needs. It is based on the concept that the family is the constant in the child's life and the primary source of strength and support for the child (American Academy of Pediatrics, 2007a; Harrison, 2010).

According to the American Academy of Pediatrics (2007a), family-centered care focuses on several core principles:

- Respect for the child and family
- Recognition of the effects of cultural, racial, ethnic, and socioeconomic diversity on the family's health care experience
- Identification of and expansion of the family's strengths
- Support of the family's choices related to the child's health care
- Maintenance of flexibility
- Provision of honest, unbiased information in an affirming and useful approach

| Term to Avoid | How Children Might Interpret It | Use These Terms Instead |
|---------------------------------|--|---|
| Catheter | Too technical | Tube |
| Deaden | Kill? | Make sleepy |
| Dye | "Die" | Special medicine to help the doctor see _____ (part of the body) better |
| Electrodes | Too technical | Stickers, ticklers, snaps |
| ICU | "I see you" | Special room with your own nurse |
| Incision, cut open, make a hole | Too explicit | Special or small opening |
| Monitor | Too technical | TV screen |
| Organ | Like a piano? | Special place in the body |
| Pain | May be too explicit | Child's word for hurt, "boo-boo" |
| Put to sleep, anesthesia | May confuse with putting a pet to sleep | Special kind of sleep |
| Shot | Children are scared of shots | Medication under the skin |
| Stool | Like you sit on? | "Poop" or child's word for it |
| Stretcher or gurney | "Stretch her" | Rolling bed or special bed on wheels |
| Take your temperature/BP | Where are you going to "take" them? | See how warm you are/hug your arm |
| Test | Like at school? (the child will need to perform) | See how your heart is working |
| Tourniquet | Too technical | Special kind of rubber band |
| Urine | "You're in?" | "Pee" or child's word for it |
| X-ray | Don't understand | Picture or big camera to take pictures of the inside of your body |

Partially adapted from Florida Children's Hospital, Child Life Department. (n.d.). *Suggested vocabulary to use with children*. Orlando, FL: Author.

- Assistance with the emotional and other support the child and family require
- Collaboration with families
- Empowerment of families

When children's health care is provided through a family-centered approach, many positive outcomes are possible, including:

- Anxiety is decreased.
- Children are calmer and pain management is enhanced.
- Recovery times are shortened.
- Families' confidence and problem-solving skills are improved.
- Communication between the health care team and the family is also improved, leading to greater satisfaction for both health care

providers and health care consumers (families).

- A decrease in health care costs is seen and health care resources are used more effectively

(American Academy of Pediatrics, 2007a).

Ways to increase collaboration between the family and the health care team may include a family advisory board, a newsletter, conferences, or parent resource notebooks. Methods for increasing communication between the health care team and the family may include the use of mailboxes or dry-erase boards for updating the daily plan of care, including the parents' participation in rounds, or through a daily assessment of health status by the child or family.

FIGURE 8.2 Providing a comfortable area for the parent to rest is an important component of family-centered care.

Vigilant parents are committed to their child's care and most want to be present for all aspects of their child's care. They want to be part of the decision-making process regarding their child's care; they want to be heard and develop a rapport with the health care professionals caring for their child. They demonstrate resilience in their ability to make it through the emotional upheaval associated with an illness. It is important to be sensitive to the inconveniences that their child's illness may impose on the family. Address the family's emotional and spiritual needs, attend to their concerns, and provide the best accommodations possible (when the child is hospitalized) (Fig 8.2). Practicing true family-centered care may empower the family, strengthen family resources, and help the child and family feel more secure and supported throughout the process.

Take Note!

Some *parents* will not know how to *advocate* or *speak* up for their child; as a nurse, you must help open this door for them.

How could family-centered care help the Moore family described at the beginning of the chapter?

PROMOTING A SENSE OF CONTROL

During times of illness, hospitalization, or health-related interventions, the child and family can experience an extreme sense of loss of control. Providing effective communication and teaching can help foster feelings of control and improve the child's and family's ability to cope. Assisting the family to obtain necessary information, resources, and relationships contributes to optimal health care for the child and family. Communication and teaching are skills that are used continuously in pediatric nursing, no matter what the setting or the child's state of health.

Enhancing Communication

Effective communication with children and their parents is critical to providing atraumatic quality nursing care. Child- and parent-centered communication enhances child outcomes and child and family satisfaction with nursing care. Effective communication is the foundation of the therapeutic relationship and leads to increased knowledge and health care behaviors on the part of the child and family (Levetown & The Committee on Bioethics, 2008). Nurses are in an ideal position to improve communication in the health care environment. They need to ensure inclusion of the child and family in health conversations and to clarify misconceptions following medical encounters.

Children are often socialized to be passive participants in health care, doing as they are told, with or without protests. "As pediatric nurses, we have an obligation to listen, to hear, and to feel the voices of the children in our care" (McPherson & Thorne, 2000, p. 28). Children can inform nurses of their experiences in an accurate fashion, and nurses need to be able to discern this information from communication with the child.

Communication patterns can vary greatly from one child to the next. Some children are very talkative, while others are quiet. Children may be more apt to communicate if they are engaged in another activity. Children often use fewer words than adults and may rely more on nonverbal communication and silence. Parents more often require neutral communication (i.e., verbal communication that is related to assessing and solving problems), whereas children more often desire affective communication (establishment of rapport and trust, giving comfort). The best communicators in pediatric nursing find a balance between neutral and affective communication (Shin & White-Traut, 2005). Communicating in the pediatric setting can be more difficult than in the adult setting. The pediatric nurse must communicate with different ages of children, as well as on a supportive level with adolescents and parents (Shin & White-Traut, 2005).

Verbal Communication

Communicating through the use of words, either written or spoken, is termed verbal communication. Nurses use verbal communication throughout the day when interacting with children. Good verbal communication skills are necessary when performing nursing assessments and providing child/family teaching. General guidelines for appropriate verbal communication include:

- Use open-ended questions that do not restrict the child's or parent's answers.
- Redirect the conversation to maintain focus.
- Use reflection to clarify the parent's feelings.
- Paraphrase the child's or parent's feelings to demonstrate empathy.
- Acknowledge emotions.
- Demonstrate active listening by using the child's or family's own words.

Remember that most parents are laypersons, so avoid using medical jargon. The abbreviations and shortened terms that health care providers use almost without thinking may sound scary or foreign to children and parents. When medical terminology is necessary, provide a definition using developmentally appropriate language.

Nonverbal Communication

Nonverbal communication is also referred to as body language. It also includes attending to others and active listening. The nurse should listen to the other person's verbal communication from the beginning of the interaction. When children and parents feel they are being heard, trust and rapport are established. Guidelines for appropriate nonverbal communication include:

- Relax; maintain an open posture, with the arms uncrossed.
- Sit opposite the family and lean forward slightly.
- Maintain eye contact.
- Nod your head to demonstrate interest.
- Note the child's or parent's posture, eye contact, and facial expressions.

Active listening is critical to the communication process. Listening may uncover fears or concerns that the nurse may not have discovered through questioning. Paying attention while children and parents talk is a powerful communication tool. By not listening, the nurse may miss critical information and the family may be reluctant to share further. When interacting with the child and family, determine whether the messages sent by the child's or parent's verbal and nonverbal communication are congruent.

Developmental Techniques for Communicating With Children

Effective communication with children involves a variety of age-appropriate methods. Encouraging children to participate actively gives them some control over the interaction (Shin & White-Traut, 2005). If the child is shy, talk to the parents first to give the child time to “warm up” to you. Use specific and clear phrases in an unhurried, quiet, yet confident manner. Communicate at the child's eye level (Fig. 8.3). Spending time and incorporating play with younger children, even just a few moments, may help them feel more at ease with you. Instead of direct questioning, use dolls, puppets, or stuffed animals with younger children (Fig. 8.4). The use of metaphors (e.g., referring to white blood cells as “bad guy fighters”) and stories can help to illustrate concepts to young and school-age children.

FIGURE 8.3 Sitting at the child's level and allowing the child time for self-expression are steps that improve therapeutic communication.

Older children need privacy. Provide the child or adolescent with honest answers at a developmentally appropriate level. Allow children to express their thoughts and feelings. Offer the child choices when possible but only when they truly exist. Encourage children to write and draw about their experiences. This may increase their understanding and also draw attention to any misconceptions or fears. Box 8.3 lists requirements for communication with children and adolescents.

Children feel empowered when health care professionals communicate directly with them. Include children in discussions and avoid talking about them in their presence. Children may also desire advice about their health care and reassurance about their health status. To be effective when communicating with children of different developmental stages, the nurse must become familiar with how children of different ages communicate and then use age-appropriate techniques for effective communication:

FIGURE 8.4 Communication or teaching with dolls may be useful with younger children.

BOX 8.3

BASICS FOR COMMUNICATING WITH CHILDREN

- Introduce yourself and explain your role.
- Position yourself at the child's level.
- Allow the child to remain near the parent if needed, so the child can remain comfortable and relaxed.
- Smile and make eye contact with the child if culturally appropriate.
- Direct your questions and explanations to the child.
- Listen attentively and pause to allow time for the child to formulate his or her thoughts.
- Use the child's or family's terms for body parts and medical care when possible.
- Speak in a calm, quiet, confident, and unhurried voice.
- Use positive rather than negative statements and directions.
- Encourage the child to express his or her feelings and ask questions.
- Observe for nonverbal cues.
- Ask for permission if you need to approach the child to avoid appearing threatening.

- Infants primarily communicate through touch, sight, and hearing. Communication with the infant can occur by cuddling, holding, rocking, and singing to the infant. Communication through play may be helpful in the older infant. Playful persuasion may help to distract the infant. When interacting with the infant, be alert for signs of overstimulation, such as yawning, turning away, decreased eye contact, and increasing irritability (Deering & Cody, 2002).
- When working with toddlers and preschoolers, allow them time to complete their thoughts. Though language acquisition at this age is exponential, it often takes longer for the young child to find the right words, particularly in response to a query. When possible, give this age group choices, ask specific questions, and respond to queries with simple answers. Participating in parallel play with toddlers or imaginative play with preschoolers or commenting on the child's toy or activity can open the door for communication with this age group (Deering & Cody, 2002).
- School-age children are very interested in learning and appreciate simple but honest and straightforward responses. When addressed first and allowed to respond, the school-age child may be eager to communicate. The school-age child may respond well to the use of a third-person conversation (such as "some children feel anxious when entering the hospital"). It is also important to understand how the child views a situation before explaining or discussing it with him or her (Deering & Cody, 2002).
- Adolescents tend to experience strong feelings and emotions and perceive situations in extreme terms. Building a trusting, respectful rapport is essential. When communicating with adolescents, remain nonjudgmental, listen attentively, and do not force them to talk in order to avoid alienating them and to keep lines of communication open (Deering & Cody, 2002).

Tips for Communicating With Parents

When communicating with parents, be honest. Parents want to feel valued and should be equal partners in the health care team. Allow the parent to express concerns and ask questions. Explain equipment and procedures thoroughly. Help the parents to understand the long-term as well as short-term effects of the treatment. Teach the parents what the child will feel like and how he or she will look during a procedure. Teach and encourage the parent to perform as much of the child's care as is reasonable and permitted. Ask the parent about his or her perception of the child's progress. Allowing the parents to be involved in the care of their child gives them a sense of control and lets them know they are valued by the health care team. Provide parents with positive reinforcement, reassurance, guidance, and support.

Communicating Across Cultures

Understanding and respecting the child's culture helps foster good communication and improves child and family education about health care. Culture, religion, and spirituality are intertwined concepts that affect the child's and family's communication styles, health status, and health beliefs. It is important to be aware of the family's background, lifestyle, and health care practices to meet their information needs.

Learning about the practices of various cultures is just the beginning; the nurse must assess each family's individual beliefs and practices rather than generalizing. The best way to assess the family's cultural practices is to ask and then listen. Determine the language spoken at home and observe the use of eye contact and other physical contact. Demonstrate a caring, nonjudgmental attitude and sensitivity to the child's and family's cultural diversity.

WORKING WITH AN INTERPRETER

Attempting to communicate with a family who does not speak English can be one of the most frustrating situations in which health care providers find themselves. In this situation, interpreters are an invaluable aid and an essential component of child and family education. Whether working with an interpreter in person or over the phone, it is important to coordinate efforts so that both the family and the interpreter understand the information to be communicated. Working as a team, the nurse questions or informs and the interpreter conveys the information to the child and family completely and accurately (see Healthy People 2020). [Box 8.4](#) presents tips on working with an interpreter to maximize teaching efforts.

| Age | Techniques |
|---------------------|---|
| Infants | <ul style="list-style-type: none"> Respond to crying in a timely fashion. Allow the infant time to warm up to you. Use a soothing and calming tone when speaking to the infant. Talk to the infant directly. |
| Toddlers | <ul style="list-style-type: none"> Approach toddlers carefully; they are often not only fearful but also quite resistant. Use the toddler's preferred words for objects or actions so he or she is better able to understand. Toddlers enjoy stories, dolls, and books. Prepare toddlers for procedures just before they are about to occur. |
| Preschoolers | <ul style="list-style-type: none"> Use play, puppets, or storytelling via a third-party approach. Speak honestly. Use simple, concrete terms. Allow the child to have choices as appropriate. Prepare preschoolers about 1 hour prior to a procedure. |
| School-age children | <ul style="list-style-type: none"> Use diagrams, illustrations, books, and videos. Allow the child to honestly express feelings. Use third-party stories to elicit desired information. Allow the child to ask questions related to care and treatment. Give the child adequate time for all of the questions to be answered. Prepare the child a few days in advance for a procedure. |
| Adolescents | <ul style="list-style-type: none"> Always respect the teenager's need for privacy. Ensure confidentiality. Use appropriate medical terminology, defining words as necessary. Use creativity. Prepare the teen up to 1 week prior to a procedure. |

| Objective | Nursing Significance |
|---|--|
| Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs. | <ul style="list-style-type: none"> • Work with professionals and individuals from various cultures to develop materials and programs for health promotion that are culturally competent. • Ensure teaching materials are provided in the appropriate language. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Several helpful resources and websites are listed on [thePointz](#), including Language Line, which offers telephone interpreters who speak 150 languages, as well as The Center for Applied Linguistics, Northwest Translators and Interpreters Society, and others.

COMMUNICATING WITH DEAF OR HEARING-IMPAIRED CHILDREN AND FAMILIES

For hearing-impaired children and families, determine the method of communication they use (e.g., lip reading, American Sign Language [ASL], or another method or a combination). If the nurse is not proficient in ASL and the child or family uses it, then an ASL interpreter must be available if another adult family member is not present for translation. According to federal law (Americans With Disabilities Act), children and family members who are deaf or hard of hearing must be provided with the ability to communicate effectively with health care providers (American Academy of Pediatrics, 2007b).

BOX 8.4

TIPS ON WORKING WITH AN INTERPRETER

- **Help the interpreter prepare and understand what needs to be done ahead of time.** A few minutes of preparation may save a lot of time and help communication flow more smoothly in the long run.
- **The interpreter is the “communication bridge,” not the “content expert.”** The nurse’s presence at teaching sessions is vital.
- **The interpreter’s timing may not match that of others involved.** It often takes longer to say in some languages what has already been said in English; therefore, plan for more time than you normally would.
- **Speak slowly and clearly.** Avoid jargon. Use short sentences and be concise. Avoid interrupting the interpreter.
- **Pause every few sentences so the interpreter can translate your information.** After 30 seconds of speaking, stop and let the interpreter express the information. Talk directly to the family, not the interpreter.
- **Give the family and the interpreter a break.** Keep sessions short; sessions that last longer than 20 or 30 minutes are too long for anyone’s attention span and concentration.
- **Express the information in two or three different ways if needed.** There may be cultural barriers as well as language and dialect differences that interfere with understanding. Interpreters may often know the correct communication protocols for the family.
- **Use an interpreter to help ensure the family can read and understand translated written materials.** The interpreter can also help answer questions and evaluate learning.
- **Avoid side conversations during sessions.** These can be uncomfortable for the family and jeopardize child/family-provider relationships and trust.
- **Just because someone speaks another language doesn’t mean that he or she will make a good interpreter.** An interpreter who has no medical background may not understand or interpret correctly, no matter how good his or her language skills are.
- **Children should not be used as interpreters.** Doing so can affect family relationships, proper understanding, and compliance with health care issues.

In the beginning of the chapter you were introduced to Emma Moore. Discuss ways to facilitate communication with Emma and her family/caregiver.

Teaching Children and Families

Regardless of the type of practice or health care setting, nurses are in a unique position to help families manage the health care needs of their child. Indeed, the family has a right and a responsibility to participate fully in making decisions about health care processes for their child. This is true whether the child is hospitalized with a long-term, devastating illness or needs only health maintenance activities. To accomplish this, families need to be knowledgeable about such things as their child's condition, the health care management plan, and when and how to contact health care providers. With the limited time available in all health care arenas and shortened stays in inpatient facilities, the pediatric nurse must focus on teaching goals and begin teaching at the earliest opportunity.

Take Note!

There is no prescription more valuable than knowledge.—C. Everett Koop, MD, former Surgeon General of the United States (Dhand, 2000).

Patient education occurs when nurses share information, knowledge, and skills with families, thus empowering them to take responsibility for their child's health care. Through patient education, families can overcome feelings of powerlessness and helplessness and gain the confidence and ability to step to the forefront of the health care team. Nurses spend innumerable hours teaching children and families; in fact, on some days in the hospital, more teaching than nursing care is provided. Given the importance of, and the amount of time spent on, child and family education, each nurse should become an expert at basic patient education principles. See Healthy People 2020.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|--|
| Increase the proportion of persons who report that their physicians have satisfactory communication skills (Developmental) Improve the health literacy of the population | <ul style="list-style-type: none">• Assess health learning needs of children and their families.• Plan health care education in collaboration with children and their families.• Provide health education at each patient encounter.• Assess for poor health literacy skills. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Goals of Child and Family Education

The goals of child and family education are to:

- Improve the child's and family's health literacy
- Encourage communication with health care providers
- Improve health outcomes and promote healthy lifestyles
- Encourage involvement of the child and family in care and decision making about care
- Improve compliance with care and treatment plan
- Promote a sense of autonomy and control

Overall goals for the child and family include the ability of children and families to make informed decisions, to perform basic health care skills, to recognize when the child has a problem and know how to respond to the problem, and to know how to get answers when questions arise.

Take Note!

To cope effectively with illness, to understand and participate in decisions about treatment plans, and to maintain and improve health after treatment, children and

their families must have access to the specific knowledge and skills relevant to their conditions (the Joint Commission, 1996).

Steps of Child and Family Education

The steps of child and family education are similar to the steps of the nursing process. The nurse must assess, plan, implement, evaluate, and document education. Once the nurse reaches a level of comfort and experience with each of these steps, they all blend together into one harmonious whole that becomes an everyday part of nursing practice. Child and family education begins with the first encounter and proceeds through discharge and beyond. Reassessment after each step or change in the process is critical to success.

ASSESSING TEACHING AND LEARNING NEEDS

Excellent nursing care begins with a thorough assessment of the child. In the same way, child and family education begins with a learning needs assessment that includes the child's and family's learning needs, learning styles and preferences, and potential barriers to learning. Based on the results of the assessment, an individualized plan can be developed to reduce the time and effort required for teaching while maximizing learning for the child and family. Although actual nursing care in pediatrics is given to the child, the educational process is targeted at both the child, when developmentally appropriate, and the adult members of the family. Therefore, it is advisable to conduct a learning needs assessment on both the adult caregivers and the child, when appropriate. [Box 8.5](#) describes the components of a learning needs assessment. This is also a good time to establish rapport with the family, demonstrating your interest in them and your confidence in their ability to learn.

BOX 8.5

COMPONENTS OF LEARNING NEEDS ASSESSMENT

Assess

- Learner characteristics: Find out more about the child's and family's life and how the child's illness has affected it. Learn more about the child's and family's social, cultural, and spiritual values.
- Learner needs and readiness: This includes what the child and family want and need to know and what they know already; their readiness and willingness to learn; their motivation to learn and emotional concerns; and their capacity to learn, such as physical or cognitive abilities including the ability to read and developmental level.
- Learning style: Determine how the child and family learn best, as well as preferred learning methods.
- Learning barriers: Identify cultural or language barriers, cognitive or physical disabilities, presence of pain, and lack of support network.

Adapted from Joint Commission Resources. (2008). Patient education. In I. J. Chatman (Ed.), *Issues in provision of care, treatment, and services for hospitals* (2nd ed.). Oakbrook, IL: Joint Commission Resources, Inc.

Share the assessment with all members of the interdisciplinary team so that the entire team can support the child's and family's learning. Although assessment generally takes place during the first or second meeting with the child and family, it should also occur with each encounter to check for any changes that may occur.

Malcolm Knowles (1990) outlined basic principles to consider when teaching adults. He found that instruction for adults needs to focus more on the process than on the content. [Box 8.6](#) lists four learner-centered principles.

CULTURAL IMPACT ON ASSESSMENT OF LEARNING NEEDS. In addition to determining the language spoken in the home and use of eye and physical contact, investigate the following during the assessment:

- Who is the person caring for the child at home?
- Who is the authority figure in the family?
- What is the social support structure?
- Are there any special dietary needs and concerns?
- Are any traditional health practices used (e.g., healers, shamans, talismans, folk remedies and herbs)?
- Are any special clothes or other items used to help maintain health?
- What religious beliefs, ceremonies, and spiritual practices are important?

Learning needs can then be negotiated with the family and met based on the assessment. Pediatric issues encountered when teaching immigrant or refugee families might include confusion regarding the use of the English versus the metric scale; preparing formulas and medicines using a "handful" or "pinch" of ingredients rather than specific measurements such as a measuring cup or

syringe; access to refrigeration for liquid antibiotics; and breastfeeding practices.

BOX 8.6

SPECIFIC LEARNING PRINCIPLES RELATED TO PARENTS

- **Adults are self-directed.** Adults value independence and want to learn on their own terms. Teaching strategies that include such concepts as role playing, demonstration, and self-evaluation are most helpful. Using this model, nurses can partner with families to ensure that education is interactive and adopt the role of facilitator rather than lecturer.
- **Adults are problem focused and task oriented.** Adults learn best when they perceive there is a gap in their knowledge base and want information and skills to fill the gap. Providing a reason to learn can often motivate families that appear slow to comply with their child's care and education.
- **Adults want an immediate need satisfied.** Adults learn best at a time when learning meets an immediate need. Presenting information in an organized, sequential, and timely fashion can often help families understand the importance of learning a particular piece of information or task.
- **Adults value past experiences and beliefs.** Adults bring an accumulated wealth of experiences to each health care encounter; this provides a rich base for new learning. Education should take into account a wide range of backgrounds. Appreciating and using individual differences during teaching encounters can help improve compliance and reduce resistance to educational goals.

Adapted from Knowles, M. (1990). *The adult learner: A neglected species* (4th ed.). Houston, TX: Gulf Publishing.

LITERACY ISSUES. Adequate literacy skills are essential for child and family education, yet many people in America today have marginal reading capabilities. According to the 2003 National Assessment of Adult Literacy, only 13% of American adults are proficiently literate, while 43% have basic or below basic literacy skills (caliteracy.org, 2008; ProLiteracy, 2008).

Even persons with adequate literacy skills may have difficulty reading, understanding, and applying information to health care situations (Fig. 8.5). **Health literacy** is the ability to read, understand, and use health care information to make appropriate health care decisions (Glassman, 2008). It is not simply the ability to read the health care information, but also includes listening, oral, analytical, and decision-making skills, and applying these skills to health care situations. The inability to read and comprehend health care information is an enormous problem for many Americans today. Low health literacy affects people of all ages, races, and educational and income levels. The 2003 National Assessment of Adult Literacy reports that 14% or 30 million adults have below basic health literacy and 22% or 47 million have basic health literacy (Weiss, 2007).

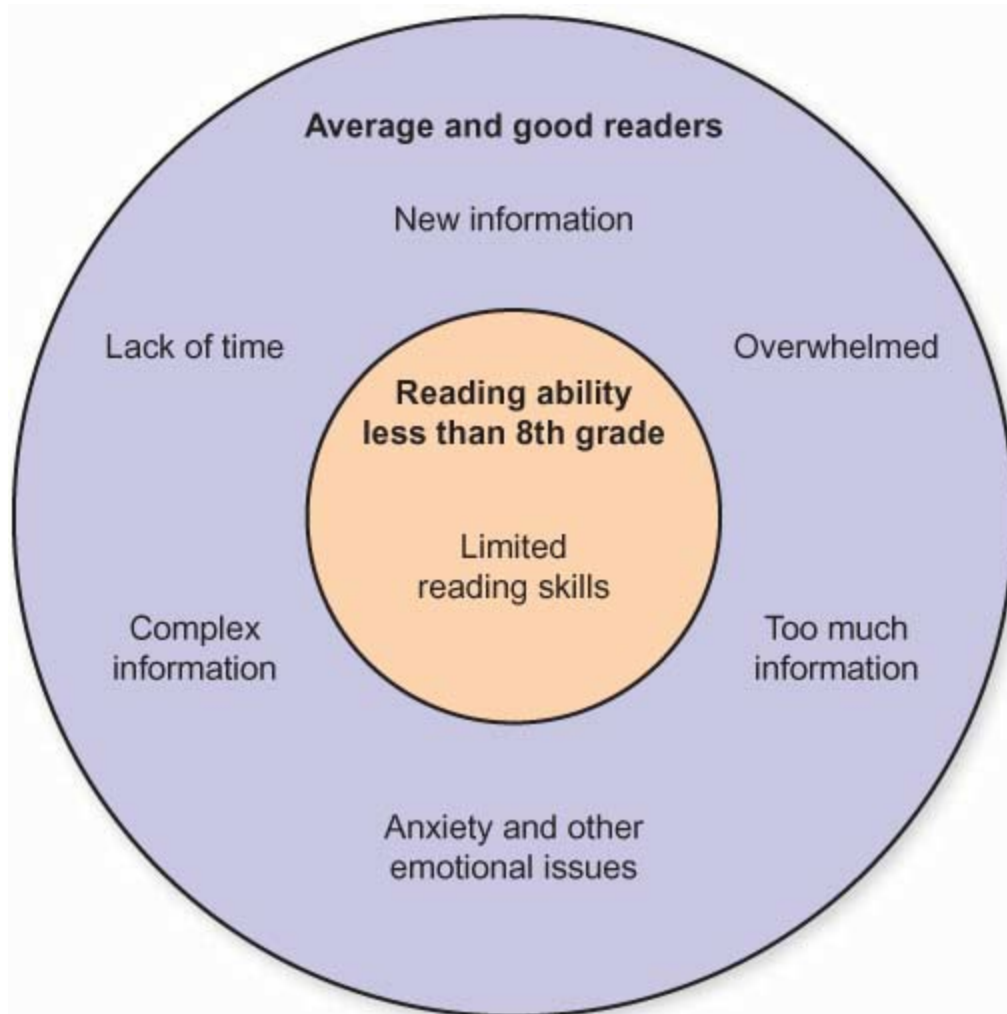

FIGURE 8.5 Factors contributing to poor health literacy.

The American Medical Association reports that poor health literacy skills are a stronger predictor of health status than age, income, employment status, education level, or racial or ethnic group (Glassman, 2008). Poor health literacy leads to poorer health status, worse health outcomes, and increased costs for the health care system (Weiss, 2007). Other health literacy studies have suggested that people with inadequate health literacy have higher rates of hospitalization and longer hospital stays, higher usage of expensive emergency services, increased medication errors, and generally a higher level of illness (Glassman, 2008; Weiss, 2007).

Medical information is becoming increasingly complex, while the amount of time nurses have to spend with children is decreasing. Also, when unfamiliar information is introduced or when emotional distress is present, reading ability and understanding are further reduced. As a result, many studies have shown that persons with limited literacy skills cannot understand basic medical words and health concepts, verbal or written. For example, in one study (Weiss, 2007):

- Twenty-six percent did not understand when their next appointment was scheduled.
- Forty-two percent did not understand the instructions “take medication on an empty stomach.”
- Seventy-eight percent misunderstood warnings on medication labels.
- Eighty-six percent could not understand the rights and responsibilities section of a Medicaid application.

RECOGNIZING POOR HEALTH LITERACY SKILLS. Poor health literacy skills are difficult to recognize: appearance, verbal ability, employment status, and educational level cannot reliably detect persons who do not read well. Also, many people who do not read well go to great lengths to hide their disability; 68% of persons with limited literacy skills have never told their spouse and 75% have never told their physician (Weiss, 2007). Poor health literacy affects all segments of the population, but certain groups such as the elderly, the poor, members of minority groups, recent immigrants to the United States who do not speak English, and those who are born in the United States but speak English as a second language are at higher risk (Weiss, 2007).

Red flags that might indicate poor literacy skills include the following (Weiss, 2007):

- Difficulty filling out registration forms, questionnaires, and consent forms; forms are incomplete, incorrect, or inaccurate
- Frequently missed appointments
- Noncompliance and lack of follow-up with treatment regimens
- History of medication errors

- Responses such as, “I forgot my glasses” or “I’ll read this when I get home”
- Inability to answer common questions about their treatment or medications
- Avoiding asking questions for fear of looking “stupid”

PLANNING EDUCATION

Once the assessment is completed, plan mutually agreed-upon, achievable learning goals and objectives. It is important that both the teacher and the learner believe the goals can be accomplished. Finding common ground and building a bridge between the child’s and family’s concerns and what the health care team believes they need to know is a critical part of an education plan. This also is an excellent time to consider which child education materials and resources can be used to maximize learning and retention.

Planning child and family education should involve input from the entire interdisciplinary team when appropriate. Through good communication and collaboration, team members can work together to empower the child and family to become knowledgeable and skillful caregivers. Leaving behind the traditional path of teacher-centered education and providing family-centered education instead requires thought and skill.

To achieve maximum success with education, nurses need to know how people learn. Edgar Dale (1969) suggested that people learn best when they are actively involved in the learning process. Figure 8.6 provides a summary of his principles, known as the “Cone of Learning.” The implications for child education are clear: the more senses used and the more actively involved the learner is, the better he or she will remember what was taught.

PRACTICAL INTERVENTIONS TO ENHANCE LEARNING

The assessed needs and planned learning objectives lead to good teaching interventions. Evaluate these interventions frequently to ensure that the child and family are learning and meeting agreed-upon goals. Table 8.4 presents six techniques that can help improve learning.

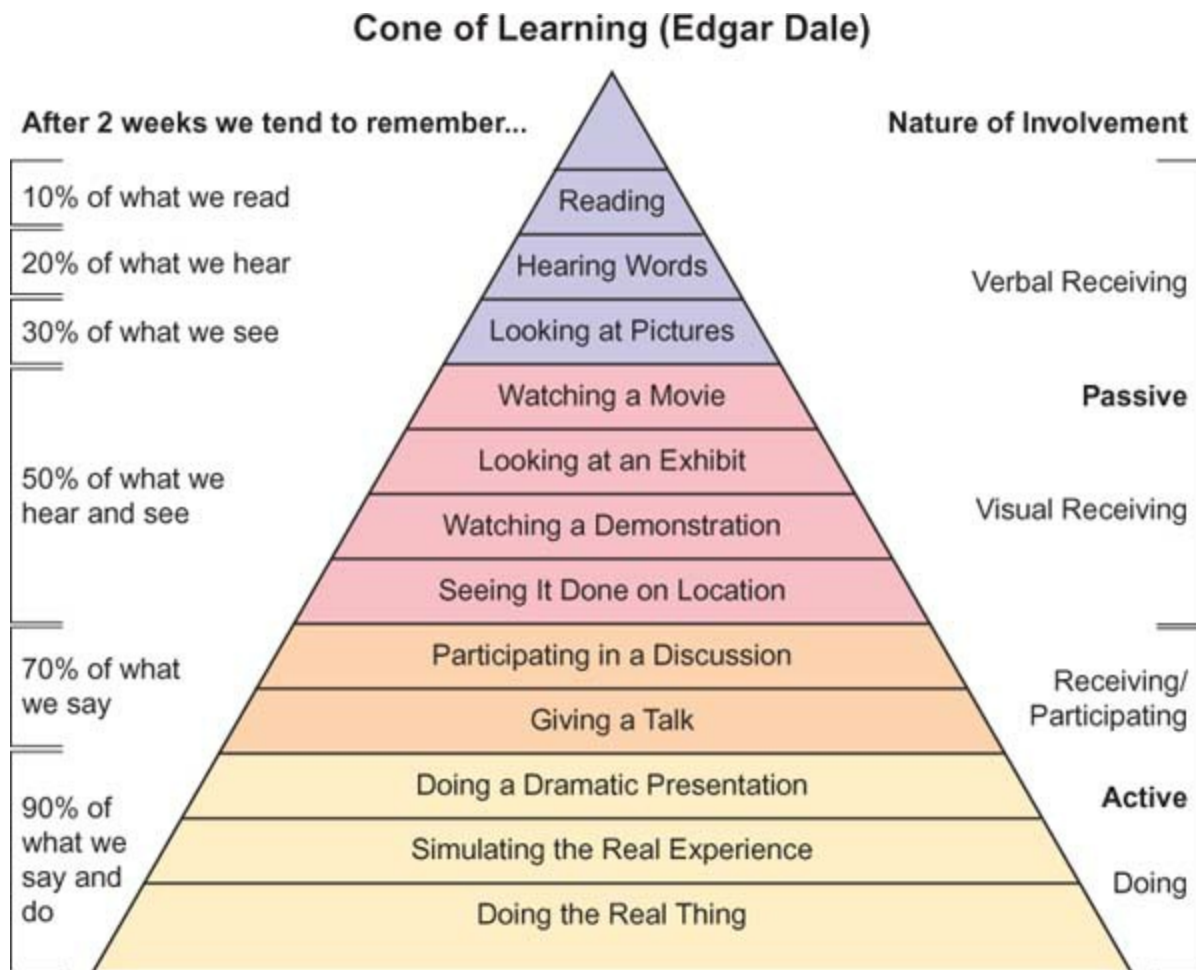

FIGURE 8.6 Cone of Learning. (Adapted from Dale, E. [1969]. *Audio-visual methods in teaching* [3rd ed.]. Austin, TX: Holt, Rinehart, and Winston.)

TABLE 8.4

SIX TECHNIQUES TO IMPROVE LEARNING

| Technique | Explanation |
|--|--|
| Slow down and repeat information often. | Since most of the education in a health care setting is done verbally, repeat important information at least four or five times. |
| Speak in conversational style using plain, nonmedical language. | When writing directions, write only several words, bullet points, or phrases. Use common, "living-room-type" language containing one or two syllables whenever possible. |
| "Chunk" information and teach it in small bites using logical steps. | This is especially important when there are large amounts of complex information for the family to learn. Teach for 10 to 15 minutes, give the learner a break, and return later to "chunk" again. |
| Prioritize information and teach "survival skills" first. | Due to time constraints and multiple demands on the part of staff, coupled with the rapid turnaround times of health care encounters for children, there never seems to be enough time to teach. Nurses must provide the child and family with the necessary information to meet their immediate needs. This may include information about: <ul style="list-style-type: none"> • The child's medical condition • Treatment information • Why the information is important • Possible problems, adverse effects, or concerns • What to do if problems arise • Who to contact for further help, information, or supplies |
| Use visuals, such as pictures, videos, and models. | Use visual resources to enhance and reinforce learning when available. Drawing simple pictures and charts or using alternative methods such as color-coding often allows learning to occur for families who are having difficulty grasping information or concepts. |
| Teach using an interactive, "hands-on" approach. | When the learner uses hands-on practice or participates in care, learning occurs more quickly and easily. Learning first on a doll or model can ease anxiety and bolster self-confidence before care or procedures on the child are actually performed. |

HELPING CHILDREN AND FAMILIES WITH POOR HEALTH LITERACY SKILLS. Nurses are in an excellent position to create a "blame-free" environment and offer help. It is entirely appropriate to say to the child or family member, "Many people have a problem reading and remembering the information on this teaching sheet (booklet, manual). Is this ever a problem for you?" For children or family members with low health literacy, the nurse can adjust oral communication techniques and written materials to assist with learning, and should communicate this need to the entire interdisciplinary health care team.

If literacy problems are known or suspected, the nurse can take several steps to enhance learning, such as:

- Draw pictures or use medical illustrations.
- Use videos.
- Color-code medications or the steps of a procedure.
- Record an audiotape.
- Repeat verbal information often and "chunk" it into small bites.
- Teach a "back-up" family member.

TEACHING CHILDREN AND ADOLESCENTS. Teaching children and adolescents is a vital part of pediatric nursing practice. Children and adolescents have a great need for information about their illness as they attempt to master their anxiety and restore feelings of competency, self-confidence, and hope. As with adults, they learn best when their input is valued and they are actively involved in the learning process. The age and developmental level of the child will determine the amount, format, and timing of the information given. Before beginning to teach a child, it is important to establish rapport and lay the foundation for good communication. Refer to Developmental Techniques for Communicating With Children above and [Table 8.3](#) for additional information related to communicating well with children and adolescents.

Teaching Preschool Children. When teaching young children, the nurse or family assumes part or all of the responsibility for what is learned, how it is learned, and when it is learned. Because they have vivid imaginations, young children often attempt to invent pieces of information, or they pick up bits and pieces of misinformation that can lead to false assumptions. Skillfully delivered and timed information can promote trust, calmness, and control in an otherwise apprehensive and uncooperative preschooler. [Table 8.5](#) presents some general guidelines for teaching young children.

TABLE 8.5

GENERAL TEACHING TIPS FOR YOUNG CHILDREN

| Teaching Tips | Practical Application |
|---|---|
| Offer simple, concise, concrete explanations based on the assessed needs, questions, and developmental level of the child. | Use a child's senses and relate what a procedure will look, sound, smell, taste, or feel like ("The MRI machine will sound very loud, like a big train"). |
| Be honest, even when the information you need to convey is not positive. This helps the child to form a bond of trust and confidence with caregivers. | Use the family's words that the child understands; use "soft words" ("This will feel warm" instead of "This will burn"). |
| Time explanations to decrease anxiety and excess worry before the event. Avoid telling unpleasant news close to bedtime. | As a general rule, give toddlers information about procedures, medicines, and other interventions immediately beforehand; give 4- to 7-year-olds information 1 or 2 days in advance. |
| Parents know their child best. Eliciting information from them about their child's past behaviors and coping skills can often mean the difference between a positive and negative experience for their child. | Teach parents how to coach their child with pain management, visualization, or other methods of distraction when appropriate ("Remember when we went to the beach . . ."). |
| Provide an active role for the child. This helps to foster a child's sense of self-confidence and control over the situation. | Allow the child to help with simple self-care activities such as holding a dressing or piece of tape. Provide props and dolls to touch and feel as much as possible ("Your job is to keep your hands still"). |
| Children's wishes must be respected when they verbalize or demonstrate that they do not want more information. | Keep explanations short and simple; know when to stop teaching. |
| Praise the child and let him or her know how much you appreciate his or her help and cooperation. | Use "please" and "thank you" often ("Thank you. I like the way you held still for me"). |

Teaching School-Age Children. Unless they are quite ill, school-age children usually want to participate in their care. They have a need to cooperate and achieve. When teaching, speak directly to them and include them in the education plan. Parents can often learn by observing the care being given and taught to their child (Fig. 8.7). Table 8.6 provides some general guidelines to keep in mind when teaching school-age children.

Teaching Adolescents. Adolescents are particularly sensitive about maintaining body image and feelings of control and autonomy. This is especially important with health care processes and decisions that affect them. Table 8.7 gives guidelines to use when teaching adolescents.

EVALUATING LEARNING

Teaching, even when done well, does not necessarily mean that learning has occurred. Evaluation of learning is critical to ensure that the child and family have actually learned what was taught. In a health care setting, perform an evaluation with each educational encounter and adjust goals and interventions accordingly. The nurse, along with the rest of the interdisciplinary team, is responsible for child and family learning. Help ensure understanding by asking for feedback and offering an opportunity for questions. Also, assessing for signs of confusion, such as increased anxiety, can help evaluate learning. If the child or family has not learned, the health care team ensures that teaching strategies are adjusted so that the child or family does learn.

FIGURE 8.7 Teach the school-age child and parent together.

| TABLE 8.6 GENERAL GUIDELINES WHEN TEACHING SCHOOL-AGE CHILDREN | |
|--|---|
| Teaching Tips | Practical Application |
| Allow the child some control and involvement in the decision-making process. | Offer choices whenever possible (taking the medicine with juice or milk), but don't offer choices when there are no alternatives (taking the medicine). |
| Children can relate present-day happenings to past experiences. | Use examples and past experiences that are familiar to the child ("Remember when you were first learning to swim . . ."). |
| Achievement and accomplishment are very important to children at this age, so anything they can be actively involved in will help them adjust and learn. | Provide an active role and allow the child to do as much of his or her care as possible. Use props, dolls, games, and computers to enhance learning. |
| At this age, most children are able to sequence, understand cause and effect, and make sense of time. | Teach children the steps involved and how long it will take ("Today I'm going to teach you how to change your dressing. This will help keep your cut clean. First, wash your hands . . ."). |
| Gaining control over the situation and preparing mentally are important for their self-confidence. | Provide information 3 to 7 days in advance, depending on the child's age and developmental level. |
| Praise the child and let him or her know how much you appreciate his or her help and cooperation. | Use "please" and "thank you" often ("Thanks! You did a great job using your inhaler"). |

The ultimate goal of education is a change in behavior on the part of the child and family; this change can occur in their level of knowledge, skill, or both.

Evaluation can occur in several different ways, depending on the topic and the method of teaching. The child or family may:

- Demonstrate a skill. Learning can quickly and easily be identified using this method.
- Repeat back or teach back the information using their own words.
- Answer open-ended questions. Open-ended questions provide an opportunity to assess for missing or incorrect information. Open-ended questions are those that cannot be answered with a simple "yes" or "no."

TABLE 8.7

GENERAL GUIDELINES WHEN TEACHING ADOLESCENTS

| Teaching Tips | Practical Application |
|--|---|
| Allow teens to be in control and involved in the decision-making process. | Speak directly to teens; consider their input in all decisions about their care and education. |
| Adolescents can process abstract information and understand how their actions affect long-term outcomes. | Provide reasons why something is important and discuss how their lives will be affected by their decision to take care of their health needs ("If you take your asthma medicine, you'll be better able to play tennis"). |
| Adolescents are very concerned about how they look and how they fit in with peers. | Collaborate with the teen to develop acceptable solutions and strategies for dealing with health issues that affect personal appearance and peer acceptance (e.g., wig vs. head scarves for hair loss from chemotherapy). |
| Adolescents strive for independence and have personal values and ideologies that may conflict with those of parents and the medical community. | Expect some noncompliance with care, despite your best educational efforts. Work together to achieve win-win outcomes of educational goals. |

Another option to evaluate learning is to provide a "pretend" scenario for the family, mentally placing them in their own home. Have them verbalize all the steps needed to care for their child, from routine care to handling an emergency situation. They will need to convey information accurately and completely as they walk through the steps necessary to provide care for their child independently at home.

DOCUMENTING EDUCATION FOR THE CHILD AND FAMILY

Documenting child care and education on the medical record is part of every nurse's professional practice and serves four main purposes. First and foremost, the child's medical record serves as a communication tool that the entire interdisciplinary team can use to keep track of what the child and family have learned already and what learning still needs to occur. Next, it serves to testify to the education the family has received if and when legal matters arise. Third, it verifies standards set by the Joint Commission, Centers for Medicare and Medicaid Services (CMS), and other accrediting bodies that hold health care providers accountable for child and family education activities. And last, it informs third-party payers of goods and services provided for reimbursement purposes.

Documentation of child and family education is imperative. It is the only way to ensure that the family's educational plan and objectives have been completed and that the family is ready for discharge. Documentation of child and family education should include such topics as:

- The learning needs assessment
- Information on the child's medical condition and plan of care
- Goals of child education; date goal is met
- Teaching method used and how received by child and family
- Medications, including drug-drug and drug-food interactions
- Modified diets and nutritional needs
- Safe use of medical equipment
- Follow-up care and community resources

KEY CONCEPTS

- Atraumatic care focuses on minimizing stressors and separation from the family and promoting a sense of control for the child and family.
- Children and families need appropriate explanation and education before a procedure is performed. Preparation may include explaining the procedure as well as physically preparing the child. Appropriate preparation helps to decrease the child's and family's anxiety, promote the child's cooperation, and support the child's and family's coping skills.
- A major aspect of preparation involves play.
- Include the child's parents in preparation, because parents are usually the greatest source of comfort for the child.
- Be short, simple, and appropriate in explaining situations at the child's level of development. Explain what is to be done and what is expected of the child.
- Utilize a child life specialist when available.
- Family centered care involves a beneficial partnership between the patient, family and health care providers in planning, providing

and evaluating care.

- Family-centered care is based on the concept that the family is the primary source of strength and support for the child.
- Family centered care includes: respect for the child and family, recognition of cultural diversity, identification of the family's strengths, assistance with emotional and other support of the family, providing honest and unbiased information, and collaborating and empowering families.
- Maintain open and honest lines of communication with children and their families.
- Therapeutic communication involves the use of open-ended questions, reflection, paraphrasing, acknowledgement of emotions, and active listening.
- To communicate effectively with children, provide information and support on the child's developmental level and utilize age-appropriate methods.
- When communicating with parents, be honest. Parents want to feel valued and should be equal partners in the health care team.
- It is vital for the family to have knowledge about their child's health.
- The nurse should assess the family's culture and language before planning teaching. An interpreter may be needed if the family does not speak English. The nurse must assess each family's individual beliefs and practices rather than generalizing.
- The steps of health education are assessment of learning needs and styles, collaborative establishment of the goals and plan of education, implementation, evaluation, and documentation of education.
- Patient education begins with the first patient encounter and proceeds through discharge and beyond. Reassessment after each step or change in the process is critical to success.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. When providing atraumatic care to a child, which action would be most appropriate?
 - a. Applying restraints for any procedure that would be uncomfortable
 - b. Keeping the lights on in the child's room throughout the day and night
 - c. Limiting the use of topical anesthetics for painful injections
 - d. Allowing parents and children an informed choice about being together
2. When caring for children, how does the nurse best incorporate the concept of family-centered care?
 - a. Encourages the family to allow the physician to make health care decisions for the child
 - b. Uses the concepts of respect, family strengths, diversity, and collaboration with the family
 - c. Advises the family to choose a pediatric provider who is on the child's health care plan
 - d. Recognizes that families undergoing stress related to the child's illness cannot make good decisions
3. When working with children and families, which is a critical strategy for promoting therapeutic communication?
 - a. Detailed explanations
 - b. Attentive listening
 - c. Comforting touch
 - d. Closed-ended questions
4. The nurse is caring for a 2-year-old in the hospital, and the mother expresses concern that the toddler will be scared. Which response by the nurse would be most appropriate?
 - a. "Don't worry; we practice family-centered and atraumatic care here."
 - b. "We will do our best to minimize the stress that your child experiences."
 - c. "It will probably be upsetting for you as well, so you should stay home."
 - d. "Our practice of atraumatic care will eliminate all pain and stress for your child."
5. When planning education for a child and parents, what is the first step the nurse should take?
 - a. Decide which procedures and medications the child will be discharged on.
 - b. Determine the child's and family's learning needs and styles.
 - c. Ask the family if they have ever performed this type of procedure.
 - d. Tell the child and family what the goals of the teaching session are.

CRITICAL THINKING EXERCISES

1. A 5-year-old boy is being admitted to your unit. The physician has ordered IV fluids along with laboratory work including a complete blood count, electrolytes, and a urine culture. As his nurse, how will you prepare him and his family before the procedure and support them during and after the procedure, to promote the best outcome and to ensure atraumatic care?
2. A 3-year-old girl from Saudi Arabia has become seriously ill while visiting the United States. She will require a lengthy hospital stay. Describe the steps the nurse should take to communicate effectively with and provide extensive health care teaching to this child's family.

STUDY ACTIVITIES

1. Develop a teaching plan for one of the families that you care for in the clinical setting. Be sure to follow the appropriate steps for providing education.
2. Interview a child life specialist about the effects that the traditional (not atraumatic) approach to restraining a child for procedures might have on a child of various ages.
3. Research the availability of language interpreters and translators in your local community, compiling a list of the available resources.

Words of Wisdom It is never too late to start prevention. It begins with a genuine desire for health improvement.

KEY TERMS

active immunity

developmental screenings

developmental surveillance

immunity

medical home

passive immunity

risk assessment

screening tests

selective screening

universal screening

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Describe the principles of health supervision.
2. Identify challenges to health supervision for children with chronic illnesses.
3. List the three components of a health supervision visit.
4. Use instruments appropriately for developmental surveillance and screening of children.
5. Demonstrate knowledge of the principles of immunization.
6. Identify barriers to immunization.
7. Identify the key components of health promotion.

8. Describe the role of anticipatory guidance in health promotion.

Three-year-old Maya Randall and 9-month-old Evan Randall are brought to the clinic by their father. Maya was last seen in the clinic when she was 1 year old and Evan has never been seen. The father says that they have both been healthy so they did not need to come to the clinic before this. Maya is complaining of a sore throat, which is what prompted today's visit.

PRINCIPLES OF HEALTH SUPERVISION

Health supervision involves providing services proactively, with the goal of optimizing the child's level of functioning. It ensures the child is growing and developing appropriately and it promotes the best possible health of the child by teaching parents and children about preventing injury and illness (e.g., proper immunizations and anticipatory guidance). This chapter is organized around the three components of health supervision: developmental surveillance and screening; injury and disease prevention; and health promotion. Health supervision of the child begins at birth and continues through adolescence. It is vital to every child and is most effective when the child has a centralized source of health care. Any place publicly accessible by children and families can be an appropriate setting for health supervision services—private physicians' offices, community health departments, sliding-scale clinics, homeless shelters, day care centers, and schools. The framework for the health supervision visit is developed from national guidelines available through the U.S. Department of Health and Human Services (DHHS), the American Medical Association (AMA), and the American Academy of Pediatrics (AAP). These organizations also provide guidelines for children with chronic health problems and services and information regarding unique situations such as the internationally adopted child.

Wellness

The focus of pediatric health supervision is wellness. The health supervision visit provides an opportunity to maximize health promotion for the child, family, and community. Nurses have the ability to promote optimal health during these encounters. Health supervision visits must be viewed as part of a continuum of care, not as the accomplishment of isolated tasks.

Medical Home

A **medical home** is the primary physician who has a long-term and comprehensive relationship with the family. This continuing relationship promotes trust between the provider and the family and leads to comprehensive, continuous, coordinated, and cost-effective care. The medical home is the setting that allows the highest level of health supervision. To be effective, the medical home must be accessible, family centered, culturally effective, and community based. It must be integrated into the child's world, not adjacent to it. Characteristics of a medical home are displayed in [Box 9.1](#).

Partnerships

The child is the focus of the health supervision visit. However, the child's health is linked to the needs and resources of his or her family and community. For instance, if the family is in turmoil because of divorce, drug abuse, or parental health problems, the child is less likely to receive the attention and energy that he or she needs to thrive. Likewise, a community with high levels of poverty, poor infrastructure, and lack of resources will not be able to provide the support services needed to allow children to reach their full potential. To be effective, the nurse must offer commitment and develop an ongoing partnership with the child, family, and community. These partnerships allow for mutual goal setting, marshalling of resources, and development of optimal health practices.

The partnership between the child and the health supervision team develops over time. In infancy the family is the surrogate for the child in the partnership. The child's participation in the partnership increases at a rate that is developmentally appropriate. The child's increasing influence in the partnership allows the nurse to tailor health supervision to the child's needs. The partnership allows the child to take increasing responsibility for his or her personal health and optimizes health promotion.

BOX 9.1

CHARACTERISTICS OF A MEDICAL HOME

- Care accessible and in the child's community
- All insurance, including Medicaid, accepted
- Family-centered care provided
- Child or family able to speak directly to the physician when needed
- Partnership based on mutual trust and respect between the family and physician
 - Preventive care activities provided
 - Ambulatory and inpatient care available 24 hours a day
 - Continuity of care from infancy through adolescence
- Coordinated care with other care providers
 - Availability of subspecialty consultation and referrals

- Work with family to meet the nonmedical and medical needs of the child and family
 - Interactive relationships with school and community agencies
 - A centralized database containing all pertinent information
- Concern for the well-being of the child and family expressed
- Respect for family's cultural and religious beliefs

Adapted from American Academy of Pediatrics, Medical Home Initiatives for Children With Special Needs Project Advisory Committee. (2008). *The medical home*. Retrieved April 17, 2011, from <http://aappolicy.aappublications.org/cgi/content/full/pediatrics;110/1/184#T1>

Nurses must validate and enhance the role of family members as they influence and inform the child's concept of wellness. The health care community must involve the family to have a significant impact on a child's health. The family wants the best possible outcome for their child, and health care decisions are based on the knowledge they possess. The nurse can greatly facilitate trust by acknowledging that the family has unique insights to offer on their child's health. Nurses can also strengthen the partnership between the family and the health care community by recognizing the family's healthy practices, addressing their health issues, and strengthening their skills. By contributing to the partnership, both the nurse and the family enhance the chance of success for health care plans, but families are the ones who must implement any health care strategy and know what expected outcomes are reasonable. Their feedback is invaluable to formulating an effective long-term health supervision plan that optimizes their child's wellness.

Take Note!

Observe the parent-child interaction during the health supervision visit. The nurse can learn much about the family dynamic by observing the family for behavioral clues:

- Does the parent make eye contact with the infant?
- Does the parent anticipate and respond to the infant's needs?
- Are parents effective when dealing with a toddler's temper tantrum?
- Do the parents' comments increase the school-age child's sense of self-worth?

Behavioral observations are crucial to the proper assessment of the family's needs and issues.

Partnerships between the community and the health promotion team benefit the community as well as individual children. When nurses develop partnerships with community agencies such as schools, churches, and ancillary health facilities, barriers to care can be overcome. The nurse becomes aware of available resources in the community that can benefit an individual family. With input from community partners, the nurse can perform an assessment of the community's needs. The assessment then provides the foundation for the development of community-based health promotion programs. These programs expand the resources of the community, which in turn enhances the health of its members.

Special Issues in Health Supervision

Special issues in health supervision include cultural influences, community influences, health supervision and the chronically ill child, and health supervision and the internationally adopted child.

Cultural Influences on Health Supervision

A person's definition of health is influenced by his or her culture. Successful interactions result when the nurse is aware of the beliefs and interactive styles that are often present in members of a specific culture. If the goals of the health care plan are not consistent with the health belief system of the family, the plan has little chance for success. Optimal wellness for the child requires the nurse and the family to negotiate a mutually acceptable plan of care. A plan must balance the cultural beliefs and practices of the family with those of the health care establishment. The nurse must possess cultural competence and sensitivity for the partnership to be successful.

Most health promotion and disease prevention strategies in the United States have a future-based orientation and view the child as an active and controlling agent in his or her own health. This reflects the dominant culture; however, the challenge to the nurse is to develop strategies that are meaningful to children from other cultures. Significant numbers of children belong to cultures with a present-based orientation. These cultures are more concerned about what is going on now. For these children, health promotion activities need shorter-term goals and outcomes to be useful. Children with a fatalistic world-view will see any actions on their part as ineffective. They may feel that a god figure or supernatural forces control their fate and that health is a gift to be appreciated, not a goal to be pursued. Certain cultures believe health is the result of being in harmony within oneself and the larger universe. From this

viewpoint, taking a medication or receiving a treatment may not be an effective way to restore health because it does not address the problem of being “out of harmony.”

However, just because an individual belongs to a certain culture does not guarantee that he or she subscribes to all of its values. The nurse should explore each child’s specific beliefs during the health interview.

Community Influences on Health Supervision

The child is a member of a community as well as a family and a culture. Each community has unique strengths, weaknesses, and values. A community can be a contributor to a child’s health or be the cause of his or her illnesses. The child’s health cannot be totally separated from the health of the surrounding community.

Ideally the child’s medical home is within the family’s community. If home and access to medical care are close, barriers such as lack of transportation, expense of travel, and time away from the parents’ workplace are reduced. Having the medical home within the community facilitates bonds between the health team and schools, churches, and support services and agencies. Community support and resources are necessary for children with significant problems. A close working relationship between the child’s physician and community agencies is an enormous benefit to the child (see the earlier section on partnerships).

The community assessment may reveal problems that are causing or contributing to the child’s health problems. A deteriorating infrastructure can contribute to decreased access to care and increased risk of injury or illness. Poverty has been linked to low birthweight and premature birth, among other health problems (Shore & Shore, 2009). Substandard housing can be directly related to lead poisoning and asthma (Centers for Disease Control and Prevention [CDC], 2009a). A thorough knowledge of the family’s community is needed before a health surveillance program can be effective.

Health Supervision and the Child With Chronic Illness

Effective health supervision must be responsive to the individual child’s situation. The child with a chronic illness needs to be assessed repeatedly to determine his or her health maintenance needs. These assessments determine the frequency of visits and types of interventions needed. The impact of the illness on the child’s functional health patterns determines whether standard health supervision visits need to be augmented.

An effective partnership among the child’s medical home, family, and community is vital for a child with a chronic illness. Coordination of specialty care, community agencies, and family support networks enhances the quality of life and health of these children. Access to care and services minimizes the risk of injury from the illness. Support groups and community-based resources optimize the family’s adaptation to the stressors of chronic illness.

Comprehensive health supervision includes frequent psychosocial assessments. Issues to be covered include:

- Health insurance coverage
- Transportation to health care facilities
- Financial stressors
- Family coping
- School’s response to the chronic illness

These are often stressful and emotionally charged issues. The nurse with a trusting and ongoing relationship with the child and family is in the best position to help with these issues. The nurse can assist the family to find financial and medical assistance programs, take advantage of community resources, and participate in support groups. The nurse can also educate school personnel about the child’s illness and assist them in maximizing the child’s potential for academic success.

Health Supervision and the Child Adopted Internationally

Health supervision of the internationally adopted child must include comprehensive screening for infectious disease. In 2010, approximately 11,050 children were adopted from countries outside the United States, many from areas with a high prevalence of infectious diseases (Intercountry Adoption, Office of Children’s Issues, U.S. Department of State, 2010a). China, Ethiopia, and Russia supplied over half of all international adoptees in 2010, followed by South Korea and the Ukraine (Intercountry Adoption, Office of Children’s Issues, U.S. Department of State, 2010b). Proper screening is important not only to the child’s health but also to the adopting family and the larger community. Screening is recommended within the first few weeks of the child’s arrival into the United States.

Intestinal parasites are a common problem with *Giardia lamblia*, the most common pathogen (Miller, 2008). Infected children are frequently symptom-free, so universal screening is recommended (Simms & Freundlich, 2007).

Latent tuberculosis is also common. Though active tuberculosis infection has been rarely reported, an extensive outbreak of

tuberculosis occurred in a North Dakota community in 1998. The index case was an internationally adopted child from the Marshall Islands (Curtis et al., 1999; Miller, 2008). Universal screening is recommended for this high-risk population (Shetty, 2010; Simms & Freundlich, 2007).

Universal screening for hepatitis B, HIV, and syphilis infections is recommended (Shetty, 2010). Due to lack of resources in the home country, screening and treatment for these diseases are sporadic and ineffective. If testing is documented, it is likely to be unreliable. Testing supplies may have been outdated or improperly stored. Also, the test may have been performed before the child's seroconversion occurred.

COMPONENTS OF HEALTH SUPERVISION

Developmental surveillance and screening, injury and disease prevention, and health promotion are the critical components of health supervision for children. Health supervision visits for children without health problems and appropriate growth and development are recommended at birth, within the first week of life, by 1 month, then at 2 months, 4 months, 6 months, 9 months, 12 months, 15 months, 18 months, 24 months, 30 months, and then yearly until age 21 (Hagan, Shaw, & Duncan, 2008). Children with special needs or concerns will have more frequent and intensive visits. Health supervision visits include assessment of physical health along with intellectual and social development and parent-child interaction.

Each health supervision visit will include (Hagan et al., 2008):

- A history and physical assessment, including head circumference (until 2 years of age), height, and weight
- Developmental/behavioral assessment
- Sensory screening (vision and hearing)
- Appropriate at-risk screening (such as lead screening, anemia screening, tuberculin test, hypertension screening, cholesterol screening)
- Immunizations
- Health promotion/anticipatory guidance (injury prevention, violence prevention, nutrition counseling)

Disease prevention and health promotion are concepts well established in adult health supervision. Injury prevention and developmental surveillance/screening are additional components of pediatric health supervision visits that help every child achieve his or her optimal state of wellness.

Developmental Surveillance and Screening

Developmental surveillance is an ongoing collection of skilled observations made over time during health care visits. Components include:

- Noting and addressing parental concerns
- Obtaining a developmental history
- Making accurate observations
- Consulting with relevant professionals

Developmental screenings are brief assessment procedures that identify children who warrant more intensive assessment and testing. Developmental screening assessments may be observational or by caregiver report (Fig. 9.1).

Development, or the emergence of the child's abilities, is a longitudinal process. Within the trust and security of the medical home, family and physicians can share observations and concerns. In collaboration, the family and the physician observe the child's accomplishments or milestones over time. Data collection for developmental surveillance of infants and young children is performed through developmental questionnaires, physician observations, and a thorough physical examination. School records and test results can provide academic performance data for the older child. Input from teachers, coaches, and other adults involved with the child can give insight into the child's emotional and social development.

When developmental delay is suspected, frequent developmental surveillance is warranted. Reemphasizing parental roles and responsibilities fosters cooperation and compliance. It is therefore crucial that parents understand the need for frequent assessments. A pattern of developmental delays warrants a formal evaluation.

The pediatric nurse must understand normal growth and development and become proficient at screening for problems related to development. The historical information obtained from the parent or primary caregiver about developmental milestones may indicate warning signs or identify risks for developmental delay (Table 9.1). Factors placing the infant or toddler at risk for developmental problems include:

FIGURE 9.1 Developmental screening provides the opportunity for the nurse to identify problems in the child's development.

- Birthweight less than 1,500 g
- Gestational age less than 33 weeks
- Central nervous system abnormality
- Hypoxic ischemic encephalopathy
- Maternal prenatal alcohol or drug abuse
- Hypertonia
- Hypotonia
- Hyperbilirubinemia requiring exchange transfusion
- Kernicterus
- Congenital malformations
- Symmetric intrauterine growth deficiency
- Perinatal or congenital infection
- Suspected sensory impairment
- Chronic (more than 3 months) otitis media with effusion
- Inborn error of metabolism
- HIV infection
- Lead level above 19 mg/dL
- Inappropriate parental concern about developmental issues (e.g., not allowing a developmentally appropriate 3-year-old feed him- or herself)
- Parent with less than high school education
- Single parent
- Sibling with developmental problems
- Parent with developmental disability or mental illness

Infants or children with any of these risk factors should be screened carefully for developmental delays. This screening should occur in a prospective manner, with screenings occurring at frequent intervals to identify concerns early.

| TABLE 9.1 EARLY CHILDHOOD DEVELOPMENTAL WARNING SIGNS | |
|---|--|
| Age | Warning Sign |
| Any age | No response to environmental stimulus |
| Any age | Persistently up on toes (longer than 30 seconds) in supported standing position |
| Before 3 months | Rolls over |
| After 2–3 months | Persistent fisting |
| After 4 months | Persistent head lag |
| 5 months | Not reaching for toys |
| 6 months | <ul style="list-style-type: none"> • Lack of tripod sitting • Not smiling • Primitive reflex persistence • Not babbling |
| 9 months | No reciprocal vocalizations or facial expressions |
| 12 months | No spoon or crayon use |
| 15–18 months | <ul style="list-style-type: none"> • Not walking • No first word |
| Prior to 18 months | Hand dominance present |
| By 18 months | <ul style="list-style-type: none"> • Not walking • Not speaking 15 words • Does not understand function of common household items • No imitative play |
| After independent walking for several months | <ul style="list-style-type: none"> • Persistent tiptoe walking • Failure to develop a mature walking pattern |
| By 2 years | <ul style="list-style-type: none"> • Does not use two-word sentences • Does not imitate actions • Does not follow basic instructions • Cannot push a toy with wheels • Echolalia (repetitive speech) |
| By 3 years | <ul style="list-style-type: none"> • Difficulty with stairs • Frequent falling • Cannot build tower of more than four blocks • Difficulty manipulating small objects • Extreme difficulty in separation from parent or caregiver • Cannot copy a circle • Does not engage in make-believe play • Cannot communicate in short phrases • Does not understand simple instructions • Little interest in other children • Unclear speech, persistent drooling |
| 4 years | <ul style="list-style-type: none"> • Cannot jump in place or ride a tricycle • Cannot stack four blocks • Cannot throw ball overhand • Does not grasp crayon with thumb and fingers • Difficulty with scribbling • Cannot copy a circle • Does not use sentences with three or more words • Cannot use the words “me” and “you” appropriately • Ignores other children or does not show interest in interactive games • Will not respond to people outside the family, still clings or cries if parents leave • Resists using toilet, dressing, sleeping • Does not engage in fantasy play |

- | | |
|------------|---|
| By 5 years | <ul style="list-style-type: none"> • Unhappy or sad often • Little interest in playing with other children • Unable to separate from parent without major protest • Is extremely aggressive • Is extremely fearful or timid, or unusually passive • Cannot build tower of six to eight blocks • Easily distracted; cannot concentrate on single activity for 5 minutes • Rarely engages in fantasy play • Trouble with eating, sleeping, or using the toilet • Cannot use plurals or past tense • Cannot brush teeth, wash and dry hands, or undress efficiently |
|------------|---|

Take Note!

Any child who “loses” a developmental milestone—for example, the child able to sit without support who now cannot—needs an immediate full evaluation, since this may indicate a significant neurologic problem.

A number of developmental screening tools are available to guide the nurse in assessing development (Table 9.2). The Denver II is a frequently used tool (see Appendix B). The Denver II should be used for diagnostic purposes only when administered by specifically trained personnel. Nurses not trained in the use of the Denver II should use screening tools based on the Denver II. Many screening methods assist the nurse in identifying infants and children who may have developmental delays, thus allowing for prompt identification and referral for evaluation. Additional data can be used to determine a school-age child’s developmental level, include handwriting samples, ability to draw, school performance, and social skills.

Injury and Disease Prevention

Disease prevention is defined as interventions performed to protect children from a disease or to identify it at an early stage and lessen its consequences. These interventions are determined by the results of the nurse's assessment, nationally accepted practice guidelines, and the family's goals. Components of disease prevention include screening tests and immunizations.

Injury prevention is primarily accomplished through education, anticipatory guidance, and physical changes in the environment. Injuries can be unintentional (poisoning, falls, or drowning) or intentional (child abuse, homicide, or suicide). The types of injuries a child is most likely to encounter vary greatly among age groups. Although aggressive public health initiatives have decreased mortality rates of childhood unintentional injuries significantly in the past 50 years, continued vigilance and innovation are needed (Singh, 2010). The nurse, in partnership with the family and the community, can have an enormous impact on child safety. Specific interventions are discussed in [Chapters 3 through 7](#).

Screening Tests

Screening tests are procedures or laboratory analyses used to identify children with a certain condition. These tests are done to ensure that no child with the disorder is missed. They have a high sensitivity (a high false-positive rate) and a low specificity (a low false-negative rate). If a screening test is positive, follow-up tests with higher specificity are performed. A **risk assessment** is performed by the physician in conjunction with the child and includes objective as well as subjective data to determine the likelihood that the child will develop a condition.

In **universal screening**, an entire population is screened regardless of the child's individual risk. This type of screening is performed when a reliable risk assessment procedure is not available. In contrast, **selective screening** is done when a risk assessment indicates the child has one or more risk factors for the disorder.

Take Note!

To increase cooperation from young children during screenings, set up a reward system. Easy-to-do rewards include:

- Stamping the back of the child's hand with a "smiley face"
- Making an eye cover by placing two stickers back to back over a tongue blade and letting the child keep the cover after the screening
- Copying a design onto a sheet of paper and letting the child take it home to color
- Letting the child play with a simple device such as a pen-light or stethoscope

| TABLE 9.2 | | DEVELOPMENTAL SCREENING TOOLS | |
|---------------|--|--|---|
| Age | Screening Tool | Definition | Nursing Implications |
| Birth–6 years | Denver II | Assesses personal–social, fine motor–adaptive, language, and gross motor skills | Administered by nurse. Requires props (e.g., ball, crayon, doll), available in the Denver II kit. Simple to learn to administer |
| Birth–6 years | Denver PRQ | Assesses personal–social, fine motor–adaptive, language, and gross motor skills | Parental report of all items on the Denver II |
| Birth–6 years | Child Development Inventory (CDI) | Simple questions about infant, toddler, or preschooler behaviors. Measures social, self-help, gross motor, fine motor, expressive language, language comprehension, letters, numbers, and general development as appropriate | A parental-report screening tool |
| Birth–6 years | Ages and Stages Questionnaire (ASQ) | Assesses communication, gross motor, fine motor, personal–social, and problem-solving skills | A parental-report screening tool, scored by the nurse after completion to determine child's progress in each of the developmental areas |
| Birth–8 years | Parents' Evaluation of Developmental Status (PEDS) | Screens for a wide range of developmental, behavioral, and family issues | A parental-report screening tool that can also be used in nurse interview format. Also available in Spanish. |
| 12–96 months | Batelle Developmental Inventory Screening Test | Assesses fine and gross motor, adaptive, personal–social, receptive and expressive language, and cognitive skills | Direct elicitation, parental description, and examiner observation. Requires special training |
| 1–42 months | Bayley Scales of Infant Development II | Provides a mental and motor scale for assessment of cognitive, language, personal–social, and fine and gross motor development. A behavior rating scale is obtained during the testing. | Direct elicitation. Thorough. Requires special training |
| Birth–3 years | Early Language Milestone Scale | Screens for auditory expressive and receptive, visual components of speech | Requires standardized kit |
| 2½–7 years | Denver Articulation Screening | Screens for articulation disorders | 5 minutes to administer. Does not evaluate language ability |
| 5–17 years | Goodenough-Harris Drawing Test | A nonverbal screen for mental ability (intelligence) | Child draws a person, which is analyzed for body parts, clothing, proportion, and perspective. |

METABOLIC SCREENING

State law determines which metabolic screening tests are mandatory in that state. In some states, mandatory screening is limited to as few as four diseases. In addition to screening for hearing loss, the March of Dimes currently recommends universal newborn metabolic screening tests for 29 disorders for which effective treatment is available (March of Dimes, 2010):

- Amino acid metabolism disorders: phenylketonuria, maple syrup urine disease, homocystinuria, citrullinemia, argininosuccinic acidemia, tyrosinemia type I
- Organic acid metabolism disorders: isovaleric acidemia, glutaric acidemia type I, hydroxymethylglutaric aciduria, multiple carboxylase deficiency, methylmalonic acidemia due to mutase deficiency, methylmalonic acidemia cblA and cblB forms, 3-methylcrotonyl-CoA carboxylase deficiency, propionic acidemia, P-ketothiolase deficiency
- Fatty acid oxidation disorders: medium-chain acylCoA dehydrogenase deficiency, very-long-chain acylCoA dehydrogenase deficiency, long-chain 3-OH acylCoA dehydrogenase deficiency, trifunctional protein deficiency, carnitine uptake defect
- Hemoglobinopathies: sickle cell anemia, HbS/p-thalassemia, HbS/C disease
- Others: congenital hypothyroidism, biotinidase deficiency, congenital adrenal hyperplasia, classical galactosemia, cystic fibrosis, and severe combined immunodeficiency (SCID)

During the initial health supervision visit, the nurse should confirm that newborn metabolic screening was performed prior to discharge from the birthing unit. If the test was not performed or was performed at younger than 48 hours of age, the screening should be performed at that visit. The metabolic screening results need to be noted in the child's permanent record at the medical home.

HEARING SCREENING

The AAP recommends hearing screening of all infants. Hearing loss is a common condition in newborns, and even mild hearing loss can cause serious delays in social and emotional development, language acquisition, and cognitive function (De Michele & Meyers,

2010). Identification of hearing loss by 6 months of age is crucial to reduce the impact on the child's development (De Michele & Meyers, 2010). Refer to Healthy People 2020. Targeted screening based on risk factors will identify only 50% of infants with hearing loss, and with reliable screening tests available, universal screening has been implemented (De Michele & Meyers, 2010). Screening should be done before discharge from the birthing unit; if not, the newborn needs to be screened before 1 month of age. Behavioral observations of the infant's response to sounds, such as a ringing bell or clapping hands, are not sensitive enough to preclude mild to moderate hearing loss (De Michele & Meyers, 2010). Accepted methodologies for screening newborn hearing are displayed in [Table 9.3](#).

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|--|
| Increase the proportion of newborns who are screened for hearing loss by age 1 month, have audiologic evaluation by age 3 months, and are enrolled in appropriate intervention services by age 6 months. | <ul style="list-style-type: none"> • Determine results of newborn hearing screening at first newborn check-up. • Refer any infant with possible hearing deficit for further evaluation. • Ensure infants with hearing impairment receive appropriate augmentation (hearing aids). • Ensure all children and adolescents receive hearing screenings with well-child check-ups as appropriate. |
| Increase the proportion of persons who have had a hearing examination on schedule. | |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Screening for hearing loss in older children begins with a history from the primary caregivers. If any problems are noted, audiometry should be performed. When the child is capable of following simple commands reliably, the nurse can perform some basic procedures to screen for hearing loss. The whisper test is easy to perform but to be valid requires a quiet room that is away from distractions. The Weber and Rinne tests can be used to screen for sensorineural or conductive hearing loss ([Fig. 9.2](#)).

Universal hearing screening with objective testing is recommended at ages 4, 5, 6, 8, and 10 (Hagan et al., 2008). At the ages of 7, 9, and 11 through 21 years, age-appropriate risk assessment should be performed (Hagan et al., 2008). See [Box 9.2](#) for examples of risk assessment. More frequent screening is recommended if there is any behavior that indicates the child's hearing may be impaired. Repeated hearing screenings are recommended if a child has risk factors for acquired hearing loss such as those listed in [Box 9.3](#).

BOX 9.2

HEARING RISK ASSESSMENT

Ages 3 months to 4 years

- Auditory skill monitoring
- Developmental surveillance
- Assessment of parental concerns

Age 4 years

- Difficulty hearing on the telephone
- Difficulty hearing people in a noisy background
- Frequent asking of others to repeat themselves
- Turning the television up too loudly

TABLE 9.3 HEARING SCREENING METHODS

| Test Name | Age Group | Characteristics | Nursing Implications |
|---------------------------------------|---|--|--|
| Auditory brain stem response (ABR) | Newborn–6 months | Measures electroencephalographic waves Test results may be affected by ear debris | Infant must be quiet (sedation may be needed). |
| Evoked otoacoustic emissions (EOAE) | Newborn–6 months or developmentally delayed children at the infant's level of functioning | The machine produces clicks that stimulate cilia in the cochlea and measures the response. | Infant must be quiet. Test results may be inaccurate in first 24 hours of life. |
| Visual reinforcement audiometry (VRA) | 6 months–2 years | Visual reward is linked to a tone signal. Child looks to the visual reward in response to the tone. Reward is activated, reinforcing the response. | Child must be alert and happy for best results. Schedule for after sleep/rest period. Allow child to sit in parent's lap. |
| Tympanometry | Over 7 months | Measures tympanic membrane mobility and determines middle ear pressure | The probe must form a seal with the canal. The child must remain still to obtain a valid result. |
| Conditioned play audiometry (CPA) | 2–4 years | Similar to VRA except uses "listening games" Child does listening game at the tone and receives social reward. May be used when developmental age is 2 years | See Nursing Implications for VRA. |
| Pure-tone (conventional) audiometry | 4 years and older | Measures hearing acuity through a range of frequencies and intensities Child must wear earphones. Performed in a soundproof room if possible | Teach the child the desired motor response before screening. Administer conditioning trials. Offer two presentations of stimulus to ensure reliability. At a minimum, screen 1,000-, 2,000-, and 4,000-hertz levels at 20 decibels. |
| Whisper test | 4 years and older | One ear is occluded. Examiner stands behind the child and whispers a word. The child must accurately repeat the whispered word. | The child must be in a quiet room and away from distractions. The child should be alert and well rested for accurate results. Consider a reward system to increase compliance. |
| Weber test | 6 years and older | Place a vibrating tuning fork in the middle of the top of the head. Ask if the sound is in one ear or both ears. The sound should be heard in both ears. | The child must understand the instructions and be able to cooperate. |

| | | | |
|------------|-------------------|---|--|
| Rinne test | 6 years and older | Place a vibrating tuning fork on the mastoid process to assess bone conduction. The child signals when the sound is gone. Next place a vibrating tuning fork outside the ear to test air conduction. The child signals when the sound is gone. For a passing test, air conduction time should be twice as long as bone conduction time. | The child must understand the instructions and be able to cooperate. |
|------------|-------------------|---|--|

VISION SCREENING

Newborns with ocular structural abnormalities are at high risk for vision impairment. Vision screening is performed at every scheduled health supervision visit. The screening procedures for children younger than 3 years of age or for nonverbal children involve evaluating the child's ability to fixate on and follow objects. The neonate should be able to fixate on an object 10 to 12 inches from the face. After fixation, the infant should be able to follow the object to the midline. By 2 months of age, the infant should be able to follow the object 180 degrees. The technique of photoscreening can help identify problems such as ocular malalignment, refractive error, and lens and retinal problems.

Take Note!

Use objects with black-and-white patterns when performing vision screening on an infant younger than 6 months of age. The infant's vision at this age is more attuned to high-contrast patterns than to colors. Try checkerboard patterns or concentric circles. Animal figures like pandas and dalmatians also work well.

FIGURE 9.2 (A) The Weber test screens for hearing by assessing sound conducted via bone. (B) The Rinne test screens for hearing by comparing sound conduction via bone to sound conduction via air.

BOX 9.3

RISK FACTORS FOR HEARING IMPAIRMENT

- Family history of hearing loss
- Prenatal infection
- Anomalies of the head, face, or ears
- Low birthweight (<1,500 g)
- Hyperbilirubinemia requiring exchange transfusion
- Ototoxic medications
- Low Apgar scores: 4 or less at 1 minute, or 6 or less at 5 minutes
- Mechanical ventilation lasting 5 days
- Syndrome associated with hearing loss
- Head trauma
- Bacterial meningitis
- Neurodegenerative disorders
- Persistent pulmonary hypertension
- Otitis media with effusion for 3 months

Adapted from De Michele, A. M., & Meyers, A. D. (2010). Newborn hearing screening. *eMedicine*. Retrieved April 12, 2011, from <http://emedicine.medscape.com/article/836646-overview>

After the age of 3 years, a variety of standardized age-appropriate vision screening charts are available. These charts include the “tumbling E” and Allen figures (Fig. 9.3A, B). These charts allow for a more precise vision assessment and aid the nurse in identifying preschool children with visual acuity problems. By age 5 or 6, most children know the alphabet well enough to use the traditional Snellen chart for vision screening (see Fig. 9.3C). Refer to Healthy People 2020. Table 9.4 gives further information about vision screening tools.

Objective**Nursing Significance**

Increase the proportion of preschool children age 5 years and younger who receive vision screening.

- Use a preschool-appropriate vision screening tool to assess vision.
- Ensure screening begins at age 3 years.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Screenings should be performed when children are alert, as fatigue and lack of interest can mimic poor vision. When using any vision screening chart, several simple steps need to be followed (Bowden & Green-burg, 2008):

- Place the chart at the child's eye level.
- Make sure there is sufficient lighting.

FIGURE 9.3 (A) The “tumbling E” chart is appropriate for children who do not yet know the alphabet but who can follow instructions to indicate the direction that the arms of the “E” are pointing. (B) A picture chart similar to the Allen object recognition chart is appropriate for vision screening in the preschool-age child. (C) The Snellen eye chart may be used for children age 6 or older who know the alphabet. The test can be obtained at www.preventblindness.org/children or by calling 1-800-331-2020.

| TABLE 9.4 VISION SCREENING TOOLS | | |
|--|------------|--|
| Screening Tool | Age | Nursing Implications |
| Snellen letters or numbers | School-age | The child must know his or her letters or numbers for the test to be valid. |
| “Tumbling E” | Preschool | The child points in the direction that the “E” is facing. |
| LEA symbols or Allen figures | Preschool | The child should first identify the pictures with both eyes at a comfortable distance prior to monocular testing to ensure validity of the test. |
| Ishihara | School-age | Screens for color discrimination (numbers composed of dots, hidden within other dots) |
| Color Vision Testing Made Easy (CVTME) | Preschool | Uses dot pictures like the Ishihara, but instead of numbers has easily identified shapes imbedded in the dots |

- Place a mark on the floor 10 to 20 feet from the chart (distance depends on what the tool is calibrated for).
- Align the child's heels on the mark.
- Have the child read each line with one eye covered and then with the other eye covered. Explain to the child to keep the eye covered but open (Fig. 9.4).
- Have the child read each line with both eyes.

In addition to visual acuity screening, children should also be screened for color discrimination. Any child with eye abnormalities or who has failed visual screening needs to be evaluated by a specialist appropriately trained to treat children.

IRON-DEFICIENCY ANEMIA SCREENING

Iron deficiency is the leading nutritional deficiency in the United States (CDC, 2011a). Iron deficiency can cause cognitive and motor deficits resulting in developmental delays and behavioral disturbances. The increased incidence of iron-deficiency anemia is directly associated with periods of diminished iron stores, rapid growth, and high metabolic demands. At 6 months of age, the in utero iron stores of a full-term infant are almost depleted (Baker, Greer, & The Committee on Nutrition, 2010). The adolescent growth spurt warrants constant iron replacement. Pregnant adolescents are at even higher risk for iron deficiency due to the demands of the mother's growth spurt and the needs of the developing fetus (CDC, 2011a).

FIGURE 9.4 One eye must be covered while the other is tested in order to detect discrepancies in visual acuity between the two eyes and identify amblyopia early.

Guidelines for universal iron-deficiency anemia screening vary. It is important for the nurse to assess for risk factors related to iron-deficiency anemia at each health supervision visit. Refer to [Box 9.4](#) for Bright Future Guidelines and [Box 9.5](#) for risk factors for iron-deficiency anemia.

LEAD SCREENING

Elevated blood lead levels (10 mcg/dL or higher) remain a preventable environmental health threat. Approximately 25% of children live in housing with lead-based paint, therefore leading to a risk of lead exposure and resulting cognitive impairments (American Academy of Pediatrics, 2009). Although the prevalence of elevated lead levels has declined significantly over the past two decades, certain communities still possess a high level of lead exposure. A shift to targeted screening has occurred, with criteria continuing to develop. In the past, 80% of children on Medicaid were found to have an increased blood lead concentration (American Academy of Pediatrics, 2009). Therefore, screening of all children eligible for Medicaid was recommended and even required by federal Medicaid. Recent research has shown that blood lead levels have decreased in certain enrolled Medicaid children and in response the CDC Advisory Committee on Childhood Lead Poisoning Prevention is updating their recommendations to targeted screenings of specific groups of children that state and local officials deem to be living in areas of higher risk (Wengrovitz & Brown, 2009). Until these recommendations are finalized, the CDC and AAP continue to support universal screening of Medicaid-eligible children (American Academy of Pediatrics, 2009).

BOX 9.4

GUIDELINES FOR IRON-DEFICIENCY ANEMIA SCREENING

Universal Screening

- Screen all full-term infants at 9-12 months.

Selective Screening

- 4 months: Screen children with risk factors of prematurity, with low birthweight, on low-iron formula or not receiving iron-fortified formula or foods, and with early introduction of cow's milk.
- 18 months and annually beginning at 2 years: Screen children with special health needs that put them at risk for iron-deficiency anemia, on low-iron diets such as nonmeat, with environmental factors such as poverty, and with limited access to food.
- 6-10 years: Screen children on a strict vegetarian diet and not receiving iron supplementation.
- 11-21 years: Screen all nonpregnant females every 5 to 10 years throughout childbearing years at routine health care visits. Annually screen females with risk factors such as extensive menstrual flow, low iron intake, or previous diagnosis of iron-deficiency anemia.

Adapted from Hagan, J. F., Shaw, J. S., & Duncan, P. M. (Eds.). (2008). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (3rd ed., rev.). Elk Grove Village, IL: American Academy of Pediatrics. Retrieved August 23, 2009, from http://brightfutures.aap.org/pdfs/Guidelines_PDF/13-Rationale_and_Evidence.pdf

For children not eligible for Medicaid some states have developed targeted screening based on risk assessment by the CDC or their own data (American Academy of Pediatrics, 2009). Targeted screening is recommended at 9 to 12 months with a repeat screening at 24 months (Hagan et al., 2008). For children who live in areas where health authorities have not made clear recommendations on risk, screening guidelines are less clear and therefore universal screening is currently recommended. Refer to Healthy People 2020.

HEALTHY PEOPLE 2020

Objective

Eliminate elevated blood lead levels in children.

Nursing Significance

- Screen for lead exposure.
- Ensure that high-risk children have blood lead levels measured.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

BOX 9.5

RISK FACTORS FOR IRON-DEFICIENCY ANEMIA

- Periods of rapid growth
- Low-birthweight or preterm infants
- Low dietary intake of meat, fish, poultry, and ascorbic acid
- Macrobiotic diets
- Inappropriate consumption of cow's milk
- Use of infant formula not fortified with iron
- Exclusive breastfeeding after age 4 months without iron-fortified supplemental foods
- Meal skipping, frequent dieting
- Exposure to lead
- Feeding problems
- Pregnancy or recent pregnancy Intensive physical training
- Recent blood loss, heavy/lengthy menstrual periods
- Chronic use of aspirin or nonsteroidal antiinflammatory drugs
- Parasitic infections

Children at High Risk for Iron-Deficiency Anemia

- Low-income families
- Those eligible for the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC)
- Migrants or recently arrived refugees

Adapted from Baker, R. D., Greer, F. R., & The Committee on Nutrition. (2010). Clinical report. Diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants and young children (0-3 years of age). *Pediatrics*, 126(5), 1040-1050. Retrieved April 13, 2011, from

Take Note!

Many cases of elevated blood lead levels have been reported in children who are recent immigrants, refugees, or international adoptees. The CDC recommends blood lead testing for these children upon entering the United States and a repeat test 3 to 6 months after placement in a permanent residence (American Academy of Pediatrics, 2009).

HYPERTENSION SCREENING

Obesity and resulting hypertension have been on the rise in children and can lead to adult cardiovascular disease. Universal hypertension screening for children beginning at 3 years of age is recommended (Hagan et al., 2008). If the child has risk factors for systemic hypertension, such as preterm birth, very low birth-weight, renal disease, organ transplant, congenital heart disease, or other illnesses associated with hypertension, then screening begins when the risk factor becomes apparent (Hagan et al., 2008).

BOX 9.6

PREADOLESCENT CHILDHOOD HYPERTENSION GUIDELINES

Optimal/normal <90th percentile for sex, age, and height

High normal >90th but <95th percentile for sex, age, and height

Prehypertension BP at or above 120/80 mm Hg but <95th percentile for sex, age, and height

Hypertension >95th percentile for sex, age, and height on three separate occasions

Adapted from National Heart, Lung, and Blood Institute. (2005). *The fourth report on the diagnosis, evaluation and treatment of high blood pressure in children and adolescents* (NIH Publication No. 05-5267). Washington, DC: U.S. Department of Health and Human Services. Retrieved April 17, 2011, from http://www.nhlbi.nih.gov/health/prof/heart/hbp/hbp_ped.pdf

The guidelines for determining hypertension in children and adolescents utilize body size in order to be more precise. Gender and age are used to determine specific systolic and diastolic blood pressure percentiles. Refer to [Appendix C](#) for Blood Pressure Charts for Children and Adolescents. Auscultation is the preferred method of measuring blood pressure in children, and an elevated blood pressure must be confirmed on repeated visits before a diagnosis of hypertension is given. Refer to [Box 9.6](#) for hypertension guidelines. Anticipatory guidance on diet and lifestyle changes is appropriate for any child with prehypertension (National Heart, Lung, and Blood Institute, 2005). Refer to [Chapter 19](#) for additional information on hypertension.

HYPERLIPIDEMIA SCREENING

Atherosclerosis has been documented in children, and a link exists between high lipid levels and the development of these lesions. Bright Futures Guidelines recommend universal screening for dyslipidemia once in late adolescence (Hagan et al., 2008). Selectively screening children at high risk for hyperlipidemia can reduce their lifelong risk of coronary artery disease.

The risk assessment focuses on the child's family history. Refer to [Box 9.7](#) for details regarding screening for hyperlipidemia.

Remember Maya and Evan, the children introduced at the beginning of the chapter? How would you assess their growth and development? Which screening tests are warranted for them, and why? What further information would you need to determine which tests should be performed?

BOX 9.7

HYPERLIPIDEMIA SCREENING

Screen if parents or grandparents, at <55 years of age, have/had documented:

- Coronary atherosclerosis
- Myocardial infarction
- Angina pectoris
- Peripheral vascular disease
- Cerebrovascular disease

- Sudden cardiac death

Screen if a parent's blood cholesterol level is 240 mg/dL or higher.

Screen at physician's discretion:

- Parental history is unobtainable.
- Child has diabetes or hypertension.
- Child has lifestyle risk factors:
 - Cigarette smoking
 - Obesity
 - Sedentary lifestyle
 - High-fat dietary intake

Adapted from Hagan, J. F., Shaw, J. S., & Duncan, P. M. (Eds.). (2008). *Bright futures: Guidelines for health supervision of infants, children, and adolescents* (3rd ed., rev.). Elk Grove Village, IL: American Academy of Pediatrics. Retrieved April 17, 2011, from http://brightfutures.aap.org/pdfs/Guidelines_PDF/13-Rationale_and_Evidence.pdf

Immunizations

Immunization is the key disease prevention activity during childhood health supervision visits. The development of effective vaccines, beginning in the 1940s, revolutionized children's health care. Immunization allowed the focus to shift from disease treatment to disease prevention. The nurse needs to understand the principles of immunizations, the proper use of vaccines, and barriers to immunization. Armed with this knowledge, the nurse can partner with families to provide the highest level of disease protection to children (Fig. 9.5). Refer to Healthy People 2020.

HEALTHY PEOPLE 2020

Objective

Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children.

Nursing Significance

- Immunize at every opportunity. If a child is due or past due for vaccinations, provide them at a sick visit if not contraindicated.
- Educate families about the benefits and risks of immunization.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

FIGURE 9.5 Nurse administering intramuscular injection into the vastus lateralis of an infant.

PRINCIPLES OF IMMUNIZATION

The immune system has the ability to recognize materials present in the body as “self” or “non-self.” Foreign materials (non-self) are called antigens. When an antigen is recognized by the immune system, the immune system responds by producing antibodies (immunoglobulins) or directing special cells to destroy and remove the antigen.

Immunity is the ability to destroy and remove a specific antigen from the body. The acquisition of immunity can be active or passive. **Passive immunity** is produced when the immunoglobulins of one person are transferred to another. This immunity lasts only weeks or months. Passive immunity can be obtained by injection of exogenous immunoglobulins. It can also be transferred from mothers to infants via colostrum or the placenta. **Active immunity** is acquired when a person’s own immune system generates the immune response. Active immunity lasts for many years or for a lifetime. This long-term protection is the result of immunologic memory. After the initial immune response, specialized cells for that antigen continue to exist. When an antigen returns, these memory cells very rapidly produce a fresh supply of antibodies to reestablish protection. This immunity can occur after exposure to natural pathogens or after exposure to vaccines. Vaccines mimic the characteristics of the natural antigen. The immune system mounts a response and establishes an immunologic memory as it would for an infection.

The classification of vaccines is based on the characteristics of the antigen present. The antigen may be viral or bacterial. It may be live attenuated (weakened) or killed. It may be the whole antigen or a portion of it (fractional).

- Live attenuated vaccines are modified living organisms that are weakened. The organism can produce an immune response but does not produce the complications of the illness.
- Killed vaccines contain whole dead organisms; they are incapable of reproducing but are capable of producing an immune response.
- Toxoid vaccines contain protein products produced by bacteria called toxins. The toxin is heat-treated to weaken its effect, but it retains its ability to produce an immune response.
- Conjugate vaccines are the result of chemically linking the bacterial cell wall polysaccharide (sugar-based) portions with proteins. This dramatically increases the immune response compared to presenting the poly-saccharide portion alone.
- Recombinant vaccines use genetically engineered organisms. For example, the hepatitis B vaccine is produced by splicing a gene portion of the virus into a gene of a yeast cell. The yeast cell is then able to produce hepatitis B surface antigen to use for vaccine production.

The safety and efficacy of existing vaccines are constantly being reviewed, and research to improve vaccines is ongoing. The goal is to refine vaccines so that a maximum immune response is produced with the least amount of risk for the child.

IMMUNIZATION MANAGEMENT

The Advisory Committee on Immunization Practices (ACIP), a branch of the CDC, reviews the recommended immunization schedules at least yearly and updates the schedule to ensure that it reflects current best practices (Tables 9.5 and 9.6). In addition to the recommended schedule, the ACIP publishes a “catch-up” schedule for children who have not been adequately immunized (Table 9.7). The child’s immunization record must be compared with the latest edition of these schedules when assessing the need for immunization.

When obtaining an immunization history from the parent, ask, “When and where did your child receive his (or her) last immunization?” The answer will provide more information than simply asking, “Are your child’s immunizations up to date?” The nurse can compare this information with that on the immunization record, discover in what settings the child is getting health care, and use the information as a starting point in a discussion of any reactions to previous immunizations.

TABLE 9.5 RECOMMENDED IMMUNIZATION SCHEDULE FOR PERSONS AGED 0–6 YEARS—UNITED STATES, 2011

For those who fall behind or start late, see the catch-up schedule

| Vaccine ▼ | Age ► | Birth | 1 month | 2 months | 4 months | 6 months | 12 months | 15 months | 18 months | 19–23 months | 2–3 years | 4–6 years |
|---|--------------------|-------|---------|----------|------------------|---------------------------|----------------|-----------|----------------------------|--------------|-----------|-------------|
| Hepatitis B ¹ | HepB | HepB | HepB | | | | HepB | | | | | |
| Rotavirus ² | RV | | RV | RV | RV ³ | | | | | | | |
| Diphtheria, tetanus, Pertussis ⁴ | DTaP | | DTaP | DTaP | DTaP | see footnote ⁵ | DTaP | | | | | DTaP |
| Haemophilus influenzae type b ⁴ | Hib | | Hib | Hib | Hib ⁴ | | Hib | | | | | |
| Pneumococcal ⁶ | PCV | | PCV | PCV | PCV | | PCV | | | | PPSV | |
| Inactivated Poliovirus ⁷ | IPV | | IPV | IPV | IPV | | IPV | | | | | IPV |
| Influenza ⁸ | Influenza (Yearly) | | | | | | | | | | | |
| Measles, mumps, Rubella ⁹ | MMR | | | | | | MMR | | see footnote ¹⁰ | | | MMR |
| Varicella ⁹ | Varicella | | | | | | Varicella | | see footnote ¹¹ | | | Varicella |
| Hepatitis A ¹² | HepA (2 doses) | | | | | | HepA (2 doses) | | | | | HepA Series |
| Meningococcal ¹³ | MCV4 | | | | | | | | | | | MCV4 |

This schedule includes recommendations in effect as of December 21, 2010. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Considerations should include provider assessment, patient preference, and the potential for adverse events. Providers should consult the relevant Advisory Committee on Immunization Practices statement for detailed recommendations: <http://www.cdc.gov/vaccines/imz/updates.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS) at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967. Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services.

- Hepatitis B vaccine (HepB)**, (Minimum age: birth)
 - Administer monovalent HepB to all newborns before hospital discharge.
 - If mother is hepatitis B surface antigen (HBsAg)-positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
 - If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if HBsAg-positive, administer HBIG (no later than age 1 week).
 - Doses following the birth dose:**
 - The second dose should be administered at age 1 or 2 months. Monovalent HepB should be used for doses administered before age 6 weeks.
 - Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg 1 to 2 months after completion of at least 3 doses of the HepB series, at age 9 through 18 months (generally at the next well-child visit).
 - Administration of 4 doses of HepB to infants is permissible when a combination vaccine containing HepB is administered after the birth dose.
 - Infants who did not receive a birth dose should receive 3 doses of HepB on a schedule of 0, 1, and 6 months.
 - The final (3rd or 4th) dose in the HepB series should be administered no earlier than age 24 weeks.
- Rotavirus vaccine (RV)**, (Minimum age: 6 weeks)
 - Administer the first dose at age 6 through 14 weeks (maximum age: 14 weeks 6 days). Vaccination should not be initiated for infants aged 15 weeks 0 days or older.
 - The maximum age for the final dose in the series is 8 months 0 days.
 - If Rotarix is administered at ages 2 and 4 months, a dose at 6 months is not indicated.
- Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP)**, (Minimum age: 6 weeks)
 - The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.
- Haemophilus influenzae type b conjugate vaccine (Hib)**, (Minimum age: 6 weeks)
 - If PRP-OMP (PedvaxHB or Comvax [HepB-Hib]) is administered at ages 2 and 4 months, a dose at age 6 months is not indicated.
 - Hibrix should be used for doses at ages 2, 4, or 6 months for the primary series but can be used as the final dose in children aged 12 months through 4 years.
- Pneumococcal vaccine**, (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPSV])
 - PCV is recommended for all children aged younger than 5 years. Administer 1 dose of PCV to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
 - A PCV series begun with 7-valent PCV (PCV7) should be completed with 13-valent PCV (PCV13).
 - A single supplemental dose of PCV13 is recommended for all children aged 14 through 59 months who have received an age-appropriate series of PCV2.
 - A single supplemental dose of PCV13 is recommended for all children aged 60 through 71 months with underlying medical conditions who have received an age-appropriate series of PCV2.
- The supplemental dose of PCV13 should be administered at least 8 weeks after the previous dose of PCV2.** See MMWR 2010;59(No. RR-11).
- Administer PPSV at least 8 weeks after last dose of PCV to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant.**
- Inactivated poliovirus vaccine (IPV)**, (Minimum age: 6 weeks)
 - If 4 or more doses are administered prior to age 4 years an additional dose should be administered at age 4 through 6 years.
 - The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
- Influenza vaccine (seasonal)**, (Minimum age: 6 months for inactivated influenza vaccine [IIV]; 2 years for live, attenuated influenza vaccine [LAIV])
 - For healthy children aged 2 years and older (i.e., those who do not have underlying medical conditions that predispose them to influenza complications), either LAIV or IIV may be used, except LAIV should not be given to children aged 2 through 4 years who have had wheezing in the past 12 months.
 - Administer 2 doses (separated by at least 4 weeks) to children aged 6 months through 8 years who are receiving seasonal influenza vaccine for the first time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.
 - Children aged 6 months through 8 years who received no doses of monovalent 2009 H1N1 vaccine should receive 2 doses of 2010–2011 seasonal influenza vaccine. See MMWR 2010;59(No. RR-8): 33–34.
- Measles, mumps, and rubella vaccine (MMR)**, (Minimum age: 12 months)
 - The second dose may be administered before age 4 years, provided at least 4 weeks have elapsed since the first dose.
- Varicella vaccine**, (Minimum age: 12 months)
 - The second dose may be administered before age 4 years, provided at least 3 months have elapsed since the first dose.
 - For children aged 12 months through 12 years the recommended minimum interval between doses is 3 months. However, if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
- Hepatitis A vaccine (HepA)**, (Minimum age: 12 months)
 - Administer 2 doses at least 6 months apart.
 - HepA is recommended for children aged older than 23 months who live in areas where vaccination programs target older children, who are at increased risk for infection, or for whom immunity against hepatitis A is desired.
- Meningococcal conjugate vaccine, quadrivalent (MCV4)**, (Minimum age: 2 years)
 - Administer 2 doses of MCV4 at least 8 weeks apart to children aged 2 through 10 years with persistent complement component deficiency and anatomic or functional asplenia, and 1 dose every 5 years thereafter.
 - Persons with human immunodeficiency virus (HIV) infection who are vaccinated with MCV4 should receive 2 doses at least 8 weeks apart.
 - Administer 1 dose of MCV4 to children aged 2 through 10 years who travel to countries with highly endemic or epidemic disease and during outbreaks caused by a vaccine serogroup.
 - Administer MCV4 to children at continued risk for meningococcal disease who were previously vaccinated with MCV4 or meningococcal polysaccharide vaccine after 3 years if the first dose was administered at age 2 through 6 years.

The Recommended Immunization Schedules for Persons Aged 0 Through 18 Years are approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/vaccines/imz/acip/>), the American Academy of Pediatrics (<http://www.aap.org/>), and the American Academy of Family Physicians (<http://www.aafp.org/>).
Department of Health and Human Services • Centers for Disease Control and Prevention

For those who fall behind or start late, see the schedule below and the catch-up schedule

| Vaccine ▼ | Age ► | 7–10 years | 11–12 years | 13–18 years | |
|---|---------------------------|------------|------------------------|-------------|--|
| Tetanus, Diphtheria, Pertussis ¹ | | | Tdap | Tdap | Range of recommended ages for all children |
| Human Papillomavirus ² | see footnote ¹ | | HPV (3 doses)(females) | HPV Series | |
| Meningococcal ³ | | MCV4 | MCV4 | MCV4 | Range of recommended ages for catch-up immunization |
| Influenza ⁴ | | | Influenza (Yearly) | | |
| Pneumococcal ⁵ | | | Pneumococcal | | Range of recommended ages for certain high-risk groups |
| Hepatitis A ⁶ | | | HepA Series | | |
| Hepatitis B ⁷ | | | Hep B Series | | |
| Inactivated Poliovirus ⁸ | | | IPV Series | | |
| Measles, Mumps, Rubella ⁹ | | | MMR Series | | |
| Varicella ¹⁰ | | | Varicella Series | | |

This schedule includes recommendations in effect as of December 21, 2010. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Considerations should include provider assessment, patient preference, and the potential for adverse events. Providers should consult the relevant Advisory Committee on Immunization Practices statement for detailed recommendations: <http://www.cdc.gov/vaccines/pubs/acip-list.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS) at <http://www.vaers.hhs.gov> or by telephone, 800-822-7962.

1. Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).

- (Minimum age: 10 years for Boostrix and 11 years for Adacel)
- Persons aged 11 through 18 years who have not received Tdap should receive a dose followed by Td booster doses every 10 years thereafter.
- Persons aged 7 through 10 years who are not fully immunized against pertussis (including those never vaccinated or with unknown pertussis vaccination status) should receive a single dose of Tdap. Refer to the catch-up schedule if additional doses of tetanus and diphtheria toxoid-containing vaccine are needed.
- Tdap can be administered regardless of the interval since the last tetanus and diphtheria toxoid-containing vaccine.

2. Human papillomavirus vaccine (HPV).

- (Minimum age: 9 years)
- Quadrivalent HPV vaccine (HPV4) or bivalent HPV vaccine (HPV2) is recommended for the prevention of cervical precancers and cancers in females.
- HPV4 is recommended for prevention of cervical precancers, cancers, and genital warts in females.
- HPV4 may be administered in a 3-dose series to males aged 9 through 18 years to reduce their likelihood of genital warts.
- Administer the second dose 1 to 2 months after the first dose and the third dose 6 months after the first dose (at least 24 weeks after the first dose).

3. Meningococcal conjugate vaccine, quadrivalent (MCV4).

- (Minimum age: 2 years)
- Administer MCV4 at age 11 through 12 years with a booster dose at age 16 years.
- Administer 1 dose at age 13 through 15 years if not previously vaccinated.
- Persons who received their first dose at age 13 through 15 years should receive a booster dose at age 16 through 18 years.
- Administer 1 dose to previously unvaccinated college freshmen living in a dormitory.
- Administer 2 doses at least 8 weeks apart to children aged 2 through 10 years with persistent complement component deficiency and anatomic or functional asplenia, and 1 dose every 5 years thereafter.
- Persons with HIV infection who are vaccinated with MCV4 should receive 2 doses at least 8 weeks apart.
- Administer 1 dose of MCV4 to children aged 2 through 10 years who travel to countries with highly endemic or epidemic disease and during outbreaks caused by a vaccine serogroup.
- Administer MCV4 to children at continued risk for meningococcal disease who were previously vaccinated with MCV4 or meningococcal polysaccharide vaccine after 3 years (if first dose administered at age 2 through 6 years) or after 5 years (if first dose administered at age 7 years or older).

4. Influenza vaccine (seasonal).

- For healthy nonpregnant persons aged 7 through 18 years (i.e., those who do not have underlying medical conditions that predispose them to influenza complications), either LAIV or TIV may be used.
- Administer 2 doses (separated by at least 4 weeks) to children aged 6 months through 8 years who are receiving seasonal influenza vaccine for the first

time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.

- Children 6 months through 8 years of age who received no doses of monovalent 2009 H1N1 vaccine should receive 2 doses of 2010–2011 seasonal influenza vaccine. See *MMWR* 2010;58(No. RR-8):33–34.

5. Pneumococcal vaccines.

- A single dose of 13-valent pneumococcal conjugate vaccine (PCV13) may be administered to children aged 6 through 18 years who have functional or anatomic asplenia, HIV infection or other immunocompromising condition, cochlear implant or CSF leak. See *MMWR* 2010;58(No. RR-11).
- The dose of PCV13 should be administered at least 8 weeks after the previous dose of PCV2.
- Administer pneumococcal polysaccharide vaccine at least 8 weeks after the last dose of PCV to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant. A single revaccination should be administered after 5 years to children with functional or anatomic asplenia or an immunocompromising condition.

6. Hepatitis A vaccine (HepA).

- Administer 2 doses at least 6 months apart.
- HepA is recommended for children aged older than 23 months who live in areas where vaccination programs target older children, or who are at increased risk for infection, or for whom immunity against hepatitis A is desired.

7. Hepatitis B vaccine (HepB).

- Administer the 3-dose series to those not previously vaccinated. For those with incomplete vaccination, follow the catch-up schedule.
- A 2-dose series (separated by at least 4 months) of adult formulation Recombivax HB is licensed for children aged 11 through 15 years.

8. Inactivated poliovirus vaccine (IPV).

- The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.

9. Measles, mumps, and rubella vaccine (MMR).

- The minimum interval between the 2 doses of MMR is 4 weeks.

10. Varicella vaccine.

- For persons aged 7 through 18 years without evidence of immunity (see *MMWR* 2007;56(No. RR-1)), administer 2 doses if not previously vaccinated or the second dose if only 1 dose has been administered.
- For persons aged 7 through 12 years, the recommended minimum interval between doses is 3 months. However, if the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
- For persons aged 13 years and older, the minimum interval between doses is 4 weeks.

The Recommended Immunization Schedules for Persons Aged 0 Through 18 Years are approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/vaccines/imz/acip/>), the American Academy of Pediatrics (<http://www.aap.org/>), and the American Academy of Family Physicians (<http://www.aafp.org/>).
Department of Health and Human Services • Centers for Disease Control and Prevention

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

| PERSONS AGED 4 MONTHS THROUGH 6 YEARS | | | | | |
|---|------------------------|---|--|--|-----------------------|
| Vaccine | Minimum Age for Dose 1 | Minimum Interval Between Doses | | | |
| | | Dose 1 to Dose 2 | Dose 2 to Dose 3 | Dose 3 to Dose 4 | Dose 4 to Dose 5 |
| Hepatitis B ^a | Birth | 4 weeks | 8 weeks (and at least 16 weeks after first dose) | | |
| Poliovirus ^b | 6 wks | 4 weeks | 4 weeks ^c | | |
| Diphtheria, Tetanus, Pertussis ^d | 6 wks | 4 weeks | 4 weeks ^e | 6 months | 6 months ^f |
| Haemophilus influenzae type b ^g | 6 wks | 4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose) if first dose administered at age 12–14 months No further doses needed if first dose administered at age 15 months or older | 4 weeks if current age is younger than 12 months 8 weeks (as final dose) ^h if current age is 12 months or older and first dose administered at younger than age 12 months and second dose administered at younger than 15 months No further doses needed if previous dose administered at age 15 months or older | 8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 2 doses before age 12 months | |
| Pneumococcal ⁱ | 6 wks | 4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older if current age 24 through 59 months No further doses needed for healthy children if first dose administered at age 24 months or older | 4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older | 8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 2 doses before age 12 months or for children at high risk who received 2 doses at any age | |
| Inactivated Poliovirus ^b | 6 wks | 4 weeks | 4 weeks | | |
| Measles, Mumps, Rubella ^j | 12 mos | 4 weeks | 4 weeks | | |
| Varicella ^k | 12 mos | 3 months | | | |
| Hepatitis A ^l | 12 mos | 6 months | | | |
| PERSONS AGED 7 THROUGH 18 YEARS | | | | | |
| Tetanus, Diphtheria ^m Tetanus, Diphtheria, Pertussis ⁿ | 7 yrs ^o | 4 weeks | 4 weeks if first dose administered at younger than age 12 months 6 months if first dose administered at 12 months or older | 6 months if first dose administered at younger than age 12 months | |
| Human papillomavirus ^p | 9 yrs | | Routine dosing intervals are recommended (see table) ^q | | |
| Hepatitis A ^l | 12 mos | 6 months | | | |
| Hepatitis B ^a | Birth | 4 weeks | 8 weeks (and at least 16 weeks after first dose) | | |
| Inactivated Poliovirus ^b | 6 wks | 4 weeks | 4 weeks ^c | 6 months ^f | |
| Measles, Mumps, Rubella ^j | 12 mos | 4 weeks | | | |
| Varicella ^k | 12 mos | 3 months | | | |
| Hib ^g | 12 mos | 4 weeks if person is younger than age 13 years 4 weeks if person is aged 13 years or older | | | |

- Hepatitis B vaccine (HepB).**
 - Administer the 3-dose series to those not previously vaccinated.
 - The minimum age for the third dose of HepB is 24 weeks.
 - A 2-dose series (separated by at least 4 months) of adult formulation Recombivax HB is licensed for children aged 11 through 15 years.
- Rotavirus vaccine (RV).**
 - The maximum age for the first dose is 14 weeks 6 days. Vaccination should not be initiated for infants aged 15 weeks 0 days or older.
 - The maximum age for the final dose in the series is 8 months 0 days.
 - If Rotarix was administered for the first and second doses, a third dose is not indicated.
- Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).**
 - The fifth dose is not necessary if the fourth dose was administered at age 4 years or older.
- Haemophilus influenzae type b conjugate vaccine (Hib).**
 - 1 dose of Hib vaccine should be considered for unvaccinated persons aged 5 years or older who have sickle cell disease, leukemia, or HIV infection, or who have had a splenectomy.
 - If the first 2 doses were PRIPOMP (PediVaxIM or Comvax), and administered at age 11 months or younger, the third (and final) dose should be administered at age 12 through 15 months and at least 8 weeks after the second dose.
 - If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a final dose at age 12 through 15 months.
- Pneumococcal vaccine.**
 - Administer 1 dose of 13-valent pneumococcal conjugate vaccine (PCV13) to all healthy children aged 24 through 59 months with any incomplete PCV schedule (PCV7 or PCV13).
 - For children aged 24 through 71 months with underlying medical conditions, administer 1 dose of PCV13 if 3 doses of PCV were received previously or administer 2 doses of PCV13 at least 8 weeks apart if fewer than 3 doses of PCV were received previously.
 - A single dose of PCV13 is recommended for certain children with underlying medical conditions through 18 years of age. See age-specific schedules for details.
 - Administer pneumococcal polysaccharide vaccine (PPSV23) to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant, at least 8 weeks after the last dose of PCV. A single revaccination should be administered after 5 years to children with functional or anatomic asplenia or an immunocompromising condition. See MMWR 2010;58(No. RR-11).
- Inactivated poliovirus vaccine (IPV).**
 - The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
 - A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months following the previous dose.
 - In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk for imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).
- Measles, mumps, and rubella vaccine (MMR).**
 - Administer the second dose routinely at age 4 through 6 years. The minimum interval between the 2 doses of MMR is 4 weeks.
- Varicella vaccine.**
 - Administer the second dose routinely at age 4 through 6 years.
 - If the second dose was administered at least 4 weeks after the first dose, it can be accepted as valid.
- Hepatitis A vaccine (HepA).**
 - HepA is recommended for children aged older than age 23 months who live in areas where vaccination programs target older children, or who are at increased risk for infection, or for whom immunity against hepatitis A is desired.
- Tetanus and diphtheria toxoids (Td) and tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).**
 - Doses of DTaP are counted as part of the Td/Tdap series.
 - Tdap should be substituted for a single dose of Td in the catch-up series for children aged 7 through 10 years or as a booster for children aged 11 through 18 years; use Td for other doses.
- Human papillomavirus vaccine (HPV).**
 - Administer the series to females at age 13 through 18 years if not previously vaccinated or have not completed the vaccine series.
 - Quadrivalent HPV vaccine (HPV4) may be administered in a 3-dose series to males aged 9 through 18 years to reduce their likelihood of genital warts.
 - Use recommended routine dosing intervals for series catch-up (i.e., the second and third doses should be administered at 1 to 2 and 6 months after the first dose). The minimum interval between the first and second doses is 4 weeks. The minimum interval between the second and third doses is 12 weeks, and the third dose should be administered at least 24 weeks after the first dose.

Information about reporting reactions after immunization is available online at <http://www.vaers.hhs.gov> or by telephone, 800-432-7887. Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for immunization, is available from the National Center for Immunization and Respiratory Diseases at <http://www.cdc.gov/vaccines> or telephone, 800-CDC-INFO (800-232-4636).

Vaccine storage and administration affect the efficacy of a vaccine. Improperly stored or reconstituted vaccines can be ineffective (CDC, 2011c). The vaccine must be given by the correct route; not all vaccines are given intramuscularly (Box 9.8, Table 9.8). The manufacturer’s package insert is the best reference source for any vaccine.

Take Note!

Proper vaccine storage is critical to vaccine efficacy. If you suspect that a vaccine was not maintained at the proper storage temperature, do not use it! An ineffective vaccine is of no use in preventing disease.

The National Childhood Vaccine Injury Act (NCVIA) requires that Vaccine Information Statements (VISs; Fig. 9.6) be provided to parents before an immunization is given (CDC, 2010b). In accordance with the concept of partnership with the parents, allow ample time for them to read the VIS and to discuss their concerns. If the parents do not understand the information presented, they should feel comfortable asking questions. If the parents are illiterate, present the information orally and verify that the parents understand it. If the information in the VIS is not in the parent’s native language, have a translator present the information.

At this time, ask the parents about the child’s reactions to previous immunizations, and screen for precautions and contraindications for each vaccine to be administered. Before the vaccine is given, the parents must sign consent forms.

Any clinically significant adverse event that occurs after an immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS), which is a cosponsored surveillance program by the CDC and the U.S. Food and Drug Administration (FDA) (Vaccine Adverse Event Reporting System, n.d.). For assistance in obtaining and completing a VAERS form, call 800-822-7967 or visit www.vaers.hhs.gov.

Documentation in the child’s permanent record includes the following:

- Date the vaccine was administered
- Name of vaccine (commonly used abbreviation is acceptable)

DIPHTHERIA TETANUS & PERTUSSIS VACCINES

WHAT YOU NEED TO KNOW

1 Why get vaccinated?

Diphtheria, tetanus, and pertussis are serious diseases caused by bacteria. Diphtheria and pertussis are spread from person to person. Tetanus enters the body through cuts or wounds.

DIPHTHERIA causes a thick covering in the back of the throat.

- It can lead to breathing problems, paralysis, heart failure, and even death.

TETANUS (Lockjaw) causes painful tightening of the muscles, usually all over the body.

- It can lead to "locking" of the jaw so the victim cannot open his mouth or swallow. Tetanus leads to death in about 1 out of 10 cases.

PERTUSSIS (Whooping Cough) causes coughing spells so bad that is hard for infants to eat, drink, or breathe. These spells can last for weeks.

- It can lead to pneumonia, seizures (jerking and staring spells), brain damage, and death.

Diphtheria, tetanus, and pertussis vaccine (DTaP) can help prevent these diseases. Most children who are vaccinated with DTaP will be protected throughout childhood. Many more children would get these diseases if we stopped vaccinating.

DTaP is a safer version of an older vaccine called DTP. DTP is no longer used in the United States.

2 Who should get DTaP vaccine and when?

Children should get 5 doses of DTaP vaccine, one dose at each of the following ages:

- ✓ 2 months
- ✓ 4 months
- ✓ 6 months
- ✓ 15-18 months
- ✓ 4-6 years

DTaP may be given at the same time as other vaccines.

3 Some children should not get DTaP vaccine or should wait.

- Children with minor illnesses, such as a cold, may be vaccinated. But children who are moderately or severely ill should usually wait until they recover before getting DTaP vaccine.
- Any child who had a life-threatening allergic reaction after a dose of DTaP should not get another dose.
- Any child who suffered a brain or nervous system disease within 7 days after a dose of DTaP should not get another dose.
- Talk with your doctor if your child:
 - had a seizure or collapsed after a dose of DTaP,
 - cried non-stop for 3 hours or more after a dose of DTaP,
 - had a fever over 105°F after a dose of DTaP.

Ask your health care provider for more information. Some of these children should not get another dose of pertussis vaccine, but may get a vaccine without pertussis, called **DT**.

4 Older children and adults

DTaP should not be given to anyone 7 years of age or older because pertussis vaccine is only licensed for children under 7.

But older children, adolescents, and adults still need protection from tetanus and diphtheria. A booster shot called **Td** is recommended at 11-12 years of age, and then every 10 years. There is a separate Vaccine Information Statement for Td vaccine.

Diphtheria/Tetanus/Pertussis

7/30/2001

5 What are the risks from DTaP vaccine?

Getting diphtheria, tetanus, or pertussis disease is much riskier than getting DTaP vaccine.

However, a vaccine, like any medicine, is capable of causing serious problems, such as severe allergic reactions. The risk of DTaP vaccine causing serious harm, or death, is extremely small.

Mild Problems (Common)

- Fever (up to about 1 child in 4)
- Redness or swelling where the shot was given (up to about 1 child in 4)
- Soreness or tenderness where the shot was given (up to about 1 child in 4)

These problems occur more often after the 4th and 5th doses of the DTaP series than after earlier doses. Sometimes the 4th or 5th dose of DTaP vaccine is followed by swelling of the entire arm or leg in which the shot was given, lasting 1-7 days (up to about 1 child in 30).

Other mild problems include:

- Fussiness (up to about 1 child in 3)
- Tiredness or poor appetite (up to about 1 child in 10)
- Vomiting (up to about 1 child in 50)

These problems generally occur 1-3 days after the shot.

Moderate Problems (Uncommon)

- Seizure (jerking or staring) (about 1 child out of 14,000)
- Non-stop crying, for 3 hours or more (up to about 1 child out of 1,000)
- High fever, over 105°F (about 1 child out of 16,000)

Severe Problems (Very Rare)

- Serious allergic reaction (less than 1 out of a million doses)
- Several other severe problems have been reported after DTaP vaccine. These include:
 - Long-term seizures, coma, or lowered consciousness
 - Permanent brain damage.These are so rare it is hard to tell if they are caused by the vaccine.

Controlling fever is especially important for children who have had seizures, for any reason. It is also important if another family member has had seizures. You can reduce fever and pain by giving your child an *aspirin-free* pain reliever when the shot is given, and for the next 24 hours, following the package instructions.

6 What if there is a moderate or severe reaction?

What should I look for?

Any unusual conditions, such as a serious allergic reaction, high fever or unusual behavior. Serious allergic reactions are extremely rare with any vaccine. If one were to occur, it would most likely be within a few minutes to a few hours after the shot. Signs can include difficulty breathing, hoarseness or wheezing, hives, paleness, weakness, a fast heart beat or dizziness. If a high fever or seizure were to occur, it would usually be within a week after the shot.

What should I do?

- Call a doctor, or get the person to a doctor right away.
- Tell your doctor what happened, the date and time it happened, and when the vaccination was given.
- Ask your doctor, nurse, or health department to report the reaction by filing a Vaccine Adverse Event Reporting System (VAERS) form.

Or you can file this report through the VAERS website at www.vaers.org, or by calling 1-800-822-7967.

VAERS does not provide medical advice.

7 The National Vaccine Injury Compensation Program

In the rare event that you or your child has a serious reaction to a vaccine, a federal program has been created to help pay for the care of those who have been harmed.

For details about the National Vaccine Injury Compensation Program, call 1-800-338-2382 or visit the program's website at www.hrsa.gov/osp/vicp

8 How can I learn more?

- Ask your health care provider. They can give you the vaccine package insert or suggest other sources of information.
- Call your local or state health department's immunization program.
- Contact the Centers for Disease Control and Prevention (CDC):
 - Call 1-800-232-4636 (1-800-CDC-INFO)
 - Visit the National Immunization Program's website at www.cdc.gov/nip

U.S. DEPARTMENT OF HEALTH & HUMAN SERVICES

Vaccine Information Statement
DTaP (7/30/01) 42 U.S.C. § 300aa-26

FIGURE 9.6 Federal law mandates the use of Vaccine Information Statements (VISs). These should be given to the parent or primary caregiver for each vaccine the child receives. (Obtained from Centers for Disease Control and Prevention. [2010]. *Pneumococcal conjugate vaccine: What you need to know*. Retrieved April 19, 2011 at, from <http://www.cdc.gov/vaccines/pubs/vis/downloads/vis-pcv.pdf>)

- Lot number and expiration date of vaccine
- Manufacturer's name
- Site and route by which vaccine was administered (e.g., left deltoid, intramuscularly)
- Edition date of VIS given to the parents
- Name and address of the facility administering the vaccine (where the permanent record will be kept)
- Name of the person administering the immunization

Families should be provided with a copy of the child's immunizations. This reinforces the importance of the procedure and reminds the parents to keep the child's immunizations up to date.

Figure 9.7 shows a typical vaccine administration record.

VACCINE DESCRIPTIONS

This section reviews the most commonly used vaccines. These immunizations are recommended by the ACIP and the AAP. Each state has laws that determine which immunizations are required for school admittance. These requirements can be waived if a contraindication or precaution to the vaccine exists. *Contraindications* are conditions that justify withholding an immunization either permanently or temporarily. The only permanent contraindication to all vaccines is an anaphylactic or systemic allergic reaction to a vaccine component (Kroger, Sumaya, Pickering, & Atkinson, 2011). Children who are severely immunocompromised or women who are pregnant should not receive live vaccines (such as MMR and varicella, see below); with pertussis immunization (DTP, DTaP, or Tdap, see below), encephalopathy without an identified cause within 7 days of the immunization permanently contraindicates

further immunization with pertussis-containing vaccine (Kroger et al., 2011). Temporarily postponing vaccinations is recommended for moderate to severe illness, immunosuppression, pregnancy, or recently received blood products or other antibody-containing products (Kroger et al., 2011). Vaccination should not be postponed because of a minor respiratory illness or a low-grade fever (Kroger et al., 2011). *Precautions* are conditions that increase the risk of an adverse reaction or may impair the child's ability to acquire immunity from the vaccine. On an individualized basis, providers must weigh the benefits of immunization against the likelihood of an adverse event.

DIPHTHERIA, TETANUS, AND PERTUSSIS VACCINES. Immunization against diphtheria, tetanus, and pertussis diseases is given via a combination vaccine. The vaccine currently used for children younger than age 7 is diphtheria, tetanus, acellular pertussis (DTaP). It contains diphtheria and tetanus toxoids and pertussis cell wall proteins. The older version of this vaccine—diphtheria, tetanus, pertussis (DPT)—contained killed whole cells of pertussis bacteria and caused more frequent and severe adverse reactions than DTaP. Diphtheria and tetanus (DT) vaccine is used for children younger than age 7 who have contraindications to pertussis immunization. Full-strength diphtheria toxoid causes significant adverse reactions in people older than age 7 years. For this group, the Tdap adolescent preparation vaccine is used: it contains tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine. The lowercase “d” is used to designate the lower dose of diphtheria toxoid. The ACIP recommends that Tdap be used for all tetanus boosters in older children (11 to 12 years) and adolescents, because Tdap provides a boost to diphtheria and pertussis immunization.

HAEMOPHILUS INFLUENZAE TYPE B VACCINES. *Haemophilus influenzae* type B is a bacterium that causes several life-threatening illnesses in children younger than 5 years of age. These infections include meningitis, epiglottitis, and septic arthritis. *H. influenzae* type B conjugate vaccines (Hib) have been extremely effective in cutting the rates of these diseases in children. There are several different types of Hib conjugate vaccines. HibTITER (HbOC) and ActHib (PRP-T) require three doses for the primary infant series, while Pedvax-HIB and Comvax (PRP-OMP) require two doses. These vaccines are interchangeable, but if different brands are administered to a child, then a total of three doses are necessary to complete the primary series in infants. Hib vaccine is not given to children 5 years of age or older and is contraindicated in children younger than 6 weeks (Kroger et al., 2011).

POLIO VACCINE. Inactivated polio vaccine (IPV) is the only polio vaccine currently recommended in the United States (ACIP, 2000). It is a killed virus vaccine that poses no risk for vaccine-acquired disease. Oral polio vaccine (OPV), a live attenuated virus vaccine, was the preferred polio vaccine until 2000. At that time it became apparent that the only victims of poliomyelitis were people who had acquired it from OPV. The ACIP determined that in this country the risks of OPV outweighed the benefits and withdrew its recommendation of OPV (ACIP, 2000).

MEASLES, MUMPS, AND RUBELLA VACCINES. Measles, mumps, and rubella (MMR) is a live attenuated virus combination vaccine. It is the one most commonly used in childhood immunizations. MMR can be given the same day as other live attenuated virus vaccines such as varicella vaccine. However, if not given on the same day, the immunizations should be spaced at least 28 days apart (Kroger et al., 2011). Anaphylactic reactions are believed to be associated with the neomycin or gelatin components of the vaccine rather than the egg component. The vaccine is not prepared from the allergenic albumen portion of the egg, so egg allergy is no longer a contraindication for measles vaccine (Kroger et al., 2011). Pregnancy in a child's mother is not a contraindication to the vaccination of the child (Kroger et al., 2011). Individual measles, mumps, and rubella vaccines are available if needed.

Vaccine Administration Record for Children and Teens

Patient name: _____
 Birthdate: _____
 Chart number: _____

| Vaccine | Type of Vaccine ¹ (generic abbreviation) | Date given (month/day/yr) | Source (F,S,P) ² | Site ³ | Vaccine | | Vaccine Information Statement | | Signature/ Initials of vaccinator |

HEPATITIS A VACCINE. Hepatitis A vaccine (HepA) is an inactivated whole virus vaccine. Hepatitis A is spread through close physical contact and by eating or drinking contaminated food or water. It is one of the most frequently reported vaccine-preventable diseases in the United States. Young children are particularly susceptible to hepatitis A because of their close contact with other children, inadequate hygiene practices, and tendency to place everything in their mouth. Hepatitis A vaccine is recommended to be given to all children at age 12 months, followed by a repeat dose in 6 to 12 months.

HEPATITIS B VACCINE. Hepatitis B vaccine (HepB) is a recombinant vaccine. For infants, the mother’s HBsAg status determines when immunization for hepatitis B begins. If the mother’s status is positive or unknown, the neonate is immunized within the first 12 hours of life, at 1 to 2 months of age, and at 6 months of age. This is vital, because up to 90% of infected neonates develop chronic carrier status and will be predisposed to cirrhosis and hepatic cancer (CDC, 2010e). If the mother’s status is negative, immunizations are given routinely at 2, 4, and 6 months of age. Because hepatitis B is a sexually transmitted infection, it is important to verify the immunization status of all adolescents.

VARICELLA VACCINE. Varicella vaccine (Var) is a live attenuated virus vaccine. All children age 12 to 15 months who have not had varicella (chickenpox) should be immunized. A second dose is recommended at age 4 to 6 years. The vaccine provides effective postexposure prophylaxis if administered within 3 to 5 days after exposure. Varicella vaccine may be given the same day as other live attenuated virus vaccines. However, if not given on the same day, the immunizations should be spaced at least 28 days apart. Pregnancy in a child’s mother is not a contraindication to the vaccination of the child.

PNEUMOCOCCAL VACCINES. *Streptococcus pneumoniae* (pneumococcus) is the most common cause of pneumonia, sepsis,

meningitis, and otitis media in young children (CDC, 2011d). The two available pneumococcal vaccines are pneumococcal conjugate vaccine (PCV) and pneumococcal polysaccharide vaccine (PPSV). Beginning in 2010, PCV13, which contains 13 strains of *S. pneumoniae*, replaced PCV7, which only contained 7 strains, for use in routine vaccination for children (CDC, 2010d). It stimulates an immune response in infants and is given at 2 months of age as part of the initial immunization series but can be given as early as 6 weeks of age (CDC, 2010d). PPSV contains 23 strains of *S. pneumoniae*. It does not provoke an immune response in children younger than 2 years of age (CDC, 2010d). PPSV is given to children older than 2 years of age who are at high risk for pneumococcal sepsis. This group includes children with anatomic/functional asplenia; sickle cell disease; chronic cardiac, pulmonary, or renal disease; diabetes mellitus; or HIV infection; children getting or who have cochlear implants; and children with immunosuppression (CDC, 2010d).

INFLUENZA VACCINES. Influenza immunization is recommended yearly for healthy and high-risk children 6 months of age or older. Caregivers and household contacts of these children should also be immunized. In 2009-2010, in addition to the seasonal influenza vaccinations, the CDC began recommending vaccination against H1N1 influenza due to the influenza pandemic that was occurring worldwide (American Academy of Pediatrics, 2010). In the 2010-2011 influenza season, one vaccine was recommended, which protects against three strains of influenza, including the 2009 H1N1 (American Academy of Pediatrics, 2010). For children younger than 9 years old who are receiving their first influenza vaccination, who were immunized for the first time last season but did not receive two doses, or who did not receive two doses of the 2009 H1N1 vaccine, the CDC recommends two doses separated by 4 weeks (American Academy of Pediatrics, 2010).

There are two influenza vaccines available, the live attenuated influenza vaccine (LAIV) and the trivalent inactivated influenza vaccine (TIV). LAIV is given intranasally and is indicated for healthy persons between the ages of 2 and 49 years (American Academy of Pediatrics, 2010). The virus in LAIV can replicate, and a person who has received LAIV can shed virus for a week (American Academy of Pediatrics, 2010). LAIV should not be given to anyone who will be in contact with an immunosuppressed person requiring a protected environment. TIV is suitable for any eligible person age 6 months or older. TIV is not capable of causing disease and is given by intramuscular injection (American Academy of Pediatrics, 2010).

ROTAVIRUS VACCINE. Rotavirus is the most common cause of severe gastroenteritis among young children (Cortese & Parashar, 2009). The virus is shed in the stool and easily spreads via the fecal-oral route. Rotavirus accounts for about 30% to 50% of annual hospitalizations for gastroenteritis in children younger than 5 years of age (Cortese & Parashar, 2009). Severe, watery, crampy diarrhea quickly leads to dehydration in the infected child. The most severe disease occurs in children ages 4 to 23 months (Cortese & Parashar, 2009). The rotavirus vaccine is a live vaccine targeting five strains of rotavirus and is given via the oral route to infants younger than 32 weeks of age. Recently, administration of rotavirus vaccine to children with severe combined immunodeficiency (SCID) was contraindicated (Centers for Disease Control and Prevention, 2010f).

HUMAN PAPILLOMAVIRUS VACCINE. Human papillomavirus (HPV) is a DNA tumor virus transmitted through direct skin-to-skin contact. HPV is contracted most often during vaginal or anal penetrative sexual acts. HPV infection is most common in adolescents and young adults aged 15 to 24 years who are sexually active. HPV causes genital warts and is responsible for the development of cervical cancer. For these reasons, the ACIP and AAP have recommended that HPV vaccination occur in preadolescent girls (CDC, 2010g). Two vaccines have been licensed: Cervarix, or HPV2, and Gardasil, or HPV4. The three-vaccine series of either HPV2 or HPV4 is recommended to be given at 11 to 12 years of age but can be given as early as 9 years of age (CDC, 2010g). The vaccine is anticipated to prevent most cases of genital warts and cervical cancer. HPV4 has been licensed for use in males to prevent genital warts. Routine immunization has not been recommended, but it may be offered to adolescent males ages 9 to 26 years of age (CDC, 2010h).

MENINGOCOCCAL VACCINE. Meningococcal disease may manifest as meningitis or as a deadly blood infection (meningococemia). It is caused by the bacterium *Neisseria meningitidis*, which is spread through direct contact or by air droplets. The incidence of meningococcal disease has decreased since 2000 but a peak in cases still is seen around the age of 18 years (CDC, 2011h). About 10% to 14% of infected persons die; of the remaining victims, about 11% to 19% suffer severe long-term consequences (CDC, 2009b). For these reasons, the meningococcal vaccine is recommended for all previously unvaccinated children at age 11 to 12 years with a booster dose at the age of 16 years (CDC, 2011h). These children should receive the meningococcal conjugated vaccine (MCV4). Certain high-risk groups may be vaccinated at 2 years of age (through age 10) with the meningococcal polysaccharide vaccine (MPSV4).

Recall the Randall children, introduced at the beginning of the chapter. What immunizations would be appropriate for them to receive? Explain how you would administer the injections, and discuss any contraindications or precautions.

BARRIERS TO IMMUNIZATION

A fully immunized child is protected from the discomforts and complications of many infectious diseases. Disease prevention spares the family the emotional and financial burdens that serious illnesses can cause. Immunization programs prevent devastating epidemics in a community. Health care dollars not spent treating preventable diseases can be used for other urgent issues. Despite the numerous advantages of immunization and improved immunization rates, some communities in this country continue to have high numbers of undervaccinated or unvaccinated children (CDC Online Newsroom, 2010).

Many factors lead to children not being fully immunized. Parental concerns about vaccine safety are a significant cause of inadequate immunization (CDC Online Newsroom, 2010). See Evidenced-Based Practice 9.1. Misconceptions of what constitutes a contraindication to vaccination and having more than one physician are major contributors to inadequate immunization status. The more children in a family, the less likely the children are to be fully vaccinated. The costs for vaccines can also deter families from obtaining immunizations. Parents may want to postpone some of the scheduled immunizations because they are concerned about the effects of multiple injections on their child. Postponing a portion of the immunizations puts the child at risk for contracting disease. Disrupting the optimal spacing of the immunizations can decrease the efficacy of vaccine, further putting the child at risk.

OVERCOMING BARRIERS TO IMMUNIZATION

The AAP recommends the use of a manufacturer-produced combination vaccine whenever it will reduce the number of injections at a visit (Freed, Cowan, Clark, Santoli, & Bradley, 2006). These combination vaccines have been studied and approved by the FDA. The nurse should never mix separate vaccines in the same syringe unless expressly permitted in the product insert for all vaccines involved. Examples of combination vaccines are:

- MMR: measles, mumps, rubella
- Comvax: HepB-Hib
- Pediarix: DTaP-Hep B-IPV
- Pentacel: DTaP-IPV/Hib

The Vaccines for Children (VFC) program was implemented in 1994 (Ching, 2007). Prior to this program, free vaccines were available only through public health agencies. By providing free vaccines to low-income and uninsured families through their private physicians, immunization rates have improved (Ching, 2007). Additional information on the VFC program is available at <http://www.cdc.gov/vaccines/programs/vfc/>.

Establishing a medical home for every child will alleviate many of the factors associated with lack of immunization. Parents who have a long-term, trusting relationship with a physician are more likely to have their concerns about vaccine safety discussed and removed. Missed opportunities for immunizations can be reduced by:

EVIDENCE-BASED PRACTICE 9.1

WHICH INTRAMUSCULAR VACCINATION TECHNIQUE RESULTS IN THE FEWEST ADVERSE REACTIONS IN CHILDREN?

STUDY

The incidence of vaccine-preventable diseases is decreasing, yet concern remains about adverse reactions following intramuscular immunizations. Also, inconsistencies in recommendations and practice exist. This study conducted a literature review of clinical trials and studies on intramuscular vaccine administration technique primarily in the pediatric population. Databases searched included the Cochrane Database of Systematic Review, Medline, and Embase. Prior to 2002, there are almost no published studies investigating the best technique for administering intramuscular injections, which has led to the wide variation in recommendations and techniques.

Findings

Existing evidence supports fewer reactions noted when the buttock versus the thigh is used as the site of injection and fewer reactions when the vaccine is administered intramuscularly versus subcutaneously. Longer needles and a 90-degree angle are associated with fewer reactions. Existing research did not provide evidence to support reactogenicity for aspiration, speed of injection, age/size of vaccine, experience of nurse, and pain on injection.

Nursing Implications

Parents often have concerns about adverse reactions associated with immunization. Current recommendations and techniques vary greatly internationally. Existing research supports the use of longer needles and a 90-degree angle, which is the technique supported by the World Health Organization. This technique decreases the potential of administering an intramuscular injection into the subcutaneous tissue along with decreasing the incidence of adverse reactions. The amount of muscle varies with the size of the infant and toddler, so the nurse must ensure that the needle chosen is long enough to place the medication intramuscularly. When appropriate, the buttocks as a site of injection needs to be considered.

Adapted from Perousis-Harris, H. (2008). Vaccine injection technique and reactogenicity-Evidence for practice. *Vaccine*, 26(50), 6299-6304.

- Maintaining a centralized immunization record
- Verifying immunization status at every visit, not just health supervision visits
- Verifying the status of siblings accompanying the child to the appointment
- Providing parents with up-to-date information on vaccines geared to their concerns and needs

Two excellent resources for vaccination recommendations in the United States are the CDC's Vaccines and Immunizations website (<http://www.cdc.gov/vaccines/default.htm>) and the CDC Hotline (800-232-4636 or 800-CDC-INFO).

Discuss potential barriers to the Randall children being fully immunized. As a nurse, how can you help overcome these barriers?

Health Promotion

Health promotion focuses on maintaining or enhancing the physical and mental health of children. The principal components of health promotion are identifying risk factors for a disease, facilitating lifestyle changes to eliminate or reduce those risk factors, and empowering children at the individual and community level to develop resources to optimize their health. The nurse implements health promotion through education and anticipatory guidance.

Partnership development is the key strategy for success when implementing a health promotion activity. Identifying key stakeholders from the community allows problems to be solved and provides additional venues for disseminating information. Health promotion messages can be reinforced at schools, day care centers, community agencies, and churches. If families have difficulty getting to health care facilities, the community arenas may be the primary source of health promotion.

Providing Anticipatory Guidance

Anticipatory guidance is primary prevention. The nurse partners with the parents to create a "road map" to optimal health for the child. Healthy People 2020 provides a framework for determining health promotion goals. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* (Hagan et al., 2008) is another valuable resource.

The "skeleton" of the guidance provided involves common childhood health problems. The nurse fleshes out that information using the results of risk assessments and screening tests, health concerns unique to the child, and the interests and concerns of the parents. Age-related anticipatory guidance information is provided in [Chapters 3](#) through [7](#).

Provide appropriate anticipatory guidance for 3-year-old Maya and 9-month-old Evan.

Promoting Oral Health Care

Effective oral health practices are essential to the overall health of children and adolescents. Dental caries are the most common chronic illness seen in children, and 19.5% of children ages 2 to 5 years and about 23% of children ages 6 to 19 years have untreated dental caries (CDC, 2011i; Hagan et al., 2008; The Kaiser Commission on Medicaid and the Uninsured, 2008). Poor oral health can have significant negative effects on systemic health. Children who suffer from untreated dental caries have an increased incidence of pain and infections and may have problems with eating and playing, difficulty at school, and sleep pattern disturbances (CDC, 2011i). Refer to Healthy People 2020.

| Objective | Nursing Significance |
|---|--|
| Reduce the proportion of children and adolescents who have dental caries in their primary or permanent teeth. | <ul style="list-style-type: none"> • Teach children and adolescents appropriate toothbrushing and flossing techniques. • Encourage use of fluoride-containing toothpastes. • Encourage routine dental visits. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Optimal oral health is not limited to the prevention and treatment of dental caries. It includes anticipatory guidance about nonnutritive sucking habits, injury prevention, oral cancer prevention, and tongue and lip piercing. Preventing and treating malocclusion can have a significant benefit for children. Comprehensive health care is not possible if oral health is not a priority in the health delivery system.

Optimizing oral health can benefit the community as well as the individual child. There has been a 60% reduction in early childhood caries over the past 50 years since community water supplies were fluoridated at optimal levels (American Academy of Pediatric Dentistry [AAPD], 2008). The cost of pediatric oral health care could be reduced by 50% with the proper use of fluoride treatments coupled with other preventive measures (AAPD, 2008). These health care dollar savings will enhance community resources.

Having a dental home enhances the likelihood that the child will obtain appropriate preventive and routine care. The AAPD adopted the policy of the dental home in 2001 (AAPD, 2010). It is modeled on the AAP medical home policy. The dental home provides the same benefits to the child as the medical home. Characteristics of a dental home are listed in [Box 9.9](#). The AAPD (2010) recommends that the dental home be established by the infant's first birthday.

BOX 9.9

CHARACTERISTICS OF THE DENTAL HOME

- Preventive health program based on risk assessment
- Anticipatory guidance on oral health developmental issues, including dietary counseling related to oral health
- Plans for emergency dental trauma
- Anticipatory guidance on oral hygiene
- Comprehensive dental care (acute and preventative services)
- Referral to specialists for care not available at the dental home

Adapted from American Academy of Pediatric Dentistry. (2010). *Policy on the dental home*. Retrieved April 17, 2011, from http://www.aapd.org/media/Policies_Guidelines/P_DentalHome.pdf

Promoting Healthy Weight

Childhood obesity is a growing problem. The number of overweight children has doubled since 1980; the rate for teens has tripled (CDC, 2008). The principal causes of this increase in obesity are unhealthy eating habits and decreased physical activity. Weight is best managed by balancing calories with a combination of diet and exercise (U.S. Department of Agriculture and U.S. Department of Health and Human Services, 2010). Nurses can have the maximum effect in promoting healthy weight in children by encouraging activities that address both healthy eating patterns and physical fitness. Children, parents, and communities are all targets for healthy weight promotion by nurses. Refer to Healthy People 2020.

| Objective | Nursing Significance |
|--|---|
| Reduce the proportion of children and adolescents who are obese. | <ul style="list-style-type: none"> • Screen all children for the development of overweight as indicated by an increasing body mass index (BMI) for their age. • Provide accurate diet counseling. • Encourage daily physical activity. • Counsel parents to limit television/computer time daily. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

The focus of healthy weight promotion should be health centered, not weight centered. Linking success to numbers on a scale increases the possibility of developing eating disorders, nutritional deficiencies, and body hatred. Instead, emphasizing the benefits of health through an active lifestyle and nutritious eating creates a nurturing environment for the child. This allows the child to maintain his or her self-esteem. In addition, a health-centered orientation also allows the family to develop a lifestyle that incorporates its cultural food patterns and traditions.

The nurse can stress the benefits of the mother’s healthy nutritional habits on the fetus at prenatal visits. Parents who have a healthy eating pattern are likely to maintain and encourage those patterns in their children. The nurse provides parents with anticipatory guidance about age-related eating patterns during each health supervision visit. Parents with toddlers and preschoolers may need training in ways to cope with the child’s growing autonomy while providing a variety of nutritious options.

The nurse can begin directly advising the young child on healthy foods. Information and teaching modalities need to be age appropriate. With colorful posters and games, the nurse can teach the preschool child the difference between healthy and unhealthy food choices. As children enter school, group and peer-led activities can be very effective. The nurse must gear material toward the teen’s growing autonomy in making self-care decisions.

Before providing education to school-age and teenage children, it is important to obtain nutritional histories directly from them because increasingly they are eating meals away from the family table. As they spend more time away from their parents, they need to develop the ability to make nutritious choices. The goal is to help older children develop strategies for making healthy choices as part of their increasingly independent lifestyle. Detailed anticipatory guidance is provided in [Teaching Guidelines 9.1](#) and in [Chapters 3 through 7](#).

Teaching Guidelines 9.1

HEALTHY EATING

Breakfast

1. Don’t skip breakfast. You will not have enough energy to play well later in the day. Skipping breakfast can also lower your grades in school.
2. Avoid eating high-sugar foods at breakfast. They will make you sleepy during the day.
3. Start your breakfast with some fruit. A small glass of juice, berries on your cereal, or a banana is a good choice.
4. Protein is important at breakfast. Milk, either in a glass or on cereal, is a good source of protein; so is yogurt or peanut butter.

Lunch

1. Check the quality of school-provided lunches. If they are high in fat or sugar, bring your lunch. Many schools publish their daily menus in advance. Check the newspaper or ask the school for a copy.
2. Add a variety of healthy alternatives to your lunches.
 - a. Try different types of breads. Pitas, wraps, bagels, and taco shells can be a good change of pace in the sandwich routine.
 - b. Freeze fruits before putting them in the lunch box. This will keep the lunch items cool and the fruit fresh tasting. Canned pineapple and grapes freeze well; so do bananas.
 - c. Try alternatives to high-fat chips. Dried fruits, baked pretzels, and animal crackers are a few examples of tasty, healthy treats.

d. Low-fat chocolate milk is more nutritious than prepackaged juice boxes, which have high sugar concentrations.

Snacks

1. Limit snacks to after school and bedtime. Light snacks such as yogurt or fruit provide good hunger management. A very hungry child will tend to overeat at meals.
2. Children need to learn to eat only when they are hungry. Children often eat out of boredom. Discourage nonstop grazing by planning activities to occupy the child.
3. A small bedtime snack is OK if the child is hungry but should not become a habit. A light carbohydrate such as graham crackers or a piece of fruit works well.

Dinner

1. Plan your menu a week ahead. Planning ahead reduces the likelihood of eating out or getting takeout food. Restaurant foods are more likely to be high in fats and carbohydrates.
2. Prepare homemade healthy versions of take-out favorites. Top prepared pizza crust with cooked chicken, vegetables, mushrooms, and cheese. Serve the pizza with a salad for a complete and healthy meal. “Make your own tacos” nights, using lean hamburger and low-fat sour cream, can be a lot of fun for children.
3. Don’t turn dinner into a battle zone. Forcing children to eat foods they do not like will only deepen their dislike of them. Give them the healthy foods they do enjoy and eventually they will explore more options.
4. Lead by example. Children eventually adopt the eating patterns of their parents. If they see their parents eat vegetables, they will eventually try them.

Promoting Healthy Activity

Healthy physical activity can take many forms. During the preschool years, encourage parents to provide a wide variety of physical activities. This exposure to multiple types of exercise allows the child to find the one that is most enjoyable and increases the chances that he or she will maintain an active lifestyle. The focus should be on noncompetitive, fun activities. When the child enters school, the lure of television and computers can significantly diminish the amount of time spent in physical activity. Parents can encourage their children to stay physically active in several ways. They can limit the amount of time spent in sedentary activities and actively encourage the child to pursue any exercise that he or she enjoys. In addition to verbal encouragement, parents can promote exercise by participating in exercise with the child. A simple family walk can increase physical fitness while providing time for interaction between parent and child. Refer to Healthy People 2020. Teaching

HEALTHY PEOPLE 2020

Objective

Increase the proportion of adolescents who meet current federal physical activity guidelines for aerobic physical activity and for muscle-strengthening activity.

Nursing Significance

- For the nonexercising teen, advise him or her to start slowly by walking.
- Work with the teen to identify physical activities that interest him or her.
- Praise efforts to participate in a routine exercise plan.
- Identify an athletic individual with whom the teen identifies, and encourage similar activities in the teen.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

HEALTHY ACTIVITY

1. Plan physical activities that your family can do as a group.
2. Write exercise activities on your family's daily schedule.
3. Look for activities that appeal to your child's interest, such as dance, team sports, or swimming.
4. Place value on noncompetitive as well as competitive activities.
5. Show your child you believe exercise is important. Exercise daily yourself.
6. Encourage the community to develop safe areas for spontaneous games and activities.

[Guidelines 9.2](#) gives additional suggestions for promoting physical activity.

Promoting Personal Hygiene

Handwashing is the first personal hygiene topic that needs to be introduced to children. Handwashing prevents disease by limiting a child's exposure to pathogens. The nurse can introduce the topic to preschool children using cartoons and games. Have the child sing "Twinkle, Twinkle Little Star" while washing his or her hands; this encourages adequate cleansing time. Use soap containers and towels with colorful characters to make the experience more fun. The school-age child can understand the concepts of germs and disease. Slogans such as "Let's drown a germ" can serve as a reminder of the importance of handwashing. The "Glogerm" program (n.d.) (see websites on [thePoint](#)) is very effective in this age group. A nontoxic substance that shines under a black light is placed on the children's hands. The children can follow how germs travel from object to object. After washing their hands, the children can see if they did a good job (Glogerm program, n.d.).

In response to peer pressure, teenagers are usually stringent about personal hygiene. Young teens may need guidance in dealing with pubescent body changes such as body odor, fungal infections such as *astinea pedis* (athlete's foot), and acne.

Promoting Safe Sun Exposure

Skin cancer is a significant health problem in the United States. Blistering sunburns in children substantially increase the risk of melanoma and other skin cancers (National Cancer Institute, 2011). People with fair skin are at highest risk for skin cancers, but anyone can become sunburned and develop skin cancer. When teaching children about safe sun exposure, remind them that harmful ultraviolet (UV) rays can reflect off water, snow, sand, and concrete, so being in the shade or under an awning does not guarantee protection. Adequate sun protection requires using sunscreen, avoiding peak sun hours, and wearing proper clothing. [Teaching Guidelines 9.3](#) gives more detailed instructions.

Teaching Guidelines 9.3

SAFE SUN EXPOSURE

Sunscreen

1. Use sunscreen lotions every day. Harmful ultraviolet (UV) rays penetrate clouds and cause damaging sunburns.
2. Use sunscreens with a sun protection factor (SPF) of 15 or higher. An adequate amount for an averagesized child is half an ounce.
3. Apply sunscreens half an hour before sun exposure.
4. Reapply every hour if the child is perspiring heavily.
5. Reapply immediately after swimming.
6. Infants 6 months old or younger should not use sunscreens. Take steps to avoid sun exposure completely with this age group.

Clothing

1. Wear hats. The brim of the hat should be 4 inches or more and should shade the ears. Straw hats need to have a sun proof liner to be effective. Children introduced to hats as infants usually accept hats as part of the "outfit."
2. Wear UV-blocking sunglasses. The eye is the second most common site for melanoma.
3. Wear long, loose, and lightweight clothing for maximum sun protection.

Lifestyle

1. Avoid sun exposure between 10 a.m. and 4 p.m. This is when UV rays are strongest.
2. Ask your physician if your medication will increase your sensitivity to UV rays. If the answer is yes, take extra precautions to reduce sun exposure.
3. Avoid tanning parlors. The devices emit UV rays just like the sun and can cause damage.
4. Check the UV index before going out. The higher the index, the more precautions you should take. UV index figures are available in newspaper, TV, and radio weather reports and on the Internet.
5. Advocate for safe-sun scheduling of recreational activities. Talk to others about scheduling outdoor activities before 10 a.m., after 4 p.m., or in the shade.
6. Consider UV-blocking plastic film for your house and car windows.

Take Note!

Give children the following physical reference when doing health promotion on safe sun exposure. Tell the child, “Play outside only when your shadow is taller than you are.” The child’s shadow will be “taller” before 10 a.m. and after 2 p.m. The nurse can demonstrate this concept by placing a ruler on end and shining a bright light over it. As the nurse moves the light, the child will see the ruler’s shadow lengthen.

KEY CONCEPTS

- Health supervision for children is a dynamic process. Optimal wellness for the child can only occur if the nurse forms meaningful partnerships with the child, the family, and the community. These partnerships allow for free exchange of information and the establishment of mutually agreed upon goals. The medical home exists when there is a single primary care provider for the child. The medical home establishes a trusting long-term relationship with the child and family. This relationship leads to comprehensive, coordinated, and cost-effective care for the child.
- Children with chronic illnesses have a critical need for comprehensive and coordinated health supervision. Children with chronic illnesses require more frequent health supervision assessments. These children must have a medical home. The location of that medical home may be with a knowledgeable primary physician or at a multidisciplinary specialty facility. The location is determined by the child’s needs and the family’s preferences.
- The nurse incorporates frequent assessments of the many psychosocial stressors faced by families of children with chronic illnesses when establishing health care plans for them.
- Health supervision has three components: developmental surveillance and screening; injury and disease prevention; and health promotion.
- Developmental surveillance is an ongoing process requiring a skilled observer and interviewer. To be effective, the nurse must understand normal growth and development expectations and be proficient at developmental screening procedures and techniques. Caregivers are most likely to reveal risk factors or warning signs for developmental delay when the nurse has a long-term and trusting relationship with the family.
- Screening tests are part of injury and disease prevention. They are modalities that identify treatable disease in an early or asymptomatic state and allow for cure or lessening of the disease’s injury.
- Vision and hearing screening are functional testing modalities that the nurse must be proficient in administering in order for the child’s results to be valid.
- Immunizations are a cornerstone of pediatric disease prevention. The nurse increases the effectiveness of immunization by understanding the principles of immunization and applying them to the child’s individual circumstances. Adhering to good immunization management practices, as outlined by the ACIP and the AAP, enhances the benefits and reduces the risks of immunization.
- Barriers to full immunization include fragmentation of health care, concerns about vaccine safety, financial constraints, and lack of knowledge. The nurse can be pivotal in ensuring that children and adolescents are fully immunized by serving as child educator and advocate.
- The principal components of health promotion are identifying risk factors for a disease, facilitating lifestyle changes to eliminate or reduce those risk factors, and empowering children at the individual and community level to develop resources to optimize their health.
- The nurse implements health promotion through education and anticipatory guidance.
- Anticipatory guidance provided involves common childhood health problems and seeks to prevent or improve the health of

children.

- The nurse uses the results of risk assessments and screening tests, health concerns unique to the child, and the interests and concerns of the parents to develop appropriate anticipatory guidance for each child and family.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. During the health interview, the mother of a 4-month-old says, "I'm not sure my baby is doing what he should be." What is the nurse's best response?
 - a. "I'll be able to tell you more after I do his physical."
 - b. "Fill out this developmental screening questionnaire and then I can let you know."
 - c. "Tell me more about your concerns."
 - d. "All mothers worry about their babies. I'm sure he's doing well."
2. An infant boy is at your facility for his initial health supervision visit. He is 2 weeks old and responds to a bell during his examination. You review all his birth records and find no documentation that a newborn hearing screening was performed. What is the best action by the nurse?
 - a. Do nothing; responding to the bell proves the infant does not have a hearing deficit.
 - b. Schedule the infant immediately for newborn hearing screening.
 - c. Ask the mother to observe for signs that the infant is not hearing well.
 - d. Screen again with the bell at the infant's 2-month health supervision visit.
3. A 15-month-old girl is having her first health supervision visit at your facility. Her mother has not brought a copy of the child's immunization record but believes she is fully immunized: "She had immunizations 3 months ago at the local health department." Which would be the best action by the nurse?
 - a. Ask the mother to bring the records to the 18-month health supervision visit.
 - b. Start the "catch-up" schedule because there are no immunization records.
 - c. Keep the child at the facility while the mother returns home for the records.
 - d. Call the local health department and verify the child's immunization status.
4. A 4-year-old child is having a vision screening performed. Which screening chart would be best for determining the child's visual acuity?
 - a. Snellen
 - b. Ishihara
 - c. Allen figures
 - d. CVTME
5. Which facility fulfills the characteristics of a medical home?
 - a. An urgent care center
 - b. A primary care pediatric practice
 - c. A mobile outreach immunization program
 - d. A dermatology practice
6. When should the child's first examination by a dentist occur?
 - a. By the first birthday
 - b. By the second birthday

- c. By entry into kindergarten
- d. By entry into first grade

CRITICAL THINKING EXERCISES

1. During a health supervision visit for a 5-year-old boy, the mother tells you she is worried about his hearing. Your facility has been his medical home since birth. He was the product of a normal pregnancy and delivery. He has had frequent ear infections since the age of 8 months. Six months ago he had a ruptured appendix. He was treated with an aminoglycoside. He has been fully recovered for 4 months.
 - a. During the health interview, what information should the nurse elicit from the mother?
 - b. What information should the nurse verify from the permanent medical record?
 - c. What risk factors for hearing loss does this child have?
 - d. What is the best course of action at this time?
2. The nurse is examining a 4-year-old to determine his readiness for school. Describe the developmental, vision, and hearing screening tools that will help the nurse to identify any problems.

STUDY ACTIVITIES

1. Develop an immunization plan for the following well children: a 2-month-old, an 18-month-old who has never been immunized, and a 5-year-old who was current with all immunizations at age 2.
2. This is the first health supervision visit, since arriving in this country 1 week ago, for a 3-year-old international adoptee from Russia. Develop a plan for this visit.
3. Develop a healthy weight program for the following: a preschool class, a family in which the parents and the two school-age children are mildly overweight, and a teenage girl who is of normal weight but fears “getting fat.”

Health Assessment of Children

Words of Wisdom Astute nursing assessment of the child provides a snapshot of the child's overall health, growth, and development.

KEY TERMS

accommodation

acrocyanosis

body mass index (BMI)

chief complaint

fontanel

lanugo

obligate nose breathing

palpation

PERRLA

point of maximal impulse (PMI)

stadiometer

Tanner stages

Tympanometer

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Demonstrate an understanding of the appropriate health history to obtain from the child and the parent or primary caregiver.
2. Individualize elements of the health history depending on the age of the child.
3. Discuss important concepts related to health assessment in children.
4. Perform a health assessment using approaches that relate to the age and developmental stage of the child.
5. Describe the appropriate sequence of the physical examination in the context of the child's developmental stage.
6. Distinguish normal variations in the physical examination from differences that may indicate serious alterations in health status.
7. Determine the sexual maturity of females and males based on evaluation of the secondary sex characteristics.

Elliot Simmons, 3 years old, is brought to the clinic for his annual examination. His mother states that he is very fearful and anxious about this visit.

Assessment of the child's health status involves many components: the health interview and history; observation of the parent-child interaction; assessment of the child's emotional, physiologic, cognitive, and social development; and physical examination. The nurse's skills are vital to the success of the assessment process. The nurse must (Mandleco, 2005):

- Establish rapport and trust
- Demonstrate respect for the child and the parent or caregiver
- Communicate effectively by listening actively, demonstrating empathy, and providing feedback
- Observe systematically
- Obtain accurate data
- Validate and interpret data accurately

The focus of the assessment process depends on the purpose of the visit and the needs of the child. Assessment is an ongoing process and is repeated to varying degrees at every encounter. The expert nurse is constantly evaluating the children in his or her care, whether directly or indirectly as part of conversation and play. Indeed, some of the subtlest developmental signs may express themselves only during relaxed and casual interaction with a child (Burns, Dunn, Brady, Starr, & Blosser, 2009). The nurse may observe gait while watching a child run down the hall, assess fine motor skills and social adaptation while the child is playing a board game, or observe balance and coordination while the child is bouncing a ball. Playful activities such as tickling a child can give the nurse feedback related to upper body strength when the child attempts to push the nurse's arms away. The nurse must also learn to perform a comprehensive and thorough examination of a child in an efficient manner.

A thorough and thoughtful assessment of a child is the foundation upon which the nurse determines the needs of the child. A comprehensive history, a thorough examination, and developmental or cognitive testing as appropriate will provide practical information about the health of a child and guide the nurse's plan of care (developmental testing is covered in [Chapter 9](#)). The history and physical examination also provide a time for health education, teaching about expected growth and development, and discussing healthy lifestyle choices. The nurse uses critical thinking skills to analyze the data and establish priorities for nursing intervention or follow-up care (Burns et al., 2009).

The health assessment may be documented using a number of formats such as a written narrative, a written flow sheet, or an electronic health record. The information should be easily retrievable and available to all members of the child's health care team.

HEALTH HISTORY

The health history provides the nurse with an overall picture of what the child has experienced, highlighting areas of concern such as recurrent upper respiratory infections or headaches. This not only helps the nurse to assess those specific areas more comprehensively but also provides the opportunity to ask focused questions and identify areas where education may be needed. The time used to obtain the health history also gives the nurse an opportunity to interact with the child in a nonthreatening manner while the child watches the interactions between the nurse and the primary caregiver (Burns et al., 2009; Miller, 2011).

Preparing for the Health History

Appropriate materials and a suitable environment are needed when performing a thorough health history. Take into account family roles and values. Consider the age and developmental stage of the child in order to approach the child appropriately and possibly involve him or her in the health history. Observe the child-parent interaction. Determine the extent of the health history that is needed in a given situation. Being well organized and staying flexible will help ensure success (Burns et al., 2009).

Gathering Materials

Before beginning, make sure the following are available: materials to record the history data (either a computer or chart paper and a pen), a private space with adequate lighting, chairs for adults and the nurse, and a bed or examination table for the child. The space should be safe for the child's developmental stage. Sit down for as much of the history taking as possible to demonstrate a relaxed and welcoming manner (Burns et al., 2009).

Approaching the Parent or Caregiver

Greet the parent or caregiver by name. While interviewing the parent, provide toys or books to occupy the child, allowing the parent to concentrate on the questions. Use open-ended questions and avoid making judgmental comments. Show respect by remaining approachable. Remember that the structure of the family and its roles and dynamics will affect how the family communicates and how they make decisions about health care. Demonstrate patience and help the parent stay on track when there are several children in the family. Throughout the interview, refer to the child by name and use the correct gender when referring to the child, demonstrating interest and competence.

Take Note!

Illness can cause great stress in families and individuals, so nurses must remember to protect themselves from potentially threatening behavior on the part of the family. Sit close to the door, and if uncomfortable with a family member, ask for assistance. The nurse may need to alert security personnel in certain cases (Griffin, 2003).

Approaching the Child

Show a professional demeanor while still being warm and friendly to the caregivers and child. A white examination coat or all-white uniform may be frightening to children, who may associate the uniform with painful experiences or find it too unfamiliar (Roohafza et al., 2009). The nurse can wear a variety of professional-looking outfits, whether colorful uniform tops, aprons, or smocks worn over white uniforms, or everyday clothing, depending on the setting of the nurse's practice. Make eye contact if possible and address the child by name. Use slow deliberate gestures rather than very quick or grand ones, which may be frightening to shy children.

Some young children will warm up when given time to be invisible in the room, such as hiding behind a parent before they tentatively appear. Make physical contact with the child in a nonthreatening way at first. Briefly cuddling a newborn before returning him or her to the caregiver, laying a hand on the head or arm of toddlers and preschoolers, and warmly shaking the hand of older children and teens will convey a gentle demeanor. A joke, a puppet, a silly story, or even a simple magic trick may coax the child into warming up. Being at the same eye level as the child can also be more reassuring than standing over the child (Miller, 2011). This may require having extra seating for the nurse at the same level as the child and parent/caregiver. Aim to be seen as a trustworthy adult who is the child's partner in feeling better and staying healthy.

Elicit the child's cooperation by allowing him or her control over the pace and order of the health history, or anything else that the child can control while still allowing the nurse to obtain the information needed. All of this establishes a personal relationship with the child and helps gain his or her cooperation (Miller, 2011).

Communicating With the Child During the Health History

Give the child opportunities to actively participate in the health history and assessment process. For young children, such as toddlers and preschoolers, ask them to point to where it hurts and allow them to answer questions. Validation of the information by the parent/caregiver is essential because of the limited comprehension and language use of children at these ages. The school-aged child can answer more accurately because of his or her increased language skills and maturity level.

Initially, address the child and obtain as much information from him or her as possible. School-aged children should be able to answer questions about interactions with friends and siblings and school and activities they enjoy or in which they are involved. Ask the parent/caregiver if any additional information or observations should be included.

Adolescents may not feel comfortable addressing health issues, answering questions, or being examined in the presence of the parent/caregiver. The nurse must establish a trusting relationship with the adolescent to provide him or her with optimal health care. Ask adolescents whether they would be more comfortable answering questions alone in the examination area or whether they prefer their parents to be present. Either way, the parent/caregiver will have an opportunity to talk with the nurse after the health history and assessment are completed (Burns et al., 2009).

Demonstrate an interest in the teen by asking questions about school, work, hobbies or activities, and friendships. Begin with these topics to make the teen feel comfortable in communicating with the nurse. Communicate honestly with the adolescent and explain the rationale for various aspects of the health history. Teens are very sensitive to nonverbal communication, so be very aware of gestures and expressions (Sass & Kaplan, 2011). Once a rapport has been established, move on to more emotionally charged questions that relate to sexuality, substance use, depression, and suicide.

Always assure the teen that complete confidentiality will be maintained to the extent possible. Current state law will determine the types of information that may be withheld from parents. If the information that the nurse receives indicates that the teen may be in danger, then the nurse must inform the teen that the information will be shared with other providers and/or the parents (Burns et al., 2009).

Take Note!

Do not try to become the adolescent's peer. Remain in the role of the nurse while demonstrating respect and acceptance toward the teen. Clarify the meaning of jargon or slang that the teen uses, but do not use these words yourself; the teen will simply not accept the nurse as a peer.

Observing the Parent-Child Interaction

Observation of the parent-child interaction begins during the focused conversation of the health interview and continues throughout the physical examination. Explore the family dynamics, not only through questions but also by observing the family for behavioral clues. Does the parent make eye contact with the infant? Does the parent anticipate and respond to the infant's needs? Are the parents ineffective when dealing with a toddler's temper tantrum? The plan of care may need to be adjusted to teach appropriate responses to the infant's needs or toddler's behavior. Do the parents' comments increase the school-age child's sense of self-worth? Behavioral observations are crucial to proper assessment of the family's needs (Burns et al., 2009; Columbia University, 2011).

Further observe the parent-child interaction to determine if the parent appears to be overwhelmed and if his or her behavior seems appropriate (Burns et al., 2009). Monitor the child's behavioral cues. Does the child look at the parent/caregiver before answering? Does the child seem relaxed and happy with the parent/caregiver, or is the child tense? The infant will appear calm and relaxed if his or her needs are generally met. Crying may occur when the baby is ill or frightened, but may also indicate discomfort with the parent or caregiver. Use a calm and comforting voice with the infant. Infants respond well to higher-pitched and soothing voices.

When observing the relationship between the adolescent and the parent/caregiver, does the parent/caregiver allow the adolescent to speak, or does he or she frequently interrupt? Does the parent/caregiver contradict what is being said? Observe the body language of the adolescent: does the teen seem relaxed or tense? Since adolescents are between childhood and adulthood, they have unique needs. They are experiencing a time of multiple physical and emotional changes, many of which they cannot control. They need to know that the nurse is interested in what they have to say (Sass & Kaplan, 2011). The use of open-ended questions allows the adolescent to talk. "Tell me about your...." or "What have you noticed about ... ?" are comfortable phrases to use to elicit the information needed.

Be aware of your own reactions to the adolescent's questions or behaviors, such as nonverbal and facial expressions. Talk with the adolescent using accurate language that is developmentally and age appropriate.

Determining the Type of History Needed

The purpose of the examination will determine how comprehensive the history must be. If the physician rarely sees the child or if the child is critically ill, a complete and detailed history is in order, no matter what the setting. The child who has received routine health

care and presents with a mild illness may need only a problem-focused history. In critical situations, some of the history taking must be delayed until after the child's condition is stabilized. Evaluate the situation to determine the best timing and the extent of the history (Burns et al., 2009). Also, be sensitive to repetitive interviews in hospital situations, and collaborate with physicians or other members of the health care team to ensure that a family already under stress does not need to undergo prolonged or repetitive questioning.

Remember Elliot, the 3-year-old being seen for his annual examination? When you enter the room, he is hiding behind his mother's legs. Considering his age and developmental level, how will you proceed with obtaining a health history?

Performing a Health History

The health interview is the foundation of an accurate health assessment. Careful conversation and interview with the child and/or the caregiver will provide important information about the child's health (Burns et al., 2009). Depending on the intent of the health assessment, many of the questions will be direct, and many will require the caregiver or child to answer simply "yes" or "no." In other than emergency situations, though, asking open-ended questions offers an excellent opportunity to learn more about the patient's life. For example, "Are you happy at school?" may elicit a brief nod of the head, whereas "Tell me what it's like on your school playground" may result in a story about the child's friends, the kind of activities the child enjoys, any bullying that goes on, and so forth. These stories will provide the nurse with clues to the child's stage of physical, emotional, and moral development as well as his or her functional status (Burns et al., 2009; Columbia University, 2011).

Establish a therapeutic relationship with the child and family. Without the trust that comes from this therapeutic relationship, the family may not reveal vital information due to fear, embarrassment, or mistrust (Bunik, Brayden, & Fox, 2011). Use therapeutic communication techniques such as active listening, open-ended questions, and eliminating barriers to communication. Establishing a "medical home" where ongoing health supervision occurs encourages trust through continuity of care and the family's continuing relationships with primary care providers (see [Chapter 9](#)).

The structure of the health interview is determined by the nature of the visit. At an initial visit, large amounts of historical data are collected. Having the family fill out a questionnaire can save time, but a questionnaire is not a substitute for the health interview. The questionnaire may serve as a springboard to begin structured conversations between the family and the nurse. At subsequent visits the health interview can focus on the pertinent issues of that visit as well as any health issues that are being monitored.

The health history includes demographics, chief complaint and history of present illness, past health history, review of systems, family health history, developmental history, functional history, and family composition, resources, and home environment.

Take Note!

Any questionnaires used in the health care setting should be written at a fifth-grade reading level and be in the primary language of the person completing them (The Joint Commission, 2010).

Demographics

Initially, questions should be simple and nonintrusive; once a rapport between the nurse and patient has started, sensitive questions can be asked. First obtain data such as the child's name, nickname, birth date, and gender. Determine the child's race or ethnicity, the language the child understands, and the language the child speaks. Record the child's address and home telephone number and the parent's or caregiver's work telephone number. Identify who the historian is (the child or the parent or caregiver), and note how reliable this source of information is considered to be. Do not assume that an adult with the child is the child's parent. Establish the relationship of the adult to the child, and ask who cares for the child if that person does not. Determine the composition of the household, including other children and other family members or other persons who live there.

Chief Complaint and History of Present Illness Review of Systems

Next, ask about the **chief complaint** (reason for the visit). The reason may not always be apparent to you. A question such as, "What can I help you with today?" or "What did you notice in your baby/child that you wanted to have checked today?" is very welcoming. The response from the child or parent may be a functional problem, a developmental concern, or a disease. Record the chief complaint in the child's or parent's own words.

Next address the history related to the present illness. For each concern, determine its onset, duration, characteristics and course (location, signs, symptoms, exposures, and so on), previous episodes in patient or family, previous testing or therapies, what makes it

better or worse, and what the concern means to the child and family. Inquire about any exposure to infectious agents.

Past Health History

Ask about the prenatal history (any problems with pregnancy), perinatal history (any problems with labor and delivery), past illnesses, or any other health or developmental problems. Document the child's prior history of illnesses (recurrent, chronic, or serious) and any accidents or injuries in the past. Inquire about any operations or hospitalizations the child has had. Document the child's diet. Note the child's allergies to foods, medications, animals, environmental or contact agents, or latex products. Determine the child's reaction to the allergen as well as its severity. Determine the child's immunization status (refer to [Chapter 9](#) for further information on immunizations). Record any medications the child is taking, the dosage and schedule, as well as when the last dose was given. In preadolescent and adolescent females, determine menstrual history.

Family Health History

Obtaining information about the family's health is a key part of a health interview. Perform a three-generation family health history. This information may be documented in a genogram ([Fig. 10.1](#)). Asking about the age and health status of mother, father, siblings, and other family members helps to identify trends and specific health issues (Burns et al., 2009; Hagan, Shaw, & Duncan, 2008). For example, do the grandparents have early-onset coronary artery disease? If they do, the child may benefit from additional health screening. Siblings may exhibit a genetic disease or carry a trait for the disease. This family health information helps to guide future health planning.

Review of Systems

- Inquire about current or past history of problems related to:
- Growth and development
- Skin
- Head and neck
- Eyes and vision
- Ears and hearing Mouth, teeth, and throat
- Respiratory system and breasts
- Cardiovascular system

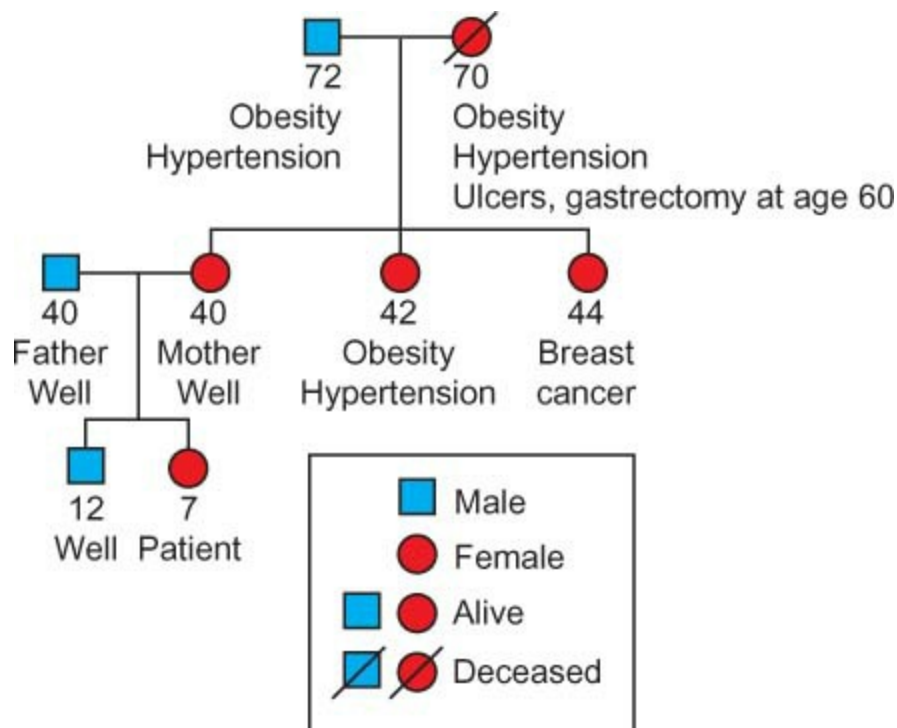

FIGURE 10.1 Genogram.

- Gastrointestinal system
- Genitourinary system

- Musculoskeletal system
- Neurologic system
- Endocrine system
- Hematologic system

Table 10.1 provides specific questions related to each of these systems.

Developmental History

Determine the age when landmarks in gross motor control were achieved, such as sitting, standing, walking, pedaling, and so on. Ask whether the child has attained fine motor skills such as grasping, releasing, pincer grasp, crayon or utensil use, and handwriting skills. Note the child’s age and extent of language acquisition. Document speech problems such as a lisp or stuttering. The rate of developmental skill acquisition may vary from child to child, but the sequence of skill attainment should remain the same. Inquire about self-care ability (e.g., tying shoes, dressing, brushing teeth) and, in the younger child, how toilet training is progressing. Question the parents about the child’s feeding skills, including how well the child drinks from a cup and uses utensils or whether the child has any special requirements. Inquire about social skills and comfort articles (e.g., blankets, stuffed animals). Note whether the child has a habit of thumb or finger sucking or using a pacifier. Document day care attendance and preschool or school adjustment and achievements.

| TABLE 10.1 QUESTIONS FOR THE REVIEW OF SYSTEMS | |
|--|--|
| Systems | Has the Child Experienced |
| Growth and development | Weight loss or gain, appropriate energy and activity levels, fatigue, behavioral changes such as irritability, nervousness, anger, or increased crying |
| Skin | Easy bruising or bleeding, rash, lesion, skin disease, pruritus, birthmarks, or change in mole, pigment, hair, or nails |
| Head and neck | Head injury, headache, dizziness, syncope |
| Eyes and vision | Pain, redness, discharge, diplopia, strabismus, cataracts, vision changes, reading difficulties, need to sit close to the board at school or close to the TV at home |
| Ears and hearing | Earache, recurrent ear infection, tubes in eardrums, discharge, difficulty hearing, ringing, excess cerumen |
| Mouth, teeth, and throat | Swollen gums, pain with teething, caries, tooth loss, toothache, sores, difficulty with chewing or swallowing, hoarseness, sore throat, mouth breathing, change in voice |
| Respiratory system and breasts | Nasal congestion or discharge, cough, wheeze, noisy breathing, snoring, shortness of breath or other difficulty breathing, problems with or changes in breasts |
| Cardiovascular system | Murmur, color change (cyanosis), exertional dyspnea, activity intolerance, palpitations, extremity coldness, high blood pressure, high cholesterol |
| Gastrointestinal system | Nausea, vomiting, abdominal pain, cramping, diarrhea, constipation, stool holding, anal pain or itching |
| Genitourinary system | Dysuria; polyuria; oliguria; narrow urine stream; dark, cloudy, or discolored urine; difficulty with toilet training; bedwetting <i>Boys:</i> undescended testicles, pain in penis or scrotum, sores or lesions, discharge, scrotal swelling when crying, changes in scrotum or penis size, addition of pubic hair <i>Girls:</i> vaginal discharge, itching rash, problems with menstruation or menstrual cycle, development of pubic hair |
| Musculoskeletal system | Joint or bone pain, stiffness, swelling, injury (e.g., broken bones or sprains), movement limitation, decreased strength, altered gait, changes in coordination, back pain, posture changes or spinal curvature |
| Neurologic system | Numbness, tingling, difficulty learning, altered mood or ability to stay alert, tremors, tics, seizures |
| Endocrine system | Increased thirst, excessive appetite, delayed or early pubertal changes, problems with growth |
| Hematologic system | Swelling of lymph nodes, pale color, excessive bruising |

Adapted from Burns, C., Dunn, A., Brady, M., Starr, N., & Blosser, C. (2009). *Pediatric primary care* (4th ed.). Philadelphia: Saunders; and Jarvis, C. (2008). *Physical examination and health assessment* (5th ed.). St. Louis: Saunders.

Functional History

The functional history should contain information about the child’s daily routine. Inquire about:

- Safety measures (e.g., car seats and their placement, use of seat belts, smoke detectors, bike helmets)
- Routine health care and dental care (including dates of dental care and what was done)
- Nutrition, including a 24-hour dietary recall or week-long food diary, use of supplements and vitamins, feeding pattern and satisfaction with diet, amount of “junk food” consumed, food likes and dislikes, and the parent’s perception of the child’s nutrition (refer to Chapters 3 through 7 for nutritional needs at various ages)

- Physical activity, recreation, play, and organized sports
- Television and computer habits
- Sleep behavior and bedtime
- Elimination patterns and any concerns
- Hearing or vision problems (dates of last screenings and results)
- Relationships with other family members and friends, coping and temperament, discipline strategies, attention or school behavior problems
- Religious involvement and other spiritual practices
- Use of adaptive and assistive devices such as eyeglasses or contact lenses, hearing aids, walker, braces, wheelchair
- Sexual practices (Burns et al., 2009; Hagan et al., 2008)

Family Composition, Resources, and Home Environment

Determine the marital status of the parents. Does the child live with the parents, a stepparent, or other family member? Is the child adopted or in foster care? Are the parents the primary caretakers for the child? If not, the primary caretaker should be included in the interview process if possible. Parents may not know some of the child's routines if the child spends much of the time being cared for by someone else. Working parents may learn about a health or behavior issue only after being alerted by the child's day care center or babysitter. It may be helpful to expand the family history to include the grandparents and their interaction with the child.

Determine the employment status of the parents and their occupations, as this could affect the child's overall well-being; for example, the parents' work schedule may not allow them to spend much time with the child. Assess family income and financial resources, including health insurance and Supplemental Nutrition Assistance Program (formerly food stamps); Aid for Women, Infants, and Children (WIC); or other governmental supplemental income. Major family changes can also affect how the parents and child interact, so evaluate for relationship problems or changes.

Ask about the family's home and its age and environment. Is there a safe outdoor play area? If there is a pool, are safety features in place? Determine whether the home has electricity and an indoor water supply. Also determine whether the home has heating, air conditioning, and refrigeration. What pets does the family have? How are they housed? Are there infestations of insects or rodents in the home?

Take Note!

Homes or apartments built prior to 1978 may contain lead-based paint, and children who live there are at an increased risk for the development of lead poisoning (Hagan et al., 2008).

PHYSICAL EXAMINATION

The next step after the health history is the physical examination. It should focus on the chief complaint or any of the systems that engaged the nurse's critical thinking while obtaining the history. The examination will reflect the nurse's general practice style, the developmental stage and age of the child, the temperament of the child and caregiver, and the health status of the child. For example, a very ill child will not waste energy protesting the examination, so the nurse can move quickly in that situation. A healthy child, however, will express his or her normal developmental stage and will show varying degrees of resistance to the examination (Miller, 2011; Columbia University, 2011).

Preparing for the Physical Examination

When performing the physical examination, being prepared and organized ensures that the needed information will be obtained efficiently. The appropriate methods to use and ways to approach the child depend on the child's developmental stage.

Gathering Materials

The examination area should include an examination table or the child's hospital crib or bed. Appropriate lighting is necessary for adequate observation and inspection. Gather the equipment necessary for the examination such as clean gloves, stethoscope, thermometer, sphygmomanometer, tape measure, reflex hammer, pen-light, otoscope/ophthalmoscope, tongue depressor, and cotton ball. An infant or adult scale is needed, as well as a **stadiometer** for children capable of standing independently. Young children may be frightened by seeing a large amount of equipment, so take out one piece of equipment at a time. Some children can be very resistant to what they see as a threat or an invasion of their privacy, so it may help to have washable toys in the examination area to use as distractions during the assessment (Burns et al., 2009; Hagan et al., 2008; Miller, 2011).

Children and their parents may be able to sense any frustration or anxiety on the part of the examiner, so display a confident and matter-of-fact approach. If the child is not cooperative, do not become discouraged; more time and explanation will usually do the trick.

Regardless of the child's age, if the examination room is cold, the child will be uncomfortable and possibly less cooperative. Provide appropriate covers to ensure the child's comfort, or have the child remain dressed until the time of the examination (Miller, 2011).

Approaching the Child

Approach the child according to his or her developmental age and stage. [Table 10.2](#) outlines a general approach to the physical examination in each broad developmental category.

If several children are to be seen at the same time, begin with the child who will be most cooperative. If the other children do not see anything scary and realize that their sibling was examined without a problem, it sets the stage for better cooperation from the younger ones.

NEWBORNS AND INFANTS

If the infant is asleep, auscultate the heart, lungs, and abdomen first while the baby is quiet. Count the heart rate and respiratory rate before undressing the baby. Completely undress newborns and infants down to their diaper, removing it just at the end to examine the genitalia, anus, spine, and hips. It is best to examine the infant 1 to 2 hours before a feeding. Having the parent or care-giver hold the child during the examination can help to alleviate fears and anxieties ([Fig. 10.2](#)). Allow the parent or caregiver to be a nurturer rather than assisting with painful procedures, unless there are no other choices available (Miller, 2011).

Perform the assessment in a head-to-toe manner, leaving the most traumatic procedures, such as examination of the ears, nose, mouth, and throat, until last (Burns et al., 2009; Miller, 2011). Also delay eliciting the Moro reflex until the end of the examination, as the startling sensation may make the infant cry. Use firm, gentle handling while examining the infant. Make sure your hands and the stethoscope are warm. Perform the assessment as quickly and completely as possible. Use a soft and crooning voice, smile, and engage the infant in eye contact. In addition, use brightly colored objects to help distract him or her. If the baby is crying, a pacifier may be useful.

FIGURE 10.2 The infant or toddler may feel more comfortable and secure being examined while sitting in the parent or caregiver's lap.

Take Note!

Many older infants demonstrate stranger anxiety as a normal part of development. If the parent is not holding the infant, make sure the parent is within the infant's view; this will increase the baby's comfort and cooperation (Bickley & Szilagyi, 2009; Burns et al., 2009; Miller, 2011).

TODDLERS

Toddlers usually prefer to remove their clothing one item at a time as needed for the examination. After one area is examined, the child may feel more comfortable replacing that item of clothing before removing another one (Bunik et al., 2011). An examination gown is usually not necessary before school age. Again, make certain the room temperature is comfortable.

When the nurse enters the room, a child of this age is often sitting or standing by the parent. Incorporate play as appropriate during the health assessment. Remember your own facial expressions and tone. Use little touch at the beginning of the encounter with the child and the caregiver.

TABLE 10.2

DEVELOPMENTAL CONSIDERATIONS FOR EXAMINATION

| | Newborn | Infant | Toddler | Preschool | School-age | Early Teen | Late Teen |
|------------------------------|---|--|---|--|--|---|--|
| Place to perform examination | May lie on examination table or in caregiver's lap. | In caregiver's lap or on examination table with caregiver right beside infant. | Allow some freedom of movement when possible; child may stand between seated caregiver's legs or sit on the lap. | Some may be willing to sit on examination table with caregiver standing close by with hand on the leg. | sitting on examination table where they still have eye contact with caregiver. | Some may be willing to have their caregiver wait outside the examination room. | Explain to the caregiver that the teen needs privacy and that he or she should wait outside the examination room. |
| Examination direction | Keep up a running dialog with the caregiver, explaining each step as you do it. | Continue to explain each step to the caregiver; address child by name. Perform most invasive parts last. | Introduce yourself to caregiver and child, explain most steps to the child and all steps to caregiver; allow child to handle instruments. Perform most invasive parts last. | Allow child to decide the order of the examination; explain what the instruments do and let the child try them; speak to the caregiver before and after the examination. | Include the child in all parts of the examination; use head-to-toe approach with genital exam last. Speak to the caregiver before and after the examination. | Speak to the child using mature language; appeal to his or her desire for self-care. Use a head-to-toe approach, with genital examination last. | Explain confidentiality to caregiver and teen; allow time talking with them together and separately. Use a head-to-toe approach, with genital exam last. |

FIGURE 10.3 The preschooler enjoys listening to her mother's heart first.

Introduce the equipment to be used slowly, explaining briefly what is going to happen. Let the child touch and hold the equipment whenever possible, even taking a parent's temperature or putting the blood pressure cuff on a teddy bear (Fig. 10.3). The toddler will prefer to sit on the caregiver's lap. When the toddler must be supine for the abdominal examination, sit in your chair knee-to-knee with the caregiver so the toddler may lie back on the caregiver's and your laps. Praise the child for being cooperative during the examination. "You did such a good job holding still while I listened to your chest" and similar phrases give positive feedback to the child.

If the child is uncooperative, assess as thoroughly as possible and move on to the next area to be assessed. The caregiver may need to place an arm around the toddler's body to provide restraint for invasive procedures. Use short phrases to tell the toddler what you are going to do, rather than asking if it is OK (Miller, 2011; Nettina, 2010).

Take Note!

Toddlers are *egocentric*. Telling a toddler how well another child behaved probably will not be helpful in gaining the young child's cooperation.

PRESCHOOLER

The preschooler may fear body invasion and mutilation and will withdraw from any procedure or assessment that is viewed as intrusive. Otherwise, the sense of initiative often leads the preschooler to be cooperative. Use simple explanations to inform the child about each step of the examination, offering reassurance as appropriate. Allow him or her to “help” by holding the stethoscope or penlight. If choices are available, offer them to the child. Again, always compliment the child on his or her cooperation.

Take Note!

Preschoolers like to play games. To encourage deep breathing during lung auscultation, hold up a finger or a lit penlight and instruct the child to “blow it out” (Miller, 2011).

SCHOOL-AGE CHILDREN

The school-age child’s thinking is still very concrete, but he or she can be objective and realistic. Avoid using medical jargon and words that may have a double meaning to a young child. Instead of “take your temperature,” “take your blood pressure,” “hit your knee,” or “test,” say, “Let’s see how warm you are,” “I want to listen to you breathe,” and other phrases that describe, in words the child can understand, what you are preparing to do. The school-age child may be very interested in how things work and why certain things need to be done and will be responsive to truthful and simple explanations. Instruments that are colorful or look like toys are very helpful throughout early childhood and the school-age period (Burns et al., 2009; Miller, 2011).

Always respect a child’s desire to avoid pain and insult. Allow children to wear their underpants under the examination gown to provide a sense of security until the genitalia need to be examined. Allow the child to replace his or her clothing as soon as possible. Privacy and respect for the child’s feelings are important to children of this age (Bunik et al., 2011).

Take Note!

Describing and commenting on your findings during the physical examination is interesting to the school-age child, as children of this age like to learn about how the body works (Miller, 2011).

ADOLESCENTS

Provide privacy while the adolescent is undressing and putting on a gown. Demonstrate an attitude of respect. Perform the assessment in a head-to-toe manner, exposing only the area to be examined. Provide information about physical changes in a matter-of-fact way, such as, “The hair on your legs is what is expected at this time.” This provides information related to sensitive areas that the teen may be reluctant to ask about. It also provides the adolescent with information about the sexual development that is normal and expected. Allow opportunities for the teen to ask questions without the caregiver being present. Assure the adolescent that there are no “dumb questions” about the changes being experienced. Teenage girls should remove their bras so that the nurse can perform a breast examination, teach breast self-examination, and check for scoliosis. If the nurse is a male and the patient is an adolescent female, it is appropriate for a female staff member to be present during the breast and genital examination (Sass & Kaplan, 2011).

Steps of the Physical Examination

The physical examination of children, just as for adults, begins with a systematic inspection: checking color, warmth, characteristics, and texture visually and smelling for any odor. **Palpation** follows inspection to validate your observations. Percussion is a useful tool for determining the location, size, and density of organs or masses. Tapping with the reflex hammer elicits deep tendon reflexes. The stethoscope is used to auscultate the heart, lungs, and abdomen.

Performing a Physical Examination

A complete examination includes assessment of the general appearance, vital signs, body measurements, and pain, as well as examination of the head, neck, eyes, ears, nose, mouth and throat, skin, thorax and lungs, breasts, heart and peripheral perfusion, abdomen, genitalia and rectum, musculoskeletal system, and neurologic system. The nurse in most settings will not be assessing the breasts, genitalia, or eyes or ears in detail. Be aware of the role of the nurse in different settings and how the nurse can facilitate the assessment process.

General Appearance

Never discount first impressions. Does the child give an impression of being ill or well? What is the child’s expression and energy

level? Note lethargy, listlessness, excessive activity, or inappropriate attention span for the child's age. Observe the child's state of alertness and whether he or she is responding appropriately to the stress of the situation. Note the child's posture and positioning:

- The newborn's posture is flexed, with arms and legs tucked in.
- The older infant should have improving head and then trunk control.
- The toddler demonstrates lordosis (swayback) and bowlegs, with a relatively large head and protuberant belly.
- The preschooler is more slender and upright in appearance.
- The school-age child and adolescent should demonstrate an upright, straight, and well-balanced posture.

Note whether the child's development appears appropriate. Observing the child initially may yield a wealth of information about the child's development. Is the child active, moving about the room? Does the child's speech seem appropriate for his or her age? Notice whether the family interacts appropriately with one another and the child. Does the child appear clean and well cared for? Does the child appear well nourished or small for age or obese? Note the scent of tobacco smoke or alcohol on family members. Notice if the baby bottle or pacifier is nearby and whether the child has a toy or transitional object. Assess whether the siblings appear equally well cared for. Observe for tension in the room between adults or children/adolescents. This initial quick assessment of general appearance will serve the nurse well if it is objective; delay interpretation of this assessment until additional data are gathered.

Measurement of Vital Signs

Measure, document, and interpret the vital signs of children using age-appropriate equipment and approaches. The child's age and size, as well as knowledge of underlying health conditions, will affect analysis of the vital signs. Vital signs are the temperature, pulse rate, respiratory rate, and blood pressure. These measurements fluctuate normally in children; assessing vital signs while the child is quiet is most appropriate. Comforting an infant or distracting a young child may be necessary while obtaining vital signs. If the child is crying or otherwise active during the assessment, document that fact. Many acute care settings require continuous measurement of vital signs using specific monitoring equipment. Also assess the child's pain level when assessing the vital signs.

TEMPERATURE

Temperature is measured as it is in adults. Thermometers are available in glass, electronic, and digital types. Use the same type of equipment consistently to allow reliable comparisons to be made and to permit tracking of temperatures during the course of illness (Bowden & Greenberg, 2008). No matter which type of thermometer is used, ensure accuracy by carefully following the manufacturer's instructions.

The routes for taking the child's temperature are tympanic, temporal, oral, axillary, and rectal. Numerous research studies have been undertaken to determine the best method for temperature assessment in children. Take the child's temperature using the least invasive method that is best accepted by the child, parent, and physician.

Take Note!

Glass thermometers are not recommended for use due to the mercury they contain (Bowden & Greenberg, 2006).

Choosing a method of measuring temperature depends on what is available at the facility and the child's age and physical condition. Tympanic temperature reflects the pulmonary artery temperature and can be measured with the tympanic thermometer within seconds. The accuracy of a tympanic temperature reading depends on the user's technique and can be safely and effectively used in children 3 months of age and older (Bowden & Greenberg, 2008). Refer to [Nursing Procedure 10.1](#).

NURSING PROCEDURE 10.1

Measuring Tympanic Temperature

1. Note age of child. If younger than 3 years, pull the earlobe back and down.
2. Insert the tympanic thermometer gently into the ear canal with the infrared sensor beam directed toward the center of the tympanic membrane rather than the sides of the ear canal.
3. Push the button to take the temperature and hold until a reading is obtained. The length of time required for the temperature to register varies per manufacturer but is only a few seconds at most.

Temporal scanning uses infrared scanning on the skin over the temporal artery combined with a mathematical computation to determine the child's arterial temperature. Temporal artery thermometry may be used with any age child except infants younger than 90 days of age who are ill or have a fever (Asher & Northington, 2008). Measure temperature on the exposed side of the head (not the side that has been lying on a pillow or covered by a hat). Slide the sensor tip externally in a horizontal line across the child's forehead, midway between the eyebrows and hairline and ending at the temporal artery (Fig. 10.4). Hold it there until the device registers the temperature reading, which usually requires 1 second. Accuracy may be affected by excessive sweating (Exergen Corporation, 2007). Oral temperature is highly reliable if the child can cooperate. By 5 years of age, the child can hold an electronic oral thermometer in the mouth well enough to obtain a reading. Place the probe under the tongue and ensure the child's mouth remains closed until the device registers the temperature. Oral intake, oxygen administration, and nebulized medications or treatments may affect oral temperature.

The axillary method may be used for children who are uncooperative, neurologically impaired, or immunosuppressed or have injuries or have had surgery to the oral cavity (Bowden & Greenberg, 2008). Place the tip of the electronic or digital thermometer in the axilla to obtain the reading. Make sure the tip is indeed in the axilla and not just between the arm and the child's side. Hold the thermometer parallel rather than perpendicular to the child's side to obtain the most accurate reading. Keep the child's arm pressed down to the side until the thermometer registers, which will be as little as 10 seconds with certain electronic models but 2 or 3 minutes with digital models commonly used at home.

Though long considered to reflect core temperature, the rectal route is invasive, not well accepted by children or parents, and probably unnecessary with the modern alternative methods now available. To take the rectal temperature, position the young infant supine with legs flexed. The older infant or child should be prone or side-lying. Small children may lie across the parent's lap for additional comfort. Apply a water-soluble jelly to the covered probe, insert the thermometer past the anal sphincter no more than 1 inch (2.5 cm), and hold it there until the temperature registers (as little as 15 seconds with certain electronic models but longer with digital models).

FIGURE 10.4 Temporal artery thermometers are noninvasive and well tolerated by young children. For an accurate reading, move hair to expose forehead and hairline.

EVIDENCE-BASED PRACTICE 10.1

PACIFIER THERMOMETERS

STUDY

Nurses and parents are concerned with being able to measure temperature accurately with the least invasive method possible. Research trials on pacifier thermometry in the past have been limited. The researchers utilized a convenience sample of children aged 7 days to 24 months in a prospective, cross-sectional study. Subjects were limited to those without gastrointestinal illness or contraindication to either the sublingual or rectal method of temperature measurement. Each child underwent pacifier temperature measurement with recordings at 3 and 6 minutes. The result was adjusted upward 0.5°F as recommended by the thermometer manufacturer. Rectal temperature was then taken.

Findings

Analysis of the pairs of recorded temperatures for each subject revealed close agreement between the rectal temperature and the adjusted 6-minute pacifier temperatures. Differences between the two were not statistically significant. Variations between measurements are certain to occur when temperature is measured at different sites, so the researcher does not recommend replacing rectal thermometers with pacifier thermometers when a rectal temperature is indicated. Rather, it is the researcher's recommendation to use the pacifier thermometer as a screening tool.

Nursing Implications

Pacifier thermometers are an acceptable tool for temperature screening in children 7 days to 24 months of age. Nurses must use the thermometer properly, as well as instruct parents in its appropriate use if it is to be used at home. Consistent use of one particular method is important for tracking trends in temperature management over time. The mathematical upward adjustment of 0.5°F must be included in the reporting of temperatures measured by pacifier thermometry.

Adapted from Braun, C. A. (2006). Accuracy of pacifier thermometers in young children. *Pediatric Nursing*, 32(5), 413-418.

A newer method of temperature measurement is with the pacifier thermometer. See [Evidence-Based Practice 10.1](#).

Take Note!

Avoid the rectal route of temperature measurement in the immunosuppressed child as well as the child who has diarrhea, a bleeding disorder, or a history of rectal surgery (Asher & Northington, 2008).

PULSE

Assess the heart rate while the child is resting or sleeping. The heart rate in infants is much faster than in adults. It also varies in infants

and children who are anxious, fearful, or crying. As the child grows, the heart rate slows and the range of normal values narrows. [Table 10.3](#) lists heart rate ranges according to the child's age. The radial pulse is difficult to palpate accurately in children younger than 2 years of age because the blood vessels lie close to the skin surface and are easily obliterated (Bickley & Szilagy, 2009). For children younger than 10 years of age, auscultate the apical pulse with the stethoscope for a full minute (Jarvis, 2008). In older children, palpate the radial pulse for a full minute ([Fig. 10.5](#)). Note any irregularities in strength or rhythm. Finally, document the method used to obtain pulse measurement as well as any activity of the child during the assessment and any action taken.

Take Note!

In the infant and young child, the heart rate is often quite elevated due to fear or anxiety when the stethoscope is placed on the chest initially. For an accurate heart rate, wait several seconds until the rate slows, and then count for 1 full minute.

RESPIRATORY RATE

Assess respirations when the child is resting or sitting quietly, since respiratory rate often changes when infants or young children cry, feed, or become more active. They also tend to breathe faster when they are anxious or scared. The most accurate respiratory rate is obtained before disturbing the infant or child (Bowden & Greenberg, 2008). This can often be done easily when the parent/caregiver is holding the child before any clothing is removed. Count the respiratory rate for a full minute to ensure accuracy. Infants' respirations are primarily diaphragmatic, so count the abdominal movements. After 1 year of age, count the thoracic movements. [Table 10.3](#) lists ranges of respiratory rate according to the child's age. Document the rate, activity of the child, any deviations from normal, and any action taken.

FIGURE 10.5 Assessing the radial pulse of a young child.

| TABLE 10.3 HEART RATE AND RESPIRATORY RATE RANGES BY AGE GROUP | | | | | |
|---|--------|---------|-------------|------------|------------|
| | Infant | Toddler | Preschooler | School-age | Adolescent |
| Heart rate | 80–150 | 70–120 | 65–110 | 60–100 | 55–95 |
| Respiratory rate | 25–55 | 20–30 | 20–25 | 14–22 | 12–18 |

Adapted from Kliegman, R. M., Behrman, R. E., Jenson, H. B., & Stanton, B. F. (2007). *Nelson textbook of pediatrics* (18th ed.). Philadelphia: Saunders; and Schaider, J. (Ed.), (2007). *Rosen & Barkin's 5-minute emergency medicine consult*. Philadelphia: Lippincott Williams & Wilkins.

Take Note!

Infants normally display an uneven or irregular breathing pattern, with short pauses between some breaths. This may be accentuated when they are ill (Bickley & Szilagy, 2009).

MEASURING OXYGEN SATURATION

Since the incidence of respiratory dysfunction is high in ill children, pulse oximetry is often routinely included in the vital signs assessment. This method is reliable and noninvasive. Pulse oximetry determines the oxygen saturation (SaO₂) in blood by using a sensor that measures the absorption of light waves as they pass through highly perfused areas of the body. The pulse rate on the oximeter should coincide with the apical pulse rate to ensure that the oxygen saturation reading is accurate. [Nursing Procedure 10.2](#) details how to use the pulse oximeter. Identify whether pulse oximetry monitoring will be continuous or intermittent (as with vital signs).

A few guidelines to follow when using pulse oximetry are as follows:

- The probe may be placed on the finger, toe, ear, or foot. Avoid placing the probe on the same extremity with a blood pressure cuff or an intravenous or other type of line.
- Use the physician's orders or health care agency guidelines to set parameters for high and low pulse rate as well as high and low oxygen saturation. Never turn off the alarm settings.
- Ensure that the probe is not applied too tightly, as this will prevent venous flow and cause inaccurate readings.

Potential sources of errors in pulse oximeter readings include abnormal hemoglobin value, hypotension, hypothermia, ambient light interference, motion artifact, and skin breakdown. Falsely low readings may be associated with a nonsecure connection (movement of child's foot or hand), cold extremities/hypothermia, and hypovolemia. Falsely high readings may be associated with carbon monoxide poisoning and severe anemia (DeMeulenaere, 2007).

BLOOD PRESSURE

The National Heart, Lung, and Blood Institute (NHLBI) recommends that children older than 3 years of age have their blood pressure measured at least once during every health care episode (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005). Children younger than 3 years old should have blood pressure measured if they have one of the following risk factors:

- History of prematurity, very low birthweight, or other neonatal intensive care complication
- Congenital heart disease
- Recurrent urinary tract infections, hematuria, proteinuria, known renal disease or urologic malformations, family history of congenital renal disease
- Malignancy, bone marrow transplant, or solid organ transplant
- Treatment with medications that raise blood pressure
- Systemic illnesses associated with hypertension such as neurofibromatosis and tuberous sclerosis
- Increased intracranial pressure (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005)

In the hospital or outpatient setting when a child is ill or undergoing surgery or a procedure, the frequency of blood pressure measurement will depend on the child's physical status. Measurement of blood pressure can be frightening to a young child, so include an age-appropriate explanation and perform the procedure after obtaining the pulse rate and respirations ([Fig. 10.6](#)). Accuracy of blood pressure measurement depends on the cuff size, as well as the operator's skill and accurate calibration of an electronic device. The NHLBI recommends that the cuff bladder width be at least 40% of the circumference of the upper arm at its midpoint (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005). The cuff bladder length should cover 80% to 100% of the circumference of the upper arm. Various pediatric and infant cuffs are available, as well as larger thigh cuffs that may be used on an arm in an obese adolescent.

NURSING PROCEDURE 10.2

Pulse Oximetry Monitoring

1. Explain the procedure to the child and family (use a penlight to show how the sensor "looks through the skin").
2. Attach the probe to the child and connect to the monitor.
3. Set the parameters for the alarm if monitoring pulse oximetry continuously.
4. Observe and record pulse rate and oxygen saturation.
5. Record the activity level of the child and the percentage of oxygen in use.
6. Check skin condition and rotate sensor position every few hours.

Types of probes

a. Infant continuous

b. Finger continuous

c. Finger intermittent

Adapted from Nellcor Puritan Bennett, Inc. (2011). *Clinician's guide to Nellcor sensors*. Retrieved March 24, 2011, from http://www.nellcor.com/_Catalog/PDF/Product/CliniciansSensorGuide.pdf

Take Note!

Using an *accurate cuff* size is important: a wider cuff yields a lower reading and a narrower cuff yields a higher reading.

Measure blood pressure in the upper arm, lower arm, thigh, or calf/ankle. The size of the cuff should match the extremity used. The measurement should be taken in the same limb, at the same place, and in the same position with each subsequent measurement to ensure consistency in tracking the blood pressure. To measure blood pressure using the upper arm, place the limb at the level of the heart, place the cuff around the upper arm, and auscultate at the brachial artery. When obtaining blood pressure in the lower arm, again, position the limb at the level of the heart, place the cuff above the wrist, and auscultate the radial artery. For measurement in the thigh, place the cuff above the knee and auscultate the popliteal artery. To obtain blood pressure on the calf or ankle, place the cuff above the malleolus or at the midcalf and auscultate the posterior tibial or dorsal pedal artery. [Figure 10.7](#) shows appropriate cuff placement and auscultation points for the various sites.

FIGURE 10.6 Allowing children to handle the equipment gives them some control over the situation.

The NHLBI recommends auscultation as the preferred method of obtaining blood pressure readings in children (U.S. Department of Health and Human Services, National Institutes of Health, National Heart, Lung, and Blood Institute, 2005) (Fig. 10.8). Systolic pressure in children is read at the moment the first Korotkoff sound is heard as the manometer pressure is lowered. The point at which the sound disappears is the diastolic pressure. The systolic blood pressure sometimes can be heard to a measurement of zero, so document the reading as systolic pressure over “P” for pulse.

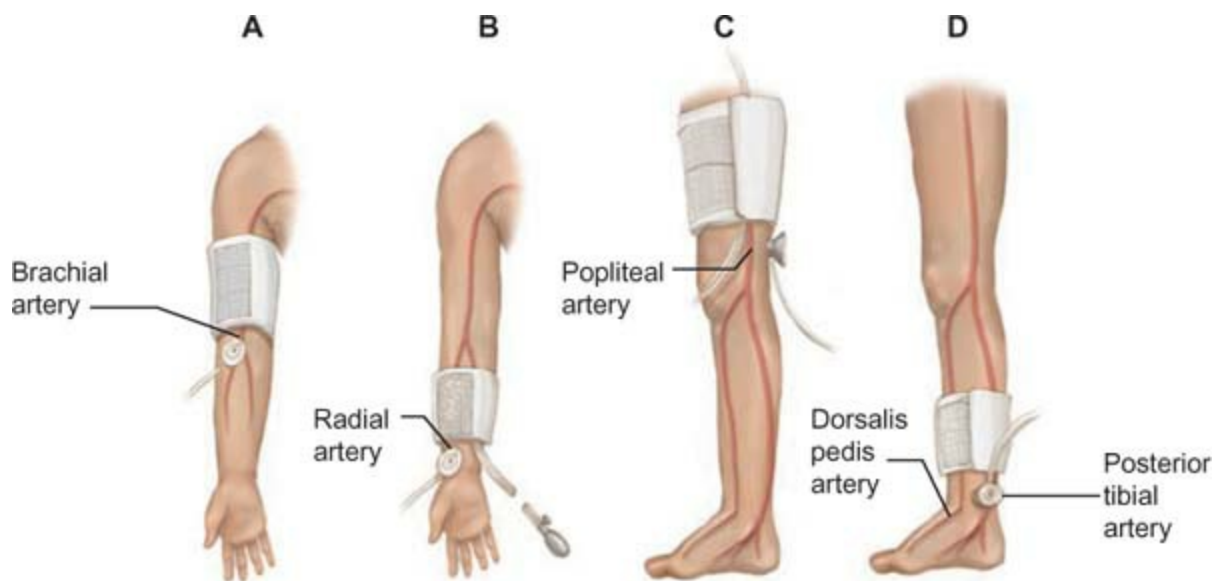

FIGURE 10.7 Various positions of cuff placement and auscultation area for obtaining blood pressure. (A) Upper arm. (B) Lower arm. (C) Thigh. (D) Calf/ankle.

FIGURE 10.8 Auscultation is the preferred method for measuring blood pressure in children.

Due to the small arm vessels in infants and young children, it may be very difficult to hear the Korotkoff sounds by auscultation (Jarvis, 2008). Alternative methods for obtaining blood pressure measurements in children include the use of Doppler or oscillometric (Dinamap) devices. The Doppler ultrasound method uses high-frequency sound waves that bounce off body parts to obtain blood pressure. Apply the gel to the Doppler end and listen with the Doppler device where Korotkoff sounds would normally be auscultated.

With either the Doppler method or auscultation, inflate the cuff 20 mm Hg past the point where the distal pulse disappears. Oscillometric equipment measures the mean arterial pulse and then calculates the systolic and diastolic readings. The accuracy of this method depends heavily on ongoing validation and calibration. Also, the cuff inflates to a preset value often far higher than the infant or child's blood pressure, resulting in a tight, uncomfortable cuff being in place for a longer period of time.

Take Note!

If the oscillometric device yields a blood pressure greater than the 90th percentile for gender and height, repeat the reading using auscultation.

In children older than 1 year, the systolic pressure in the thigh tends to be 10 to 40 mm Hg higher than in the arm; the diastolic pressure remains the same. Refer to [Appendix C](#) for the NHLBI blood pressure levels based on gender and height. Systolic blood pressure increases if the child is crying or anxious, so measure the blood pressure with the child quiet and relaxed. If the reading is lower in the leg than in the arm, always consider coarctation of the aorta or interference with circulation to the lower extremities. Also pay attention to the pulse pressure (the difference between the systolic and diastolic readings): unusually wide (more than 50 mm Hg) or narrow (less than 10 mm Hg) pulse pressure readings suggest a congenital heart defect (Burns et al., 2009).

Pain Assessment

Pain is considered to be the “fifth vital sign” (Jarvis, 2008). Use the FLACC pain scale to measure pain in children who are too young to verbally or conceptually quantify their pain, or when there is a language barrier (Manworren & Hynan, 2003). The FLACC pain scale consists of a possible 10 points, with 0, 1, or 2 points given for each of five clinical signs (see [Table 14.7](#) in [Chapter 14](#)).

Children who are older and can express that pain is worsening or improving should use the Pain Faces Scale (see [Fig. 14.3](#) in [Chapter 14](#)). Explain that each face represents a person who is happy or sad, depending on how much or how little pain he has: 0 is for a person who is “very happy because he doesn’t hurt at all”; 1 means “it hurts just a little bit”; 2, “it hurts a little more”; 3, “it hurts even more”; 4, “it hurts a whole lot”; and 5, “it hurts as much as you can imagine—but you don’t have to be crying to feel this bad.” Then ask the child to point to the face that best describes the amount of pain being felt (Wong & Baker, 1988).

For additional information related to pain assessment, refer to [Chapter 14](#).

Body Measurements

Appropriate growth in children is usually an indicator of good health. A child who is not growing well may be in poor health, have inappropriate or inadequate dietary intake, or have a chronic disease (Bickley & Szilagy, 2009). Accurate assessment of growth is a critical skill for the pediatric nurse.

Determine the child's height or length, weight, and weight for length or body mass index (BMI). Measure the head circumference for healthy children younger than age 3. Plot these measurements on a graph so they can be compared with earlier measurements and those of the child's peers. Additional anthropometric measurements used in children may include the chest circumference, mid-upper arm circumference, and skin-fold measurement at the triceps, abdomen, or subscapular regions, but these are not performed routinely and are usually used only when a nutritionist consultation is necessary.

The growth chart is a screening tool for nutritional problems as well as a useful screen for chronic illness. Record each measurement in ink with a small dot at the correct location for the child's age and the date of the measurement written above it. Then use a plastic straightedge to connect the previous measurement to the most current one. Children grow at variable rates; in infancy and prepuberty, the growth velocity is normally more rapid. The growth chart allows the nurse to compare the child to other children of the same age and gender while allowing for normal genetic variation. When measurements fall close to the same percentiles over time, growth is normal for that child. Children whose measurements fall within the 5th and 95th percentiles are generally considered within the normal growth range (Rebeshi & Brown, 2007).

Sudden or sustained changes in percentile may indicate a chronic disorder, emotional difficulty, or nutritional intake problem (Bickley & Szilagy, 2009). These findings require further assessment of the physical status of the child as well as other types of evaluations such as dietary intake or serum laboratory measurements.

Appendix A provides growth charts for boys and girls, ages birth to 36 months and 2 to 20 years. The Centers for Disease Control and Prevention (CDC) (2002) recommends the use of these growth charts with all children, though special growth charts are also available for children with specific conditions. Look for a trend over time of healthy growth that is neither too fast nor too slow.

Take Note!

The most valid and reliable growth charts are those supplied by epidemiologists at the Centers for Disease Control and Prevention.

LENGTH OR HEIGHT

Calculate the length of the infant and toddler in a lying position until the age of 24 months. Use a measuring board (Fig. 10.9) or a cloth or paper measuring tape. Stretch out the legs to get a full extension of the body. Marking the examination paper at the child's head and extended foot is an option. Make sure that the growth chart where the measurement is plotted is marked for length and not height, as the two measurements differ. Document the length in centimeters and inches.

FIGURE 10.9 The recumbent measuring board is the most accurate method for obtaining a length measurement in infants and very young children.

Once the child can cooperate and stand independently, begin measuring the standing height. Using a stadiometer is best (Fig. 10.10), but a cloth or paper tape can be used. Ask the child to remove his or her shoes and check that the back, shoulders, buttocks, and heels are against the wall, with the pelvis tucked as much as possible to correct for lordosis. The chin should be parallel to the floor. Plot this measurement on a growth chart marked for height rather than length. Record the height in centimeters as well as feet and inches.

FIGURE 10.10 Standing height is most accurately measured with the stadiometer.

Take Note!

Cloth and paper measuring tapes may stretch over time. Periodically replace or recalibrate all measuring tools.

WEIGHT

Measure weight on a scale that is calibrated between every measurement. Just before placing the child on the electronic scale, press the “zero” or “tare” button and make sure the reading is 0. Calibrate the balance-type scale by setting the weight at zero, observing the beam balance, and making adjustments as necessary. Infants and toddlers should be weighed on a platform-type electronic or balance scale, with an examination paper placed between the child and the scale surface. Calibrate the scale with the examination paper in place. Remove the infant’s diaper immediately before placing him or her on the scale. Toddlers may sit on the scale with the nurse or caregiver nearby to avoid falls (Fig. 10.11). Weigh older children and adolescents on a standing scale (Fig. 10.12). They may keep their underpants on and wear a lightweight examination gown.

An alternate method for obtaining weight, though much less accurate, is to weigh the caregiver initially and then weigh the caregiver holding the child. The difference between the two weights is the child’s weight. Regardless of the method used, weigh the infant to the nearest 10 g (or half-ounce) and the toddler and older child to the nearest 100 g (or quarter-pound). Record the weight in kilograms and in pounds.

WEIGHT FOR LENGTH

For children between the ages of newborn and 36 months, plot weight on the growth chart in comparison to the child’s length. This

allows the nurse to determine whether the child is a healthy weight for how long he or she is. Children placing less than the 5th percentile on the weight-for-length chart are considered underweight. Those placing greater than the 95th percentile are considered to be overweight.

BODY MASS INDEX (BMI)

With the recent increase in obesity in children, BMI is becoming an important measurement. **BMI** is a measure of body fat and is determined by comparing the child's height and weight (CDC, 2002). Calculate the BMI using the child's weight and height by either the English or metric method. **Box 10.1** provides BMI calculation formulas. BMI is included on the charts for children ages 2 to 20 years. Plot the BMI on the growth chart according to the child's age. A child whose BMI for age plots at less than the 5th percentile is considered to be underweight. BMI between the 85th and 95th percentiles indicates risk for overweight. BMI greater than the 95th percentile indicates the child is overweight.

FIGURE 10.11 A nurse or caregiver should remain nearby while weighing the infant or toddler.

FIGURE 10.12 Children who can stand independently can be weighed on a regular standing balance scale.

BOX 10.1

CALCULATION OF BODY MASS INDEX (BMI)

English Formula:

$$\frac{\text{weight in pounds}}{(\text{height in inches}) \times (\text{height in inches})} \times 703$$

Metric Formula:

$$\frac{\text{weight in kilograms}}{(\text{height in meters}) \times (\text{height in meters})} \times 10,000$$

The growth chart can indicate when a child is not growing adequately and can also be used to predict the development of overweight and obesity (CDC, 2002). Refer to Healthy People 2020.

| Objective | Nursing Significance |
|---|---|
| Reduce the proportion of children and adolescents who are considered obese. | <ul style="list-style-type: none"> • Screen for overweight in all children by plotting weight for length of children younger than 36 months and body mass index for age for children age 2–20 years. • Assess dietary intake and activity level in all children at risk for or overweight. • Provide diet and activity recommendations to attain a healthy weight or BMI. • Refer significantly overweight children to a pediatric endocrinologist. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

FIGURE 10.13 Measure occipitofrontal head circumference at the largest point.

HEAD CIRCUMFERENCE

Measure head circumference at well-child visits and upon hospital admission until the third birthday. Then measure it at the annual well-child visit until 6 years old if there are problems such as microcephaly or macrocephaly present at age 3. Measure the largest point across the skull, not including the ears, with a nonstretching cloth or paper tape. Begin at the forehead just above the eyebrows and bring the tape around the head in a taut circle just above the occipital prominence at the back of the head ([Fig. 10.13](#)). Plot this measurement in relation to the child's age on the appropriate standardized growth chart (usual growth charts include head circumference only up to age 3 years).

Monitoring Equipment

Sometimes children in acute care settings require continuous monitoring of vital signs. This monitoring could be via an apnea monitor or a cardiopulmonary monitor. The apnea monitor measures abnormal or irregular breathing in infants. The cardiopulmonary monitor generally measures heart rate and respiratory rate. Additional equipment on this monitor also allows for blood pressure and

temperature monitoring. Set high and low alarm limits according to the health care facility's policies. [Figure 10.14](#) indicates the placement of electrodes for the apnea and cardiopulmonary monitors. Assess the skin where the electrodes are placed to ensure there is no skin breakdown. If the alarm sounds, immediately check the child to ensure the leads are not disconnected or the child is not in distress.

Skin

The skin is the body's largest organ and reveals information about a child's nutrition, respiratory, cardiac, endocrine, and hydration status at a glance. A careful skin examination provides an invaluable understanding of a child's health (Jarvis, 2008).

FIGURE 10.14 Placement of cardiac apnea monitor leads: white on the right upper chest, black on the left upper chest, green or red on the abdomen (not over bone).

INSPECTION

Inspect the color of the skin. The color should be appropriate to the child's racial or ethnic background, with the nail beds, conjunctivae, soles of the feet, and palms of the hands appearing pink. Normal variations include the following:

- Blueness of the hands and feet, known as **acrocyanosis**, is normal in babies up to several days of age and results from an immature circulatory system completing the switch from fetal to extrauterine life (see [Fig. 3.3A](#) in [Chapter 3](#)).
- Cooling or warming the newborn and young infant may produce a vasomotor response that causes a mottling of the skin over the trunk and extremities (see [Fig. 3.3B](#)).
- Babies of darkly pigmented Native American, African, and Asian parents will be paler than their parents for many months until the melanocytes in the epidermis begin production.
- Dark-skinned infants commonly have hyperpigmented areolas, genitals, and lineanigra.

Other variations related to skin color are discussed in [Box 10.2](#).

Inspect the skin for the presence of **lanugo**. All infants display some degree of lanugo (soft, downy hair on the body, particularly the face and back). Lanugo is more abundant in infants of Hispanic descent and in premature infants and recedes over the first few weeks of life.

Inspect the entire body for nevi and vascular and other lesions. Note their location, size, distribution, characteristics, and color. Pigmented nevi (also termed birthmarks) are indicated by a darker patch of skin and generally do not fade over time. Note the presence of hyperpigmented nevi (formerly called Mongolian spots), which appear as blue or gray, variably and irregularly shaped macules ([Fig. 10.15](#)). These are a common finding in dark-skinned infants. These nevi fade over months to years as the child's skin pigment darkens. Do not mistake hyperpigmented nevi for bruises. Inspect the skin for vascular lesions. [Table 10.4](#) describes vascular lesions and their significance.

BOX 10.2

VARIATIONS IN SKIN COLOR AND THEIR CAUSES

- **Pallor** (defined as decreased pinkness in light-skinned patients, ashy-gray in dark-skinned) is caused by anemia, shock, fever, or syncope.
- **Peripheral cyanosis** (blue discoloration) occurs in nails, soles, and palms and may be caused by anxiety or cold; also associated with central cyanosis.

- **Central cyanosis** (blueness of the lips, tongue, oral mucosa, trunk) is caused by hypoxia or circulatory collapse.
- Overall yellow color (**jaundice**) may be physiologic in the newborn or related to liver or hematopoietic disease in any age child.
- **Yellowing** of nose, palms, and soles may result from excess intake of yellow vegetables.
- **Redness** of the skin results from blushing, exposure to cold, hyperthermia, inflammation (localized), or alcohol ingestion.
- **Lack of color** in skin, hair, and eyes is related to albinism.

Adapted from Bickley, L., & Szilagyi, P. G. (2009). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2008). *Physical examination and health assessment* (5th ed.). St. Louis: Saunders.

Rashes are common in children and are often associated with communicable diseases. Describe the rash in detail, noting types of lesions, distribution, drying, scabbing, scaling, and any drainage. The newborn and young infant may display milia (small white papules) on the forehead, chin, nose, and cheeks. These recede spontaneously. In adolescents the skin examination may reveal open or closed comedones (pimples or blackheads) across the face, chest, and back. Teens may sport tattoos, brandings, or various body piercings; inspect these areas for signs of infection such as erythema or drainage (Fig. 10.16).

FIGURE 10.15 Transient hyperpigmentation most often occurs in darker-skinned infants.

FIGURE 10.16 Adolescent with multiple piercings.

Document the presence of any lacerations, abrasions, or burns. Note the distribution of the injury and whether it seems consistent with the mechanism described in the health history. Be alert to the possibility of child abuse if the type or number of burns, lacerations, or bruises seems unusual for the situation.

Take Note!

Petechiae or ecchymosis may be found over areas traumatized by the birth process; these may take a few weeks to resolve. Certain cultures use “cupping” or “coining” when a child is ill, and these practices may yield bruises or mild burns (International Cupping Therapy Association, 2006).

PALPATION

Palpate the skin for temperature, moisture, texture, turgor, and edema. Use the back of your hand to assess the skin’s temperature, comparing the right side of the body to the left and the upper body to the lower. The skin should feel uniformly warm. Cool extremities are associated with environmentally cool temperatures as well as impending circulatory collapse and shock. Warm skin may be associated with fever or sunburn, or locally a burn or infectious process. The skin should feel fairly dry, occasionally moister in the creases. Dry, flaking skin may occur in the young infant, particularly if born postmaturely. Overall skin dryness in the well-hydrated child may occur with excess sun exposure, poor nutrition, or overbathing. Moist skin occurs with perspiration, fever resolution, and shock. The infant’s and young child’s skin is very soft ordinarily. Older children should continue to have a smooth and even skin texture. The preadolescent and adolescent may have oily-feeling skin on the face, shoulders, or back.

| Description | Significance |
|--|--|
| Salmon nevi: light pink macule usually on eyelids, nasal bridge, back of neck (“stork bite”) | Usually fade over time, but may never go away completely. No complications. |
| Strawberry nevus: raised reddish papule made of blood vessels (hemangiomas) | Present at or develop after birth; recede over time, usually by age 9 years. Usually no complications. |
| Nevus flammeus: dark purple-red flat patch, grows with the child (“port-wine stain”) | May be associated with Sturge-Weber syndrome. May be disfiguring; may be removed with laser therapy. |
| Ecchymosis: purplish discoloration, changing to blue, brown, black (bruise) | Common on lower extremities in young children. Should correlate with the injury. |
| Petechiae: pinpoint reddish purple macules that do not blanch when pressed | Broken tiny blood vessels; occur with coughing, bleeding disorders, meningococemia |
| Purpura: larger purple macules that do not blanch when pressed | Bleeding under the skin; occur with bleeding disorders, meningococemia |

Adapted from Bickley, L., & Szilagyi, P. G. (2009). *Bates’ guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2008). *Physical examination and health assessment* (5th ed.). St. Louis: Saunders.

Assess skin turgor by elevating the skin on the abdomen in the infant or on the back of the hand in the older child or teen. The “pinched-up” skin should quickly return to place. Skin that remains tented is strongly suggestive of moderate to severe dehydration. When edema is present, palpate the edematous area to determine its extent. Palpate any lumps or protrusions to determine firmness or tenderness. Palpate lesions or rashes with a gloved hand to document the size and extent of the lesions.

Hair and Nails

Inspect the hair and scalp, noting distribution of hair as well as color, texture, amount, and quality. The young infant’s hair may be absent entirely or quite thick; it will be replaced by hair that is of a texture and color closer to what the child will have throughout childhood. Coarse, dry hair at any age may indicate a thyroid disorder or nutritional deficiency. Inspect the scalp thoroughly; it should be free from lesions and infestations. Note the presence of a greasy, scaly plaque on the scalp of infants; termed seborrheic dermatitis or cradle cap, it is benign and easily treated.

Inspect the nails for color, shape, and condition. Full-term infants may have long, papery fingernails that can scratch their skin if not trimmed. Children should have healthy nails. Dry, brittle nails may indicate a nutritional deficiency. Inspect the skin around the nails to ensure that it is intact and without signs of infection. Many children (especially school-age children) have a nervous habit of nail biting or hangnail biting or pulling.

Inspect the school-age child’s or adolescent’s toenails to ensure they are trimmed in a horizontal fashion. Self-trimming of toenails

either too low or in a curved fashion places the child at risk for the development of ingrown nails. Clubbing of the nails indicates chronic hypoxemia related to respiratory or cardiac disease. Nails that curve inward or outward may be hereditary or linked with injury, infection, or iron-deficiency anemia.

Head

Examining the head is critical in the newborn and infant periods but should not be overlooked in older children as an opportunity to check for diseases of the scalp and functional and developmental problems that are reflected in poor hygiene of the head and scalp. Note hair distribution and any bald or thinning areas. Use of gloves may be indicated, depending on the overall scalp cleanliness and chance of infestation by head lice (seen as small grayish specks near the base of hair shafts).

INSPECTION

Examine the head and face for shape and symmetry. In newborns, the head may be temporarily misshapen from uterine positioning or a lengthy vaginal delivery. Some infants have a slight flattening of the back of the head since the recommended sleeping position is supine. Note any irregularities or asymmetry. Observe the infant's head shape by looking down on it from above. Observe whether the head appears centered on the neck or tilts to one side. After 4 months of age, the infant should have achieved enough head control to hold the head erect and in midline when placed in a vertical position. Pull the infant from the supine position into sitting to determine the extent of head lag. To determine the extent of head control in older infants and children, ask the child to turn the head in different directions, either by simple commands or by following a colorful object.

Observe the infant's face when crying, smiling, or babbling for symmetry of muscle movement. In children who are old enough to follow directions, a game of "Simon Says" is a playful way to determine facial symmetry and strength; ask them to puff out their cheeks, make kisses, look surprised, stick out their tongue, and so on (effectively testing function of cranial nerve VII [facial]) (Bickley & Szilagy, 2009).

Take Note!

When you note a flattened occiput in an infant, encourage the parent or caregiver to allow the infant "tummy time" while awake and observed and to change the infant's head position frequently when upright in an infant seat (Dowshen, 2008).

PALPATION

Gently palpate the anterior and posterior **fontanel**s (Fig. 10.17). The fontanel is the soft areas on the skull that remain open in infancy to allow for rapid brain growth in the first months of life. Note the size of the fontanel. The anterior fontanel is about the size of a quarter at birth and slowly gets smaller until it can no longer be felt when it is closed by the age of 9 to 18 months. The posterior fontanel is much smaller and may close any time between shortly after birth and approximately 2 months of age. The fontanel should not be depressed or taut and bulging, though it is not uncommon to see them pulsate or briefly bulge if the baby cries. In an acutely ill infant, assess the fontanel while obtaining the vital signs. Dehydration can cause the fontanel to be sunken; increased intracranial pressure and overhydration can cause them to bulge. Palpate the skull for asymmetry, overriding or open sutures, and lumps or other deformities. Palpate the jaw joints as the child bites down to assess cranial nerve V (trigeminal). Use the fingertips to palpate for occipital, postauricular, preauricular, submental, and submandibular lymph nodes, noting their size, mobility, and consistency (Fig. 10.18).

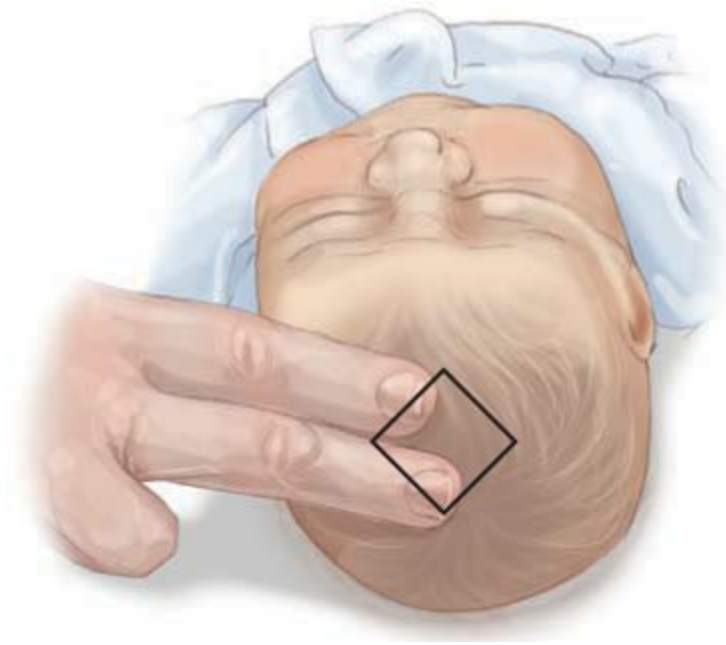

FIGURE 10.17 Note location and size of the fontanel. The anterior fontanel is diamond shaped and closes between the ages of 9 and 18 months.

Take Note!

Large fontanel may be associated with Down syndrome or congenital hypothyroidism. A fontanel that becomes larger over time rather than smaller may indicate the development of hydrocephalus, especially if accompanied by an accelerated increase in head circumference (Bickley & Szilagy, 2009).

FIGURE 10.18 Location of lymph nodes.

Neck

Inspect the neck for symmetry. The infant's neck is short, but by 4 years of age the child's neck should be similar in appearance to the adult's. Webbing or excessive neck skin folds may be associated with Turner syndrome, and lax neck skin may occur with Down syndrome. Assess the flexibility of the neck through a full range of motion. Take younger children through a passive range of motion. Older children will be able to look in all directions on command and stretch their chins to their chests themselves. Test cranial nerve XI (accessory) in the older child by having the child attempt to turn the head against resistance. Assessment of neck mobility is particularly important when infections of the central nervous system are suspected. Pain or resistance to range of motion may indicate meningeal irritation. Do not assess neck mobility in the trauma victim.

Take Note!

The infant or child who has experienced trauma should have the cervical spine maintained completely immobile until a radiologist has determined that the spinal cord is not damaged.

Palpate the neck for masses and lymph nodes. Palpate the cervical and clavicular lymph nodes with the distal part of the fingers using gentle but firm pressure in a circular motion. Tilt the child's head upward slightly to allow better access. Assess the lymph nodes for swelling, mobility, temperature, and tenderness. In healthy infants and adolescents, the cervical lymph nodes are usually not palpable; in healthy children between 1 and 11 years, the cervical nodes are often found to be small, nontender, and mobile (see Fig. 10.18 for locations of lymph nodes). Enlarged cervical lymph nodes frequently occur in association with upper respiratory infections and otitis media. Report significant enlargement to the physician or nurse practitioner. Palpate the trachea; the thyroid is usually palpable only in older children.

Eyes

Assessment of the eyes includes evaluation of the external and internal structures as well as screening for visual acuity. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal structures will also be covered below but is usually performed only by the advanced practitioner. Refer to Chapter 9 for information on vision screening. Determination of visual acuity tests the function of cranial nerve II (optic).

EXTERNAL STRUCTURES

Observe the eyes for symmetry and spacing, even distribution of eyelashes and eyelids, and presence of epicanthal folds. Note the child's ability to blink, and report an inability to do so. The eyes should look symmetric and both should be facing forward in the midline when the child is looking directly ahead. The iris should be perfectly round and the sclerae should be clear. The cornea should be uniformly transparent. Inspect the corners of the eye (medial and lateral canthus) and the conjunctiva (lining of the eyelids). They should be free of discharge, inflammation, or swelling. Epicanthal folds may be present in children of Asian descent, children with genetic abnormalities, or those with fetal alcohol spectrum disorder. Using a small penlight or ophthalmoscope, inspect the function and clarity of the pupil by putting your nondominant hand on the child's forehead and moving the light toward and away from each eye. This will elicit the blink reflex. Next observe whether the pupil contracts with the light and expands when the light is removed. Make the same motion with a small toy or object and direct the child to look at it. The eyes demonstrate **accommodation**, or focusing at different distances, if the pupil constricts as the object moves closer. If normal findings are present, report **PERRLA** (pupils are equal, round, reactive to light and accommodation) (Fig. 10.19). This is a particularly important assessment in head and eye injuries, as well as when other neurologic concerns are present. Absence of pupillary reflexive action after age 3 weeks may indicate blindness (Jarvis, 2008).

Take Note!

The normal infant may exhibit intermittent strabismus (crossing of the eyes) until about 3 months of age. However, persistent strabismus at any age or intermittent strabismus after 6 months of age should be evaluated by a pediatric ophthalmologist (Burns et al., 2009).

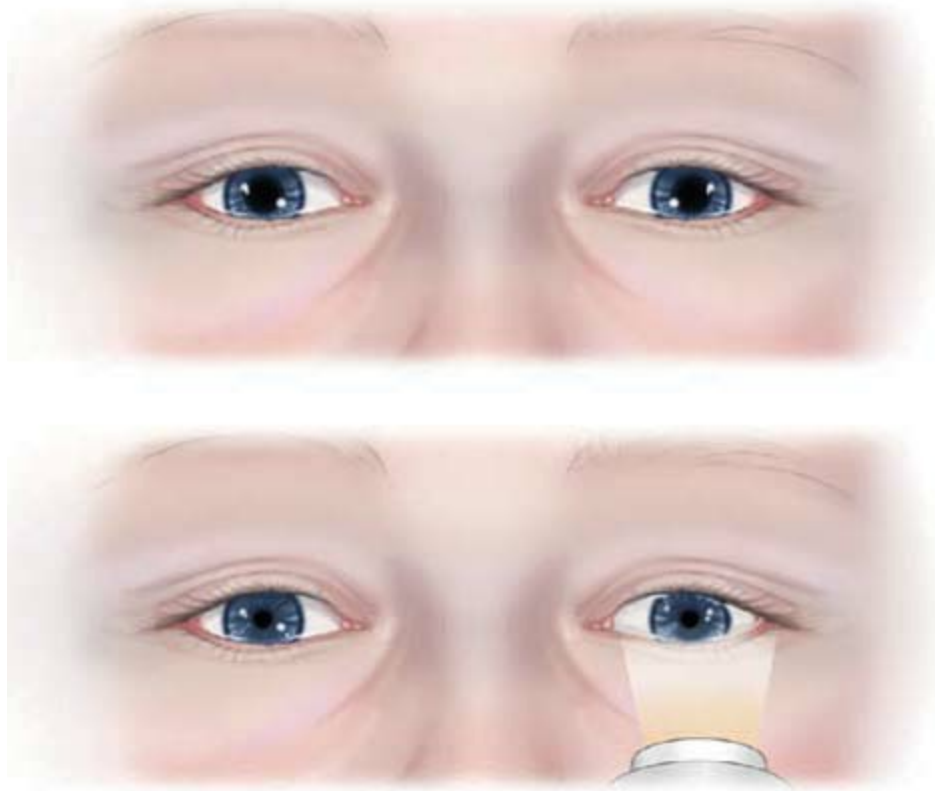

FIGURE 10.19 The pupils should be equal, round, and reactive to light and accommodation (PERRLA).

FIGURE 10.20 Note reflected light falling symmetrically on each pupil with the Hirschberg test.

Check extraocular muscle motility and function of cranial nerves III and IV (oculomotor and abducens) by instructing the child to follow the light through the six cardinal positions of gaze. Infants and very young children will follow an interesting object. Instruct the older child to look downward and inward (testing cranial nerve IV [trochlear]). Assess eye muscle strength using two tests. Using the Hirschberg test, bring the penlight to the middle of your face and direct the child to look at it. The small dot of reflected light seen in the iris should be placed symmetrically in each eye (Fig. 10.20). The cover test also assesses eye muscle strength. Cover one of the child's eyes and instruct the child to focus on an interesting object. The eye should not waver. While the child is still focusing with the first eye, remove the cover from the second. Observe the uncovered eye for movement. Report any movement or drift.

To test peripheral vision, have the child focus on a specific point or object directly in front. Bring a finger or a small object from beyond the range of vision into the area of the peripheral vision. When the child sees the object from the side, while still focusing on the object or point in front, the child should say "stop." This also tests cranial nerve II (optic).

INTERNAL STRUCTURES

An advanced practitioner with experience in this type of assessment best accomplishes assessment of the internal structures of the eye. An adequate assessment requires that the child cooperate. Restraint for eye examination does not usually prove fruitful, as movement and tearing of the eyes interfere with the accuracy of the examination. Use the ophthalmoscope to inspect the internal eye structures. Observe the glow of the pupil, which appears red (creamy colored in children with very dark eye color). Inspect the optic disc, macula, fovea, and blood vessels. Refer any child with blurring or bulging of the optic disc or hemorrhage of vessels to a pediatric ophthalmologist for further evaluation.

Take Note!

Immediately report absence of the red reflex in one or both eyes, as this may indicate the presence of cataracts (Bickley & Sziiagyi, 2009).

Ears

Assessment of the ears includes evaluation of the external and internal structures as well as screening for hearing. Any nurse caring for a child should be adept at examining the external structures. Assessment of the internal structures will also be covered below but is usually performed only by the advanced practitioner. Refer to [Chapter 9](#) for information on hearing screening. Testing of hearing also tests the function of cranial nerve VIII (acoustic).

EXTERNAL STRUCTURES

Assess the placement of the external ears on the head. They should be symmetric and placed no lower than the eyes. The pinna should deviate no more than 10 degrees from an imaginary line that is perpendicular to a line drawn between the outer canthus of the eye and the top of the ear. Low-set ears may be associated with genetic abnormalities or syndromes ([Fig. 10.21](#)). Note protrusion or flattening of the ears, which may be normal for that child or may indicate inflammation (protrusion) or persistent side-lying (flattening). Note the presence of pits or skin tags in the preauricular area. Observe the exterior ear canal. A waxy cerumen that is soft and an orangish-brown color is normally found lubricating and protecting the external ear canal and should be left in place or washed gently away when bathing. Note drainage from the ear canal, which is always considered abnormal. Pull on the auricle and palpate the mastoid process, neither of which should result in pain in the healthy child.

FIGURE 10.21 Low-set ears may be associated with chromosomal or other genetic anomalies.

Take Note!

Impacted and dry cerumen can be softened with a few drops of mineral or cooking oil and then gently irrigated from the canal with an ear syringe and warm water (Nettina, 2010).

INTERNAL STRUCTURES

Use a **tympanometer** to assess the mobility of the eardrum (tympanic membrane). Gently pull down on the earlobe of infants and toddlers and up on the outer edge of the pinna in older children to straighten the ear canal, and press the tip of the tympanometer over the external canal. A reading of air pressure is recorded by the instrument, and this is useful to assess middle ear disease. Many tympanometers record a wave pattern that may be printed to include in the child's chart.

A nurse practitioner or physician generally performs inspection of the ear canal and tympanic membrane with an otoscope (Fig. 10.22). The otoscopic examination is usually performed near the end of the physical assessment for infants and young children, as they are often quite resistant to this intrusive procedure. The infant or toddler may require restraint in the parent's lap for the otoscopic evaluation. The preschooler may cooperate if the nurse uses a game such as looking for pretend puppies or potatoes in the child's ear. As with the tympanometer, gently pull down on the earlobe of the infant or toddler and up on the outer edge of the pinna in older children to straighten the ear canal. Use an otoscopic speculum appropriate to the size of the child's ear canal. Insert the speculum into the ear canal to visualize the canal and the tympanic membrane. The canal should be pink, should have tiny hairs, and should be free from scratches, drainage, foreign bodies, and edema. The tympanic membrane should appear pearly pink or gray and should be translucent, allowing visualization of the bony landmarks. It may be red if the child has been crying recently. Compress the pneumatic insufflator bulb to provide a puff of air; this causes motion of the tympanic membrane when the middle ear is healthy. Note abnormalities such as a fluid level, bubble or pus behind the tympanic membrane, tympanic membrane immobility, holes or perforations in the tympanic membrane, and the presence of tympanostomy tubes, scarring, or vesicles.

FIGURE 10.22 Otoscopic examination allows visualization of the internal structures of the ear.

Take Note!

Never attempt to flush a foreign object out with water until it has been identified, because small pieces of sponge, clay, or vegetative material like peas or beans swell with water, further obstructing the ear canal (Nettina, 2010).

Nose and Sinuses

The nose, as with all facial features in a child, should be symmetric, but it can be displaced temporarily by birth trauma in newborns. Children of Asian or African descent often display a flattened nasal bridge as a normal variation. Ensure that the nares provide unobstructed airflow by alternately occluding one nostril at a time and observing for air movement through the other nostril. If the child is breathing comfortably, there should be little nostril movement visible. Adolescents may have pierced their nose or nasal septum;

ensure that the site is free from infection or loose jewelry that could migrate into the sinuses. Ideally the nose should not be draining, though clear mucus may be present if the child has been crying. Assess the amount, color, thickness, and presence of any odor if drainage is present. Inspect the interior of the nose by tilting the child's head backward and pushing the tip of the nose upward. Direct the beam of a penlight in the nostril. The nasal mucosa should be uniformly firm, pink, and free from edema, excoriation, or masses. Test the older child's sense of smell by having the child close the eyes and identify a familiar scent such as peppermint or coffee (cranial nerve I [olfactory]). Palpate the sinuses for tenderness.

Take Note!

Infants up to 3 to 6 months of age have traditionally been thought to be obligate nose breathers because of their long soft palate and relatively large tongue, which allows for swallowing without aspiration during breast or artificial nipple feeding. This lessens with age and as the infant becomes better able to breathe through the mouth when necessary (Bickley & Szilagy, 2009).

Mouth and Throat

Wear a powder-free glove to examine the mouth, teeth, and throat. Inspection of the exterior of the mouth may be done at any point in the examination. Infants and young children may find assessment of the mouth and particularly the pharynx and uvula to be quite intrusive, so delay that part of the assessment until the end of the examination, after otoscopic evaluation. Assess the character and quality of the child's voice and the infant's cry. It should be neither too hoarse nor too shrill.

INSPECTION OF THE MOUTH

Observe the lips for color, symmetry, and absence of inflammation or edema. Salivation in infants begins at about 3 months of age; drooling occurs because the infant does not learn to swallow saliva until several months later. Next, inspect the interior of the mouth. The mouth is the first part of the digestive system, and a pink, moist, healthy mucosal lining is indicative of a healthy gastrointestinal tract. In infants, the tongue should lie within the mouth at rest and should be capable of extending over the lower gum line to help the baby feed. The tongue extrusion reflex is normal in infants up until the age of 6 months and allows the infant to suckle easily from birth. Observe movement of the tongue when the infant or young child babbles or cries. Ask the older child to touch the tongue to the roof of the mouth and then stick out the tongue and move it from side to side (testing cranial nerve XII [hypoglossal]). Full movement should be present and the tongue should be free from lesions or exudate. Visualize the hard and soft palate (which should be intact) or palpate with the gloved finger.

Most infants have no teeth before the fifth to sixth month. When the teeth begin to erupt, they usually erupt symmetrically at the rate of about one a month, until toddlers have 20 teeth by 30 months of age. The infant may drool for several months before teething. During teething the gums will be swollen at the location of the impending tooth. In older children, the secondary teeth replace the primary teeth much more slowly and with little discomfort from the 5th to the 20th year. [Figure 10.23](#) shows the usual permanent tooth eruption pattern.

Look for dental caries or alignment problems and inspect the gums for signs of infection. Test cranial nerve IX (glossopharyngeal) by having the child identify taste with the posterior portion of the tongue.

Take Note!

Natal (present at birth) or neonatal (erupting by 30 days of age) teeth should be evaluated by a pediatric dentist for potential extraction, as they may pose an aspiration risk (Bickley & Szilagy, 2009).

INSPECTION OF THE THROAT

Inspect the tonsils, uvula, and oropharynx. Assess the infant's throat during a yawn or cry, as any forcible attempt to depress the tongue with a tongue depressor produces a strong reflex elevation of the base of the tongue that completely blocks the view of the pharynx. The young child will require restraint so that the nurse can depress the tongue and visualize the back of the mouth without injuring the child ([Fig. 10.24](#)). Asking the older child to open wide, stick out the tongue, and say "aaaah" simultaneously will allow for a quick look at the tonsils and pharynx without the need to use a tongue depressor, but the nurse must be very quick because the tongue rises rapidly after those maneuvers are performed.

Tonsils usually cannot be seen in the infant. As the child becomes a toddler, the tonsils become dramatically larger and then begin to decrease in size again by the ninth year. The tonsils should be pink and often have crypts on their surfaces, which are sometimes filled with debris. Ensure that the uvula is midline and rises if the gag reflex is elicited (cranial nerve X [vagus]). Inspect the oropharynx, which should be pink and free from exudate.

Thorax and Lungs

Assessment of the thorax and lungs begins by observing the shape and contour of the thorax and determining work of breathing. Accurate auscultation of the lungs is essential, since children often have respiratory infections and disorders and may exhibit alterations in respiratory effort and breath sounds. Note the child's color, which should be pink; cyanosis indicates hypoxia. Listen for audible stridor (inspiratory high-pitched sound), expiratory grunting or snoring, audible wheezing (heard with the naked ear), or cough. Document type and extent of cough. Observe the nail beds for clubbing, which occurs with diseases inducing chronic hypoxic states.

THORAX

Examine the chest with the head in a midline position to determine size and shape as well as symmetry, movement, and bony landmarks. The newborn's chest should be smooth and round, with the transverse diameter nearly equal to the anterior-posterior diameter. The shape of the chest progresses to that of the adult by age 5 to 6 years. At that time the anterior-posterior diameter is about half the transverse diameter (Fig. 10.25). At the point where the xiphoid process and the right and left costal margins meet, the costal angle should measure 90 degrees or less. Inspect for structural deformity such as pectus excavatum (depressed sternum) or pectus carinatum (protuberant sternum) (Fig. 10.26). Note symmetric movement of the chest wall with respiration. Infants and younger children are primarily diaphragmatic breathers, so the abdomen and chest will rise and fall together. Older children, particularly adolescent females, demonstrate thoracic breathing, yet the abdomen and chest should continue to rise and fall together. Asymmetry of chest wall movement is an abnormal finding.

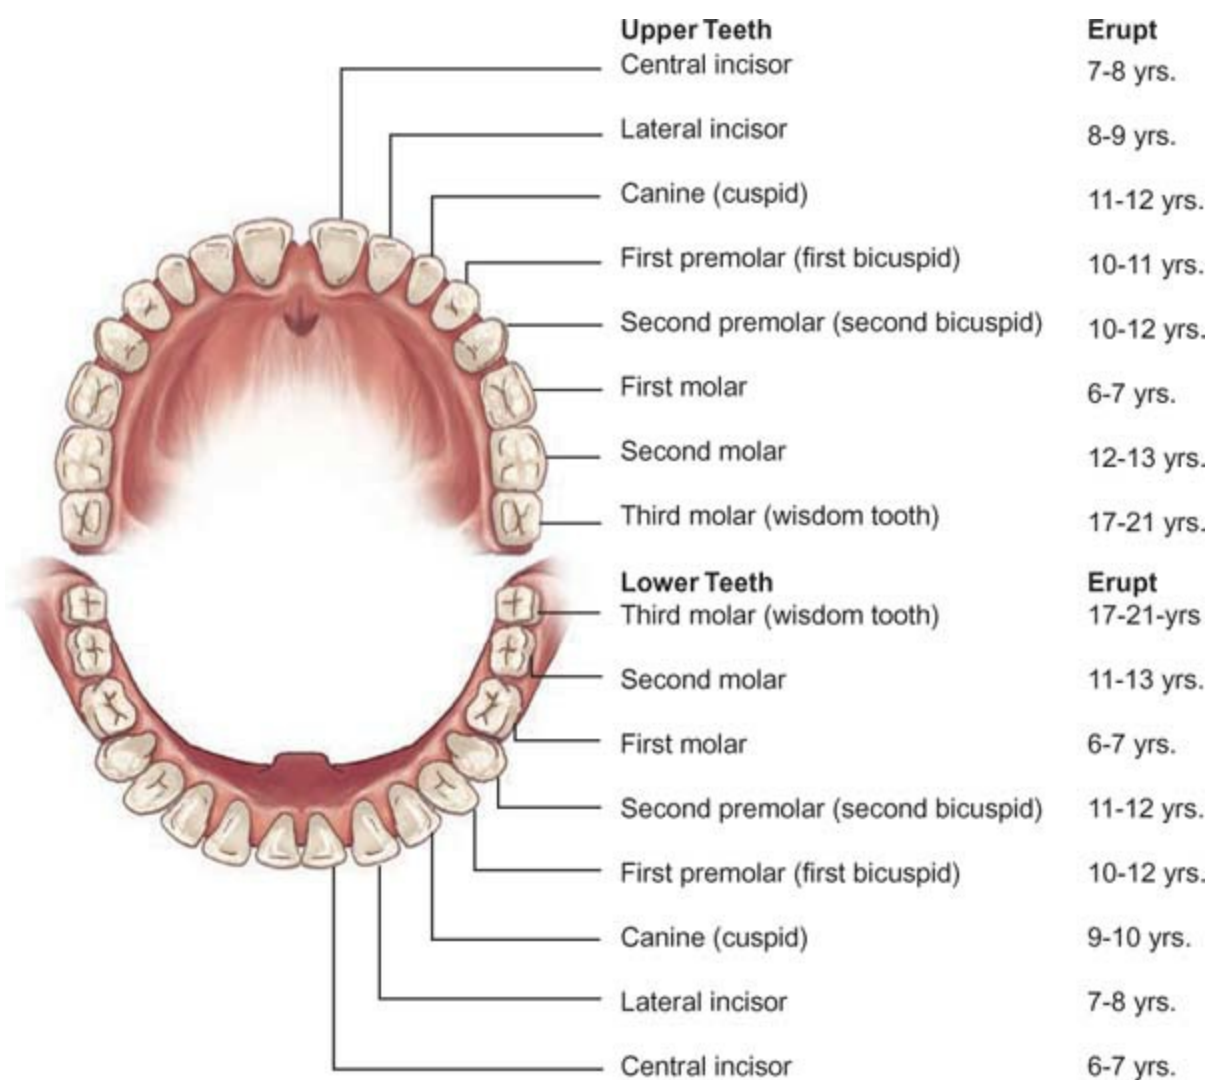

FIGURE 10.23 Usual sequence of permanent tooth eruption.

FIGURE 10.24 The young child may need to be restrained so that the throat examination can be done safely.

Observe the depth and regularity of respirations, noting the length of the inspiratory and expiratory phases in relation to each other. The newborn and young infant demonstrate an irregular respiratory pattern. Older infants and children should have a more regular respiratory pattern.

Assess the child's respiratory effort by first observing for nasal flaring, which indicates labored breathing. Observe the chest wall and shoulders for accessory muscle use, which normally is not present. If retractions are present, note their location and severity. Typical locations for retraction include the intercostal, subcostal, substernal, suprasternal, and clavicular regions (Fig 10.27). Pay attention to the position the child naturally assumes to breathe comfortably; children in respiratory distress often sit forward and are uncomfortable lying down or talking (Jarvis, 2008).

LUNGS

Experienced examiners may palpate and percuss the lungs before using auscultation to evaluate the breath sounds.

FIGURE 10.25 (A) The newborn's chest is round. (B) The adult chest has an anterior-posterior diameter about half the transverse diameter.

PALPATION AND PERCUSSION. Palpate for symmetric respiratory excursion by placing the thumbs and fingers together along the costal margin on the chest or back. Movement should be symmetric with each breath. Palpate for the normal presence of tactile fremitus with the palms or fingertips while the infant is crying or the older child says "99." Indirectly percuss the lungs of older children, noting resonance over lung fields. Hyperresonance may be present in conditions resulting in hyper-aeration of the lungs, such as asthma.

AUSCULTATION. Use the bell of the stethoscope or switch to a small diaphragm to auscultate lung sounds in the infant or child. The adult-sized diaphragm may be used for the adolescent. Auscultate the lung fields with the infant or child in a sitting position, even if

that requires propping the infant in a parent's lap. Infants and young children have loud breath sounds because of their thin chest walls. Breath sounds should be clear with adequate aeration throughout all lung fields. Listen to a full inspiration and expiration at the apices of the lungs as well as symmetrically across the entire lung field, systematically comparing the right to the left side. Listen on the anterior chest, on the posterior chest, and in the axillary regions.

FIGURE 10.26 Pectus excavatum: note depression in xiphoid area.

Playing games may encourage younger children to cooperate with deep breathing during lung assessment. The child can blow a cotton ball up in the air, blow a pinwheel, or “blow out” the light of the penlight (Miller, 2011). Older children are capable of deep breathing when instructed to do so.

The child who has a respiratory disorder or who is experiencing respiratory distress may exhibit diminished breath sounds, most often in the lung bases. Diminished breath sounds are softer and quieter than lung sounds demonstrating adequate aeration. In the healthy infant or child, no adventitious sounds should be heard. If noisy breath sounds are heard in the infant or young child, particularly over all lung fields, compare the sound to the noises heard over the trachea or within the nose. Infants and young children with secretions in the nasopharyngeal area may have those sounds transmitted over the lung fields. These sounds usually clear with coughing or airway suctioning; they are not true adventitious sounds. Note adventitious breath sounds such as wheezes or crackles, documenting their location and whether they are present on inspiration, expiration, or both. It is most important to describe the abnormal breath sounds being heard rather than attempting to classify the sounds. Adventitious lung sounds are associated with a variety of disorders, and extensive experience is required to appropriately classify lung sounds. Adventitious breath sounds should be reported for further evaluation.

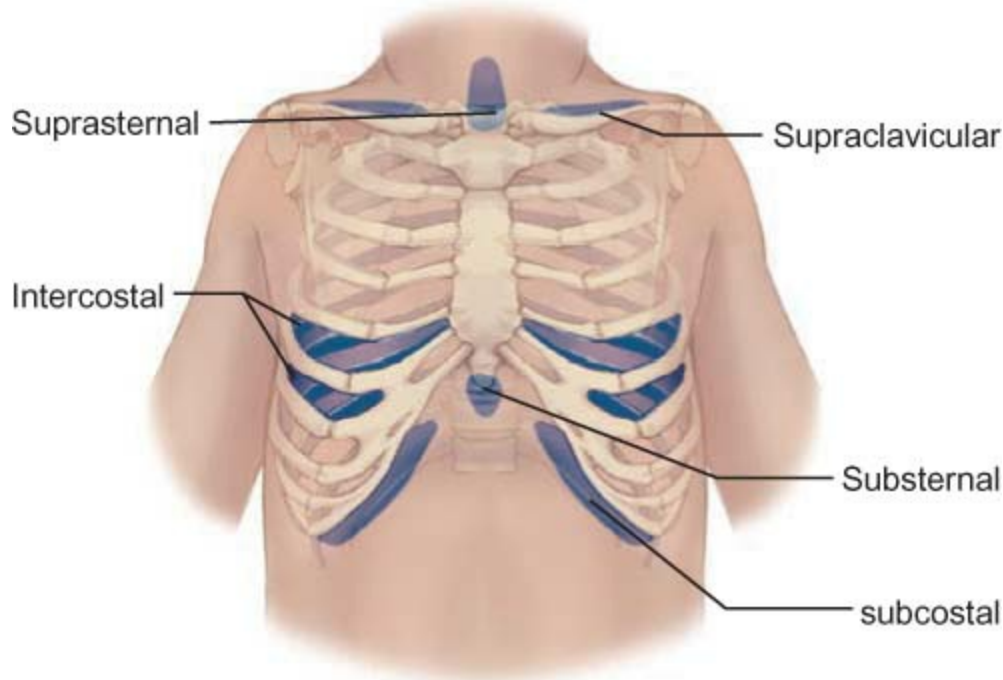

FIGURE 10.27 Location of retractions.

Breasts

Assess the breasts of children of all ages and both genders. Note the size of the breasts in relation to the age of the child. Palpate the axillary lymph nodes during the breast assessment.

INSPECTION

Observe the breasts for position, shape, size, symmetry, and color. Newborns of both genders may have swollen nipples from the influence of maternal estrogen, but by several weeks of age the nipples should be flat and should continue to be so in all prepubertal children. In children the nipples are located lateral to the midclavicular line, usually between the fourth and fifth rib. The areola becomes darker in color as the child approaches puberty. Overweight children may appear to have enlarged breasts due to adipose tissue. Note the location of additional (supernumerary) nipples if present (usually located along the mammary ridge); they may appear as darkly pigmented, elevated or nipplelike spots. These are usually of no concern as they do not change over time, but they may be associated with renal disorders.

Inspect the breasts for the current stage of development: widening of the areola, elevation of the nipple, and increase in breast size. Female breast development may begin as early as age 8, but starts by age 13 in most girls. Breast development then continues in a characteristic, but usually asymmetric, pattern, with one breast larger than the other throughout the lifespan. The sexual maturity rating scale developed by Tanner in 1962 is used to describe breast development (**Tanner stages**; Fig. 10.28). Adolescent boys may develop gynecomastia (enlargement of the breast tissue) due to hormonal pubertal changes. When the hormone levels stabilize, male adolescents then have flat nipples. Occasionally gynecomastia is caused by marijuana use, anabolic steroids, or hormonal dysfunction (Jarvis, 2008).

PALPATION

Palpate the breasts in a systematic fashion. A tender nodule palpated just under the nipple confirms pubertal changes. This change may be difficult to assess in girls with excessive adipose tissue. Normal breast tissue should feel smooth, firm, and elastic. Note masses or nodules if present. Palpate for axillary lymph nodes with the child's arms relaxed at the side but slightly abducted. Note size and texture of nodes if present.

Heart and Peripheral Perfusion

The examination of the heart in children is identical to that of adults except for the focus of the examiner's attention. Congenital heart defects are the most common cause of heart problems in children, and children with these defects present differently than adults with heart disease.

Take Note!

The *younger the child*, the more responsive the heart rate is to activity changes. It increases with fever, fear, crying, or anxiety and decreases with sleep, sedation, or vagal stimulation (Jarvis, 2008).

INSPECTION

Observe the child's posture. Note the presence of pallor, cyanosis, mottling, or edema, which may indicate a cardiovascular problem. Inspect the anterior chest from the side or at an angle, noting symmetry in shape as well as movement. Observe for the apical impulse, which is visible in about half of children. It occurs at the **point of maximum intensity (PMI)**, which is located at the third to fourth intercostal space just medial of the child's left midclavicular line until age 4 years, at the fourth intercostal space at the left midclavicular line in children ages 4 to 6 years, and then lateral to the left midclavicular line at the fifth intercostal space in children ages 7 years and older (Fig. 10.29). Note clubbing of the fingertips or distention of neck veins, both of which may be associated with congenital heart disease.

PALPATION

Using the fingertips, palpate the chest for lifts and heaves or thrills, which are not normal. Palpate the apical pulse in the area of the PMI (see Fig. 10.29). Check the pulses and compare the upper body to lower body pulses, as well as left versus right, noting strength and quality (Fig. 10.30). The pedal, brachial, and femoral pulses are usually easily palpated. The radial pulse is very difficult to palpate in children younger than 2 years of age. Note warmth of the distal extremities. To assess capillary refill time, place slight pressure on the nail beds and quickly release it. Observe the length of time required for refill and return to original color. Compare capillary refill time of the fingers to the toes. A capillary refill time of less than 3 seconds indicates adequacy of perfusion.

FIGURE 10.28 Tanner sexual maturity rating for breast development. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

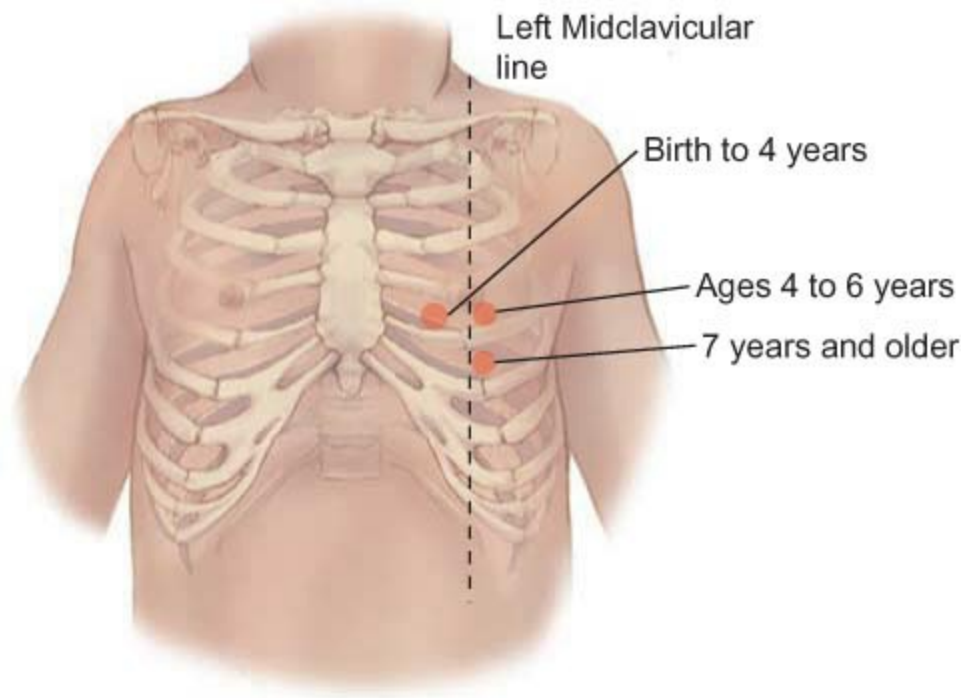

FIGURE 10.29 The point of maximal intensity (PMI) or apical impulse.

FIGURE 10.30 It is important to assess brachial and femoral pulses simultaneously to determine equality or differences in strength and intensity.

FIGURE 10.31 Auscultating the child's heart.

AUSCULTATION

Perform auscultation of the heart with the child in two different positions, upright and reclined (Fig. 10.31). Auscultate the heart rate in the area of the PMI as this is the point on the chest wall where the heartbeat is heard most distinctly (see Fig. 10.29). As you begin auscultation, listen first for respirations and note their timing so as not to confuse the heart sounds with the lung sounds. A crying infant may help by briefly holding his or her breath between cries. Once you are confident that you are listening to the heart, be sure to listen for 1 full minute because of the irregularity of rhythms in some children. Count the heart rate, which should be consistent with the palpated pulse (either radial or brachial, depending on the child's age).

Develop a systematic approach to auscultation of the heart. Listen over all four valvular areas anteriorly (Fig. 10.32). In the infant or younger child, also auscultate the heart in the axillary region and posteriorly (certain murmurs radiate to these areas). Note S_1 , S_2 , extra heart sounds, or murmurs. S_1 is usually loudest at the mitral and tricuspid areas and increases in intensity with fever, exercise, and anemia. S_2 is usually most intense at the aortic and pulmonic areas. A split S_2 heard at the apex occurs in many infants and young children. S_3 may be heard in many healthy children and is considered normal, though the child with a chronic cardiac condition may develop an S_3 when congestive heart failure is present. S_4 is usually considered abnormal, most often occurring with cardiac disease.

Sinus arrhythmia is a common and normal finding in children and adolescents. It results in an irregular heart rhythm: the heart rate increases with inhalation and decreases with exhalation. If the child holds his or her breath, the rhythm becomes regular.

FIGURE 10.32 Areas where the sounds of heart valves radiate. A: Aortic valve—second intercostal space, just right of sternum. P: Pulmonic valve—second intercostal space, just left of sternum. T: Tricuspid valve—fourth intercostal space, just left of sternum. M: Mitral valve—fourth intercostal space at left midclavicular line.

Auscultate for murmurs. Note the location (where it is heard best or loudest) and timing of the murmur. A systolic murmur occurs in association with S1 (closure of the atrioventricular valves), a diastolic murmur in association with S2 (closure of the semilunar valves). Also note the duration of murmur. Does it occur early or late in diastole or systole? Does it occur all the way across systole (holosystolic)? Note the intensity of the murmur. [Table 10.5](#) discusses grading of murmur intensity.

Innocent murmurs occur frequently in children because of the child’s more dynamic circulation, thin chest wall, and angulated vessels (Menashe, 2007). An innocent murmur is most often heard at the second or fourth intercostal space, and its timing is systolic. The innocent murmur is usually medium pitched and musical. Often an innocent murmur disappears when the child changes position. A venous hum that is heard in the supraclavicular area and possibly radiating down the chest is considered an innocent murmur. Refer any child with a murmur to an experienced practitioner for further evaluation.

Abdomen

The abdomen contains organs related to the genitourinary and lymphatic systems, in addition to the gastrointestinal system. These structures lie within the abdomen in approximately the same location as they do in adults. Dividing the abdomen into quadrants simplifies the description of normal organ location and the reporting of abnormalities. Draw an imaginary vertical line from the xiphoid process to the symphysis pubis. Cross this with an imaginary perpendicular line through the umbilicus. The sequence of physical examination is altered for the abdominal assessment: auscultation is done before percussion and palpation because manipulation of the lower abdomen may affect the bowel sounds (Bickley & Szilagy, 2009).

TABLE 10.5 GRADING HEART MURMURS IN CHILDREN

| Grade | Sound |
|-------|---|
| 1 | Barely audible; sometimes heard, sometimes not. Usually heard only with intense concentration |
| 2 | Quiet, soft; heard each time the chest is auscultated |
| 3 | Audible, intermediate intensity |
| 4 | Audible, with a palpable thrill |
| 5 | Loud, audible with edge of the stethoscope lifted off the chest |
| 6 | Very loud, audible with the stethoscope placed near but not touching the chest |

Adapted from Menashe, V. (2007). Heart murmurs. *Pediatrics in Review*, 28, e19–e22.

INSPECTION

Inspect the abdomen for size, shape, and symmetry. The abdomen in the infant and toddler is rounded and protuberant until the abdominal musculature becomes well developed. Though rounded, the abdomen should not be distended (at any age). By adolescence, the stature is more erect and the abdomen begins to appear flat when standing and concave when supine. The thin skin of a young child may allow the visualization of superficial venous circulation across the abdomen. Inspect the abdomen for movement. At eye level with the abdomen, note abdomen and thorax movement occurring simultaneously. Visible peristaltic waves are abnormal and should be reported immediately.

Inspect the newborn's umbilicus for color, bleeding, odor, and drainage. The umbilical stump should slowly dry, become black and hard, and fall away from the cutaneous navel by the end of the second week of life. Note drainage or granulation at the umbilical site indicating delayed drying of the umbilical stump. Inspect the umbilicus in older infants and young children for the presence of umbilical hernia. Because the umbilicus divides the rectus abdominis muscle, it is not uncommon to see an umbilical hernia protrude through and become larger when the infant or toddler strains or cries. This is a benign finding and will usually disappear as the abdomen becomes stronger. Adolescents may have jewelry piercing the umbilicus.

AUSCULTATION

Auscultate the abdomen using the diaphragm or the bell of the stethoscope pressed firmly against the abdomen. Count the bowel sounds in each of the four quadrants for a full minute. Bowel sounds should be present by a few hours after birth and should remain active throughout life. Note whether bowel sounds are normally active, hyperactive, hypoactive, or absent. Normal bowel sounds can be described as growls, gurgles, and clicking sounds. Hypoactive bowel sounds may occur postoperatively. Hyperactive bowel sounds are common with diarrhea. Classify bowel sounds as absent after listening for 5 full minutes in each area. Absent bowel sounds may indicate ileus or peritonitis.

PERCUSSION

Indirectly percuss all areas of the abdomen. Normal findings include dullness along the costal margins and tympany over the remainder of the abdomen. A full bladder may yield dullness to percussion.

PALPATION

Palpate the abdomen with the child in a supine position. If the child's legs are small enough, the knees may be brought up with the nondominant hand to flex the hips and relax the abdomen. Palpate all four quadrants of the abdomen in a systematic fashion, first lightly and then deeply. Apply light pressure with the fingertips to perform light palpation, assessing for tenderness and muscle tone (Fig. 10.33). Note skin turgor by gently elevating a piece of skin and allowing it to fall back into place. Perform deep palpation to assess the organs and any masses. Place one hand on top of the other and palpate from the lower quadrants to the upper (see Fig. 10.33). The edge of the liver may be felt at the right costal margin, and the tip of the spleen can be felt at the left costal margin. The descending colon may be felt in the left lower quadrant as a small column and the bladder as a soft balloon below the umbilicus. The kidneys are rarely palpable. The abdomen should be soft and nontender to palpation. Report firmness, tenderness, or masses. Palpate the inguinal area for the presence of hernia or enlarged lymph nodes.

FIGURE 10.33 (A) Light and (B) deep palpation of the abdomen.

Take Note!

To decrease ticklishness with abdominal palpation, place a flat, warm, still hand on the abdomen while distracting the child before palpation begins. An alternate technique is to first palpate with the child's hand under the examiner's hand.

Genitalia and Anus

Examination of the genitals should immediately follow the abdominal assessment in the younger child and should be reserved for the end of the assessment in the adolescent. Though the anus is part of the gastrointestinal tract, it is best assessed during the genital examination. Ensure privacy for the older child and adolescent. Keep the child covered as much as possible. Use a casual, matter-of-fact approach to place the child or teen at ease. During the genital examination, teach the child or adolescent about normal variations and changes with puberty, as well as issues related to health promotion.

MALE

Inspect the penis and scrotum for size, color, skin integrity, and obvious masses. The obese boy's penis may appear small because of additional skin folds. Penis size should correlate with pubertal stage (Fig. 10.34). The penis may have a foreskin that covers the glans, protecting and lubricating it. If present, do not forcibly retract the foreskin. In circumcised males the urinary meatus is exposed and should be at the tip of the glans. Assess the meatus for absence of discharge. If possible, observe the stream of urine for strength of flow and patency of the urethral orifice. Skin lesions may indicate sexually transmitted infection. A foreskin that cannot be retracted in a boy older than 3 years of age may indicate phimosis. Report abnormal findings.

FIGURE 10.34 Tanner male sexual maturity rating for genitalia and pubic hair. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

Take Note!

When you first *remove* a male infant's diaper, this is the ideal time to assess the force of the urine stream and the erection reflex, as the cool air may make the infant void and briefly experience an erection.

Assess the presence and distribution of pubic hair. Inspect the scrotum for size, slight asymmetry, color, and absence of edema. The scrotum may initially be swollen from birth trauma or maternal hormones, but this swelling should decrease in the first few days of life. The scrotum is ordinarily more deeply pigmented than the rest of the boy's skin. [Figure 10.34](#) illustrates scrotal changes that occur with puberty. Assess the testicles by placing one finger over the inguinal canal and palpating the scrotum with the other. This prevents the retractile testes in a young child from slipping back up the inguinal canal. The testicles should be smooth, of similar sizes, and freely moveable. The infant's testicles may be palpated in the scrotum or in the inguinal canal, where they can be easily moved into the scrotum with gentle pressure from the examiner's nondominant hand ([Fig 10.35](#)). Beyond infancy, allow the boy to sit cross-legged to reduce the cremasteric reflex that retracts the testicles during palpation. An adolescent boy may need to stand for the nurse to fully palpate the scrotum. Document the presence of both testicles in the scrotal sac, if they are retractile, or if they are absent. Report unde-scended testicle or other abnormal findings.

FIGURE 10.35 Placing a digit over the inguinal canal during testicular palpation prevents retraction of the testis into the canal.

FEMALE

In most cases, the female genitalia examination is limited to assessment of the external genitalia. Internal examination is not routinely performed before maturity unless the adolescent anticipates becoming or is sexually active or requests birth control, or if pathology is suspected. If an internal examination is needed, refer the child or adolescent to the appropriate advanced practitioner or physician.

Position the infant in the parent's lap or on the examination table or crib. The toddler or preschooler should be examined in the parent's lap, in a frog-legged position. The school-age or adolescent girl should lie on the examination table or bed. Provide for privacy by keeping the genital area covered until it is time for the examination.

Perform the assessment of the external genitalia in a systematic fashion. First, determine the presence and distribution of pubic hair. Infants and young girls (particular those of dark-skinned races) may have a small amount of downy pubic hair. Otherwise, the appearance of pubic hair indicates the onset of pubertal changes, sometimes prior to breast changes. Pubic hair generally begins to appear by age 11 years, with age 13 being the latest. [Figure 10.36](#) illustrates the development of pubic hair through puberty in girls.

Inspect the labia majora and minora for size, color, and skin integrity. The newborn's labia minora are swollen from the effects of maternal estrogen but will decrease in size and be hidden by the labia majora within the first weeks of life. Redness or swelling of the labia may occur with infection, sexual abuse, or masturbation. Lesions on the external genitalia may indicate sexually transmitted infection. Gently spread the labia to inspect the clitoris, urethral meatus, and vaginal opening. Some girls may prefer to spread the labia themselves. The urinary meatus and vaginal orifice should be visible and not occluded by the hymen. It is not uncommon to see a hymenal tag. Note clitoral size. Inspect the urinary meatus and vaginal opening for edema or redness, which should not be present. Observe for any vaginal discharge. A small amount of blood-tinged or mucoid discharge may be noted in the first few weeks of life as a result of maternal hormone exposure. A small amount of clear mucus-like discharge is normal in all females. If present, document labial adhesion or other abnormal findings.

ANUS

Inspect the anal area for fissures, rash, hemorrhoids, prolapse, or skin tags. Examine the infant's anal area while examining the genitalia. The younger child may lie back in the parent's lap and flex the knees to the chest. The older child or adolescent may be prone or in a side-lying position. If the adolescent boy is already standing for the scrotal assessment, have him bend forward so that you can assess the anal area. The anus should appear moist and hairless. Gently stroke the anal area to elicit the anal reflex (quick contraction). If indicated, inspect anal sphincter tone by inserting a gloved finger lubricated with water-soluble jelly just inside the anal sphincter.

FIGURE 10.36 Tanner female sexual maturity rating for pubic hair. (Adapted from Tanner, J. M. [1962]. *Growth at adolescence*. Oxford, England: Blackwell Scientific Publications.)

Musculoskeletal

Assessment of the musculoskeletal system includes examination of the clavicles and shoulders, spine, extremities, joints, and hips. Determining the child's ability to move all extremities through the full range of motion is also important.

CLAVICLES AND SHOULDERS

Palpate the clavicles. In the newborn, tenderness or crepitus reveals a fracture sustained at birth. In the older infant or child, a bump indicates callus formation with clavicle fracture. Test shoulder strength and the function of cranial nerve XI in the older child by requesting that the child shrug the shoulders while you apply downward pressure.

SPINE

Observe the child's resting posture and alignment of the trunk. The newborn's position will look like the position the baby preferred in utero and is one of general flexion. The older infant moves more and can sit unassisted in the second half of the first year. Toddlers stand with a wide-based gait, a slightly swayed back, and the abdomen slightly protruding. The posture straightens in the preschool and school-age years. Adolescents often demonstrate kyphosis as the skeleton and muscles are both growing rapidly (Fig. 10.37).

Inspect the child's spine. The newborn's spine has a single C-shaped curve and remains rounded for the first 3 months of life. The cervical curve begins to develop around 3 to 4 months of age as the baby gains head control. By 12 to 18 months of age, the lumbar curve develops, which corresponds to the onset of walking. The S-shaped spine in older children and adolescents is similar to that of the adult's. The spine should be flexible, with good muscle tone and no rigidity. Assess the back, and hip and shoulder heights for symmetry.

FIGURE 10.37 The teen's posture often demonstrates kyphosis.

Examine the preadolescent and adolescent for the development of scoliosis. Refer to [Chapter 23](#) for information about scoliosis screening. Scoliosis screening is generally performed during well-child examinations by the physician or nurse practitioner or by the middle or high school nurse on a particular day of the school year.

Note mobility of the vertebral column by having the child bend forward and side to side. Flex the neck and move it from side to side. No resistance or pain should occur. Inspect the back for discoloration, tufts of hair, or dimples. A normal pilonidal dimple is sometimes seen at the base of the spine, but there should be no tuft of hair or nevi along the spine. Document and report abnormal findings.

EXTREMITIES

All children, even newborns, should be able to move all extremities spontaneously. Screen the infant younger than 6 months of age for developmental dysplasia of the hip by performing the Ortolani and Barlow maneuvers (refer to [Chapter 23](#) for additional information). These maneuvers are usually best performed by a proficient examiner. Inspect and palpate the child's upper and lower extremities. Assess for symmetry in size, contour, movement, warmth, and color of the extremities. The infant's feet and legs appear bowed secondary to in utero positioning but can be straightened through passive range of motion. Observe the child in a standing position. Bowing of the lower legs (internaltibial torsion) lessens as the toddler begins to bear weight and usually resolves in the second or third year of life as the strength of the muscles and bones increases. When it persists past that time, it is termed genu varum (bow legs). Genu valgum (knock knee) is usually present until the child is 7 years old. Observe the child walking, noting any difficulty with leg position or balance. If the child is reluctant to walk, use play as a way to elicit the behavior. The school-age child should have gait and leg appearance similar to that of the adult.

Note the normal flat foot in the toddler and young child. The arch develops as the child grows and the muscles become less lax, though some children may continue with flexible flat feet; this is considered a normal variation.

Perform passive range of motion of the young infant's extremities. Inability to straighten the foot to midline may indicate clubfoot. Count the fingers and toes, noting abnormalities such as polydactyly (increased number of digits) or syndactyly (webbing of the digits). Palpate the joints for warmth or tenderness. Check the mobility of the joints of the upper and lower extremities by performing range of motion. Determine lower extremity muscle strength by having the child push against the examiner's hands with the soles of the

forefoot. Assess upper extremity strength by having the child squeeze the examiner's crossed fingers and/or push up or down against the examiner's outstretched hands.

Take Note!

Slight tremors may be noticed in the infant's extremities in the first month of life.

Neurologic

The neurologic examination should include level of consciousness, balance and coordination, sensory function, reflexes, and a developmental screening. Motor function is assessed within the musculoskeletal section. Cranial nerve function is generally tested within other portions of the physical assessment as it applies to that section.

LEVEL OF CONSCIOUSNESS

Note the state of alertness and attentiveness to parents and the environment in the newborn and infant. Older infants become interactive with other people, as do toddlers and preschoolers. Younger children demonstrate orientation by positive interaction with family members and by crying or fussing when they feel threatened. By school age, the child should be oriented to name and place and a few years later should be able to state the date as well (even if only the day of the week).

BALANCE AND COORDINATION

The cerebellum controls balance and coordination. Observe the child's gait to assess balance and coordination. Observe toddlers and older children rising and walking from a seated and supine position. They should be able to stand and balance without straining or holding on to objects. Continue to test cerebellar function by having the younger child skip or hop and requesting that the older child or adolescent walk heel to toe. Further tests of cerebellar function responsible for balance and coordination are discussed in [Box 10.3](#). Demonstrate each test and make sure the child understands your instructions.

SENSORY TESTING

Portions of sensory testing related to most of the cranial nerves, vision, hearing, taste, and smell have already been incorporated into other sections as appropriate within the physical assessment. Test cranial nerve V (trigeminal) by lightly touching the child's cheek with a cotton ball. The young infant will root toward the side that is touched. With the child's eyes closed, ask the child to identify other locations where he or she is lightly touched (several different ones) to assess sensation. Ask the child to tell you when he or she is touched. Make a game of this activity to encourage cooperation in younger children. In the older child who knows the definition of sharp and dull, test for these sensations with the child's eyes closed. Use the rounded end of a tongue blade for dull and the broken edge of a tongue blade for the sharp sensation. The child should be able to discriminate the sensations of sharp and dull.

BOX 10.3

CEREBELLAR FUNCTION TESTING

- **Romberg:** Ask the school-age or older child to stand still with eyes closed and arms down by the sides. Observe the child for leaning (stand close in case this does occur). This is considered a positive Romberg test, indicating cerebellar dysfunction. For the following tests, the child should demonstrate accuracy and smoothness:
- **Heel-to-shin:** Have the child lie in a supine position, place one heel on the opposite knee, and run it down the shin.
- **Rapid alternating movements:** The child pats the thighs with the hands, lifts them, turns them over, pats the thighs with the back of the hands, and repeats the process multiple times. An alternate test is for the child to touch the thumb to each finger of the same hand starting at the index finger, then reverse the direction and repeat.
- **Finger-to-finger:** The child's eyes are open. The child touches the examiner's outstretched finger with the index finger, then touches his or her own nose. The examiner moves the finger to a different spot and the child repeats this process several times.
- **Finger-to-nose:** The child's eyes are closed. The child stretches the arm with the index finger extended, then touches his or her nose with that finger, keeping the eyes closed.

Adapted from Bickley, L., & Szilagy, P. G. (2009). *Bates' guide to physical examination and history taking* (10th ed.). Philadelphia: Lippincott Williams & Wilkins; and Jarvis, C. (2008). *Physical examination and health assessment* (5th ed.). St. Louis: Saunders.

REFLEXES

Assess the infant's primitive and protective reflexes. The primitive reflexes involve a whole-body response and are subcortical in nature. Selected primitive reflexes present at birth include Moro, root, suck, asymmetric tonic neck, plantar and palmar grasp, step, and Babinski. Most of the primitive reflexes diminish over the first few months of life, giving way to protective or postural reflexes. Protective reflexes are motor responses related to maintenance of equilibrium. They are necessary for appropriate motor development and remain throughout life once they are established. The protective reflexes include the righting and parachute reactions.

Place one finger in each of the infant's hands to elicit the palmar grasp reflex (usually disappears by age 3 to 4 months). Touch the thumb to the ball of the infant's foot to elicit the plantar grasp reflex. The infant's toes will curl down (this reflex disappears by 8 to 10 months). Refer to [Table 3.2](#) for illustrations and additional explanation of the other reflexes. Appropriate presence and disappearance of primitive reflexes, as well as development of protective reflexes, is indicative of a healthy neurologic system. Primitive reflexes that persist beyond the usual age of disappearance may indicate an abnormality of the neurologic system and should be further investigated (Bickley & Szilagy, 2009).

Assess deep tendon reflexes in all infants and children. Appropriate responses indicate that the reflex arc is intact. Use the reflex hammer in all ages or the curved tips of the two first fingers to elicit the responses in infants. The limb must be relaxed and the muscle partly stretched. Use a snapping motion of the wrist to tap with the fingertips or the reflex hammer. Test the biceps, triceps, patellar, and Achilles reflexes as you would in the adult. It may help to place a finger under the infant's knee to encourage relaxation. Young children who tense up when their reflexes are being tested may relax the area if you have them focus on another area, so have the child clasp the hands while testing the Achilles and patellar reflexes. As the child focuses on the hands, the lower extremities relax (Jarvis, 2008). Distraction may also be helpful.

Grade the strength of the response using the standard scale from 0 to 4+:

- 0: no response
- 1 +: diminished or sluggish
- 2 +: average
- 3 +: brisker than average
- 4+: very brisk, may involve clonus

The newborn's deep tendon reflexes are normally brisk (3+). They decrease to average (2+) usually by 4 months of age. Healthy children should have reflexes of 2 + if the reflex has been elicited properly. Absent, sluggish, or hyperreactive responses usually indicate disease (Bickley & Szilagy, 2009).

DEVELOPMENTAL SCREENING

An important component of the neurologic assessment and a comprehensive child health assessment is developmental screening. Developmental screening may be used to identify children whose developmental status may warrant additional evaluation. Become comfortable with the developmental screening tools used and what the results of the screening mean. Upon completion of the screening, discuss the child's abilities with the parent or caregiver. Developmental screening is often performed separately from the physical examination and is discussed in further detail in [Chapter 9](#) (refer to [page 239](#)).

Refer back to Elliot, the 3-year-old from the beginning of the chapter. What are some important considerations when performing his physical examination?

KEY CONCEPTS

- The health history in children includes more than just the chief complaint, history of present illness, and past medical history; it is important to include the perinatal history and developmental milestones.
- Allow the chief complaint to determine which parts of the history require more in-depth investigation.
- The developmental history will warrant more attention in the younger child, while school performance and adjustment will be more important in the school-age child and adolescent.
- Though the parent will provide most of the health history for the infant and young child, allow the young verbal child to answer questions during the health history as appropriate.
- Direct health history questions to the school-age child and adolescent, seeking clarification from the parents as needed.
- Provide confidentiality and privacy for the adolescent during the health history.
- Weight and length or height should be assessed at each well-child visit to determine adequacy of growth.
- Measure head circumference until age 3 years to monitor brain growth.
- Perform hearing and vision screenings for children of all ages.

- BMI can be used to identify children who are overweight or at risk for being overweight.
- The normal range of vital signs varies based on the child's age.
- The sequence of the physical examination in children should be based on the child's developmental age, his or her level of cooperation, and the severity of the illness.
- Obtain heart rate and respiratory rate and auscultate the heart and lungs while the infant or young child is quiet.
- Perform intrusive procedures such as examination of the ears, mouth, and throat last in the infant or young child.
- Perform the health assessment in a head-to-toe fashion in the school-age child or adolescent, reserving the genitalia and anus examination for last.
- Plan the health assessment in such a way as to minimize trauma to the child or adolescent.
- Use age-appropriate measurement tools to assess pain in children.
- Allow the infant or young child to remain in the parent's lap for as much of the assessment as possible so that the child feels secure.
- Use age-appropriate games during the health assessment to gain cooperation in the younger child.
- Having the young boy sit cross-legged for a testicular examination may reduce the cremasteric reflex.
- The newborn may exhibit a wide variety of normal skin variations.
- The infant's fontanelles should be soft and flat; report a bulging fontanel immediately.
- Jaundice (outside of the newborn period), pallor, cyanosis, and poor skin turgor indicate illness and may need immediate intervention.
- Heart murmurs should be assessed for intensity, location, and duration. They may be innocent or may indicate a congenital heart defect.
- The infant's chest wall is relatively thin, allowing upper airway sounds to be transmitted throughout the lung fields.
- Substernal or xiphoid retractions indicate that the child is laboring to breathe, whereas a fixed, depressed sternum (pectus excavatum) is a structural abnormality.
- The Tanner stages of sexual maturity provide a basis for assessing pubertal development in boys and girls. Use the breast and pubic hair charts for girls and the pubic hair and penis and scrotum size chart for boys.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. A 5-year-old boy visits the physician's office with an upper respiratory infection. Which approach would give the nurse the most information about the child's developmental level?
 - a. Playing a game with the child
 - b. Talking with the child about the teddy bear next to him
 - c. Using a screening tool during a follow-up office visit
 - d. Asking the 10-year-old sibling about the child
2. Which statement indicates the best sequence for the nurse to conduct an assessment in a nonemergency situation?
 - a. Introduce yourself, ask about any problems, take a history, and do the physical examination.
 - b. Perform the physical examination and then ask the family if there are any problems in the child's life.
 - c. Do the physical examination while at the same time asking about the child's previous illnesses; then talk about the family's concerns.
 - d. Get a complete history of the family's health beliefs and practices, and then assess the child.
3. What approach by the nurse would most likely encourage a child to cooperate with an assessment of physical and developmental health?

- a. Explain to the child what's going to happen when the child asks questions.
- b. Explain what is going to happen in words the child can understand.
- c. Force the child to cooperate by having a parent hold him or her down.
- d. Give the child a sticker before beginning the examination.

4. A sleeping 5-month-old girl is being held by the mother when the nurse comes in to do a physical examination. What assessment should be done initially?
 - a. Listening to the bowel sounds
 - b. Counting the heart rate
 - c. Checking the temperature
 - d. Looking in the ears
5. Which assessment finding is considered normal in children?
 - a. Irregular respiratory rate and rhythm
 - b. Split S₂ and sinus arrhythmia
 - c. Decreased heart rate with crying
 - d. Genu varum past the age of 5 years

CRITICAL THINKING EXERCISES

1. A soft and muffled heart murmur is heard in a 4-year-old patient. The mother states that she has never heard that the child has a murmur. What should the nurse do?
2. A nurse is helping a new mother breastfeed her 4-day-old baby. The mother notices that the baby has a bluish cast to the skin on his hands and that sometimes the infant has a tremor. She asks the nurse if the baby is cold, though the baby is swaddled and comfortably resting against the mother's skin. How might the nurse help teach this mother?
3. Devise a plan for encouraging cooperation of the toddler or preschooler during various parts of the physical examination.

STUDY ACTIVITIES

1. In the clinical setting, obtain a health history on an infant, child, or adolescent.
2. In the clinical setting, compare the approach you use for the physical examination of a toddler versus a school-aged child or adolescent.
3. No matter how thoughtfully and appropriately you plan your assessment, odds are good that you will have difficulty assessing a 2-year-old. Discuss with your classmates the strategies that you have used for success and brainstorm with them about their ideas for assessing a crying or resistant young child.

Caring for Children in Diverse Settings

Words of Wisdom Nurses should leave their “comfort zone” of practice and reach out to children on their turf to make a difference.

KEY TERMS

community

Individualized Health Plan

magical thinking

medically fragile child

regression

separation anxiety

therapeutic play

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify the major stressors of illness and hospitalization for children.
2. Identify the reactions and responses of children and their families during illness and hospitalization.
3. Explain the factors that influence the reactions and responses of children and their families during illness and hospitalization.
4. Describe the nursing care that minimizes stressors for children who are ill or hospitalized.
5. Discuss the major components of admission for children to the hospital.
6. Discuss appropriate safety measures to use when caring for children of all ages.
7. Review nursing responsibilities related to client discharge from the hospital.
8. Describe the various roles of community and home care nurses.
9. Discuss the variety of settings in which community-based care occurs.
10. Discuss the advantages and disadvantages of home health care.

Jake Jorgenson, 8 years old, was brought to the clinic with a history of headaches, vomiting not related to feeding, and changes in his gait. Initial testing leads to a suspected brain tumor. Jake is to be admitted to the neurologic service at a pediatric hospital for further testing and treatment. Up until this point he has been a healthy child with no previous hospitalizations. He lives at home with his parents and two siblings, Jenny, age 11, and Joshua, age 5. As a nurse on this unit, how can you help prepare Jake and his family for this hospitalization?

Nursing care of the child occurs in a variety of settings, from acute care in a hospital to well and ill care in community settings, such as physicians' offices, schools, churches, health departments, community centers, and even within the child's own home. Within each setting, the nurse incorporates basic nursing care with specific strategies to help promote positive outcomes for the child, family, and community as a whole.

In today's health care environment, children receive much of their care for illnesses in community health settings such as physicians' offices, urgent care settings, or day surgery centers. As a result of this trend, fewer children may actually be admitted to a hospital unit, and those who are hospitalized are generally acutely ill. In addition, hospital stays are often shorter due to economic trends in the health care environment, such as the delivery system of managed care and other factors that attempt to control costs. Acute conditions, trauma, or chronic diseases or illnesses requiring surgical intervention lead to hospitalization for children.

According to *Child Health USA 2010*, diseases of the respiratory system account for the majority of hospitalizations in children younger than 5 years of age, while diseases of the respiratory system, mental health problems, injuries, and gastrointestinal disorders lead to more hospitalizations in older children. Adolescents between 15 and 19 years of age are often hospitalized because of problems related to pregnancy, childbearing, mental health, and injury (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010).

Other health problems begin before birth or immediately following birth, such as congenital heart disease or gastrointestinal atresia. Just when they are getting used to the idea of having a new child, the family must also deal with illness and possibly extended hospitalizations. Specific genetic or environmental factors also predispose the child to disease and injury, such as the genetic disorder of hemophilia or the environmental situation of homelessness. Many of these factors or situations put the child and family at greater risk for chronic health conditions and long periods of illness, hospitalization, and even death.

Hospitalization is often confusing, complex, and overwhelming for children and their families. Reactions and responses to illness and hospitalization depend on a number of factors, including the child's developmental stage. Nursing strategies are needed to prepare children and their families for this experience while minimizing negative effects. These strategies include identifying the needs of children and families through astute assessment of nonverbal and verbal behaviors, then validating the information with accurate interpretation and providing appropriate responses and interventions.

Although the nurse implements these strategies throughout the interaction with the child and family, a critical time to ensure the best outcome for the child and family is during the admission process. The nurse assesses the learning needs and abilities of the child and family. For the interventions to be successful, the nurse must communicate and teach in the most effective method for the individual child and family. The nurse also evaluates the child's and family's competence in performing specific activities prior to discharge.

Children's Reactions to Hospitalization

In general, children are more vulnerable to the effects of illness and hospitalization because this is a change from their usual state of health and routine. They also have limited understanding and coping mechanisms to assist them in resolving the stressors that might occur during this time. Hospitalization creates a series of traumatic and stressful events in a climate of uncertainty for children and their families, whether it is an elective procedure that is planned in advance or an emergency situation resulting from trauma. The stressors that children experience in relation to hospitalization may result in various reactions. Children react to the stresses of hospitalization before admission, during hospitalization, and after discharge.

Besides the physiologic effects of the health problem, the psychological effects of illness and hospitalization on a child include anxiety and fear related to the overall process and the potential for bodily injury, physical harm, and pain. In addition, children are separated from their homes, families, and friends and what is familiar to them, which may result in **separation anxiety** (distress related to removal from family and familiar surroundings). There is a general loss of control over their lives and sometimes their emotions and behaviors. The result may be feelings of anger and guilt, **regression** (return to a previous stage of development), acting out, and other types of defense mechanisms to cope with these effects. Children's typical coping strategies are tested during this experience.

Anxiety and Fear

For many children, entering the hospital is like entering a foreign world. The result is anxiety and fear. Anxiety often stems from the rapid onset of the illness or injury, particularly when the child has limited experiences with disease or injury. Normal fears of childhood include the fear of separation from their parents and family or guardians, loss of control, and bodily injury, mutilation, or harm. Children's fears are similar to adult fears of the unknown, including fear of unfamiliar environments and losing control.

Therefore, when the child is in the hospital, he or she becomes distressed about the unfamiliar environment; health care procedures, especially the use of needles or associated pain that may occur; and situations, such as the strange words being used, ominous-looking equipment, strangers in unusual attire (e.g., surgical caps, masks, gowns), unfamiliar and frightening noises and smells, or the sounds of other children crying. This exposure to people, situations, and procedures that may be new to them and cause

them pain leads to increased anxiety and fear (Fig. 11.1). Overall, hospitalization is a difficult experience for children.

FIGURE 11.1 The presence of familiar objects and home routines normalizes the environment and helps the child cope with hospitalization. Reading a favorite bedtime story can be comforting.

Separation Anxiety

Separation anxiety is a major stressor for children of certain ages. It usually begins around 8 months and ends as the child nears 3 years of age (American Academy of Pediatrics, 2010).

John Bowlby described three stages that the infant goes through during separation anxiety—protest, despair, and detachment (Main, 2000). The first phase, protest, occurs when the child is separated from the parents or primary caretaker. This phase may last from a few hours to several days. The child reacts aggressively to this separation and exhibits great distress by crying, expressing agitation, and rejecting others who attempt to offer comfort. The child may also display anger and inconsolable grief.

If the parents do not return within a short time, the child exhibits the second phase, despair. The child displays hopelessness by withdrawing from others, becoming quiet without crying, and exhibiting apathy, depression, lack of interest in play and food, and overall feelings of sadness.

Detachment (also known as denial) is the third and final phase of separation anxiety. During this phase the child forms coping mechanisms to protect against further emotional pain. This occurs more often in long-term separations. During this stage, the child shows interest in the environment, starts to play again, and forms superficial relationships with the nurses and other children. If the parents return, the child ignores them. A child in this phase of separation anxiety exhibits resignation, not contentment. It is more difficult to reverse this stage, and developmental delays may occur.

Today, health care providers primarily observe the first and second stages because of the shorter hospital stays and the more common use of a family-centered approach to care.

Loss of Control

When hospitalized, children experience a significant loss of control. This loss of control increases the perception of threat and affects their coping skills. They lose control over routine self-care and their usual tasks and play as well as decisions related to the care of their own bodies. In the hospital, the child's usual routine is disrupted. He or she cannot choose what to do and at what time. The child can no longer accomplish simple tasks independently as he or she does at home or school. Confinement to the bed or crib worsens this loss of control. For example, if connected to tubes or intravenous lines, the child may not even be able to visit the bathroom alone.

Hospitalization also affects the child's control over decisions related to his or her own body. Many of the procedures and treatments that occur in the hospital are invasive or are at least disturbing to children, and much of the time they do not have the option to refuse to undergo them. Adults are presumed to be competent to make health care decisions, but generally children are not. Though the parents and nurses of hospitalized children have the children's best interest in mind, children often feel powerless when in

the hospital, not having their feelings and wishes respected and having minimal control over events.

Take Note!

When advocating for a child, make sure to include the child's voice. Do not assume what his or her wishes may be; ask about them directly.

Factors Affecting Children's Reaction to Hospitalization

Various factors have a great impact on the ability of children to handle illness and hospitalization. These factors may increase or diminish the fears of the child who is ill and hospitalized. Each child responds differently and will perceive the hospital experience differently. [Box 11.1](#) lists the various factors affecting a child's response to illness and hospitalization.

BOX 11.1

FACTORS AFFECTING A CHILD'S RESPONSE TO ILLNESS AND HOSPITALIZATION

- Amount of separation from parent/caregiver
- Age
- Developmental level
- Cognitive level
- Previous experience with illness and hospitalization
- Recent life stresses and changes
- Type and amount of preparation
- Temperament
- Innate and acquired coping skills
- Seriousness of the diagnosis/onset of illness or injury (e.g., acute or chronic)
- Support systems available, including the family and health care professionals
- Cultural background
- Parents' reaction to illness and hospitalization

Developmental Level

The child's age, cognitive level, and developmental level will affect his or her perceptions of actual events, and this in turn will affect his or her reaction to illness and hospitalization. Children's responses to the stressors of fear, separation anxiety, and loss of control vary depending on their age and developmental level. Younger children, with their limited life experience and immature intellectual capacities, have a more difficult time comprehending what is happening to them. This can be particularly true for toddlers and preschoolers, who perceive the intactness of their bodies to be exposed during physical intrusions. In addition, they frequently interpret illness as punishment for wrongdoing or hospital procedures as hostile, mutilating acts. Although children are increasingly able to adapt as they grow older, lack of understanding about the need for hospitalization and threatened sense of control can make adaptation difficult.

INFANTS

Newborns and infants are adapting to life outside the womb with rapid growth and development and establishment of a healthy attachment to parents or primary caregivers. They are dependent on others for nurturance and protection. They gain a sense of trust in the world through rhythmic and reciprocal patterns of contact and feeding, resulting in bonding to the primary caregiver. They need a secure pattern of restful sleep, satisfaction of oral and nutritional needs, relaxation of body systems, and spontaneous response to communication and gentle stimuli. The caregiver-infant attachment is critical for psychological health, especially during periods of illness and hospitalization.

Unfortunately, during illness and hospitalization, these critical patterns of feeding, contact, comfort, sleeping, elimination, and stimulation are disrupted, resulting in fear, separation anxiety, and loss of control. By 5 to 6 months of age, infants have developed an awareness of self as separate from mother. As a result, infants of this age are acutely aware of the absence of their primary caregiver and become fearful of unfamiliar persons. Infants may be separated from their parents when hospitalized if the parents cannot room-in because of hospital policy or if they must work or care for other children. This results in separation anxiety.

The infant's oral needs, the basic source of infant satisfaction, are often not met in the hospital due to the condition of the child or

the procedures that must be performed. The infant is accustomed to having his or her basic needs met by the parent when he or she cries or gestures. The constraints of hospitalization result in loss of control over the environment, leading to additional anxiety in the infant.

TODDLERS

Toddlers are more aware of self and can communicate their desires. Because their autonomy is developing, toddlers need to master accomplishments to minimize the development of shame and doubt. Control becomes an issue for toddlers. Toddlers also need opportunities to explore, and they need consistent routines. In addition, toddlers are aware of the need for care and protection from others, so they need familiarity and closeness to the primary caregiver. When the toddler is hospitalized, disruption occurs in this development of autonomy.

Toddlers are often fearful of strangers and can recall traumatic events. Simply walking toward the treatment room where a traumatic procedure previously occurred may upset the toddler. Ordinarily a resurgence in separation anxiety occurs during the toddler years. When the toddler is separated from his or her parents or caregivers in an unfamiliar environment, separation anxiety is compounded. In response to this anxiety, toddlers may demonstrate behaviors such as pleading for the parents to stay, physically trying to go after the parents, throwing temper tantrums, and refusing to comply with usual routines. Restrictions related to mobility and new skill acquisition result in loss of control. Disruption in usual routines also contributes to loss of control, and the toddler feels insecure. As a result, regression in toilet training and refusal to eat are common reactions in toddlers.

PRESCHOOLERS

The preschooler has better verbal and developmental skills to adapt to various situations, but illness and hospitalization can still be stressful. Preschoolers may understand that they are in the hospital because they are sick, but they may not understand the cause of their illness. Preschoolers fear mutilation and are afraid of intrusive procedures since they do not understand the body's integrity. They interpret words literally and have an active imagination. Therefore, when the nurse says, "I need to take some blood," preschoolers' fantasies may run wild. They may not understand the concept of blood and may think everything will come out of their body. They may think that blood is "taken" the same way a child picks up a toy to take it out of the room. Preschoolers' thinking is egocentric; they believe that some personal deed or thought caused their illness, which can lead to guilt and shame. These feelings may be internalized. Overall, preschoolers' concrete, egocentric, and **magical thinking** (type of thinking that allows for fantasies and creativity) limits their ability to understand, so communication and interventions must be on their level.

Separation anxiety may not be as much of an issue as it is for toddlers since preschoolers may already be spending time away from parents in preschool. They are, however, still acutely aware of the comfort and security that their family provides for them, so disruptions in these relationships lead to challenges. The preschooler may constantly ask for his or her parents or ask to call the parents. He or she may quietly cry, refuse to eat or take medication, or generally be uncooperative.

In addition, the hospitalized preschooler loses control over the environment. The preschooler is naturally curious about his or her surroundings and learns best by observing and working with objects. This might be limited during hospitalization. Because the preschooler cannot participate in typical activities and explore the environment as usual, the child's normal creative, curious nature may give rise to a variety of fantasies that may present challenges.

SCHOOL-AGE

School-age children generally are hospitalized because of long-term illnesses or trauma. The general task of their development stage, to develop confidence through a sense of industry, can be disrupted during hospitalization. Even at this time, they generally want to continue to learn and maintain their skills and abilities. The stress of illness or anxiety related to diagnostic tests and therapeutic interventions may lead to inward or outward expressions of distress. If they have learned various coping skills, this distress may be minimized. After 11 years of age there is an increased awareness of physiologic, psychological, and behavioral causes of illness and injury. Typically, the school-age child has a more realistic understanding of the reasons for the illness and can better comprehend explanations. School-age children are concerned about disability and death, and they fear injury and pain. They want to know why procedures and tests are being performed. They can understand cause and effect and how it relates to their illness. They are uncomfortable with any type of sexual examination.

Separation anxiety is not as much of an issue for school-age children. They are accustomed to periods of separation and may already be experiencing some separation anxiety related to being in school. At the same time, they may be missing school and friends as they try to adjust to the unfamiliar environment. They may feel that friends will forget them if they remain in the hospital for a long time. Some school-age children may regress and become needy, demanding their parents' attention or playing with special "comfort toys" they used at a younger age.

Since school-age children are accustomed to controlling self-care and typically are highly social, they like being involved. They are used to making choices about meals and activities. Hospitalization presents loss of control by limiting their activities, making them feel helpless and dependent. This may result in feelings of loneliness, boredom, isolation, and depression. The key is to give them opportunities to maintain independence, retain a sense of control, enhance self-esteem, and continue to work toward achieving a sense of industry.

ADOLESCENTS

Adolescents fear injury and pain. Since appearance is important to them, they are concerned with how the illness or injury will affect their body image. Anything that changes their perceptions of themselves has a major impact on their response. Typically, adolescents do not like to be different; they like “being cool,” which means being in control and not showing how afraid they really are. They also may feel ambivalent about wanting their parents. Adolescents typically do not experience separation anxiety from being away from their parents; instead, their anxiety comes from being separated from friends.

Loss of control is a key factor affecting the behavior of adolescents who are hospitalized. Anger, withdrawal, or general lack of cooperation may occur due to the feelings of loss of control. In addition, their desire to appear confident may lead them to question everything that is being done or that they are asked to do. Their feelings of invincibility may cause them to take risks and be non-compliant with treatment. Overall, adolescents strive for independence, self-assertion, and liberation while developing their identity.

Previous Experiences

In general, children’s lack of understanding and experience of illness, hospitalization, and hospital procedures contributes to their anxiety level. However, previous experience with hospitalization and other health-related experiences can either facilitate preparation or impair it if the experiences were perceived as negative. For example, the child who associates the hospital with the birth of a sibling may view this experience as positive. However, the child who associates the hospital with the serious illness or death of a relative or close friend will probably view the experience as negative.

The type of experience may contribute to increased anxiety and fear if the child must be admitted to the hospital. If children have had previous experiences, how the experience unfolded and their response to it will determine many of their reactions to hospitalization. Older children may cling to their parents, kick, or create a scene because of their previous experience.

Recent Stresses and Changes and Individual Coping Skills

The effects of hospitalization on children are influenced by the nature and severity of the health problem, the condition of the child, and the degree to which activities and routines differ from those of everyday life. A lack of sensory stimulation in the hospital environment can lead to listlessness, indifference, unhappiness, and even appetite changes. When the child’s motor activity is restricted, anger and hyperactivity may result. Play, recreation, and educational opportunities can provide an outlet to distract the child from the illness, provide pleasant experiences, and help the child understand his or her condition.

The child’s ability to work through a situation will also affect his or her responses to illness and hospitalization. This ability depends on the age of the child, his or her perceptions of the event, previous encounters with health care personnel, and support from significant others. **Box 11.2** lists various coping skills used by children and suggestions for promoting positive coping.

Parents’ Response to Child’s Hospitalization

Children take in their parents’ anxiety and concern. Even whispers can set off children’s imaginations. For example, preschoolers may invent elaborate stories to explain what is happening to them. Parents who do not tell children the truth or do not answer their questions confuse and frighten them and may weaken the child’s trust in the parents. It is important for children to believe that someone is in control and that the person can be trusted. Some parents, however, have their own fears and insecurities. Thus, a child’s reaction often is related to the parents’ reaction to the illness and hospitalization.

| BOX 11.2 | |
| CHILDREN AND COPING | |
| Behavior/Methods for Coping | Suggestions to Promote Coping |
| Ignore or negate the problem | Breathing techniques such as blowing bubbles, pinwheels, or party noise-makers |
| Stoicism, passive acceptance | Distraction with books or games |
| Acting out—yelling, kicking, screaming, crying | Imagery with tapes or scenarios |

Anger, withdrawal, rejection
Intellectualizing

Music
Teaching before events or procedures

The relationship between the family and the hospital staff may either add to or ease the child's stress. This relationship can contribute significantly to the quality of the environment. Hospital personnel must assume responsibility for the care of hospitalized children by maintaining good partnerships with families.

Remember Jake, the 8-year-old with a suspected brain tumor? What responses to hospitalization might you see in him and his family?

Family's Reactions to the Child's Hospitalization

Whether planned or unplanned, hospitalization increases the family's stress and anxiety level. The illness or serious injury of one family member affects all members of the family because the process disrupts the family's usual routines and may alter family roles. Parents and siblings have their own reactions to this experience.

Reactions of Parents

Watching a child in pain is difficult, especially when the parent is assisting with the procedure by holding the child. The parent may feel guilty for not seeking care sooner. Parents may also exhibit other feelings such as denial, anger, depression, and confusion. Parents may deny that the child is ill. They may express anger, especially directed at the nursing staff, another family member, or a higher power, because of their loss of control in caring for the child. Depression may occur because of exhaustion and the psychological and physical requirements of spending long hours in a hospital caring for a child. Confusion may develop because of dealing with an unfamiliar environment or the loss of a parental role. Finally, the parents' marriage may be strained because of dual roles, long separation, and increased stress.

Reactions of Siblings

Siblings of children who are hospitalized may experience jealousy, insecurity, resentment, confusion, and anxiety. They may have difficulty understanding why their sibling is ill or getting all the attention, leaving little for them. They may wonder if their sibling is going to die or ever return home. They may worry that their sibling's illness is going to happen to them. Certain age groups, such as preschoolers, may feel that they caused the illness. Little information or understanding about what is happening, combined with their magical and egocentric thinking, contributes to their fears that they may have caused the illness or injury by their thoughts, wishes, or behaviors. If the family roles or routines change significantly, the siblings may feel insecure or anxious. They may develop changes in behavior or in school performance. See [Evidence-Based Practice 11.1](#).

EVIDENCE-BASED PRACTICE 11.1

CAN EDUCATIONAL INTERVENTIONS GEARED TOWARD SIBLINGS OF A HOSPITALIZED CHILD LOWER THEIR ANXIETY LEVELS?

Studies have demonstrated that children who receive age-appropriate information handle the stress and anxiety associated with hospitalization better. Can the same hold true for siblings of the hospitalized child?

STUDY

In order to test the effectiveness of educational interventions on siblings of hospitalized children, a pretest-posttest control group experimental design study was performed. Fifty siblings of a child hospitalized for longer than 2 days, ages 6 to 17 years, were recruited from a children's hospital within a large university medical center. The siblings were matched according to age, sex, and race, and then placed into the control or experimental groups, with 25 siblings each in the experimental and control groups. Siblings assigned to the experimental group received interventions from a standardized educational intervention focused on teaching the sibling about hospitalization, including length of stay if known, daily routine, medical equipment in the room and/or being used on the child, illness or injury, and treatment for the child. The interventions were based on cognitive stages of development and were conducted by child life specialists on staff at the hospital.

Anxiety levels were scored using the Revised Children’s Manifest Anxiety Scale (RCMAS), which is a 37-item self-report scale entitled “What I Think and Feel.”

Findings

Siblings who received educational interventions had significantly lower levels of anxiety compared to siblings who did not receive educational interventions. Anxiety levels for the experimental group, though lower than the control group, still remained about the normative mean.

Nursing Considerations

Recognize that siblings of a hospitalized child often experience stress and anxiety. Provide education to the nonhospitalized child. Address the psychosocial and emotional needs of siblings of a hospitalized child. Enlist child life specialists to assist with the nonhospitalized child. Educate parents about the needs of the nonhospitalized child.

Adapted from Gursky, B. (2007). The effect of educational interventions with the siblings of hospitalized children. *Journal of Developmental & Behavioral Pediatrics, 28(5)*, 392-398.

Take Note!

Research supports the need to provide support and information to the siblings to decrease their stress, anxiety, and confusion (Gursky, 2007).

Factors Influencing Family Reactions

The parenting style and the family–child relationship can influence the hospital experience as well as the family members’ coping skills. Cultural, ethnic, and religious variations, values, and practices related to illness, general response to stress, and attitudes about the care of a sick child have a significant influence on the family’s response. For example, religious beliefs can raise problems or can be a source of strength to the family and child. Families already in crisis or without support systems have a more difficult time dealing with the added stress of hospitalization. [Chapter 2](#) gives further explanations of some of these influences on children and their families.

Jake’s parents are very upset that he has to be hospitalized. His mother says to you, “I’m worried how Jake is going to react to all of this. What can we do to help him?” How would you address his mother’s concerns?

The Nurse’s Role in Caring for the Hospitalized Child

In most instances, the nurse is the primary person involved in the care of a hospitalized child. The nurse is probably the first one to see the child and family and will spend more time with them than other health care personnel. Nurses are part of a medical community that makes decisions in the child’s best interest, but the nurse needs to bear in mind the child’s rights and must try to minimize the child’s distress so that the hospital stay will be as pleasant an experience as possible. When establishing strategies to care for children in the hospital, nurses should examine the general effects of hospitalization on children in each developmental stage and should strive to understand both the reactions of the child and family to hospitalization and the factors affecting these reactions. [Nursing Care Plan 11.1](#) summarizes the nursing care associated with a hospitalized child.

TABLE 11.1

STRATEGIES TO REDUCE FEAR OF COMMON HOSPITALIZATION SITUATIONS

| Situation | Strategies to Reduce Fear |
|---|---|
| Procedure involving intrusion into the body or use of equipment or technology | Describe the procedure and equipment in terms the child can understand. Review the steps of the procedure or steps involved with the use of the equipment. Explain what the child's role will be and what is or isn't allowed. If appropriate, have the child rehearse with the equipment or role-play. |
| Darkness, such as with radiologic examinations or at night | Keep a light on in the examination area. Use a night light in the child's room. If possible, allow the child to hold the caregiver's or nurse's hand or a favorite toy. |
| Transport to other areas of the hospital | Allow caregiver to accompany child if possible. Inform the child of where he or she is going, about how long he or she will be there, and approximately when he or she will return. Introduce the child to the person who will be transporting the child. |
| Numerous personnel in and out of child's room | Identify all staff members working with the child (each shift and each day). Place a small board in the child's room with the name of the nurse caring for the child that shift or day. Inform the child how long the nurse will be caring for the child (adapt this information according to the child's cognitive level; for example, instead of saying that you'll be there for 8 hours, say, "I'll be your nurse until just before dinnertime" or "I'll be your nurse until you go for your test"). Say good-bye to the child when leaving for the day; tell the child about his or her new nurse; inform the child of when you will return. |

In a study of hospitalized children, Crole and Smith (2002) found the nursing care for a hospitalized child occurred in four phases: introduction, building a trusting relationship, decision-making phase, and providing comfort and reassurance. All of these phases are interconnected. For example, if trust is not established, it becomes difficult to move to the next phase.

The introduction phase involves the initial contact with children and their families and it establishes the foundation for a trusting relationship. Use favorite toys and common television shows to establish rapport. Allow the child to participate in the conversation without the pressure of having to comply with requests or undergo any procedures. Next, a trusting relationship can be built by using appropriate language, games, and play such as singing a song during a procedure, preparing the child adequately for procedures, and providing explanations and encouragement. Get down to the child's level and play on his or her terms.

In the decision-making phase, the nurse gives some control over to the child by allowing him or her to participate in making certain decisions. This phase is critical to maintaining the trust the child has developed. For example, it is imperative to decide how much control the child will have during treatment, how much information to share with the child about upcoming events, and whether parents should participate. Reinforce the child's use of coping strategies that lead to healthy outcomes by providing options whenever it is safe to do so. Finally, the comfort and reassurance phase uses techniques such as praising the child and providing opportunities to cuddle with a favorite toy.

Preparing Children and Families for Hospitalization

When preparing children for hospitalization, be aware of the situations that may create distress in a child and try to minimize or eliminate them. Even the most minor situations may be frightening to young children. Remember, new experiences, unfamiliar sights and sounds, disruption of sleep patterns, and pain associated with procedures and treatments are major causes of stress for the hospitalized child and family. Table 11.1 presents some hospital activities that may seem scary or stressful to a child and gives suggestions for preparing the child and family. Thoughtful preparation for these situations may help relieve stress. Educate children about what to expect so they can cope with their imagination and distinguish reality from fantasy. Describe the intervention and the sequence of steps that will occur, and include sensory information such as how the child will feel.

NURSING CARE PLAN 11.1

Overview for the Hospitalized Child and Family

NURSING DIAGNOSIS: Anxiety related to hospital situation, fear of injury or bodily mutilation, separation from family or friends, changes in routine, painful

procedures and treatments, and unfamiliar events and surroundings as evidenced by crying, fussing, withdrawal, or resistance

Outcome Identification and Evaluation

Child and family will exhibit a decrease in anxiety level as evidenced by positive coping strategies, verbalization or playing out of feelings, appropriate behaviors, positive interactions with staff, child and parent cooperation and participation, and absence of signs and symptoms of increasing anxiety and fear.

Interventions: Minimizing Anxiety

- Orient child and family to the unit and the child's room *to familiarize them with the facility.*
- Assess for signs and symptoms of anxiety and fear *to establish a baseline and assess effectiveness of interventions.*
- Place the child in a room with another child of a similar age, developmental level, and condition severity *to promote sharing.*
- Provide atraumatic care *to minimize exposure to distress, which would increase anxiety.*
- Explain all events, treatments, procedures, and activities to the parents and child (at a level the child can understand) in a calm, relaxed manner *to help the child prepare for what is to come and decrease fear of the unknown. A calm, relaxed manner helps to establish rapport and instill trust.*
- Enlist the aid of a child life specialist *to assist in age-appropriate preparation for all events, treatments, and procedures.*
- Encourage parents to room-in if possible *to provide the child with support;* if parents cannot stay, encourage them to call *to reduce child's fear of being alone.*
- Urge parents to inform the child when they will be leaving and when they are expected to return *to help child cope with their absence and promote trust.*
- Assess child's usual routine at home and attempt to incorporate aspects of usual routine into hospital routine *to ease the transition to the hospital and promote the child's participation in routine.*
- Offer comfort measures such as holding, stroking, and rocking *to relieve distress.* Encourage the child to play (unstructured and therapeutic play as necessary) *to allow for expression of feelings and fears and promote energy expenditure.*
- Suggest that parents bring in a special toy or object from home *to promote feelings of security.*
- Provide positive reinforcement for participation in care activities *to foster self-esteem.* Assess for regression behaviors and inform parents that such behaviors are common *to alleviate their concerns about this behavior.*
- Provide consistency with care measures *to facilitate trust and acceptance.*

NURSING DIAGNOSIS: Risk for powerlessness related to lack of control over procedures, treatments, and care, and changes in usual routine

Outcome Identification and Evaluation

Child and family will demonstrate an increase in control over the situation as evidenced by participation in care activities, identification of needs and choices, and incorporation of appropriate aspects of child's usual routine with that of the hospital.

Interventions: Promoting Control

- Encourage child and parents to identify areas of concern *to help determine priority needs.*
- Encourage parent and child to participate in care activities *to promote feelings of control.*
- Incorporate aspects of child's routine at home and use terms similar to those used at home *to foster a sense of normalcy.*
- Offer child choices as much as possible, such as options for foods, drinks, hygiene, activities, or clothing (if appropriate) *to promote feelings of individuality and control.*
- Allow child opportunities for being out of bed or room within limitations as appropriate *to foster independence.*
- Work with child, as age and development allow, and family to set up a schedule *to promote structure and routine.*

NURSING DIAGNOSIS: Deficient diversional activity related to confinement in bed or health care facility, lack of appropriate stimulation from toys or peers, limited mobility, activity restrictions, or equipment as evidenced by verbalization of boredom or lack of participation in play, reading, or schoolwork

Outcome Identification and Evaluation

Child will participate in diversional activities as evidenced by engagement in unstructured and therapeutic play that is developmentally appropriate and interaction with family, staff, and other children.

Interventions: Promoting Adequate Diversional Activities

- Question child and family about favorite types of activities *to establish a baseline for developing appropriate choices during hospitalization.*
- Assist with planning activities within the limits of the child's condition *to maintain muscle tone and strength without overexerting the child.*
- Spend time with the child *to provide stimulation and foster trust.*
- Enlist the aid of a child life specialist *to provide suggestions for appropriate activities.*
- Encourage interaction with other children *to promote sharing and avoid loneliness.*
- Provide developmentally appropriate opportunities for unstructured and therapeutic play *to facilitate expression of feelings.*
- Encourage short trips to the playroom or activity room *to provide a change of scenery and sensory stimulation.*
- Integrate play activities with nursing care *to achieve therapeutic effect.*

NURSING DIAGNOSIS: Interrupted family processes related to separation from child due to hospitalization, increased demands of caring for an ill child, changes in role function, and effect of hospitalization on other family members such as siblings, as evidenced by parental verbalization of issues, parental presence in hospital, or child's hospitalization requiring parent to miss work

Outcome Identification and Evaluation

Family will demonstrate positive coping strategies and mutual support for one another as evidenced by visiting frequently and staying with the child as necessary, sharing of family responsibilities, obtaining assistance for relief or respite, and visiting by other members of the child's family and friends.

Interventions: Maximizing Family Functioning

- Encourage parents and family members to verbalize concerns about child's illness, diagnosis, and prognosis *to promote family-centered care and identify areas where intervention may be needed.* Explain therapies, procedures, child's behaviors, and plan of care to parents *to promote understanding of the child's status and plan of care, which helps to decrease anxiety.*

- Encourage parental involvement in care *to promote feelings of the parents being needed and valued, providing them with a sense of control over their child's health.*
- Identify support system for family and child *to identify resources available for coping.*
- Educate family and child on additional resources available *to promote a wider base of support to deal with the situation.*
- Suggest ways that parents can divide time between child and other siblings *to prevent feelings of guilt.*
- Provide support and positive reinforcement *to promote family coping and foster family strength.*
- Encourage frequent visits by family members, including siblings as appropriate, *to promote ongoing family functioning.*
- Stress the need for adequate rest, sleep, exercise, and nutrition for family members *to promote family health and minimize stress of hospitalization on family.*
- Assist with referrals for resources and help from additional family members and friends as necessary *to allow for respite or relief of care responsibilities.*
- Encourage family to maintain usual routine as much as possible *to minimize the effects of hospitalization on family functioning.*

NURSING DIAGNOSIS: Self-care deficit related to immobility, activity restrictions, regression, or use of equipment, devices, or prescribed treatments as evidenced by inability to feed, bathe, or dress self or accomplish other activities of daily living

Outcome Identification and Evaluation

Child will participate in self-care within limitations of condition as evidenced by assisting with bathing and hygiene, feeding, toileting, and dressing and grooming.

Interventions: Promoting Self-Care

- Assess child's usual routine for self-care and self-care abilities *to provide a baseline for individualizing interventions.*
- Provide child-sized equipment and devices *to promote child's ability to complete the self-care task.*
- Encourage parents and child to do as much self-care as possible, within limitations of the child's condition and developmental level, *to promote feelings of independence and foster growth and development.*
- Offer praise and encouragement for activities performed *to foster self-esteem, confidence, and competence.*
- Ensure adequate rest periods *to minimize energy expenditure associated with self-care activities.*

NURSING DIAGNOSIS: Risk for delayed growth and development related to stressors associated with hospitalization, current condition or illness, separation from family, and sensory overload or sensory deprivation

Outcome Identification and Evaluation

Child will demonstrate developmentally appropriate milestones as evidenced by age-appropriate behaviors and activities.

Interventions: Promoting Growth and Development

- Assess child's developmental stage *to establish a baseline and determine appropriate strategies.*
- Use unstructured and therapeutic play and adaptive toys *to promote developmental functioning.*
- Provide stimulating environment when possible *to maximize potential for growth and development.*
- Praise accomplishments and emphasize child's abilities *to foster self-esteem and encourage feelings of confidence and competence.*
- Include parents in techniques to foster growth and development *to promote feelings of control in their child's care.*

NURSING DIAGNOSIS: Deficient knowledge related to hospitalization, surgery, treatments, procedures, required care, and follow-up as evidenced by questioning and verbalization, lack of prior exposure

Outcome Identification and Evaluation

Child and family will demonstrate understanding of all aspects of child's current situation as evidenced by identification of child's and family's needs, verbal statements of understanding and/or need for additional information, return demonstration of procedures and treatments, and verbalization of instructions for follow-up and continued care.

Interventions: Providing Child and Family Teaching

- Assess child's and family's willingness to learn *to ensure effective teaching.*
- Provide family with time to adjust to diagnosis *to facilitate their ability to learn and participate in the child's care.*
- Repeat information *to promote multiple opportunities for child and family to learn.*
- Teach in short sessions *to prevent overloading the child and parents with information.*
- Gear teaching to appropriate level of understanding for the child and the family (depends on age of child, physical condition, memory) *to promote learning.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media, when possible *to facilitate learning and retention of information.*
- Provide the child and family with written step-by-step instructions for procedures or care *to provide a reference if needed at a later date.*
- Have child and family provide return demonstrations of care procedures *to ensure effectiveness of teaching.*
- Arrange for trial home care during hospitalization and after discharge as appropriate *to ensure understanding and provide opportunities for additional teaching and learning.*

Good preparation can reduce the child's fears and increase his or her ability to cope with the hospital experience. Preparation should include exploring the child's perceptions, reviewing previous experiences, and identifying coping strategies. The goal should be to decrease fear and anxiety by allowing the child to better understand what is happening. Useful techniques include the following:

- Perform nursing care on stuffed animals or dolls and allow the child to do the same.
- Avoid the use of medical terms.
- Allow the child to handle some equipment.
- Teach the child the steps of the procedure or inform him or her exactly what will happen during the hospital stay.

- Show the child the room where he or she will be staying.
- Introduce the child to the health care personnel with whom he or she will come in contact.
- Explain the sounds the child may hear.
- Let the child sample the food that will be served.

All techniques used to prepare the child for hospitalization should emphasize the philosophy of atraumatic care. Adapt all information to the cognitive and developmental level of the child. Identify what role the child will play in the situation; it is always helpful for children to have something to do, since it shows them that they are included. A rehearsal of what will occur in the hospital allows the child to become comfortable with the situation. If time permits, provide pamphlets that describe the procedure and suggest preparation activities for the child at home before admission.

The child and family may be able to take a tour of the hospital unit or the surgical facility. Videotapes or DVDs, photographs, and books on hospitalization and surgery can serve as resources for the family and child. Many institutions offer programs to familiarize children and families with the hospital experience with a guided tour. During the tour, opportunities are provided for role-playing, and during stops along the way the child can see, touch, and feel the equipment that may be used (Fig. 11.2). If the tour guide notes a child or family member is really scared or concerned about something, the pediatric staff can be alerted and therefore address this issue, further leading to improved family-centered care.

The American Society of Anesthesiologists has prepared a coloring book entitled *My Trip to the Hospital* (American Society of Anesthesiologists, 1998). This book is designed to alleviate some of the fears that younger children may have related to the hospital experience. It describes the process from admission (whether it be to the hospital or ambulatory surgery center) through discharge and includes information about preoperative testing, anesthesia, and recovery. The book also includes information for parents. A link to the book's website is listed on [thePoint](#).

FIGURE 11.2 A child is being prepared for hospitalization by becoming familiar with some of the equipment that might be used.

Parents are instrumental in preparing children by reviewing the materials that are given, answering questions, and being truthful and supportive. [Teaching Guidelines 11.1](#) provides suggestions for parents in preparing their child for hospitalization.

Teaching Guidelines 11.1

PREPARING YOUR CHILD FOR HOSPITALIZATION

- Read stories about experiences with hospitals or surgery.
- Talk about going to the hospital and what it will be like coming home.
- Be honest and encourage the child to ask questions. Visit the hospital and go through the preadmission tour if time permits.

- Provide support to the child via your presence, telephone calls, and special items brought from home.
- Encourage the child to draw pictures to express how he or she is feeling.
- Include siblings in the preparation.

Take Note!

Remember to enlist the assistance of the child life specialist, if possible, to assist with preparing children and families for hospitalization.

Admitting the Child to the Facility

Admitting the child to the facility involves preparing him or her for admission and introducing the child to the unit where he or she will be staying. Use the appropriate hospital forms. [Chapter 8](#) gives general information about communicating with and teaching children and families.

In today's health care environment, the admission process occurs quickly, with little time for extensive preparation; this is why preparation before admission is so important. Of course, the urgency of the child's medical condition also may limit the amount of preparation that can be done in advance.

TYPES OF ADMISSIONS AND NURSING CARE

The hospital units to which a child may be admitted include:

- General inpatient unit
- Emergency and urgent care department
- Pediatric intensive care unit
- Outpatient or special procedures unit
- Rehabilitation unit or hospital

Regardless of the site of care, nursing care must begin by establishing a trusting, caring relationship with the child and family. Smile, introduce yourself, and give your title. Let the child and family know what will happen and what is expected of them. Ask the family and child what names they prefer to be called by. Maintain eye contact at the appropriate level. With a younger child, start with the family first so the child can see that the family trusts you. Communicate with children at age-appropriate levels.

The next step, as the child's medical condition allows, involves an orientation to the hospital unit. Briefly explain policies and routines and the personnel who will be involved in the care of the child.

During the nursing interview that follows, obtain information about the child's history, routines, and reason for admission. Obtain baseline vital signs and height and weight, and perform a physical assessment. Each health care setting has its own policies and procedures for this. Recognize the needs of the family and child during this process. If some of this information already exists, do not ask for it again, except to confirm vital information such as allergies, medications taken at home, and history of the illness. Typically, the information is collected immediately if the child's condition is urgent; otherwise, the information is collected within 8 hours, except for the information that is required for safe care.

General Inpatient Unit Stays. Today, general inpatient unit stays for children are shorter and involve more acute conditions, resulting in little time for admission preparation. Many times the admission procedure and treatment actually occur simultaneously. Sometimes the stay is in a special 23-hour observation unit so the child is in the setting for less than 24 hours. General hospital stays may be in a pediatric hospital, a pediatric unit in a general hospital, or a general unit that occasionally admits children. General units often lack child-oriented services, such as play areas, child-size equipment, and staff familiar with caring for children.

Take Note!

When a child is admitted to a general unit, take extra time to orient and explain the routines and procedures to the child and family. Emphasize that the parents can stay with the child (if institutional policy permits). If possible, place the child in a room close to the nurses' station and order food appropriate for the child's age and developmental level.

Emergency and Urgent Care Departments. A major cause for illness and hospitalization in children is injuries from accidents (U.S. Department of Health and Human Services, Health Resources and Services Administration, Maternal and Child Health Bureau, 2010). Many times a family's first experience with the acute care setting is the urgent care or emergency department. Due to the situation, the child and family may experience increased anxiety, and it may become overwhelming as uncertainties develop and critical decisions must be made. The family may be frightened, insecure, and in a state of shock.

Procedures and tests are performed quickly, with minimal time for preparation. The family is often ill prepared for the visit, having little money or clothing with them. Siblings may be present if the parents did not have time to get a sitter.

Due to the fast pace of the emergency department, the family may be hesitant to ask questions, so keep the family and child well informed. Allow the family to stay with the child, provide support, and allow the family, and when appropriate the child, to participate in decisions.

Families may have a strong fear of the unknown and may be terrified that the child will die or be permanently disabled. Help the family to identify their concerns and their support systems. Prepare them for what they will experience. Provide comfort such as holding, touching, talking softly, and other appropriate interventions according to age and developmental level.

Pediatric Intensive Care Units. The pediatric intensive care unit (PICU) specializes in caring for children in crisis. The same principles and concepts of general care of children apply to this setting, but everything is intensified. Families will be faced with an unfamiliar, high-tech environment and a large number of staff.

Families must deal with the critical situation that brought them to the PICU. The child will likely experience pain, unusual noises, and increased stimulation and will probably undergo uncomfortable procedures. Parents may face the possibility of losing their child. Sometimes the child cannot talk, eat, or display other appropriate developmental behaviors. Sensory overload (increased stimulation) or sensory deprivation (lack of stimulation) can affect both child and family.

Welcome families (if institutional policy permits) and encourage them to stay with the child and participate in care. Explain everything to the parents and, when appropriate, to the child. Frequently touch the child and encourage the parents to comfort him or her. Listen for clues about what the child and family need during the PICU stay.

Isolation Rooms. Isolation rooms are used for situations involving the risk for infection. When a child is admitted with an infectious disease, or to rule out an infectious disease, or if the child has impaired immune function, isolation will be instituted. Children in this setting may experience sensory deprivation due to the limited contact with others and the use of personal protective equipment such as gloves, masks, and gowns.

Encourage the family to visit often, and help them to understand the reason for the isolation and any special procedures that are required. Introduce yourself before entering the room and allow the child to view your face before applying a mask, if possible. Continue to have contact with the child and hold or touch the child often, especially if the parents are not present.

Rehabilitation Units. The rehabilitation unit provides care for children beyond the initial period of illness or injury. The care involves an interdisciplinary approach that assists the child to reach his or her potential and achieve developmental skills. For example, rehabilitation units help children regain abilities lost due to neurologic injuries or serious burns. The facilities often resemble a home environment, with special services to help children to relearn activities of daily living and to help them deal with the physical or mental challenges associated with the original illness or injury. Typically, families are encouraged to participate and are given support for their child's eventual return home. There is a balance of nurturing and firm discipline while the child reclaims independence.

Addressing the Effects of Hospitalization Developmentally

When addressing the fears, separation anxiety, and loss of control that occur in hospitalized children, the nurse should consider the child's age and cognitive or developmental level. Interventions are then based on how the child experiences these stressors at that age or developmental level. The content, timing, setting, and method of preparation are also based on the child's age and cognitive or developmental level. General guidelines for addressing fear and anxiety, separation anxiety, and loss of control are provided in [Box 11.3](#).

BOX 11.3

GUIDELINES TO ADDRESS THE GENERAL EFFECTS OF HOSPITALIZATION

Minimizing Fear and Anxiety

- Prepare the child and family for hospitalization and procedures.
- Explain everything to the child and their families before it occurs (see [Chapter 8](#)).
- Use age-appropriate communication techniques. Include the family in this process so they can help the child cope with fears.
- Allow time for children to play out their fears and concerns.
- Talk to the child and parents using a soft, friendly, comforting tone of voice.
- Have a calm, empathetic approach when caring for the child.

Addressing/Minimizing Separation Anxiety

- Know the stages of separation anxiety and be able to recognize them.
- Remember that behaviors demonstrated during the first stage do not indicate that the child is “bad.”
- Encourage the family to stay with the child and always use a family-centered approach to care.
- Help the child cope, and intervene before the behaviors of detachment occur.

Addressing Loss of Control

- Minimize physical restrictions, altered routines and rituals, and dependency issues, because they produce loss of control.
- Allow as much independence as possible within the constraints of the diagnosis.
- Allow the child to participate in care and decisions regarding care whenever possible.

NEWBORNS AND INFANTS

Assess the development or lack of development that is occurring in the infant, and assess the baby’s attachment to the parents or primary caregivers. The infant’s facial expression is the most consistent indicator of pain or bodily injury. To decrease fear and minimize separation anxiety, avoid separation from the primary caregiver if possible; this will also promote healthy attachment. If the parent or primary caregiver cannot stay with the infant, arrange for volunteers to provide consistent comfort to the baby. Maintaining the infant’s home routine related to sleep and feeding helps decrease feelings of loss of control. Weigh the infant daily, at the same time, on the same scale. Monitor intake and output closely. Be alert to signs of discomfort other than crying, such as a furrowed brow or tense body posture. Additional nursing goals related to ensuring safety and promoting growth and development of the infant are presented in [Table 11.2](#).

TODDLERS

Key nursing concerns when caring for toddlers are separation anxiety, growth and development, and autonomy. Establishing a trusting relationship with the toddler through nonthreatening play may decrease the amount of fear the toddler feels. Be alert to subtle, nonverbal indicators of grief or discontent.

Encourage the parent or primary caregiver to stay with the toddler in the hospital to decrease separation anxiety. Maintaining the home routine related to meals and sleep or a nap provides structure and may help decrease the toddler’s feelings of loss of control. If indicated, weigh the toddler daily. Closely monitor intake and output. Refer to [Table 11.2](#) for additional nursing considerations related to ensuring safety and promoting growth and development in the hospitalized toddler.

PRESCHOOLERS

Nursing care for hospitalized preschoolers focuses on their special needs, fears, and fantasies. When working with preschoolers, remember that they use magical thinking and fantasy. Be honest and specific, providing information just prior to the intervention to allay the child’s fears. As with toddlers, encouraging parental involvement may decrease the amount of separation anxiety the preschooler experiences while in the hospital. Allowing the preschooler to make simple decisions such as which color bandage to use or whether to take medicine from a cup or syringe helps the child to feel some sense of control. [Table 11.2](#) gives specific nursing considerations related to ensuring safety and promoting growth and development for the preschooler in the hospital.

SCHOOL-AGE CHILDREN

Provide honest information using concrete, meaningful words to the school-age child to minimize fear of the unknown. School-age children are still very attached to their parents, so encouraging parental involvement or rooming-in decreases separation anxiety. Involve the child in making simple decisions and planning the schedule as appropriate to give him or her a sense of control. Nursing considerations when caring for hospitalized school-age children include ensuring safety and promoting growth and development (see [Table 11.2](#)).

ADOLESCENTS

The adolescent may or may not express fears. Educate the teen honestly; younger teens require more concrete explanations, while older teens can process more abstract concepts. Respect the teen’s need for privacy. Encourage visits from the adolescent’s friends to minimize anxiety related to separation. Prepare a mutually agreeable schedule with the teen, as appropriate, that includes the teen’s preferences while incorporating the required nursing care. Collaborating with the adolescent will provide the teen with increased control. Refer to [Table 11.2](#) for additional nursing considerations related to care of the adolescent in the hospital.

Think back to Jake, the 8-year-old from the beginning of the chapter. Discuss nursing care you could provide that will

Preparing the Child and Family for Surgery

If the child is to undergo a surgical procedure, whether in the hospital or an outpatient setting, special interventions are necessary. The parents should be allowed to stay with the child until surgery begins. Parents should also be allowed to be with the child when he or she wakes up in the postanesthesia recovery area. Good preparation provides reassurance and comfort to the child and allows him or her to know what will happen and what is expected of him or her.

Preoperative care for the child who is to undergo surgery is similar to that for an adult. The major difference is that the preparation and teaching must be geared to the child's age and developmental level. [Table 11.3](#) discusses strategies for preoperative teaching. Many facilities offer special programs to help prepare children and families for the surgical experience. Presurgical preparation programs allow children and their families to experience a "trial run" in a supportive environment to reduce anxiety, increase knowledge, and enhance coping skills (Justus et al., 2006). Books, including the one cited earlier by the American Society of Anesthesiologists, are helpful in preparing the child and family.

Child and family teaching is essential. Like any intervention, adapt the teaching to the child's developmental level. For example, when teaching a toddler or preschooler about breathing exercises, have the child blow a pinwheel or cotton balls across the table through a straw. The child will enjoy the activity while also reaping the respiratory benefits of the activity.

In preparation for surgery, use items such as stuffed animals or dolls to help children understand what is going to happen to them ([Fig. 11.3](#)). Allow the child to role-play various experiences with dolls. Dolls designed to simulate surgical experiences have been developed. For example, Shadow Buddies are custom-made dolls that have the same illness or surgery as the child; the doll may have an ostomy, a scar, or a catheter (Shadow Buddies Foundation, n.d.). The dolls were developed to help children cope with their illness or disease and send the message that it is okay to be different. These dolls also provide the child with a companion to talk to. Visit [thePoint](#) for a link to the Shadow Buddies website.

TABLE 11.2

NURSING CONSIDERATIONS FOR PROVIDING SAFE, DEVELOPMENTALLY APPROPRIATE CARE

| | Ensuring Safety | Promoting Healthy Growth and Development |
|----------------------------|---|--|
| Infants | <ul style="list-style-type: none"> • Maintain close supervision of the infant. • Keep one hand on the infant when crib sides are down. • Keep crib rails up all the way when the infant is in the crib. • Avoid leaving small objects that are harmful or that can be swallowed in the crib. • Provide safe and appropriate toys for the infant. • Place infants in rooms close to the nurses' station. • Encourage a family member to stay with the infant at all times. | <ul style="list-style-type: none"> • Use the <i>en face</i> position when holding newborns. • Smile and talk to the infant during bathing, feeding, and other interactions. • Minimize the number of painful or uncomfortable procedures. • Provide comfort during and after procedures by holding or talking, using soothing tones and movements. • When handling the infant, use smooth, continuous movements. • Use gentle stroking and holding, which may reduce stress. • Serve as a role model for first-time parents. • Encourage the family to maintain home routines while in the hospital, planning nursing care around the usual feeding and sleep times. • Use the pacifier between feedings to satisfy nonnutritive sucking needs. |
| Toddlers | <ul style="list-style-type: none"> • Keep crib side rails up with overhead crib protection intact when the toddler is in the crib. • Never leave a toddler alone in the room unless secured in the crib. • Use a bed only for the older toddler who has an adult present in the room at all times. • Avoid leaving small objects that can be swallowed or are harmful in the crib or bed. • Place crib out of reach of cords, equipment, and electrical outlets. • Provide safe and appropriate toys for the toddler. • Place toddlers in rooms close to the nurses' station. • Always have someone with the toddler when ambulating. | <ul style="list-style-type: none"> • Encourage the parent to stay with the toddler to decrease separation anxiety. • To promote autonomy, allow the toddler to make appropriate choices, such as which juice to take the medicine with. • Encourage active play in the playroom or with push/pull toys in the hallway (accompanied by an adult). • Expect and plan for regression in areas of toilet training, eating, and other behaviors. • Expect increased temper tantrums in general and intense reactions to intrusive procedures. • Maintain home routine while in the hospital, planning nursing care around the usual feeding and sleep times. • Give simple directions with choices appropriate to the hospital situation. • Provide close supervision while encouraging independence. |
| Preschoolers | <ul style="list-style-type: none"> • Keep bed in low position with the side rails up when the preschooler is in the bed. • Instruct the child to call the nurse or caregiver for help getting out of bed. • Keep harmful objects out of reach of the child. | <ul style="list-style-type: none"> • Encourage parents to stay with the preschooler in the room as well as other areas of the hospital. • Encourage the preschooler to be involved in care by providing choices and opportunities for the child to help. • Use play as an opportunity to work through the preschooler's fears. • Explain activities in simple, concrete terms, being cautious with the words you use because of the preschooler's fantasies and magical thinking. • Expect reactions to pain and bodily injury to be verbally aggressive and specific. • Try to maintain home routines while the child is in the hospital, working them into the plan of care when possible. |
| School-age Children | <ul style="list-style-type: none"> • Keep the bed in the low position with the side rails up while the child is in the bed, explaining that this is a hospital rule, not a punishment. | <ul style="list-style-type: none"> • Provide opportunities for the child to be involved in care. • Allow children to select their meals, assist with treatments, and keep their rooms neat. • Allow visits with other children if the condition allows. • Encourage parents to tell the child when they will return. • Plan care around the child's usual home routines (meals, sleep). • Encourage the child to do schoolwork. |

Adolescents

- Be aware of the adolescent's whereabouts. The teen may not wish to stay in the room but may become confused about where the room or unit is located in the hospital.
- Allow teens to interact with others.
- Alter hospital routines as possible to allow the teen to sleep in or stay up later at night.
- Provide others close to their age as roommates.
- Encourage visits from friends.
- Provide emotional support for feelings of being alone or away from friends; be alert for regression, which may result in the teen becoming emotional.
- Answer questions honestly and with appropriate information.
- Give the teen a sense of control by allowing choices.
- Be sensitive to concerns about being "different."

Maintaining Safety During Hospitalization

Safety is a critical aspect of care of the child in the hospital. Due to their age and developmental level, children are vulnerable to harm. Ensure the child has an identification band in place at all times. Sometimes in implementing interventions an armband is removed, so make sure it is attached to another extremity. Monitor children closely to avoid accidents such as a child pushing the wrong knob, picking up a piece of equipment or supplies left in the bed or room, or climbing out of bed (Fig. 11.4). See Table 11.2, which highlights nursing goals for ensuring safe, developmentally appropriate care for the hospitalized child.

USE OF RESTRAINTS

When caring for children, some type of restriction may be necessary. The restriction, often referred to as a restraint, may be needed to ensure the child's safety, allow a therapeutic or diagnostic procedure to be done, immobilize a body part or limit movement, or prevent disruption of prescribed therapy. However, restraints can be overused and can cause harm (Joint Commission Resources, 2008). As a result, each facility will have specific procedures and policies in place related to the use of restraints based on standards

developed by the Joint Commission, regulations developed by the Centers for Medicare and Medicaid Services (CMS), state law, and facility requirements (Joint Commission Resources, 2008). These procedures and policies are designed to safeguard children's physical safety and psychological well-being.

| TABLE 11.3 STRATEGIES FOR PREOPERATIVE TEACHING | |
|---|--|
| Developmental Level | Implications for Teaching |
| Infants and toddlers | Encourage parents to use a soft tone of voice and stroking and secure, comfortable holding positions to promote calm. Remind parents to use positive facial expressions. Encourage the parent or caregiver to stay with the child as much as possible. Use terms that the child and parents can understand. For toddlers, provide information as close to the day of surgery as possible to prevent undue anxiety. |
| Preschoolers and school-age children | Provide factual explanations using terms the child and parents can understand. Incorporate pictures and other visual aids in explanation. Tailor the timing of education to meet the child's learning needs, allowing enough time for the child to ask questions. For preschoolers, provide information 1 to 2 days before surgery. For school-age children, provide information 3 to 5 days before surgery. |
| Adolescents | Provide detailed explanations of the procedure at least 7 to 10 days beforehand. Answer questions honestly, ensuring privacy at all times. Remain available for questions or concerns arising before or after surgery. |

FIGURE 11.3 Using a stuffed animal to explain a surgical procedure to the child.

According to these standards, hospitals are required to have a policy in place that specifies the following (Department of Health & Human Services, Centers for Medicare & Medicaid Services, 2006; Disability Rights California, 2008; Joint Commission Resources, 2008):

- Reason for the restraint
- Client assessment parameters identifying the need for the restraint

FIGURE 11.4 Safety is an essential aspect of pediatric nursing. A clear plastic cover over the crib prevents the older infant or toddler from climbing out and falling.

- Use of at least one alternative method for restriction before using a restraint
- Use of the least restrictive type of restraint for the purpose after the decision is made that a restraint is necessary
- Need for a written order by a licensed independent practitioner (LIP) within 1 hour of application of the restraint
- Need for face-to-face evaluation by LIP within 1 hour of application of the restraint

In addition, the Joint Commission standards and CMS regulations also identify the need for specific staff training and frequent assessment and appropriate discontinuation of use.

Take Note!

Always refer to your institution's policy regarding restraint use.

Restraints can promote physical distress in a child and be stressful for the parents as well. Children also may view restraints as punishment. Before a restraint is used, other measures need to be tried (Joint Commission Resources, 2008).

Take Note!

When deciding whether it is necessary to restrain a child, consider the child's age, developmental level, mental status, and threat to others and self.

Explain why the child should not touch the intravenous site or should maintain a certain position so that he or she has a basic understanding of what is necessary. This may be all that is necessary for an older child. One-to-one supervision and behavior modification techniques may be other alternatives to the use of restraints.

Atraumatic Care

Therapeutic hugging should be used for procedures and treatments, such as intravenous line insertion, where the child needs to remain still. Refer to Chapter 8 for further information.

If it is determined that a restraint is needed, select the most appropriate, least restrictive type of restraint (Disability Rights California, 2008). For example, if the child has an intravenous catheter in the antecubital space that stops flowing when the child bends the arm, an elbow restraint or arm board, rather than a soft wrist restraint or four-point extremity restraint, would be appropriate. [Table 11.4](#) lists the types of restraints and the major issues associated with the use of restraints in children.

TABLE 11.4

TYPES OF RESTRAINTS AND ASSOCIATED SAFETY CONCERNS

| Type of Restraint | Purpose | Safety Concerns |
|--|---|---|
| <p>Soft limb restraint</p>  | <p>Wrist or ankle restraint to prevent range of motion of extremities</p> | <p>Check wrist or ankle for any sign of circulatory, integumentary, or neurologic compromise.</p> |
| <p>Elbow restraint</p>  | <p>Prevents child from flexing and reaching face, head, IV and other tubes</p> | <p>Position the restraint so it does not rub against axilla. Check pulse, temperature, and capillary refill of the extremity.</p> |
| <p>Mummy restraint</p>  | <p>Body restraint using a sheet folded in a square appropriate to size of infant or young child to secure the whole body of the child or every extremity except for one</p> | <p>Ensure that all extremities are secured within the sheet.</p> |

Jacket (vest) restraint

Jacket worn by child with ties attached to the child's back and to side of bed. Used to keep children flat in bed, such as after surgery, or safe in chair

Ensure the child can turn head to side and that the head of the bed is elevated, if possible. Place ties in back so child cannot manipulate them.

Crib top bubble restraint

Clear plastic cover over the bed to prevent older infant or young child from climbing out of bed and falling

Ensure that there are no tears or loose plastic.

Take Note!

When selecting a restraint, the nurse must choose the least restrictive type and apply it for the shortest time necessary (Department of Health & Human Services, Centers for Medicare & Medicaid Services, 2006).

Before applying a restraint, explain the reason for the restraint to the child and the parents. Emphasize that the rationale is to maintain the child's safety; the restraint is not punishment. Having the child and parents state the reason for the restraint demonstrates their understanding.

A written order for the restraint and an evaluation of the child by an LIP must occur within 1 hour of applying the restraint (Department of Health & Human Services, Centers for Medicare & Medicaid Services, 2006). In addition, the nurse must do the following:

- Ensure that the restraint fits properly.
- Secure the restraints with ties to the bed or crib frame, not the side rails.
- Use a clove-hitch type of knot to secure the restraints with ties (this allows for quick, easy access and release of the restraint).
- Check restraints 15 minutes following initial placement and then every hour for proper placement.
- Assess the temperature of the affected extremities, pulses, and capillary refill, initially after 15 minutes and then every hour after placement.
- Remove the restraint every 2 hours to allow for range of motion and repositioning, with documentation of this process and any findings.
- Encourage parent participation, providing continuous explanations about the reasons for the restraints and tentative time frame for use.
- Offer positive reinforcement to the child and parents.
- Review the criteria for removing the restraints; document removal and continued assessment.

It is important the nurse is familiar with federal standards and regulations and he or she should always follow facility policy and procedures. unit, such as the playroom or treatment room; or for discharge. When the child is transported to other areas, specific guidelines need to address safety issues, the age and developmental level of the child, the child's physical condition, and the

destination. These factors need to be considered before transport so that the appropriate method can be used with the least amount of risk for the child. Various methods to transport children include carrying the infant and using strollers, wagons, or rolling beds (Fig. 11.5). If possible, the parents should accompany the child to offer support and comfort.

TRANSPORT OF THE CHILD

Children may need to be transported to other units for diagnostic tests or surgery; to different areas in the same

When carrying an infant, good support of the back and head is vital. Rails should be up on all beds and wagons. Use safety belts with strollers and wheelchairs.

Take Note!

Never leave a child unattended during transport. Keep the child visible at all times during the transport.

FIGURE 11.5 Methods for transporting the infant or child. (A) Cradle method for carrying infants up to 3 months of age. One hand grasps the infant’s thighs; the other arm supports the infant’s head and back. (B) The “over-the-shoulder” method for carrying infants up to 7 months of age. Support the head if the infant does not have head control. (C) Football method for carrying infants up to 2 months of age. The forearm and hand support the body and head of the infant. (D) A wagon with rails and padding is used to transport small children.

Providing Basic Care for the Hospitalized Child

Basic care involves general hygiene measures, including bathing, hair care, oral care, and nutritional care. Young children are dependent on an adult for most, if not all, of their self-care needs. If parents are present, allow them to provide care for the child to decrease the child’s stress. Older children may perform hygiene measures themselves but may need some assistance from the nurse.

GENERAL HYGIENE MEASURES

General hygiene measures help to maintain healthy skin, hair, and teeth. Skin is a complex structure; its primary function is to protect the tissues that it encloses and to protect itself. Injury to the child’s skin may occur when inserting and maintaining an intravenous line, removing a dressing, positioning a child in bed, changing a diaper, using and removing electrode patches, and maintaining restraints. Risk factors for problems include impaired mobility, protein malnutrition, edema, incontinence, sensory loss, anemia, and infection. A

good time to assess the skin is during bath time.

Bathing. Bathing infants and children is a common daily hygiene measure in the health care environment. Although the parents or primary caregiver often does this in today's family-centered environment, the nurse is still responsible for ensuring that bathing is done safely and hygienically. Adhere to safety principles to prevent falls, burns, and aspiration of water. Never leave a child alone in a bathtub. Use a gentle, pH-balanced soap with moisturizer if there is a need to rehydrate the skin. Note any condition that might require special considerations or further assessment, such as paralysis, loss of sensation, surgical incisions, skin traction/cast, external lines (intravenous lines, urinary catheters, or feeding tubes), or other alterations in skin integrity. Pay close attention to the ears, between skinfolds, the neck, the back, and the genital area for alterations in skin integrity. [Table 11.5](#) highlights specific developmental considerations for bathing.

Before bathing and performing other hygiene measures, assess the family's preferences and home practices for the child, such as time of day, rituals, special equipment, and allergies to products. This is a good time to assess the amount of assistance that might be required by the parents and to address learning needs related to hygiene. Follow general guidelines in bathing any client with regard to equipment, room temperature, privacy, and use of products such as deodorant and lotion.

Hair Care. Lying in bed can make the hair matted and tangled. Avoid pulling on the child's hair when combing or brushing it. If necessary, use commercial detangling solutions to ease combing.

If the hair requires washing, this is often done during the daily bath for infants. Typically, shampooing once or twice a week is sufficient for younger children. Adolescents may need more frequent shampooing due to the increase in sebaceous gland secretion. The frequency of shampooing also varies based on the child's condition; for example, if the child has experienced diaphoresis, more frequent shampooing may be indicated.

Shampooing may be done at the bedside with specially adapted equipment, at a readily accessible sink while the child is sitting in a chair or lying on a stretcher, or in a tub or shower. Commercial no-rinse shampoos may be available for use. With these products, the shampoo is applied to the hair and then brushed or combed out.

If the child uses a tub or shower for hair care, monitor the child's safety throughout to ensure that the child does not slip and fall due to the slippery surface or is burned because of improper water temperature.

The child's ethnicity may require special measures for hair care. For example, a child of African American descent may use a broad-toothed comb for hair care. Ask the child's parents to bring one from home if one is not available. Also ask the child and parents about any products used on the hair to make it easier to handle; the parents can bring some from home. Encourage the parents to help with braiding or plaiting of the hair if desired.

| Age of Child | Special Considerations |
|-------------------------------------|--|
| Infants | Use a sponge bath or tub bath to bathe young infants who cannot sit unaided. Support the infant's body at all times. Ensure appropriate water temperature. Avoid use of talcum powder. |
| Toddlers | Bathe older infants and toddlers at the bedside or in a regular bathtub, depending on their health condition. |
| School-age children and adolescents | Older children may prefer a shower if available and acceptable for their health condition. Assess whether a shower would be safe. Provide privacy. |

Take Note!

The hair of African Americans typically is *easier* to comb when wet, so if possible comb the child's hair soon after shampooing (Connecticut Department of Children and Families, 2008).

Oral Hygiene. Oral hygiene is an important part of basic care. Wipe the infant's gums with a wet cloth after each feeding. Assist children in brushing and flossing their teeth after each feeding or meal and before bedtime. The child who is immunosuppressed needs special attention to oral hygiene, such as using soft toothbrushes and moistened gauze sponges to prevent bleeding and careful inspection of the oral cavity for areas of breakdown.

NUTRITIONAL CARE

Adequate nutrition is necessary for growth and development and tissue repair, so it is an essential component of care for the ill or hospitalized child.

Frequently, the ill or hospitalized child experiences a loss of appetite, which can affect the child's nutritional status. This may be compounded by other problems such as nausea and vomiting and nothing by mouth (NPO) restrictions for testing or surgery. The hospitalized child may adopt feeding habits that do not fit his or her age or stage of development, such as use of a bottle in an older infant/child or a child capable of self-feeding wanting to be fed. Readoption of these feeding habits should be accommodated when possible.

Take Note!

Relieve pain and nausea before meals are served.

If possible, schedule procedures or treatments away from mealtimes. In younger children, refusing to eat may be related to the child's feeling of separation; in others, refusing to eat may reflect the child's attempt to control the situation. Encourage parents to use gentle persuasion instead of force to assist with intake. The use of force can lead to an aversion for food that carries beyond the hospital stay into the home environment. They should give the child choices about what to eat; this reinforces the child's sense of control. Remind parents that the child's appetite will probably improve as his or her condition improves. [Teaching Guidelines 11.2](#) provides tips for promoting nutrition in the hospitalized child. Although geared to parents, nurses also can incorporate these guidelines into the child's plan of care.

Providing Play, Activities, and Recreation for the Hospitalized Child

Play is an important component in the child's plan of care. Today many health care settings providing care for children have playrooms with age-appropriate toys, equipment, and other creative activities ([Fig. 11.6](#)). If the facility is large enough, there may even be a separate area for teens where they can listen to music, play video games, and visit with peers.

Teaching Guidelines 11.2

PROMOTING NUTRITION FOR YOUR HOSPITALIZED CHILD

- Check with the nurse about any restrictions related to your child's diet. Find out if intake and output are being monitored.
- Encourage your child to eat his or her favorite foods. Assist your child with eating or drinking as necessary; be present at mealtimes to promote socialization.
- Frequently offer small cups of fluid and finger foods; avoid giving large quantities at one time. Try offering fluids at different temperatures at different times for variety.
- Remember that children can ingest greater amounts of thin liquids (e.g., gelatin or carbonated drinks) than thicker liquids (e.g., cream soups or milkshakes). Include ice chips as fluid intake. Ice is approximately equivalent to half the same amount of water (e.g., 1 cup of ice equals a half-cup of water). Use straws (unless not allowed) and brightly colored utensils, cups, or dishes to provide contrast and stimulation.
- Offer the child choices; allow the child to choose what he or she wants from the menu. Avoid spicy or highly seasoned foods. Talk with the dietitian to see if any special preferences can be addressed.
- Offer praise to your child for what he or she eats or drinks.
- Never punish the child for not eating or drinking. Encourage the older child to help keep track of what he or she eats and drinks.

Take Note!

Avoid using the term "playroom" when caring for older school-aged children and adolescents. Instead, call it the "activity room" or "social room." Doing so promotes a greater feeling of maturity and makes it more likely that they will use the area.

Obviously, some children will not be able to use these facilities if their activity level is restricted or if isolation is necessary. Children may also play in their rooms. Ensure that opportunities for unstructured play are provided to all children who can engage in play. Therapeutic play may be used to teach children about their health status or to allow them to work through issues in their lives.

FIGURE 11.6 Children occupied in a hospital playroom. It is important to provide age-appropriate activities for younger and older children alike.

Take Note!

Keep the bed or crib and playroom as “safe” places. Perform invasive procedures such as venipunctures in the treatment room if possible. Never perform any nursing interventions in the playroom, no matter how nonthreatening they may appear to the nurse (Leahy et al., 2008).

The nurse’s greatest ally in the hospital in relation to atraumatic care is the child life specialist (CLS). They not only prepare the child for procedures but also provide activities and events to encourage play and normal growth and development.

UNSTRUCTURED PLAY

Unstructured play allows children to control events, ideas, and relationships. Encourage parents to bring small toys and favorite stuffed animals from home to make the child feel more comfortable in the strange environment of the hospital. Children also enjoy receiving small new toys as surprises when they are hospitalized. Many children enjoy diversional activities such as playing board games or electronic games, reading books, and watching TV, videos, or DVDs. Quiet activities appropriate to the child’s developmental level provide the opportunity for play and encourage the use and development of fine motor skills even if the child is confined to bed. Infants and toddlers enjoy manipulating blocks and playing with stacking toys. The preschooler may enjoy coloring, dollhouses, or playing with plastic building blocks such as Legos. School-age children and adolescents may enjoy playing video games or building a model geared toward their developmental level.

PLAY AS PART OF NURSING CARE

Play is also an important part of nursing care. Use play as appropriate while providing routine nursing care to the child. An example of the use of play in nursing care involves the school-age child’s love of competition and games. To increase range of motion in a school-

age child who is hospitalized for traction due to a fracture, have the child throw a soft sponge ball or beanbag ball into a hoop, and compete against the child. To increase deep breathing, encourage the child to blow bubbles or blow a whistle. To increase intake of fluids, help the child create a graph to chart the number of glasses of fluids he or she drinks over a period of time. Award the child a sticker, baseball card, special pencil, or other small item if he or she reaches a certain level.

When using play as part of nursing care, it is important to evaluate the outcome of play. Play used in the manner described above should enhance the child's outcome. For example, for the child blowing bubbles, determine whether this activity enhanced coughing and deep breathing.

THERAPEUTIC PLAY

Another important aspect of play is therapeutic play. **Therapeutic play** is nondirected and focuses on helping the child cope with feelings and fears. Health care professionals use therapeutic play to help the child deal with the physical and psychological challenges of illness and hospitalization. Supervised play with medical equipment in the hospital environment can help children work through their feelings about what has happened to them (Fig. 11.7). In a large hospital or a children's hospital, the CLS typically coordinates these activities. Goals include maintaining normal living patterns, minimizing psychological trauma, and promoting optimal development of the child. If a CLS is not available, the nurse provides this type of activity. There is a greater emphasis on the developmental and psychosocial implications of illness and hospitalization and validation of the child's voice.

In emotional outlet play or traumatic play, the child acts out or dramatizes real-life stressors. For example, using a wooden hammer and pegs, a soft sponge ball, or boxing gloves can allow the child to express anger over separation from family and friends. Commercial toys such as anatomically correct dolls and puppets have removable parts so children can see various organs of the body. Sometimes younger children "talk" to puppets and dolls, allowing them to express their feelings to a nonthreatening "person" about a specific situation or what they want from the health care provider. For example, the Shadow Buddies dolls mentioned earlier in the chapter provide a way of coping with a specific condition. The company creates an ostomy buddy who has a stoma, a cancer buddy with thinning hair and a chest catheter for chemotherapy treatments, and a heart buddy who has a chest incision and a repaired heart (Shadow Buddies Foundation, n.d.).

FIGURE 11.7 The nurse supervises play with medical equipment to help the child work through her feelings about being hospitalized.

Other types of therapeutic play include drawing and supervised "needle play." Drawing is a way for the child to express his or her thoughts and feelings. Supervised "needle play" assists children who must undergo frequent blood work, injections, or intravenous procedures. A doll can receive an injection as the child works out his or her anger and anxiety. Keep in mind safety and the child's growth and development level before planning this type of directed play; an adult must always be present.

Promoting Schoolwork and Education During Hospitalization

Promote schoolwork while the child is in the hospital. Determine the amount of schoolwork that can be done by assessing the child's condition, the availability of teachers, and the family situation. Many children's hospitals have teachers at the hospitals; there may be

classrooms too. These teachers work closely with the child's school to continue schoolwork as the child's condition permits. Hospitals without an educational staff will rely on parents to coordinate with the child's school. Parents may bring in schoolbooks and the child's homework for completion while in the hospital. This connection to the child's school helps maintain normalcy for the child and minimizes the disruption of everyday life.

Addressing the Needs of Family Members

Assess the factors that may influence the family's reaction to the child's hospitalization and plan the care of the child to accommodate some of these issues. Encourage families to have support systems in place before, during, and after hospitalization. The practice of family-centered care, including good communication and ensuring nursing actions address the child and family's needs and preferences, increases the child's and parents' satisfaction with the health care setting (American Academy of Pediatrics, 2007).

PARENTS AND CAREGIVERS

As stated previously, the anxiety level of caregivers greatly affects the anxiety level of the child. Thus, it is important to help the family members work through their feelings. Parents experience many emotions when a child is hospitalized, including disbelief, anger, guilt, fear, anxiety, frustration, and depression. Visiting restrictions, unexpected changes in the child's health status, lack of information or understanding of their child's health condition, changes in their routine and roles, financial stress, and feelings of being undervalued in the care of their child all contribute to their feelings.

The importance of family involvement to the well-being of the child is reflected in the philosophies, policies, procedures, and physical environments where care is delivered. The philosophy of family-centered care places the family at the core of care. The family is the primary and continuing provider of care for the child. Encourage parents to room-in with the child throughout the hospital stay, if possible. Facilities can be designed to welcome family participation. For example, having computer ports and fax machines available and providing extra meals and beds for the parents can encourage parents to participate in care. View the parents as vital members of the health care team and partners in the care of the ill child.

SIBLINGS

Family-centered care recognizes the need to treat the child in context of the family, including siblings. Important questions that will affect how siblings deal with the hospitalization of their brother or sister include:

- Was the admission an emergency?
- Were there previous admissions, and how did the siblings perceive those hospitalizations?
- How serious is the illness or trauma?
- Is the prognosis known?

Address the siblings' possible feelings of guilt. Use educational materials, allow time for visits, send photographs back and forth between siblings, and allow siblings to talk on the phone.

Providing Child and Family Teaching

Not all experiences with hospitalization are negative; in fact, the experience may enhance the child's and family's coping skills, bolster self-esteem, and provide new socialization experiences. It may allow the child to master self-care skills and provides an opportunity for the child and family to learn new information. Parents may learn more about their child's growth and development skills as well as additional parenting or caregiving skills, resulting in improved parenting abilities. In addition, the child's overall health may be improved because of the hospital stay if the child receives current immunizations and the parents learn more about health care practices.

The overall goals of child and family teaching are to minimize the child's and family's stress, educate them about treatment and nursing care in the hospital, and ensure the family can provide appropriate care at home upon discharge. Providing support before, during, and after hospitalization may minimize stress. Preadmission programs can introduce the child and family to the setting. During the hospital stay, forming partnerships with the child and family, using strategies to promote coping, and providing appropriate preparation for procedures, tests, and surgery serve to decrease stress.

Assess the child's and family's knowledge of the illness and hospital experience. This provides a baseline for teaching. Include hospital rules in child and family teaching. Behavioral changes in hospitalized children often disturb parents or caregivers. Determine the child's usual patterns of behavior and explain to the parents about the child's reaction to hospitalization. Encourage the family to maintain consistent discipline even while in the hospital to provide structure for the child as well as to prevent discipline issues after discharge. Also discuss how siblings may react to the hospitalization, and provide appropriate teaching to the siblings. Every interaction the nurse has with the child or family provides an opportunity for teaching. Explain the purpose of even simple procedures

such as vital signs assessment to the child and family. Provide ongoing information about the child's illness or trauma, treatment plan, and expected outcomes. [Chapter 8](#) provides general principles related to teaching children and their families.

Preparing the Child and Family for Discharge

Discharge planning actually begins upon admission. The nurse assesses the family's resources and knowledge level to determine what education and referrals they may need. Upon discharge, children and their parents or caregivers receive written instructions about home care, and a copy is retained in the medical record. These instructions are individualized for the child. Generally, discharge instructions should include:

- Follow-up appointment information
- Guidelines about when to contact the physician or nurse practitioner (e.g., new or worsening symptoms or indications that the child is not improving)
- Diet
- Activity level allowed
- Medications, including dose, times to be given, route, adverse effects, and special instructions; any prescriptions should be included
- Information on additional treatments the child requires at home
- Specific dates for when the child may return to school or day care
- Names and phone numbers of agencies the family has been referred to, such as durable medical equipment providers

Provide and review educational booklets that give basic health information or general care for a child with a particular disease ([Fig. 11.8](#)). Videotapes, DVDs, or CD-ROMs may also be used if available. The ability to watch a procedure over and over is helpful to some families. Explain, demonstrate, and request a return demonstration of any treatments or procedures to be done at home. Provide a written schedule if the child is to receive multiple medications, tube feedings, or other medical treatments. For complicated cases, a written teaching plan may be used to provide continuity of child/family education between various nurses. As the family attempts to perform each task, document whether the caregiver continues to require assistance or prompting with the task or whether he or she can perform the task independently.

Parents of children with multiple medical needs may benefit from a trial period of home care. This occurs while the child is still in the hospital, but the parents or caregivers provide all of the care that the child requires. Support the family and praise their accomplishments during this trial period.

FIGURE 11.8 The nurse uses charts with pictures to perform client teaching before the child goes home.

Remember Jake Jorgenson, the boy with the suspected brain tumor from the beginning of the chapter? After a long hospital stay and complications resulting from his brain tumor, Jake requires intermittent gastrostomy feedings and has frequent respiratory infections. He has been receiving nursing care at home along with therapies but is now ready to make the transition to the local elementary school.

Children receive most of their health care, well and ill care, in the community setting. Nurses play an important role in the health and wellness of a community. They not only meet the health care needs of individuals but also go beyond to create interventions that affect the community as a whole. Community health nursing refers to nursing care that strives to improve the health of a specific community as a whole. For example, community health nurses working in the Department of Health and Human Services would strive to make sure that all children in their particular community were up-to-date on immunizations. Community-based nursing focuses more on providing care to the individual or family (which, of course, impacts the community) in settings outside of acute care. For example, a community-based nurse would work in the local public school to care for students' health needs. Nurses practicing in the community promote the health of individuals, families, groups, communities, and populations and promote an environment that supports health.

Community Health Nursing

Nursing in the community is aimed at disease prevention and improvement of the health of populations and communities. Population is defined as “a collection of individuals who have one or more personal or environmental characteristics in common” (Community Health Nurses Association of Canada, 2008, p. 16). **Community** can be defined as a “specific group of people, often living in a defined geographical area, who share a common culture, values, and norms and who are arranged in a social structure according to relationships the community has developed over a period of time” (Community Health Nurses Association of Canada, 2008, p. 16). Community health nurses work in geographically and culturally diverse settings. They address current and potential health needs of the population or community. They promote and preserve the health of a population and are not limited to particular age groups or diagnoses. Public health nursing is a specialized area of community health nursing.

Epidemiology can help determine the health and health needs of a population and assist in planning health services. Community health nurses perform epidemiologic investigations in order to help analyze and develop health policy and community health initiatives. Community health initiatives can be focused on the community as a whole or a specific target population with specific needs. *Healthy People 2020* (HP 2020) is an example of national health initiatives developed using the epidemiologic process. HP 2020 ensures that health care professionals look at the individual as well as the community. It addresses the link between the individual's health and the health of the community. Nurses play a key role in the health of a community and the individuals who reside in it.

HP 2020 is the fourth edition of national health goals, which were launched in 1979. HP 2020 is a comprehensive health initiatives plan. Nurses can help the nation meet these objectives by educating those in the community on appropriate prevention strategies, such as proper immunization and smoking cessation (see individual chapters for relevant HP objectives and nursing implications). HP 2020 is available online at <http://www.healthypeople.gov/HP2020/>. Refer to **Chapter 1** for more information.

Community-Based Nursing

In the past the major role of the nurse in the community was that of the community health nurse or public health nurse. Today, nurses practice in a variety of settings within a community, such as clinics and physicians' offices, schools, shelters, churches, health departments, community health centers, and homes.

Shifting Responsibilities From Hospital-Based to Community-Based Nursing Care

Over the past century changes in health care, such as strained health care funding, shorter hospital stays, and cost containment, have led to a shift in responsibilities of care for children from the hospital to homes and communities. Community care, especially home care, is a rapidly growing service in the United States. Community-based care has been shown to be a cost-effective way to provide care. It emphasizes wellness and prevention. Increases in disposable income and the longevity of children with chronic and debilitating health conditions have also contributed to the continued shift of health care to the community and home setting. Advances in technology have allowed for improved monitoring of children in community settings and at home, as well as allowing complicated procedures, such as intravenous administration of antibiotics, to be done at home.

Another major reason for the increase in community care, especially home care, in children is the understanding that an acute care setting is not an appropriate environment for children to grow up in (Hewitt-Taylor, 2005). Caring for children at home not only

improves their physical health but also allows for adequate growth and development while keeping them within their family. They are in a familiar environment with the comfort and support of family, which leads to improved care and quality of life.

Role of the Community-Based Nurse

With the shift in responsibilities from hospital care to community care have come changes in nursing care. More opportunities exist for nurses to provide direct care to children in the community setting, especially the home. Community-based nursing care differs from nursing care in the acute setting. In the community or home care setting, the nurse provides direct care for the child but spends more time in the role of educator, communicator, and manager than the nurse in the acute care setting. In home care the nurse spends a significant amount of time in the supervision or management role. Community-based nursing focuses on the practice of nursing that provides personal care to individuals and families in the community. Community-based nurses focus on promoting and preserving health as well as preventing disease or injury. They are educators, managers of care, and advocates along with being direct providers of care.

EDUCATION AND COMMUNICATION

The community-based nurse must use the principles and techniques of interpersonal communication. The nurse must be able to assess the child's and family's learning needs and their readiness to learn. As hospital stays become shorter and admissions to the hospital become less frequent, teaching now begins wherever the child or family enters the health care system. Many times initial teaching occurs in the community setting, especially the home. In the community-based setting, teaching is often focused on assisting the child and family to achieve independence.

DISCHARGE PLANNING AND CASE MANAGEMENT

Due to the short lengths of stay in acute settings and the shift to community settings for children with complex health needs, discharge planning and case management have become important nursing roles. Discharge planning involves the development and implementation of a comprehensive plan for the safe discharge of a child from a health care facility and for continuing safe and effective care in the community and at home.

Modern pediatric health care focuses on an interdisciplinary plan of care designed to meet the child's physical, developmental, educational, spiritual, and psychosocial needs. Nurses coordinate the implementation of this interdisciplinary plan in a collaborative manner to ensure continuity of care that is cost-effective, quality oriented, and outcome focused. This type of care is termed *case management*. When the nurse functions as a case manager, child and family satisfaction is increased, fragmentation of care is decreased, and compliance is increased, leading to improved health and quality of life (White & Hall, 2006).

Case management uses a system of plans, often referred to as critical paths, which are derived from standards of care with a multidisciplinary approach that produces clinical practice guidelines. Implementing this philosophy leads to outcomes that are expected as a result of delivery of that care and may lead to future payment tied to the practice guidelines. The Agency for Health Care Policy and Research and the National Guidelines Clearinghouse maintain current clinical practice guidelines, which are rooted in evidence-based practice.

ADVOCACY AND RESOURCE MANAGEMENT

Another important role of the community-based nurse is to advocate for the child and family to ensure that their needs are being met and that they have available resources and appropriate health care services. Working in a child and family's home can lead one to become overly involved in the situation. To best serve the child and family, the community-based nurse must be an advocate and educator but avoid becoming a personal friend (Thompson, 2000).

Nurses must have a basic understanding of community, state, and federal resources to ensure they are providing families with the resources they may need. One such resource important in the community-based care of children with complex medical needs is Medicaid and Medicaid waivers. Medicaid is a national program providing medical assistance for children and families with low incomes. It is jointly run by the federal and state governments but is administered state by state; therefore, provisions vary widely. Medical model waivers are state-run programs that use federal and state funds to pay for health care for people with certain medical conditions. Home- and community-based waiver programs, such as the Katie Beckett waiver (also known as the Deeming waiver), allow children and young adults with complex medical needs to be cared for at home and make them eligible for Medicaid based on their own income and assets, regardless of their parents' income (Georgia Department of Community Health, Division of Medical Assistance, 2006). Without medical waiver programs, many children with special needs would either go without health care or would be institutionalized in order to qualify for Medicaid. (Find a link to read about Katie Beckett on [thePoint](#).)

PHYSICAL CARE

The community-based nurse performs less direct physical care than the nurse in the acute care setting. Many times the nurse observes the child or caregiver performing physical care tasks. Excellent assessment skills are especially important in the community care setting. The nurse often functions in a more autonomous role; after data collection, the community-based nurse will often decide whether to initiate, continue, alter, or end physical nursing care. Assessment will go beyond physical assessment of the child to include the environment and the community.

Community-Based Nursing Settings

Community-based nursing takes place in a variety of settings, including outpatient and ambulatory care settings, physicians' offices, clinics, health departments, urgent care centers, schools, camps, churches, shelters, and clients' homes. Community-based nurses provide well care, episodic ill care, and chronic care. They work to promote, preserve, and improve the health of children and families in these settings.

OUTPATIENT AND AMBULATORY CARE

Outpatient and ambulatory care is health care provided to individuals who do not require care in an acute setting. Due to advances in medical technology, more medical procedures, such as diagnostic tests, treatments, and surgeries, can be administered on an outpatient basis and do not require clients to be hospitalized. Outpatient and ambulatory care delivers convenient and cost-effective health care to children and their families, many times right within their own community. These settings allow for increased independence and permit children to return to their normal routine as quickly as possible. More and more outpatient and ambulatory care centers are opening, sponsored by health maintenance organizations (HMOs), physicians' offices, community agencies and public health departments, and hospitals.

Outpatient units are used to keep hospital stays short and decrease the cost of hospitalization. Outpatient units may be a part of the hospital or a freestanding facility. The child and family arrive in the morning; the child undergoes the procedure, test, or surgery and then goes home in the evening. Examples of surgeries and procedures performed in outpatient settings include tympanostomy tube placement, hernia repair, tonsillectomy, cystoscopy, bronchoscopy, blood transfusions, dialysis, and chemotherapy. The advantages of this environment include minimal separation of the child from the family, minimal disruption of the family pattern, decreased risk of infection, and decreased cost. Disadvantages include that the unit does not have the equipment for overnight stays, so if there are complications the child will need to be transported to the hospital.

Many centers offer preoperative health assessment and teaching sessions. These allow the parent and child to ask questions and resolve them before the procedure. On the day of the procedure, parents should be allowed to be with their child until the procedure begins. Parents should also be allowed to be with their child in the post-anesthesia recovery unit as quickly as possible. This provides reassurance and comfort to the child while meeting his or her physical and emotional needs.

The role of the nurse in the outpatient or ambulatory setting includes admission and assessment, preoperative teaching and preparation, client assessment and support, postoperative monitoring, case management, discharge planning, and teaching. Before the procedure the nurse reviews with the family the routine to be followed and any special instructions (such as NPO orders), and familiarizes the child with the setting to help alleviate fears. This may occur during the preoperative health assessment.

Take Note!

Encourage the parent to bring one of the child's favorite toys, blankets, or games to make the child feel more comfortable.

The nurse performs any surgical preparation and discusses intraoperative procedures as necessary. The nurse provides postoperative care and assessment of the child. Once the child's condition is stable and he or she meets the discharge criteria of the facility, the nurse reviews with the parent postoperative instructions, including pain management; care of the incision if appropriate; diet; activity, including return to school; necessary follow-up; and when to call the physician or nurse practitioner.

PHYSICIAN'S OFFICE OR CLINIC, HEALTH DEPARTMENTS, AND URGENT CARE CENTERS

Physicians' offices, clinics, health departments, and urgent care centers are used by children and their families for well care, episodic ill care, acute care, and care of chronic conditions. For well care and illness or injury, children are often seen by their primary care physician. They may visit a physician's office or clinic or the health department. In more acute situations or for after-hours issues that cannot wait until clinic operating hours, a child may be seen in an urgent care center or may be referred to the emergency department. The American Academy of Pediatrics discourages children and families from using urgent care centers or the emergency department for routine care, since it is difficult to provide coordinated, comprehensive family-centered care consistent with a "medical home"

concept (see [Chapter 9](#) on medical homes) (American Academy of Pediatrics, 2009).

The nurse's role in these settings includes preparing clients, collecting pertinent health information, performing assessments, assisting the physician with diagnostic testing and procedures, administering injections and medications, changing wound dressings, assisting with minor surgery, helping to maintain records, and educating the child and family about home care and when to call the physician or nurse practitioner or return to be seen.

An essential component of primary care practice is telephone triage. Pediatric office nurses often fill this role. When parents feel comfortable with the providers in their child's medical home office, they often call for advice in order to treat their child at home. A telephone triage nurse needs excellent assessment and critical thinking skills along with solid training and education. The triage nurse needs to assess the child's entire situation, including current signs and symptoms, history, and home treatment.

Protocols, standardized policies and procedures, and professional judgment guide the triage nurse in the decision-making process. Pediatric telephone protocols are available for purchase through the American Academy of Pediatrics (<http://www.aap.org/>). The triage nurse needs to determine whether the child requires emergency care, an office visit, or home management. Good listening and the ability to maintain a calm voice when talking to parents are skills necessary for successful telephone triage. The triage nurse should not discourage parents from bringing the child into the office to be seen; triage is not meant to keep children out of the office, and if a parent is very concerned, that is reason enough to be seen.

Take Note!

Parents often can pick up on subtle problems in their children. They may not be able to accurately describe signs and symptoms, but they know that their child "isn't acting right." Nurses must listen to parents and act on their concerns.

MEDICALLY FRAGILE DAY CARE CENTERS

The **medically fragile child** is a child whose condition is considered medically complex and requires the use of medical technology and skilled nursing interventions (Rupert & Host, 2009). The number of medically fragile children is growing. Reasons include improvements in the treatment and care of complex medical conditions, increased sophistication of medical technology, and the increase in premature deliveries. For many years these children lived in hospitals their entire lives. Due to concerns about the high cost of long-term hospitalization and the diminished quality of life for these children, alternative care settings in the community, such as medically fragile day care centers, are being developed.

Medically fragile day care centers are specifically designed to meet the needs of these children. Most centers accept children who have complicated medical needs or are dependent on technology. Examples include children with multiple congenital anomalies, children who are ventilator dependent, children with respiratory conditions, children with cardiac conditions, and children with cancer. Some centers accept children with less complicated needs, such as cardiorespiratory monitoring or asthma, and some enroll children without health care needs to promote peer relationships and acceptance. Just as at a regular day care center, the parents or caregivers can drop the child off in the morning and pick the child up in the afternoon. Some centers offer after-school, weekend, or respite services. The centers usually provide needed therapies and have indoor and outdoor play areas, educational activities, and arts and crafts.

Health professionals are present at these centers to provide for the children's medical, emotional, and developmental needs. Nurses trained in pediatric and neonatal care, physical therapists, occupational therapists, speech therapists, child life specialists, and social workers staff the centers; some centers have respiratory therapists on site. Children are able to receive all of their prescribed therapies while at the center. Nursing care includes direct care such as administering medication and changing dressings, assessing and evaluating the child's overall condition, identifying potential medical emergencies, determining the need for changes in care or treatment and monitoring, and providing frequent treatments or interventions to maintain life and health.

Most centers are located in the community to help ease transportation issues. Some centers provide transportation to and from home or school. Centers are licensed by the state day care licensing authorities or in some states prescribed pediatric extended care (PPEC) agencies. Families may be able to obtain financial assistance from their private insurance or Medicaid. Advantages of community-based services over hospitalization or home care include decreased cost, social isolation, family stress, and rehospitalization rate (Rupert & Host, 2009).

SCHOOLS

School nursing is a specialized practice of professional nursing and focuses on improving students' health and safety to improve their achievement and success. School nurses work to remove or minimize health barriers to learning to provide students with the best opportunity to achieve academic success. The National Association of School Nurses defines school nursing as follows:

A specialized practice of professional nursing that advances the well-being, academic success, and life-long achievement of students. To that end, school nurses

facilitate positive student responses to normal development; promote health and safety; intervene with actual and potential health problems; provide case management services; and actively collaborate with others to build student and family capacity for adaptation, self management, self-advocacy, and learning (Council on School Health, 2008, p. 1052).

See Healthy People 2020.

At the heart of school nursing is the belief that all children have the ability to learn and the right to an education, and that society is best served if all children are educated (Wolfe & Selekman, 2002). School nurses provide direct health care to students along with screening and referrals for health conditions. They provide leadership for health services, such as identifying health and safety concerns in the school environment and planning and training for emergencies and disasters. School nurses promote a healthy school environment by supporting Healthy People Objectives based on data from <http://www.healthypeople.gov>. healthy food services and promoting proper physical education and sports policies and practices. They promote health education through health counseling and education of students and staff. School nurses coordinate school health programs and link health service programs within the school and community. School nurses carry out a variety of roles in providing health care to children (Fig. 11.9). Box 11.4 lists some of the activities of the school nurse.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|---|
| Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, HIV/AIDS, and STD infection; unhealthy dietary patterns; and inadequate physical activity. | <ul style="list-style-type: none"> • Provide education and training to school staff in health problem areas. • Work with schools to develop appropriate health education with focus on health problem areas. • Provide adequate health care services and health education to students. |
| Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and check-ups. | |
| Increase the proportion of elementary, middle, and senior high schools that have a full-time registered school nurse-to-student ratio of at least 1:750. | |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

The population of students has changed over the years. Access to public schools for children with disabilities is mandated. Due to improvements in technology, children with chronic conditions or special needs live longer and enter school. There has been an increase in the number of children with psychiatric conditions such as depression, attention deficit/hyperactivity disorder, and more serious conditions such as bipolar disorder. All have contributed to an increase in the number of children with diverse and sometimes complex health needs in the school system. The essential role of the school nurse has not changed, but the responsibilities and expectations have. School nurses are challenged to meet the growing needs of the changing school population.

FIGURE 11.9 The school nurse provides nursing assessment as well as health education to students in the school setting.

BOX 11.4

EXAMPLES OF ACTIVITIES OF THE SCHOOL NURSE

- Conduct health screenings (such as vision, hearing, and scoliosis)
- Assess growth and development
- Provide emergency first aid
- Train and educate staff on cardiopulmonary resuscitation (CPR), first aid, and health issues
- Assess, monitor, and refer students with communicable diseases
- Educate on health promotion and disease prevention (such as immunizations; bike and car safety; decreasing high-risk behaviors, such as smoking, drinking, drug use, and sexual activity)
- Serve as a resource for health issues and education
- Act as a liaison between home, school, and community
- Act as a liaison between health care provider and school
- Reinforce client and family health education (such as discharge instructions, self-care measures)
- Monitor long-term illness in students
- Network with community agencies and make necessary referrals

Recall Jake Jorgensen, the 8-year-old boy with history of a brain tumor and resulting complex medical needs? In recent years there have been many more children with special needs attending school than ever before. This brings many challenges for the teachers, staff, and school nurses employed by the school district. The principal of Jake's elementary school tells the school nurse that many of the teachers and staff have expressed concerns that they do not know anything about the health care needs of these children, including Jake. What kinds of interventions might the nurse plan?

Just as nurses in the acute care setting develop nursing care plans, nurses in the school setting develop **Individualized Health Plans** (IHPs). An IHP formalizes the plan of support for a student with complex health care needs. It is a written agreement developed as part of an interdisciplinary collaboration of school staff along with the student, the student's family, and the student's health care provider. The plan describes the student's needs and how the school plans to meet these needs. The nurse plays a critical role in developing these plans. The nurse will use the nursing process and then, based on the nursing assessment and diagnosis, will develop goals and interventions to ensure that the child's needs are being met. Examples of students who may need an IHP are students with asthma, serious allergies, chronic conditions such as type 1 diabetes, physical disabilities, attention deficit/hyperactivity disorder, and medication needs. [Figure 11.10](#) gives an example of an IHP for a child with asthma.

Take Note!

The IHP needs to include directions for care while the child is at school and also must take into account circumstances that may affect the student's health care needs, such as variations in school routine, absence of staff, special outings such as field trips and extracurricular activities, and a plan in case of emergency.

OTHER COMMUNITY SETTINGS

Nurses work in a variety of different settings within the community. Their primary focus continues to be on promoting health, preventing disease and injury, and ensuring a safe environment. Nurses play important roles in child care centers, camps, health department clinics, and shelters. In child care centers, nurses help address infection control issues and assess for a safe environment. They provide education and training to staff members. A camp nurse ensures a safe environment for all campers and provides first-aid and acute illness care as needed. Camps for children with special needs exist, staffed by specially trained nurses. These camps cater to children with complex health care needs, such as diabetes, head injuries, and physical disabilities, and allow the children the opportunity to experience camp life while providing a safe environment and necessary medical care. Health department and shelter nurses focus on health supervision services and connecting clients to needed community resources.

Take Note!

Nurses have a unique opportunity to give back to their community by volunteering their services in various settings, such as shelters and clinics in medically underserved areas.

HOME HEALTH CARE

Home care provides short- or long-term services for children and their families in the home. It also is used for medically needy and technology-dependent children, such as ventilator-dependent children. Among those who often benefit from home care are children with acute illness, such as a child with osteomyelitis requiring intravenous antibiotics, or chronic health care issues, such as a child with bronchopulmonary dysplasia, who may have required traditional in-hospital care.

Home care is geared toward the needs of the child and family. Private-duty nursing care is used when more extensive care is needed; it may be delivered hourly (several hours per day) or on a full-time, live-in basis. Periodic visiting nurse care is used when the child needs intermittent interventions such as intravenous antibiotic administration, follow-up with child and family teaching, and periodic monitoring, such as bilirubin monitoring. The goals of nursing care in the home setting include promoting, restoring, and maintaining the health of the child. Home care focuses on minimizing the effects of the illness or disability, along with providing the child or family with the means to care for the illness or disability at home. Nurses in the home care setting are direct providers of care, child and family educators, child and family advocates, and case managers.

There are some disadvantages to home care. The presence of health care professionals in the home can be an intrusion on family privacy. Also, caring for children with complex medical needs can be overwhelming for some families. Financial issues can become a large burden: families may have higher out-of-pocket costs if their insurance does not reimburse for home care. Having one parent at home full time and not earning an income can contribute to increased financial strain, not to mention social isolation of that parent. All of these can lead to increased stress on family members. The advantages of home care usually outweigh the disadvantages, but nurses need to be aware of these potential disadvantages and provide support and resources as necessary.

Example Individualized Healthcare Plan

| | |

[1999]. *The school nurse's source book of individualized healthcare plans: Issues applications in school nursing practice*, Vol. II. North Branch, MN: Sunrise River Press; and Zentner-Schoessler, S. [1997]. *Computerized version and manual*, Vol. I. North Branch, MN: Sunrise River Press.)

Family-Centered Home Care. Family-centered care is a challenging pediatric nursing philosophy and is driven by evidence that a nurturing environment improves the chances of positive outcomes for the child. It places the family in a central position relative to the child and to the child's plan of care. Refer to [Chapter 8](#) for further information regarding family-centered care.

Family-centered home care focuses on increasing support for the emotional and developmental needs of the child. It encourages families to care for their children at home while health care professionals provide the support, empowerment, education, and expertise in caring for the child that they need. In family-centered home care, the family and health care professionals build a partnership of trust to meet the needs of the child. The nurse must value the role of the family and regard family members as the ultimate experts in caring for their child. In home care the family is extensively involved in the child's care, and the home care nurse is there to facilitate this.

Any illness, especially a chronic illness, affects the entire family and can disrupt family structure. There is a change in the role of the parent when he or she has to care for an ill child. These role changes can result in stress for the family members and can affect their participation in the child's care. It is important for home care nurses to seek a partnership role with the family regarding care of the child. This can be difficult for both parties. Many times nurses set limits on parental involvement and do not consider the parents' perspective. Many nurses are concerned that the parents may not be able to care for the child safely. It is important for nurses to use self-awareness and reflective practice to help them understand and empower families as well as to develop a partnership for care. A communication framework, developed by Berlin and Fowkes (1983), that can assist nurses in the home care setting is the LEARN framework, which can help create cross-cultural collaboration and communication between nurses and families ([Box 11.5](#)).

The Nurse's Role in Home Care. Early discharge planning, teaching, and case management are keys to promoting a successful transition from the hospital setting to home. The environment differs greatly between the acute setting and home setting. In the acute setting the nurse is in control of the environment; in the home setting, the nurse is a guest in the home. It is important for the nurse to establish a trusting relationship with both the child and family ([Fig. 11.11](#)). A trusting therapeutic relationship will make all aspects of care more effective. [Box 11.6](#) gives hints on building this relationship.

BOX 11.5

LEARN FRAMEWORK

- L: Listen empathetically and with understanding to the family's perception of the situation.
- E: Explain your perception of the situation.

- A: Acknowledge and discuss the similarities as well as differences between the two perceptions.
- R: Recommend interventions.
- N: Negotiate and agree on the interventions.

From Berlin, E. A., & Fowkes, W. C. (1983). A teaching framework for cross-cultural health care—Application to practice. *The Western journal of Medicine*, 739(6), 934-938.

Nursing in the home care setting can be challenging. The focus is on meeting the child's physical and psychological needs while involving the family. In meeting the child's needs while involving the family, the nurse uses the nursing process. Assessment in the home is similar to that in the acute care setting but involves obtaining firsthand data about the family and the way it functions. The nurse needs to assess the child's growth and development and thoroughly assess the home environment (refer to [Chapters 4 to 7](#) and [9](#) for additional information). The nurse needs to ensure that home offers a safe and nurturing environment for the child. The National Center for Healthy Housing has developed a Pediatric Environmental Home Assessment (PEHA) Survey and PEHA nursing care plan to assist in identifying and addressing hazards or potential threats that exist in the child's home (National Center for Healthy Housing, n.d.). These forms can be accessed from a link on [thePoint®](#). The nurse should always individualize these forms to meet the needs and requirements of his or her client and facility.

FIGURE 11.11 Listening to the child helps to develop a trusting relationship between the home care nurse and the child and her family.

BOX 11.6

HINTS TO ESTABLISHING A TRUSTING RELATIONSHIP IN HOME CARE

- Include the child in the conversation and make him or her feel a part of the interaction.
- Address caregivers formally unless otherwise instructed.
- Be friendly. Use a soft, calm voice.
- Be interested in the child's activities.
- Have the primary caregiver present at the initial visit.
- Listen to and show respect to the child and the family.

The nurse also needs to assess availability of resources. This includes necessary equipment such as a hospital bed and oxygen, suitable physical and emotional surroundings (are the family members able to deal with the stress of the situation?), ability to contact emergency services, power backup if needed, and ease of evacuation of the child in case of a fire. The nurse needs to assess whether electricity, sanitary conditions, heat, air conditioning, and telephone access are present. If there is no phone in the home, the family needs to have plans for accessing a phone in case of emergency (perhaps a neighbor's phone or a pay phone near the home). The

nurse should identify areas of priority and provide appropriate referrals to resources.

During the assessment phase the nurse identifies the person who is the primary caregiver; this may be the mother, father, grandparent, or older sibling. It is essential to include this person when developing the plan of care, as he or she is the expert on the child and family. The primary caregiver can provide insight into direct care and which strategies will be most effective with this child, taking into account the physical layout of the home, the financial ability of the family, and the way the family functions. The home care nurse must also assess the family's teaching and learning needs.

After the assessment is complete, the nurse develops appropriate nursing diagnoses, outcomes, and goals and implements the plan of care. This will include the frequency and duration of the home visits. The nurse will use agency policies, certification standards, and private insurance and/or Medicaid regulations to assist in the development of the plan (Thompson, 2000). The nurse may be the provider of direct care to the child, or the care may be indirect, in which case the nurse plans and supervises the care that is given by others, such as unlicensed personnel and parents.

Nursing care in the home requires excellent critical thinking skills. The nurse has a great deal of independence since there are no other nurses, supervisors, or physicians on site. When complex care is provided in the home, the nurse may need to adjust procedures to fit the setting. For example, feeding schedules may be adjusted to fit a child's school schedule or equipment may be adjusted to allow a child to receive feedings continuously while at school (Fig. 11.12).

FIGURE 11.12 The home care nurse may have to adjust procedures and equipment use to fit the home setting. Placing a feeding pump in a backpack allows this child to receive feedings continuously while at school.

An important role of the home care nurse is empowering children and their families through education (refer to [Chapter 8](#) for further information related to teaching). The nurse assesses the learning needs and provides education that is appropriate to the educational and developmental levels of the child and family. The nurse must encourage the family to participate in the child's care. The education goals of home care vary. In many situations parents or caregivers must learn care immediately so the child can be cared for at home, such as a child who needs dressing changes four times a day or a child who is ventilator dependent. A child newly diagnosed with diabetes will have some immediate teaching needs, but as the child grows and his or her condition changes, additional care will need to be taught.

As with any nursing care, the effectiveness of nursing interventions along with changes in the child's or family's status needs to be continuously evaluated and the plan of care altered as needed.

As the home care nurse, what can you do to help with Jake's transition to school? On your last visit, Jake's parents expressed concerns about this transition and the added stress it is causing the family. They appear tired from the round-the-clock care that Jake requires. What suggestions can you make to help ease their stress and fatigue?

KEY CONCEPTS

- Stressors associated with hospitalization include separation from family and routines; fear of an unknown environment; potential

for pain, bodily injury, or mutilation; and loss of control.

- Responses of children to the general stressors of hospitalization include anxiety, fear, anger, guilt, and regression.
- Parents may experience anger or guilt related to the hospitalization of their child.
- The responses of children and families to hospitalization can be influenced by the age and developmental level of the child, their perceptions of the situation, previous experiences, separation from family and peers, coping skills, and the preparation and support provided by the family, facility, and health care providers.
- Play, including therapeutic play, is an important strategy to prepare children for hospitalization and to help them adapt to the effects of illness and hospitalization. It provides an emotional outlet, opportunities for teaching and learning, and the ability to become familiar with a situation and improve physiologic abilities. A child life specialist is a specially trained individual who is a member of the child's multidisciplinary team. He or she works in conjunction with the child's health care providers and parents to foster an atmosphere that promotes the child's well-being.
- Family-centered care and atraumatic care are philosophies that pay special attention to the concerns of the family and child during hospitalization.
- Providing support to hospitalized children and their families is critical for minimizing stress.
- Whatever the reason for admission, preparation for admission is vital.
- Upon admission to the hospital or outpatient unit, orient the child and family to the unit, discuss unit policies and routines and the personnel who will be involved in the care of the child, and begin child/family teaching.
- Establish a trusting, caring relationship with the child and family. Let the child and family know what will happen and what is expected of them. Obtain information about the child's history, routines, and reason for admission. Obtain baseline vital signs and height and weight, and perform a physical assessment. Each health care setting has its own policies and procedures for this.
- Due to their age and developmental level, children may be vulnerable to harm, and the nurse must use appropriate safety measures in caring for children (e.g., identification of children, use of restraints and transportation, basic hygiene measures). These measures need to address developmental risks, such as that infants, toddlers, and preschoolers require close supervision and the nurse must avoid leaving small objects within reach.
- Discharge planning begins upon admission. Each interaction with the family is an opportunity for child and family teaching.
- Provide and review discharge instructions with the child and primary caregiver. Use educational booklets, videotapes, DVDs, or CD-ROMs that give basic health information or general care for a child with a particular disease.
- Explain, demonstrate, and request a return demonstration of any treatments or procedures to be done at home. Provide a written schedule if the child is to receive multiple medications, tube feedings, or other medical treatments.
- Community-based nurses focus on the practice of nursing that provides personal care to children and families in the community. These nurses focus on promoting and preserving health as well as preventing disease or injury. They help children and their families cope with illness and disease. They are direct providers of care as well as advocates and educators working to minimize and remove barriers to allow the child to develop to his or her full potential.
- Due to the short lengths of stay in acute settings and the shift to home care for children with complex health needs, discharge planning and case management have become important nursing roles. Discharge planning provides a comprehensive plan for the safe discharge of a child from a health care facility and for continuing safe and effective care at home. Case management focuses on coordinating health care services while balancing quality and cost outcomes. Both contribute to improved transitions from hospital to home for children, their families, and the health care team.
- Nursing in the home care setting can be challenging. The focus is on meeting the child's physical and psychological needs while involving the family. Health care professionals provide the support, empowerment, education, and expertise in caring for the child that families need.
- Goals of the nurse in the home care setting include promoting, restoring, and maintaining the health of the child. Home care focuses on minimizing the effects of the illness or disability and providing the child or family with the means to care for the illness or disability at home. Nurses in the home care setting are direct providers of care, child and family educators, child and family advocates, and case managers.
- Community-based nursing takes place in a variety of settings, including physicians' offices, clinics, health departments, urgent care centers, clients' homes, schools, camps, churches, and shelters (such as shelters for abused women, homeless shelters, and disaster shelters). Nurses provide well care, episodic ill care, and chronic care to children and their families in these various settings.
- Advantages of home care include shorter hospital stays and decreased health care costs, but the major advantage of home care is the comfort and family support it provides, promoting an improved quality of life for these children. Caring for children at home not only improves their physical health but also allows for adequate growth and development while keeping them within their

family.

- Disadvantages to home care include intrusion on family privacy. Caring for children with complex medical needs can be overwhelming for some families, and financial issues related to home care can become a large burden to families.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is preparing a 5-year-old boy for surgery on his lower leg. His mother is helping him into the hospital gown and the boy fights removal of his underwear. What is the most appropriate nursing action?
 - a. Allow the mother to remove the underwear.
 - b. Tell the boy he is acting childishly.
 - c. Notify the OR that the underwear is on.
 - d. Allow the boy to keep his underwear on.
2. A 6-month-old infant requires restraint to prevent removal of his nasogastric tube. What is the priority nursing intervention?
 - a. Tie the restraint loosely to prevent skin breakdown.
 - b. Leave the baby unrestrained when directly observed.
 - c. Position the restrained infant prone to prevent aspiration.
 - d. Place the infant in a room near the nurses' station.
3. A 10-year-old child on a regular diet refuses to eat the food on her meal tray. She requests chicken nuggets, French fries, and ice cream. What is the best nursing action?
 - a. Ask that the child's desired foods be sent up from the kitchen.
 - b. Negotiate with the child to eat at least part of the food on the tray.
 - c. Remove a privilege.
 - d. Offer the child cereal and milk from stock on the nursing unit.
4. The nurse providing home care to a 2-year-old listens to the child's parents talk about how the child and family are adjusting to the child's current illness. Which of the following roles is the nurse participating in?
 - a. Case management
 - b. Child and family advocacy
 - c. Direct nursing care
 - d. Child and family education
5. A child is to undergo a tympanostomy tube placement in a freestanding outpatient surgery center. What is the major disadvantage associated with this location?
 - a. Increased risk for infection
 - b. Increased health care costs
 - c. Need to be transferred if overnight stay is required
 - d. Increased disruption of family functioning

CRITICAL THINKING EXERCISES

1. Becky, an 8-year-old, is admitted to the pediatric unit for an emergency surgery. She is in third grade and very active in after-school programs. Her mother is with her during the admission process but will have to return to work shortly after Becky returns from surgery to the pediatric unit. Would the nurse expect Becky to show separation anxiety? What are the three top nursing diagnoses for Becky?
2. A 6-year-old is admitted to the general pediatric unit after spending several hours in the emergency department with an acute asthma attack. Her mother and two younger siblings are present, but the mother plans to leave shortly to take the siblings home. The father will visit in about 2 hours, after work. What is the overall goal for this child's care? What could the nurse say to promote coping in this child? What would be the best answer if the mother asks if she should stay?
3. A child with cerebral palsy is discharged from the hospital, where he has been receiving treatment for pneumonia. Home health care nurses, through a local agency, are to help the family administer intravenous antibiotic therapy and to monitor the child's health status.
 - a. As the home health nurse assigned to this child, what should your nursing assessment include?
 - b. In this situation, what are some nursing interventions that will help ensure family-centered care?
 - c. When this child is stable and can go back to school, what will be the role of the school nurse in caring for this child?

STUDY ACTIVITIES

1. Follow a child and family during the admission process, from preadmission to initial time on the unit, to identify the procedures and tasks involved. Examine the response of the child and family and how the nursing staff responds to their needs.
2. Develop a teaching plan to orient a toddler or preschooler and his or her family to a nursing unit. Include the resources, personnel, and techniques to include in the teaching plan.
3. Shadow a nurse working in a community setting, such as a camp, school, shelter, or health department. Identify the role the nurse plays in the health of the children and families in the setting and the community.
4. Spend a day in a medically fragile day care setting. Identify the needs of one child and his or her family, how they may differ from those of a child in a traditional day care setting, and the role of the nurse in meeting those needs.
5. Develop an IHP for a child with diabetes (use the IHP in [Fig. 11.10](#) as a reference).
6. Shadow a nurse working in a home health care setting. Identify ways he or she helps the family to promote the child's growth and development and to ensure that the child has as normal a childhood as possible. Identify interventions that embody the key concepts of family-centered care.

Caring for Children in Special Needs Child

Words of Wisdom The touch of a mother's hand and the sound of her voice bring comfort to her special child, and when you bring comfort, you strengthen both of them.

KEY TERMS

chronic illness

developmental delay

developmental disability

palliative care

respite care

terminal illness

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Analyze the impact that being a child with special needs has on the child and family.
2. Identify anticipated times when the child and family will require additional support.
3. Describe ways that nurses assist children with special needs and their families to obtain optimal functioning.
4. Discuss early intervention and public school education for the special needs child.
5. Plan for transition of the special needs child from the inpatient facility to the home, and from pediatric to adult medical care.
6. Discuss key elements related to pediatric end-of-life care.
7. Differentiate developmental responses to death and appropriate interventions.

Preet Singh, a 2-year-old boy who was born at 27 weeks' gestation, is seen in your clinic for the first time. He has a history of hydrocephalus and developmental delay. During the examination, his mother states, "I'm concerned about finding a good, affordable preschool for Preet. His older brother attends public school, but I can't imagine Preet going there." After further discussion with Preet's mother, you realize he has not been involved in an early intervention program.

The Maternal Child Health Bureau defines children with special health care needs as those who have or are at risk for a chronic physical, developmental, behavioral, or emotional condition beyond needs generally required by children (U.S. Department of Health and Human Services (USDHHS), Health Resources and Services Administration (HRSA), Maternal and Child Health Bureau, 2008). Children who have a terminal illness, or are otherwise dying, also require additional care. Nurses are in a unique position, both in the inpatient and outpatient setting, to have a significant and positive influence on the lives of these children and their families. For children with special needs, in addition to providing direct care, the nurse fills the critical role of child and family advocate and case manager. When a child is dying, nurses not only provide physical care to the child but also strive to meet the emotional needs of the child and family.

THE MEDICALLY FRAGILE CHILD

The numbers of children with **chronic illness** (a long-lasting or recurrent illness) are increasing. Children with special health care needs make up a little over one eighth of the population of children in the United States and, of those children, 24% report being affected a great deal by their condition (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). Increasing numbers of children are being diagnosed with physical and mental disorders and larger numbers of children are living with the assistance of high-tech treatments and equipment.

Impact of the Problem

Children with special needs may use or need prescription medication, medical care, mental health services, or education services more than other children their same age. They may be limited in abilities and may need physical, occupational, or speech therapy. Alternatively, they may require ongoing treatment for emotional, developmental, or behavioral problems (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). These children and their families are often insured inadequately, have financial needs and/or unmet family support needs, or have difficulty obtaining the specialty care that the child requires (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). It can be challenging for the family of a child with special needs to navigate the system and obtain all of the services their child requires.

When an infant is born very prematurely, when a child is injured and requires long-term rehabilitation and special care, or when a child is diagnosed with a complex chronic health condition, the parents are often devastated initially. The parents of medically fragile children may feel they must adapt to the risk and protect their child. They are interested in preserving their family while compensating for the past, and they cautiously look to the future and become hopeful again. While the infant or child is still in the hospital, nurses can help parents build on their strengths, empowering them to care for their medically fragile infant or special needs child. Education is paramount and should begin as early in the hospitalization as possible. In many situations, particular discharge needs are known early in the course of the infant's or child's hospitalization. Nurses should provide anticipatory guidance about the course of treatment and the expected outcome (Lewis, 2007).

Most children with chronic illness, or those who are dependent on technology, progress through stages of growth and development just as typical children do, though possibly at a slower pace. The exception is the child with significant psychomotor retardation, though some developmental progression may occur. Children with special health care needs desire to be treated as normal, and they want to experience the same events that other children do.

Of particular concern is a growing subset of children with emotional, behavioral, and developmental problems. Children with these needs have even greater difficulty receiving the care and services they require (USDHHS, HRSA, Maternal and Child Health Bureau, 2008). Many children with emotional, behavioral, or developmental problems also have health problems. Often, these children's problems are not diagnosed early and treatment is difficult (Horowitz & Marchetti, 2010). Ongoing counseling and therapy is very difficult for some families to obtain. Ultimately, this has a negative impact on the child's physical and mental health and may result in decreased achievement and productivity as the child matures. See Healthy People 2020.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|--|---|
| Reduce the proportion of people with disabilities who report serious psychological distress. | <ul style="list-style-type: none">• Screen children with special health care needs for depression or sadness.• Refer children and their families to mental health providers as needed. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Effects of Special Needs on the Child

When a child is medically fragile or has special needs, the child's coping ability is affected. In addition, the child's ability to cope is significantly affected by the family's response to stressors, which are often numerous in this population. Children with special health care needs experience differing effects of the chronic illness or disability based on their developmental level, which naturally changes over time for most children.

Infants may fail to develop a sense of trust or attach appropriately with the parents because of frequent hospitalizations, often with multiple caregivers involved; lack of consistency in nurturing; or parental detachment or grieving over the child's condition. The infant's ability to learn through sensorimotor exploration may be impaired due to lack of appropriate stimulation, confinement to a crib, or increased contact with painful experiences (Vessey & Sullivan, 2010).

The toddler may experience difficulty developing autonomy because of increased dependency on the parent or overinvolvement by the parent. Motor and language skill development may be delayed if the toddler is not given adequate opportunities to test his or her limits and abilities (Vessey & Sullivan, 2010).

Limited opportunity also reduces the preschooler's development of a sense of initiative. The preschooler may experience limited opportunities for socialization, causing him or her to withdraw or to feel criticized. Body image development may be hindered due to painful exposures and anxiety. In preschoolers, magical thinking may lead to feelings of guilt for having caused their own disease or condition (Vessey & Sullivan, 2010).

The school-age child may have limited opportunities to achieve a sense of industry because of school absence and inability to participate in activities or competitive events. Lack of socialization limits the school-age child's ability to form peer relationships. The ability to learn via concrete operations is affected by the child's physical limitations or possibly the treatments required (Vessey & Sullivan, 2010).

Adolescents may feel as though they are different from their peers because of their lack of skills/abilities or their appearance. This may hinder the teen's ability to form a sense of personal identity. Since the teen with special health care needs often requires significant amounts of support from the parents, it may be difficult for the adolescent to achieve independence. If the earlier stages of cognitive development have been delayed, then reaching the level of abstract thinking may be blocked (Vessey & Sullivan, 2010).

The child with special health care needs may be able to focus on the positive experiences in his or her life as a method of coping, leading to as much independence as possible. Other children may always feel different from their peers (in a negative sense) and withdraw. Irritability and acting out may also occur. Some children may be compliant and/or seek support for themselves. The child's coping pattern may change over time or with certain situations, such as relapse or worsening of the condition. Children with overprotective parents may display marked dependence and may be very fearful. Children whose parents have been overly indulgent may be more independent and defiant. The nurse must assess the child's individual response to the current health care status and intervene as appropriate (Vessey & Sullivan, 2010).

Effects on the Family

Each member of the family experiences effects related to the child's special needs. Family members' experiences and their responses to the child's illness influence each other directly.

Effects on Parents

Raising a child with special needs is generally not the life parents expected to have. Some parents may adapt over time and ultimately accept the child's illness or disability. Others may adapt but do not accept the child's condition and experience the continual fading and reemergence of chronic sorrow. Denial of their child's problem may prevent parents from progressing through grief, but it also allows them to have hope (Knafl & Santacroce, 2010).

Caring for the special needs child at home (rather than having the child in a facility) may decrease the parents' feelings of anxiety and helplessness (Fig. 12.1). As with typically developing children, parents enjoy witnessing the emotional and social growth of the child. Parents of special needs children experience a multitude of emotions and changes in their lives. They worry about their child's and family's well-being, and as experts in their child's care often feel burdened with continual care. They often feel helpless and overwhelmed when their child is discharged from the hospital. Though willing to carry the burden, they may experience fear, anger, sadness, guilt, frustration, or resentment. Many parents experience grief as a result of losing the perfect child of which they dreamed (Knafl & Santacroce, 2010).

FIGURE 12.1 The special needs child often requires a significant amount of care at home.

STRESSORS OF DAILY LIVING

Families with a child who has special health care needs experience life differently from other families. They may have to change their housing situation to accommodate the child's needs. Their sleep is affected. Constant supervision of the technology-dependent child makes it difficult to carry out other basic household activities. In addition to basic child care and running of the household, medical and technical care must be incorporated into daily life. The family's identity and the parents' employment may be altered radically. Holidays and vacations are affected, as it is difficult to plan activities. Nursing and other health care professional visits are disruptive to family life.

Mothers appear to carry the larger burden of care, though fathers are not unaffected. Somehow, parents eventually take charge, and though they fear failure, they display vigilance, can negotiate and seek information, and become advocates for their child and experts on his or her care. Though parents may feel trapped and isolated and experience a loss of freedom, their need to survive as a family continues to motivate them. Parents may feel a need to be with their child at all times and experience stress related to coping with the heavy load of caregiving.

The extended burden of caregiving can also have adverse health effects on caregivers: only a small percentage of parents of children with special health care needs report that they routinely participate in health-promoting activities for themselves. Additionally, parents of children with special health care needs are at increased risk for the development of depression (Knafl & Santacroce, 2010). In addition to the caregiving burden, parents experience role conflicts, financial burdens, and the struggle between independence in providing care and the isolation associated with it. It is very difficult to enjoy spontaneous events outside the home because so much planning is necessary.

The possibility of independence revolves around mobility issues, education, and assistive technology. Though education for all children is federally mandated, parents have anxiety about educational decisions and also find it difficult to obtain the support and educational services the child needs.

Additional stress is associated with transition times in the care of a special needs child. These transition times include:

- Initial diagnosis or change in prognosis
- Increased symptoms
- When the child moves to a new setting (hospital, school)
- During a parent's absence
- During periods of developmental change (Knafl & Santacroce, 2010; Looman, O'Conner-Von, & Lindeke, 2008)

VULNERABLE CHILD SYNDROME

“Vulnerable child syndrome” is a clinical state in which the parents’ reactions to a serious illness or event in the child’s past continue to have long-term psychologically harmful effects on the child and parents for many years (Duncan & Caughy, 2009). The parents view the child as being at higher risk for medical, developmental, or behavioral problems. Parents exhibit excessive unwarranted concerns and seek health care for their child very frequently. Risk factors for the development of vulnerable child syndrome include preterm birth, a congenital anomaly, newborn jaundice, a handicapping condition, an accident or illness that the child is not expected to recover from, or crying or feeding problems in the first 5 years of life. The parent has difficulty separating from the child, and the child senses that anxiety and then develops symptoms that reinforce the parent’s fears. Alternatively (or additionally), the parents may try to retain control, particularly at times of increasing independence, and fear disciplining the child as they do not want to “upset” the child.

Effects on Siblings

The siblings of children with special health care needs are also affected dramatically. Their relationship with their parents is different from what it would have been if they had a typical brother or sister. Parents often need to spend more time with the child with special needs and have less time with their healthy children. Children exhibit emotional and psychological responses to their sibling’s long-term needs (Looman et al., 2008). The sibling’s knowledge about the illness, the sibling’s attitude toward and adjustment to it, the sibling’s own self-esteem, how socially supported the sibling is, and the parents’ awareness of the sibling’s feelings are all related to how well the sibling adjusts.

Nursing Management of the Medically Fragile Child and Family

Family-centered care provides the optimal framework for caring for medically fragile children and their families. Family-centered care minimizes the impact of chronic illness and maximizes the child’s developmental potential. To provide the best nursing care for these children and their families, the nurse must first develop a trusting relationship with the family.

To ensure optimal functioning, children with special health care needs require comprehensive and coordinated services from multiple professionals. These professionals should work collaboratively to address the child’s health, educational, psychological, and social service needs. In addition to case management and advocacy, nursing management focuses on screening and ongoing assessment of the child, provision of home care, care of the technology-dependent child, education and support of the child and family, and referral for resources.

Developing a Therapeutic Relationship

Raising children is always challenging, but for the parent of a special needs child it is often overwhelming and exhausting. The parents’ needs change continuously, so it is best if the family has a permanent relationship with a physician or nurse practitioner. This promotes trust and a more efficient two-way flow of information.

Respect the parents’ range of emotions and work with them as a team to manage the child’s care. Parents need to be recognized for complying with the treatment plan or for other small gains that are made. Empowering the family strengthens them and gives them self-confidence. Feeling supported and invigorated gives parents strength, energy, and hope. **Box 12.1** lists principles related to family involvement.

Screening and Ongoing Assessment

Nurses should perform screening to identify children with unmet health care needs. A screening tool developed by the Child and Adolescent Health Measurement Initiative (**Fig. 12.2**) may help to identify children with special health care needs. Web links for additional information related to the screening tool can be found on [thePoint](#).

BOX 12.1

PRINCIPLES RELATED TO FAMILY INVOLVEMENT

Families

- Are the constant in a child’s life
- Define who they are and their culture
- Need to have access to information and training
- Deserve to receive culturally competent care

- Know their strengths, limitations, and fears
- Merit mutual respect and responsibility for outcomes

Adapted from Goode, T. D., Haywood, S. H., Wells, N., & Rhee, K. (2009). Family-centered, culturally, and linguistically competent care: Essential components of the medical home. *Pediatric Annals*, 38(9), 505-512.

Children with special health care needs may attain developmental milestones more slowly than typically developing children. If the Denver II is used for ongoing developmental surveillance of the young child, then the results should be compared from visit to visit to determine progress rather than using it as a screening tool. Assess special needs children and their families for vulnerable child syndrome.

Promoting Home Care

Home is the most developmentally appropriate environment for all children, even those who are technologically dependent (Looman et al., 2008). The child's home provides an emotionally nurturing and socially stimulating environment. Children desire to be cared for at home, and those who are cared for at home display an improved physical, emotional, psychological, and social status.

Technology-dependent children may require supplemental oxygen, assisted ventilation, tracheostomy care, assisted enteral or parenteral feeding, or parenteral medication administration. Traditionally hospitalization would have been required for these children—in fact, intensive care would have been necessary for children who need assisted ventilation—but with advances in technology, today even children with extensive medical and developmental needs may be cared for at home (Looman et al., 2008). Early discharge planning is important, and parents will need detailed instructions and support in caring for the technology-dependent child at home (Lewis, 2007).

EARLY DISCHARGE PLANNING

Early discharge planning and ongoing inclusion and education of the family facilitates continuity of care. [Box 12.2](#) provides information about preparing the medically fragile child for discharge.

CARING FOR THE TECHNOLOGY-DEPENDENT CHILD AT HOME

Home care nurses are often involved in the care of technology-dependent children. Caring for a technology-dependent child at home is a complex process, yet children thrive in the home care setting with appropriate intervention and care. Many parents feel that rearing a technology-dependent child is different only because of the presence of the equipment. Nurses may tend to think that parents treat the technology-dependent child differently from the other children, while parents value normalization and want to raise and provide discipline to all of their children in the same manner. Parents should tell nurses about their childrearing expectations, and nurses need to respect the parents' wishes.

Improved collaboration between parents and home care nurses may decrease the parents' stress and maximize opportunities for appropriate growth and development in the technology-dependent child. Thus, a strong relationship, good communication, and good negotiation skills are assets to the family and child.

CAHMI Children with Special Health Care Needs (CSHCN) Screening Tool
(mail or telephone)

1. Does your child currently need or use **medicine prescribed by a doctor** (other than vitamins)?
 - Yes ⇐ Go to Question 1a
 - No ⇐ Go to Question 2
 - 1a. Is this because of ANY medical, behavioral or other health condition?
 - Yes ⇐ Go to Question 1b
 - No ⇐ Go to Question 2
 - 1b. Is this a condition that has lasted or is expected to last for at least 12 months?
 - Yes
 - No

2. Does your child need or use more **medical care, mental health or educational services** than is usual for most children of the same age?
 - Yes ⇐ Go to Question 2a
 - No ⇐ Go to Question 3
 - 2a. Is this because of ANY medical, behavioral or other health condition?
 - Yes ⇐ Go to Question 2b
 - No ⇐ Go to Question 3
 - 2b. Is this a condition that has lasted or is expected to last for at least 12 months?
 - Yes
 - No

3. Is your child **limited or prevented** in any way in his or her ability to do the things most children of the same age can do?
 - Yes ⇐ Go to Question 3a
 - No ⇐ Go to Question 4
 - 3a. Is this because of ANY medical, behavioral or other health condition?
 - Yes ⇐ Go to Question 3b
 - No ⇐ Go to Question 4
 - 3b. Is this a condition that has lasted or is expected to last for at least 12 months?
 - Yes
 - No

4. Does your child need or get **special therapy**, such as physical, occupational or speech therapy?
 - Yes ⇐ Go to Question 4a
 - No ⇐ Go to Question 5
 - 4a. Is this because of ANY medical, behavioral or other health condition?
 - Yes ⇐ Go to Question 4b
 - No ⇐ Go to Question 5
 - 4b. Is this a condition that has lasted or is expected to last for at least 12 months?
 - Yes
 - No

5. Does your child have any kind of emotional, developmental or behavioral problem for which he or she needs or gets **treatment or counseling**?
 - Yes ⇐ Go to Question 5a
 - No
 - 5a. Has this problem lasted or is it expected to last for at least 12 months?
 - Yes
 - No

Conceptual background

The CSHCN Screener uses consequence-based criteria to screen for children with chronic or special health needs. To qualify as having chronic or special health needs, the following set of conditions must be met:

- a) The child currently experiences a specific consequence.
- b) The consequence is due to a medical or other health condition.
- c) The duration or expected duration of the condition is 12 months or longer.

The first part of each screener question asks whether a child experiences one of five different health consequences:

- 1) Use or need of prescription medication
- 2) Above-average use or need of medical, mental health or educational services
- 3) Functional limitations compared with others of same age
- 4) Use or need of specialized therapies (OT, PT, speech, etc.)
- 5) Treatment or counseling for emotional or developmental problems

The second and third parts* of each screener question ask those responding "yes" to the first part of the question whether the consequence is due to any kind of health condition and if so, whether that condition has lasted or is expected to last for at least 12 months.

*NOTE: CSHCN screener question 5 is a two-part question. Both parts must be answered "yes" to qualify.

All three parts of at least one screener question (or in the case of question 5, the two parts) must be answered "yes" in order for a child to meet CSHCN Screener criteria for having a chronic condition or special health care need.

The CSHCN Screener has three "definitional domains." These are:

- 1) Dependency on prescription medications
- 2) Service use above that considered usual or routine
- 3) Functional limitations

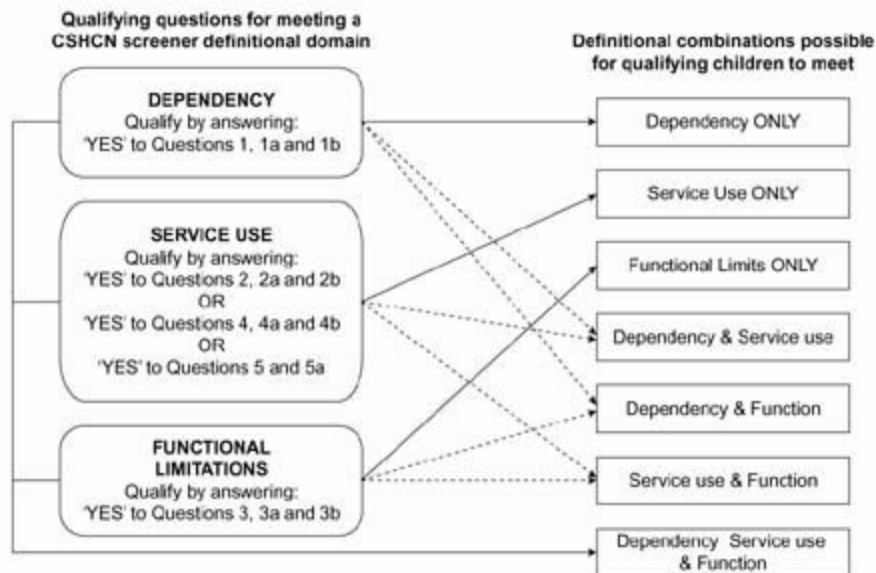

FIGURE 12.2 The CSHCN screener. (Used with permission from the Child and Adolescent Health Measurement Initiative (CAHMI) at Oregon Health & Science University.)

BOX 12.2**PREPARING FOR HOME CARE BEFORE DISCHARGE**

- Promote liaison with community resources. Develop communication between various services. Plan appointments. Set up home nursing care (either private duty or visits).
- Teach skills, encouraging active caregiving in the hospital setting to increase the parents' self-confidence.
- Discuss psychological and emotional issues with parents.
- Obtain/organize equipment and supplies (running out of supplies may cause significant stress on families).
- Refer the family for necessary financial resources.
- Ensure the family's home environment is adequate (enough room for equipment, electricity on, air conditioner for warm weather, heater for cold weather, and refrigeration for food).
- For the baby being discharged from the neonatal intensive care unit (NICU):
 - Teach the parents about the infant's cues and behaviors and the preemie's different sleep-wake patterns.
 - Encourage kangaroo care and infant massage while in the NICU (as the infant's condition allows).
 - Educate the parents about possible effects on short- and long-term neurodevelopment.
 - Refer to local early intervention program.
 - Assist the family with finding a primary care provider who is experienced in the ongoing follow-up of high-risk infants.

Help the family to incorporate the medical regimen into daily life to minimize the child's self-perception of being different from other children. Teach families about the technical issues, such as home and travel oxygen therapy, use of the ventilator, suctioning, chest percussion and postural drainage, tube feedings and care of the feeding tube, and medications. Assist parents with the planning and management of routine care, respiratory treatments, nutritional support, and developmental interventions. Reinforce exercises and techniques as prescribed by developmental therapists. Refer to [Chapter 11](#) for additional information about home care nursing.

Providing Care Coordination

Once a child with special health care needs has been identified and has been discharged to the home setting, the nurse plays a vital role in care coordination. Any child with special health care needs benefits from a medical home. The nurse in the medical home is a critical team member, providing ongoing care coordination and follow-up. If such services are available in the local area, refer the child and family with special needs to an integrated health program that provides interdisciplinary, collaborative care for children requiring complex, coordinated care. [Box 12.3](#) lists nursing interventions for families of children with special health care needs.

BOX 12.3

NURSING INTERVENTIONS FOR FAMILIES OF CHILDREN WITH SPECIAL HEALTH CARE NEEDS

- Develop written health plans.
- Provide care coordination and collaboration with specialists in other disciplines, early intervention, schools, and public agencies.
- Address needs for prior authorization for treatments, medications, or specialist referrals; retain copies in the child's chart of authorization forms and approvals.
- Modify office routines to promote family and child comfort.
- Assist parents with child care decisions.
- Know community resources available to children with special health care needs.
- When the child is hospitalized, encourage high levels of parental participation.
- Provide care coordination across multiple health settings.
- Educate child care providers on child health needs.
- Help parents get involved with parent support networks.

Adapted from Looman, W. S., O'Conner-Von, S., & Lindeke, L. L. (2008). Caring for children with special health care needs and their families: What advanced practice nurses need to know. *Journal for Nurse Practitioners*, 4(7), 512-518; and McAllister, J. W., Presler, E., Turchi, R., & Antonelli, R. C. (2009). Achieving effective care coordination in the medical home. *Pediatric Annals*, 38(9), 491-497.

Providing Ongoing Follow-Up of the Former Premature Infant

Many former premature infants experience myriad medical and developmental problems throughout infancy, early childhood, and beyond. Upon or following discharge, many former premature infants display one or many of the following medical or developmental problems:

- Chronic lung disease (bronchopulmonary dysplasia)
- Cardiac changes such as right ventricular hypertrophy and pulmonary artery hypertension
- Growth retardation, poor feeding, anemia of prematurity, other nutrient deficiencies
- Apnea of prematurity, gastroesophageal reflux disease, bradycardia
- Sudden infant death syndrome (SIDS)
- Rickets (osteopenia) of prematurity
- Hydrocephalus, ventriculomegaly, abnormal head magnetic resonance imaging results, ventriculoperitoneal shunt
- Inguinal or umbilical hernias
- Retinopathy of prematurity, strabismus, decreased visual acuity
- Hearing deficits
- Delayed dentition
- Gross motor, fine motor, and language delay; sensory integration issues (Gargus et al., 2009; Kelly, 2010)

Over the long term, former premature infants are at higher risk than typical infants of developing cognitive delay, cerebral palsy, attention deficit disorder, learning disabilities, difficulties with socialization, and vulnerable child syndrome (Duncan & Caughy, 2009; Gargus et al., 2009). Additionally, many former premature infants display alterations in muscle tone at or shortly after discharge from the neonatal intensive care unit (NICU) that require physical therapy intervention.

For these reasons, high-risk infants require special attention and thorough, appropriate assessment to discern subtle changes that may affect their long-term physical, cognitive, emotional, and social outcome. The pediatric nurse should have an understanding of the special concerns that former premature infants and children as well as their families may face.

From the beginning, encourage families to keep a binder that includes all of the infant's pertinent checkup, insurance, and medical and developmental information; this will serve as a resource for the parents, and they will be able to supply complete information when visiting various providers.

PROVIDING ROUTINE WELL-CHILD CARE OF THE FORMER PREMATURE INFANT

Former premature infants require similar well-child care as typical infants do, with additional visits for management of multiple complex medical issues and developmental screening/intervention. Teach families routine newborn care, including bathing, dressing, and avoidance of passive cigarette smoke. All visits for primary care follow-up will be scheduled based on the infant's chronological age.

Prior to discharge from the NICU, the infant will be tested for oxygen desaturation while seated in the car seat (Kelly, 2010). Clearance will be obtained prior to the infant's discharge. Former preemies require car seat use just as other infants do. Help the parents to find methods of padding the car seat or adding an additional semifirm cushion inside the seat for the infant to ride in the car safely. Some infants may need to continue cardiac/apnea monitoring while in the car seat.

Since the former premature infant is at increased risk for SIDS compared to the general population, it is critical to teach parents to put the infant on his or her back to sleep (although this is contraindicated with gastroesophageal disease) (Kelly, 2010).

Give immunizations according to the current Centers for Disease Control and Prevention (CDC)-recommended immunization schedule, based on the infant's chronological age. All former preemies should receive the flu vaccine as recommended after 6 months chronological age. Respiratory syncytial virus (RSV) prophylaxis is critical for certain groups of premature infants (Kelly, 2010). Therefore, administer palivizumab (Synagis) vaccine according to the recommended schedule (refer to [Chapter 18](#) for additional information about RSV prophylaxis).

ASSESSING GROWTH AND DEVELOPMENT OF THE FORMER PREMATURE INFANT

When assessing growth and development of the infant or child who was born prematurely, determine the child's adjusted or corrected age so that you can perform an accurate assessment. The corrected or adjusted age should be used for evaluating progression in growth as well as development. For example, if a 6-month-old infant was born at 28 weeks' gestation (12 weeks or 3 months early), his growth and development expectations are those of a 3-month-old (corrected age). Continue to correct age for growth and development until the child is 3 years old.

Many former premature infants require special diets to foster catch-up growth (Kelly, 2010). Extra calories are needed for increased growth needs. Additional calcium and phosphorus are required for bone mineralization. For these reasons, former preemies should be fed breast milk fortified with additional nutrients or a commercially prepared formula specific for premature infants. When former preemies demonstrate consistent adequate growth (usually by 6 months corrected age), they may be switched to a "term infant formula" such as Similac or Enfamil, concentrated to a higher caloric density if needed. Assess the infant's ability to suck efficiently and refer him or her to occupational or speech therapy if the infant is a slow feeder or has difficulty feeding.

All anticipatory guidance related to nutrition is based on the child's corrected age. In other words, begin solids at 6 months corrected age, not chronological age, and delay the addition of whole milk until 12 months corrected age, rather than 1 year chronological age (Kelly, 2010). Signs that the former premature infant may be ready to attempt spoon feeding include interest in feeding, decrease in tongue thrust, and adequate head control.

Early screening and intervention for issues related to development are critical to the attainment of optimal development in the former preemie. The comorbidities that ex-preemies exhibit in the form of prior and current medical problems place these infants at high risk for **developmental delay** (lag in meeting developmental milestones). Even mild developmental delays warrant evaluation and intervention. The Denver II may be used as a screening tool for developmental concerns in the ex-preemie, though it does not always identify children at risk. Parent-report questionnaires demonstrate fairly accurate estimations of developmental problems, and their use is recommended by the American Academy of Pediatrics (2008). Most importantly, assess the child's development based on corrected age until the child is 3 years old. Refer infants and children early if developmental concerns are suspected.

Failure to thrive (FTT) is a term used to describe inadequate growth in infants and children. The child fails to demonstrate appropriate weight gain over a prolonged period of time. Length or height velocity and head circumference growth may also be affected. Typical children may experience FTT, but it is much more common in the child with special needs. Adequate nutrition is critical for appropriate brain growth in the first 2 years of life and obviously for growth in general throughout childhood and adolescence (Burns, Dunn, Brady, Starr, & Blosser, 2009). **Developmental disability** (mental or physical or combination impairment resulting in lifelong disability) may contribute to FTT, as the child's ability to consume adequate nutrition is impaired because of sensory or motor delays, such as with cerebral palsy. Other organic causes of failure to thrive include inability to suck and/or swallow correctly, malabsorption, diarrhea, vomiting, or alterations in metabolism and caloric/nutrient needs associated with a variety of chronic illnesses. Infants and children with cardiac or metabolic disease, chronic lung disease (bronchopulmonary dysplasia), cleft palate, or gastroesophageal reflux disease are at particular risk. Feeding disorders or food refusal may occur in infants or children who have required prolonged mechanical ventilation, long-term enteral tube feedings, or an unpleasant event such as a choking episode. Inorganic causes of FTT include neglect, abuse, behavioral problems, lack of appropriate maternal interaction, poor feeding techniques, lack of parental knowledge, or parental mental illness. Poverty is the single greatest contributing risk factor (Block, Krebs, the Committee on Child Abuse and Neglect, and the Committee on Nutrition, 2005).

The two categories of causes are not mutually exclusive. Organic causes of FTT may lead to behavioral problems that potentiate problems with adequate growth; hence, FTT is thought of as a multifactorial problem (Locklin, 2005).

Screen all children for FTT to identify them early. In addition to poor growth, the infant or child with FTT may present with a history of developmental delay or loss of acquired milestones. Infants or children with feeding problems may display nipple, spoon, or food refusal; difficulty sucking; disinterest in feeding; or difficulty progressing from liquid to pureed to textured food. Perform a detailed dietary history and instruct the parents to complete a 3-day food diary to identify what the child actually eats and drinks. Assess the parent-child interaction, with particular attention to the parent's ability to read and respond to the infant's or child's cues. Observe feeding, noting the child's oral interest or aversion, oral-motor coordination, and swallowing ability, as well as parent-child interactions before, during, and after the feeding. Further aversion to eating may occur as the parent's anxiety over the thought of the child not eating or losing weight leads to attempts to force-feed the child (Ayoob & Barresi, 2007).

Significant FTT may require hospitalization for evaluation and management. Sometimes enteral tube feedings are necessary in order for children with FTT or feeding disorders to demonstrate adequate growth. [Box 12.4](#) lists nursing interventions for the hospitalized child with FTT.

Take Note!

Infants with FTT related to maternal neglect may avoid eye contact and be less interactive than other infants (Burns et al., 2009).

BOX 12.4

NURSING INTERVENTIONS DURING THE CHILD'S HOSPITALIZATION FOR FAILURE TO THRIVE

- Observe parent-child interactions, especially during feedings.
- Develop an appropriate feeding schedule.
- Provide feedings as prescribed (usually 120 kcal/kg/day is needed to demonstrate proper weight gain).
- Weigh the child daily and maintain strict records of intake and output.
- Educate parents about proper feeding techniques and volumes.
- Provide extensive support to alleviate parental anxiety related to the child's inability to gain weight.

Adapted from Ayoob, K. T., & Barresi, I. (2007). Feeding disorders in children: Taking an interdisciplinary approach. *Pediatric Annals*, 36(8), 478-483; and Locklin, M. (2005). The redefinition of failure to thrive from a case study perspective. *Pediatric Nursing*, 31(6), 474-479.

Promoting Growth and Development

When caring for the infant with special health care needs in the hospital, provide consistent caregivers to encourage the infant to develop a sense of trust. Allow and encourage the parent to stay with the infant, providing a comfortable place for the parent to sleep. To promote attachment, emphasize the baby's positive qualities. Encourage developmentally appropriate skills and allow the infant to have pleasurable experiences through all of the senses (Vessey & Sullivan, 2010).

For the toddler, begin developmentally appropriate limit setting and discipline. Encourage independence as the toddler is able.

Modify gross motor and sensory activities to accommodate the toddler's limitations. To encourage a sense of control, offer the toddler simple choices. As the preschooler develops, encourage mastery of self-help skills as the child is able. Encourage socialization with same-age peers to develop a sense of friendship. Reinforce to the child that the illness or disability is not a punishment for wrongdoing or the child's fault in any way (Vessey & Sullivan, 2010).

Encourage the school-age child to attend school and make up work that must be missed for medical treatments or appointments. Provide education to the school staff and other students about the child's special needs. Promote involvement in appropriate sports activities; music, drama, or art activities; and clubs such as Boy Scouts or Girl Scouts. Educate the child about the illness or disability and the course of treatment (Vessey & Sullivan, 2010).

Inform parents of teens that those with chronic illness often participate in the same activities as typical teens, such as risk taking, rebelling, and trying out different identities. Assist the teen with coping and interpersonal skills. Promote involvement in activities with other teens with special needs as well as typical adolescents. Ensure that the teen participates in rites of passage as able, such as attending the prom or obtaining a driver's license. Discuss future plans with the teen, such as college or vocation, as well as transition to a nonpediatric physician (Vessey & Sullivan, 2010). See [Evidence-Based Practice 12.1](#).

Providing Resources to the Child and Family

Nurses should be familiar with community resources available to children with special health care needs. Educational opportunities for children with special health care needs include early intervention programs and programs offered through the public school system. Financial resources, respite care, and complementary therapies are other areas the nurse should become familiar with.

EDUCATIONAL OPPORTUNITIES FOR THE SPECIAL NEEDS CHILD

The foundation for health and development in children is laid during the first years of life. Children with special health care needs often require multiple developmental interventions and special education in the early years in order to reach their developmental potential later in childhood. Children learn best when they are at the stage of maximal readiness, and the early years must not be missed as an opportunity for development. See Healthy

|-------------------------------------|--|
| EVIDENCE-BASED PRACTICE 12.1 | LIFE SKILLS INTERVENTION FOR CHILDREN WITH CYSTIC FIBROSIS AND EFFECTS OF INTERVENTION ON PSYCHOSOCIAL ADJUSTMENT, FUNCTIONAL HEALTH STATUS, AND PHYSIOLOGIC STATUS OVER TIME |
|-------------------------------------|--|

STUDY

As cystic fibrosis treatment methods have improved over the past couple of decades, enhanced survival and a healthier life course have resulted. With these improvements it has become necessary to further address the psychosocial and developmental needs of affected children. The authors performed a blinded, randomized controlled trial at four university cystic fibrosis (CF) centers. One hundred and sixteen children were participants in the study over a 9-month period of time. The intervention performed consisted of a home visit to assess each child's knowledge and management of CF. Information was provided using an educational problem-solving approach. Subsequent focus groups were held and the children discussed how to deal with peer issues.

Findings

Children who participated in the intervention group had greater improvements in loneliness, global self-worth, and perceived illness experience. The intervention did not demonstrate an impact upon physical or functional health status but did improve psychosocial status.

Nursing Implications

In addition to CF, many chronic and debilitating conditions affect children's quality of life. Any school-age or older child with a chronic condition that impairs physical functioning would benefit from interventions similar to those performed in this study. In particular, nurses who work in settings that allow them to have long-term relationships with these children have the potential to positively influence their lives. Nurses should help children learn communication and problem-solving skills that could lessen the impact of their chronic condition.

HEALTHY PEOPLE 2020

| Objective | Nursing Significance |
|---|--|
| Increase the proportion of children and youth with disabilities who spend at least 80% of their time in regular education programs. | <ul style="list-style-type: none">• Ensure that children younger than age 3 years who may qualify are referred to the local early intervention program.• Encourage families to advocate for their child's needs on the individualized education plan. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

Early intervention programs are intended to enhance the development of infants and toddlers with, or at risk for, disabilities, thereby minimizing educational costs and special education. Early intervention is also directed toward enhancing the capacity of families to meet their child's needs as well as to maximize the likelihood of independent living (Schulman, Meringolo, & Scott, 2007).

The Individuals with Disabilities Education Improvement Act of 2004 (formerly called Public Law 99-457) mandates government-funded care coordination and special education for children up to 3 years of age. This early intervention program is administered through each state. Federal law allows each state to define "developmental disability" differently, but in general qualified personnel perform an evaluation of the child's physical, language, emotional, and social capabilities to determine eligibility (108th Congress, 2004). The law guarantees that eligible children will obtain access to services that will enhance their development. Children who qualify for services receive care coordination, and an individualized family service plan is developed by the service coordinator in conjunction with the family. The service coordinator manages the developmental services and special education that the child requires.

The intent of the program is that the child receives services in a "natural environment," so most services occur in the home or day care center. Home visits by the service coordinator and maintenance of regular contact with the family ensure the success of the program.

Refer children suspected of developmental delay to the local early intervention program. For children receiving these services, collaborate with the service coordinator on an ongoing basis, with particular involvement at hospital discharge and when transition of services occurs at age 3 years.

Think back to Preet, the 2-year-old boy with a history of hydrocephalus and developmental delay, from the beginning of the chapter. Discuss with his mother the educational opportunities that are available for Preet. Explain what early intervention is and why it is important for Preet.

Schools may have a profound impact on the child's overall health and development. Some children with special needs do not require additional services to succeed in school. For these children, the nurse's role is to assess for school success or failure and determine the effect of the school environment on the child's health. The Individuals with Disabilities Education Act, reauthorized in 2004, provides for the education of children with special needs through the public school system, from age 3 to 21 years. These services are provided within the public school system.

According to the law, each special needs student is entitled to an individualized education program (IEP), which is a written plan designed to meet the preschool, primary, or secondary school student's individual needs. A committee consisting of the child's parent, a regular teacher, a special education teacher, and various other specialists develops the IEP. Nurses may be called to serve upon this committee. The IEP must include measurable short- and long-term goals. Parents are informed of the student's progress routinely and the IEP is reviewed at least annually (108th Congress, 2004).

Preschool special education through the local public school system is provided from age 3 to 5 years; access to the curriculum is ensured for all children. A child is eligible for special needs preschool when a significant delay is present in the cognitive, language, adaptive, social-emotional, or motor development domains to the extent that it adversely affects the child's learning ability. The child receives (in the school setting) developmental therapy as needed to augment his or her ability to participate in the education process. The least restrictive environment is preferred, with special needs children participating in classes containing age-appropriate typical

peers whenever possible (108th Congress, 2004). Special needs preschool services are often offered in the elementary school setting.

FINANCIAL AND INSURANCE RESOURCES

Many special needs children whose families demonstrate financial need may be eligible for Supplemental Security Income (SSI). This program was created in 1972 through Public Law 92-603. SSI is a cash assistance program, and monthly benefits vary per individual. SSI qualification also qualifies the child for state-administered Medicaid. Medicaid benefits vary slightly from state to state but generally cover medical visits, medication, hospitalization, and limited adjuvant therapies. The State Children's Health Insurance Program (SCHIP) provides low-cost health insurance to eligible children. Eligibility and the extent of benefits provided by SCHIP vary by state (Vessey & Brown, 2010).

Public Law 94-566 provides for state-administered Title V programs under the Maternal and Child Health Bureau Block Grant program. State Title V programs provide community-based, comprehensive service coordination for children with special needs (USA.gov, 2011).

Online directories providing a wealth of links to resources for special needs children include Children's Disabilities Information and Special Child. Web links to these sites can be found on [thePoint](#).

RESPIRE CARE

Primary caregivers of children with special health care needs must be dedicated, skillful, vigilant, and knowledgeable. Constant care is a stress on the primary care-giver, who needs temporary relief from the daily care-giving demands. **Respite care** provides an opportunity for families to take a break from the daily intensive caregiving responsibilities. Respite care should meet the child's health care needs and offer the child developmental opportunities. Finding and using respite care that the family is comfortable with and trusts may decrease the family's stress and lead to an enhanced quality of life for special needs children and their families. Nurses can facilitate access to respite care, educate respite providers, and ensure quality respite care practices through involvement in community agencies.

COMPLEMENTARY THERAPIES

Families of children with special health care needs often use adjuvant therapies. These may include, among others, homeopathic and herbal medicine, pet therapy, hippotherapy, music, and massage. Many families desire to blend natural or Eastern medicine with traditional allopathic medicine for their special needs child in search of palliation or a cure. When obtaining the health history, ask specifically about homeopathy or herbal medications the child may be taking. Pet therapy may be used to decrease stress or as a component of psychotherapy.

Hippotherapy is also referred to as horseback riding for the handicapped, therapeutic horseback riding, or equine-facilitated psychotherapy. Individuals with almost any cognitive, physical, or emotional disability may benefit from therapeutic riding or other supervised interaction with horses. The unique movement of the horse under the child helps the child with physical disabilities to achieve increased flexibility, balance, and muscle strength. Children with mental or emotional disabilities may experience increased self-esteem, confidence, and patience as a result of the unique relationship with the horse. A physical therapist or psychotherapist (depending on the situation) generally works very closely with specially trained equine staff (Gasalberti, 2006). [Box 12.5](#) lists chronic medical conditions for which hippotherapy may be beneficial. Additional information may be obtained through the North American Riding for the Handicapped Association or the American Hippotherapy Association. Links to these sites can be found on [thePoint](#).

BOX 12.5

CONDITIONS BENEFITING FROM HIPPO THERAPY

- Muscular dystrophy
- Cerebral palsy
- Visual impairment
- Down syndrome
- Intellectual disability
- Autism
- Multiple sclerosis
- Emotional disabilities Brain injury
- Myelomeningocele
- Spinal cord injury

- Amputation
- Attention deficit disorder
- Learning disabilities
- Deafness
- Cerebrovascular accident (stroke)

Music may be used to induce positive behavioral changes or various other positive effects. Massage therapy may be beneficial to a wide variety of children. It may be used to reduce pain, promote relaxation, or demonstrate a specific positive effect related to the child's particular medical condition (Gasalberti, 2006).

Take Note!

Become familiar with the risks and benefits of homeopathic and herbal medications, as many families use these treatments in an effort to improve their child's quality of life or outcome.

Providing Support and Education

At the time of initial diagnosis, allow and encourage the family to express their feelings. Parents of children with special health care needs require emotional, practical, economic, and social support. Encourage parents to obtain help with daily routines. Encourage stress reduction for the parents through exercise and allowing time for themselves. Be a supportive and encouraging listener, making sure to nurture the whole child, not just his or her special condition.

Parents value peer support groups, sometimes feeling that only other parents of disabled or chronically ill children could understand the heartache, fear, and other emotions they often experience. Pediatric nurses should be proactive in helping families find support systems.

Fathers have the same concerns about their children as mothers do, but they may show these concerns differently. It is important for nurses to involve them in the child's care. Teach skills to both parents, and actively involve fathers by asking about their observations and opinions.

Parents become the experts on their child's needs and care, and they should be recognized as such. Parents want to be taken seriously and do not like being ignored. They should be viewed as having reliable and valuable information about their children. By being an active and reflective listener, the nurse can demonstrate to the parents that their opinion is valued, in addition to finding out what the child really needs. Some parents may hesitate to volunteer information, unsure about which information the nurse needs. Show respect for the parents' knowledge of their child's needs by seeking advice on the child's daily care, medical/physical needs, and current developmental level, no matter what the site of care is.

Families may need additional support from the nurse at times of transition. As the equipment or treatment needs change, adjust the teaching plan. Educate the child and family about the use of adaptive equipment. Ensure that families understand how specific activities must be modified to accommodate the child's needs. Provide anticipatory guidance related to expected developmental changes, including resources and laws related to education. Act as a liaison between the family and the day care center or school. As the child grows and matures, encourage parents to relinquish caregiving tasks to the child as appropriate to encourage independence and promote self-esteem.

Assisting the Adolescent With Special Health Needs Making the Transition to Adulthood

Adolescence is a time of physical changes, psychosocial challenges, and initiation of independence from parents. The adolescent with a chronic illness or one who is technology dependent may experience this period differently from other teens. Puberty is often affected by chronic illness (either delayed or earlier). Chronic illness may lead to isolation from peers at a time when peer interaction is the core of psychosocial development. Teens may struggle to fit in with their peers by hiding their illness or health care needs (ignoring them), complying poorly with treatment regimens, or participating in risky behaviors. At a time when the child should be developing independence from the parents, he or she may be experiencing significant dependence related to the special health condition. For these reasons, the adolescent with special health care needs may require increased amounts of support from the nurse.

Making the transition to adult care for a child with special health care needs can be difficult, and advance planning leads to a smoother transition. Transition planning involves multidisciplinary care coordination; acknowledgement of the changing roles among the youth, family, and health care professionals; and fostering of the youth's self-determination skills. A written plan for transition to adult care should be initiated in midadolescence. Have ongoing conversations with the teen about this transition. Issues to be resolved

prior to the transition include financial resources for medical care, college or vocational school attendance, living arrangements, and caretaking arrangements (White & Hackette, 2009).

The Adolescent Health Transition Project (AHTP) recommends the following schedule:

- By age 14, ensure that a transition plan is initiated and that the IEP reflects post-high school plans.
- By age 17, explore health care financing for young adults. If needed, notify the local division of vocational rehabilitation by the autumn before the teen is to graduate from high school of the impending transition. Initiate guardianship procedures if appropriate.
- Notify the teen that all rights transfer to him or her at the age of majority. Check the teen's eligibility for SSI the month the child turns 18. Determine if the child is eligible for SSI work incentives.
- If the youth is attending college, contact the college's campus student disability service program.
- By age 21, ensure that the young adult has registered with the Division of Developmental Disabilities for adult services if applicable (AHTP, 2011).

Prior to moving to adult care (with an adult medical provider), ensure that the adolescent understands the treatment rationale, symptoms of worsening condition, and especially danger signs. Teach the adolescent about when to seek help from a health professional. Introduce the teen to the medical insurance process. At transition, coordinate a seamless transfer by providing a detailed written plan to the care coordinator or advanced practice nurse (after verbal collaboration).

After the transition, serve as a consultant to the adult office in relation to the teen's needs. Consult with a transition services coordinator or other service agency as available in the local community (AHTP, 2011). See Healthy People 2020.

HEALTHY PEOPLE 2020

Objective

(Developmental) Increase the proportion of children with special health care needs whose physician has discussed transition planning from pediatric to adult health care.

Nursing Significance

- In the primary care setting, assist families with planning for transition beginning in early adolescence.
- If available, refer families to multidisciplinary programs for medically complex children.

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

THE DYING CHILD

The idea that a child may die is simply unimaginable to most people, yet children die daily. Each year, about 50,000 children die in the United States; of those, about 28,500 are infants (Heron et al., 2009). A child's chronic illness may progress to the point of becoming a **terminal illness** (illness deemed to be noncurable, ultimately leading to death). For example, despite the increased survival rates for children with cancer as a result of improved treatment options and protocols, cancer remains the leading cause of death from disease in all children older than the age of 1 year (Heron et al., 2009). Less frequently, other diseases also lead to terminal illness in children, with congenital defects and traumatic injuries being the more common causes. Pediatric nurses will inevitably encounter situations in which a child dies. These situations are extremely difficult for all persons involved, and the nurse plays a key role in caring for the dying child and his or her family. Caring for the dying child is a family-centered, multidisciplinary process. Nurses must respond to the child's and family's physiologic, emotional, and spiritual needs during this difficult time. Children display differing responses to the dying process and impending death depending on their developmental level. Children and their families need significant amounts of support throughout the process of dying.

End-of-Life Decision Making

Parents are obligated not only to protect their children from harm but also to do as much good for them as possible, both from an ethical and a legal standpoint. When the time comes for end-of-life decision making, parents are often torn about the "right" course of action. Parents may be asked to make decisions about stopping treatment, withdrawing treatment, providing palliative care, or consenting to "do not resuscitate" (DNR) orders. Children, parents, and physicians are generally in agreement that continued suffering is not desired for any child with a terminal illness. When all possible curative attempts have been made, then survival is no longer possible (Rushton, 2004).

Nurses involved in this process must examine their own values related to dying and consider the American Nurses Association's code of ethics for nurses as well (2001). The family's feelings must also be acknowledged. During the process of end-of-life decision making, health care providers must assure families that the focus of care is changing and that the child is not being abandoned. Emphasize to parents that no matter what their decision is, the health care team is dedicated to the comfort and expert care of their child (Rushton, 2004).

Ensure that communication is family centered. Quality of life must be taken into consideration when making decisions to continue or withhold treatment. Provide parents facing end-of-life decisions with honest information and education from the time of the diagnosis/prognosis forward. Anticipate that parents may vacillate in the decision-making process. Clarify information for them and allow them private time to discuss the options. Do not make judgments about or question the parents' decision. Be sensitive to any ethnic, spiritual, or cultural preferences during the terminal stage of the illness. Encourage parents to interact with other parents who have a child with a terminal illness (Rushton, 2005).

Allowing Natural Death

The decision to institute a DNR order is one of the most difficult decisions a family may ever have to make. DNR refers to withholding cardiopulmonary resuscitation should the child's heart stop beating. Parents may initially feel like this means they are giving up on their child. Nurses must educate families that resuscitation may be inappropriate and lead to more suffering than if death were allowed to occur naturally. The parents need to understand that when a palliative care route is chosen, rather than continuing a curative or treatment route, the focus of the child's care is changing but the child and family are not being abandoned. Families may wish to specify a certain extent of resuscitation that they feel more comfortable with (e.g., allowing supplemental oxygen but not providing chest compressions). Some institutions are now replacing the DNR terminology with "allow natural death" (AND), which may be more acceptable to families facing the decision to withhold resuscitation (Knox & Lenehan, 2005).

Involving the Dying Child in the Decision-Making Process

End-of-life decision making often involves ethical dilemmas for the child, family, and health care team. This is particularly true when the parents' wishes conflict with the child's or adolescent's desires. Children should be involved in decision making to the extent that they are able. Discuss intervention within the context of the child's condition and wishes. Children older than the age of 7 may "assent" to the continuation or withdrawal of treatment (Kon, 2006). Be available to the older child or adolescent to provide support and information if he or she desires. Talk with the child or adolescent with the parents present, as well as in private. Maintain the child's comfort and dignity. Encourage the child to spend time with other children with a terminal illness. Assure the child that everything will be done to make him or her comfortable. Consult parents about the timing and depth of end-of-life discussions. Just as parents do,

the terminally ill child may vacillate in the decision-making process. Remain sensitive, and respect the child's decisions.

Organ or Tissue Donation

With large numbers of organ transplant candidates on waiting lists and the shortage of viable organs, pediatric organ and tissue donation is a priority (Bratton et al., 2006). For many families, knowing that a child's organs or tissues may save another child's life provides a way to help others despite their own loss. A healthy child who dies unexpectedly is an excellent candidate for organ donation. Many chronic illnesses in children preclude the option of organ or tissue donation, though individual determinations of eligibility should be made.

The discussion of organ donation should be separated from the discussion of impending death or brain death notification. Written consent is necessary for organ donation, so the family must be appropriately informed and educated. Many families who never thought about it before may consider the option of donation if adequately educated about the process. All expenses for organ procurement are borne by the recipient's family, not the donor's. Ask whether the dying child ever expressed a wish to donate organs and whether the parents have considered it.

Families need to know that procurement of the organs does not mar the child's appearance, so that an open casket at the child's funeral is still possible if the family desires. The donating child will not suffer further because of organ donation. The organs or tissues will be harvested in a timely fashion after the declaration of death, so the family need not worry about delay of the wake or funeral. The family's cultural and religious beliefs must be considered, and the team discussing organ donation with the family must do so in a sensitive and ethical manner (Bratton et al., 2006).

Palliative Care of the Dying Child

Appropriate **palliative care** is essential for any child with a life-threatening or progressive incurable condition. Whether palliative care is provided in the home, hospital, or hospice setting, the goal is to provide the best quality of life possible at the end of life while alleviating physical, psychological, emotional, and spiritual suffering. The Last Acts Palliative Care Task Force has established principles on which palliative care of children should be based. These include:

- Respecting children's goals, preferences, and choices
- Comprehensive caring
- Using the strengths of interdisciplinary resources
- Acknowledging and addressing caregivers' concerns
- Building systems and mechanisms of support (Association of Pediatric Oncology Nurses [APON], 2003)

Hospice Care

Hospice allows for family-centered care in the child's home or a hospice facility. As with adult hospice care, the comfort of the entire family is important. The goals of pediatric hospice care are enhancement of quality of life for the child and family through an individualized plan of care. The recommended standards for pediatric hospice care do not preclude involvement in ongoing treatment (this is in contrast to adult hospice), but certain eligibility criteria must be met (Children's Hospice International, 2011). Parents are educated on ways to comfort and interact with their dying child, such as massage, movement, or singing. Spiritual support is available through a chaplain, a social worker, or the family's minister. The nurse not only educates the family about the dying process but also assists them with providing basic care and pain management. The decision to withhold nutrition or hydration may be made in certain instances. Pain management is of the utmost importance for the terminally ill child (APON, 2003). Ongoing bereavement care is also provided to the family by the hospice after the child's death.

Nursing Management of the Dying Child

Though interdisciplinary care is essential for quality care at the end of life, it is the nurse who plays the key role of child/family advocate and who is usually the constant presence throughout the dying process. Nursing management of the dying child focuses on managing pain and discomfort, providing nutrition, providing emotional support to the dying child and family, and assisting the family through the grief process. Throughout the process, it is important to focus on the family as the unit of care.

Managing Pain and Discomfort

Pain management is an essential component of care for the child with a terminal illness. Providing for comfort enhances the child's quality of life and minimizes suffering (Baker et al., 2008). Assess pain using a developmentally appropriate tool (see [Chapter 14](#) for further information). Provide pain medication around the clock rather than on an "as needed" basis to prevent recurrence or escalation

of pain. Determine the child's preferred comfort measures and use them to provide additional relief. Change the child's position frequently but gently to minimize discomfort. Limit nursing care to comfort measures that ease the child's discomfort. Maintain a calm environment, minimizing noise and light.

Providing Nutrition

Since the body naturally requires less nutrition as the child is dying, do not excessively coax the child to eat or drink. Offer frequent small meals or snacks of the child's choosing. Soups and shakes require less energy to eat and so may be desirable. If the child desires a different food, provide that one. Keep strong odors away from the child to decrease nausea. Administer antiemetics as needed. Provide mouth care and keep the lips lubricated to keep the mouth feeling clean and prevent the discomfort associated with chapped lips. Make sure the environment is a pleasant one for eating.

Providing Emotional Support to the Dying Child and Family

Be attuned to the entire family's needs and emotions in order to foster a holistic connection with the child and family. Nurses provide physical care through specific tasks and interventions for the dying child, but they also need to be fully present emotionally with the child and family. In general, people are uncomfortable with the concept of a dying child. Nurses should work through their own feelings about the situation to be able to be "in the moment" with the child and family. Ask yourself: Can I be fully present with this family? If not, then what can I change to be so? (Rushton, 2005).

Families and dying children benefit from the presence of the nurse, not just the interventions he or she performs. Families report that the simple act of being present with the family is very healing (Mellichamp, 2007). Listen to the child and family; be still and silent for a time to accomplish this. Foster respect for the whole child by attending to him or her as such.

Respect the parents of the dying child by helping them honor the commitments they have made to their child. Acknowledge that parents have diverse needs for information and participation in decision making. Allow and encourage family customs or rituals in relation to death and dying. Families may desire the pastor or priest to be present when the child's death is imminent. Certain rituals may be desired, depending on the family's religious or spiritual background. Ensure that these important events occur, and alter nursing care routines as needed to accommodate them. Respect the family's need to participate in these rituals and customs (Ethier, 2010).

Work collaboratively with the family and health care team to provide for the needs of the child and family. Resources for families of a dying child are listed in [Box 12.6](#). The Make-a-Wish Foundation works to grant the wishes of terminally ill children, giving the child and family an experience of hope, strength, and love. A link to the Make-a-Wish Foundation is included on [thePoint](#).

EASING ANXIETY OR FEARS

Parents may be afraid of their child dying alone or not know what to expect in the death process. This fear may contribute to increased anxiety, which the child may sense. Younger children may fear separation from their parents and older children may not want to die alone or experience pain or discomfort associated with dying. Each child and family is individual; discuss their particular fears and anxieties in order to determine the child's and family's needs for education and support (Baker et al., 2008).

Involve the parents and other family members in all phases of the child's care. Explain all aspects of care to the child to minimize anxiety related to nursing interventions. Answer the child's questions honestly. Involve the child in decision making whenever possible. Limit interventions to those related to palliation, rather than treatment, advocating for the child as needed. Remain with the child when a parent or family member is not in the room so the child will not fear dying alone.

MEETING THE DYING CHILD'S NEEDS ACCORDING TO DEVELOPMENTAL STAGE

It is important to provide the type of support and education that the dying child needs according to his or her developmental stage. For the infant, unconditional love and trust are of utmost importance. Ensure that the infant's family is available to the child. The toddler, 1 to 3 years old, thrives on familiarity and routine. Maximize the toddler's time with parents, be consistent, provide favorite toys, and ensure physical comfort. Spirituality in the preschool years focuses on the concept of right versus wrong. The 3- to 5-year-old may see death as punishment for wrongdoing; correct this misunderstanding. Use honest and precise language. Help the parents to teach the child that though the family will miss the child, it will continue to function without him or her (Ethier, 2010).

The school-age child has a concrete understanding of death. Children who are 5 to 10 years old need specific, honest details (as desired). Encourage the child to help make decisions, and help the child to establish a sense of control (Ethier, 2010).

The young adolescent (10 to 14 years old) will benefit from reinforcement of self-esteem, self-respect, and a sense of worth. Respect the child's need for privacy and time alone as well as time requested with peers. Support the need for independence and encourage the child to participate in decision making. The older teen (14 to 18 years of age) has a more adult-like understanding of death and will need further support through honest, detailed explanations and will want to feel truly involved and listened to (Ethier, 2010).

Assisting the Family Through the Grief Process

The family may experience anticipatory grief when the diagnosis of terminal illness is made. Families may deny the prognosis, become angry at the health care system or a higher power, or experience depression. Acute grief is an intense process that occurs around the time of the actual death. Family members may feel short of breath or as though the throat is tight. They may verbalize that the situation is unreal to them or search for reasons why the death was not prevented. Families may also display hostility or restlessness. Each individual will express grief in his or her own manner. Mourning the death of a loved one takes a long time, and families should be supported throughout the process (Ethier, 2010). Local and national resources are available for grieving parents. Several resources for grieving parents are listed on [thePoint](#). Refer parents to bereavement resources as appropriate.

KEY CONCEPTS

- Children with special health care needs are those who have, or are at risk for, a chronic physical, developmental, behavioral, or emotional condition that generally requires more intensive and diverse health services, as well as coordination of those services, than do typical children.
- Most children with chronic illnesses or who are dependent on technology progress through stages of growth and development just as typical children do, though possibly at a slower pace.
- Parents of special needs children experience a multitude of emotions and changes in their lives, often carrying a heavy caregiving burden. They become the experts on their child's care and should be empowered and supported in their efforts.
- The child and family with special needs may require additional support during times of transition, such as at initial diagnosis or change in prognosis, when symptoms increase, when the child moves to a new setting (hospital, school), during periods of developmental change, or during a parent's absence.
- Children with special health care needs are at increased risk for the development of vulnerable child syndrome, which may have psychologically harmful effects on the child and parents for many years.
- Home is the most developmentally appropriate environment for children with special health care needs and those who are technology dependent. Children display an improved physical, emotional, psychological, and social status when they are cared for at home.
- Family-centered care provides the optimal framework for caring for children and families with special needs. Empowering the family strengthens them. A medical home or permanent relationship with the physician or nurse practitioner benefits the family, as

care coordination and advocacy are provided.

- Use adjusted (or corrected) age when assessing growth and development of the infant or child who was born prematurely. Provide early screening and intervention for issues related to development to maximize the former preemie's potential for growth and development.
- Become familiar with the risks and benefits of adjuvant therapies used by some families of children with special health care needs.
- Screen children with special health care needs for failure to thrive or a feeding disorder.
- Screening helps to identify children with unmet health needs so that intervention may begin.
- Early intervention provides care coordination (developmental services and special education), as well as an individualized family service plan for qualifying children and their families.
- Each special needs student is entitled to an IEP, which is a written plan that is designed to meet the preschool, primary, or secondary school student's needs.
- Early discharge planning and ongoing inclusion and education of the family facilitate continuity of care. During midadolescence, initiate a written plan to help the special needs child make the transition to adult care.
- Support the dying child and the family throughout the end-of-life decision-making process, providing facts as desired about palliative care, hospice, and organ donation.
- Younger children who are dying generally need for their families to be close and to trust their needs will be provided for. Older children require honest explanations given at a level appropriate for the child's age or developmental stage.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The parents of a 5-year-old with special health care needs talk to the parents of a 10-year-old with a similar condition for quite a while each day. What is the nurse's interpretation of this behavior?
 - a. The nurse has not provided enough emotional support for the parents.
 - b. This relationship between the children's parents is potentially unhealthy.
 - c. Support between parents of special children is extremely valuable.
 - d. Confidentiality is a pressing issue in this particular situation.
2. The nurse is caring for a child who has received all possible medical care for cancer, yet continues to experience relapse and metastasis. It is time to make the transition from curative care attempts to palliative care. What is the most important nursing consideration at this time?
 - a. The health care professionals should make the decision about the child's care.
 - b. The family may lose a sense of hope, so cancer treatments should continue.
 - c. Involve the family in the decision-making process about the shift to palliative care.
 - d. Palliative care can take place only at home, so the child should be discharged.
3. The nurse is caring for a 3-year-old with a gastrostomy tube and tracheostomy who is on supplemental oxygen and multiple medications. The mother is rooming in during this hospitalization. What is the priority nursing action?
 - a. Incorporate the mother's assistance in care when convenient.
 - b. Recognize the mother as the expert on her child's needs and care.
 - c. Recommend that the mother go home to get some rest.
 - d. Provide family-centered care since the mother is there.
4. The nurse is caring for a child with a developmental disability who is starting kindergarten this year. The mother is tearful and doesn't want the child to go to school. What is the best response by the nurse?
 - a. "Do you need some time alone to collect yourself?"
 - b. "You've known for a while this time would come."
 - c. "Can I call your husband or a friend for you?"
 - d. "It is normal to feel stressed or sad at this time."
5. The parents of a child with a developmental disability ask the nurse for advice about disciplining their child. What is the best response by the nurse?
 - a. "You should choose methods that are most congruent with your values about discipline."
 - b. "Children like this really can't follow directions, so they may be very hard to discipline."
 - c. "Punish your child only for socially unacceptable or offending behaviors."
 - d. "Spanking works well for this type of child, as they really don't like pain."

CRITICAL THINKING EXERCISES

1. A 15-year-old boy is dying of cancer after all medical care options have been exhausted. Describe the plan of care for this child and his family. What strategies should the nurse use to support the child and his family through this difficult process?
2. A 5-month-old infant who was born at 24 weeks' gestation is ready to be discharged from the NICU. She will be going home on oxygen, gastrostomy tube feedings, and eight medications. Develop a teaching plan for the family.

STUDY ACTIVITIES

1. In the clinical setting, care for a child with a terminal illness. Reflect in your clinical journal about the feelings you had during the care of the child, as well as the feelings and behaviors that you noticed in the child, siblings, parents, and nursing staff.
2. Visit a preschool that provides care for developmentally delayed and typical children. Choose two same-age children, one with a disability or impairment and the other a typical healthy child. Perform a Denver developmental screening or developmental assessment on each of the two children. Compare and contrast your findings.
3. Spend the day with a home care nurse providing care for a technology-dependent child. What obstacles has the family overcome to have this child at home? What adjustments does the nurse make to provide family-centered care in the home (as compared to the hospital setting)?

Key Pediatric Nursing Interventions

Words of Wisdom Quality technical skills delivered by a caring hand are a vital part of good nursing care.

pharmacodynamics

pharmacokinetics

residual

total parenteral nutrition

Learning Objectives

Upon completion of this chapter, you will be able to:

1. Describe the “eight rights” of pediatric medication administration.
2. Explain the physiologic differences in children affecting a medication’s pharmacodynamic and pharmacokinetic properties.
3. Accurately determine recommended pediatric medication doses.
4. Demonstrate the proper technique for administering medication to children via the oral, rectal, ophthalmic, otic, intravenous, intramuscular, and subcutaneous routes.
5. Integrate the concepts of atraumatic care in medication administration for children.
6. Identify the preferred sites for peripheral and central intravenous medication administration.
7. Describe nursing management related to maintenance of intravenous infusions in children, as well as prevention of complications.
8. Explain nursing care related to enteral tube feedings.
9. Describe nursing management of the child receiving total parenteral nutrition.

Lily Kline, a 9-month-old, is admitted to your unit for failure to thrive. The physician has ordered insertion of a

nasogastric tube to begin gavage feedings. The parents are very nervous and upset about this. They ask, “What will this tube do for Lily? It sounds very uncomfortable. What do you have to do to insert it? Will it have to stay in all the time? Won’t it move?” How would you address their concerns?

The ill child often requires medications, intravenous (IV) therapy, or enteral nutrition to restore health. These interventions occur most often in the inpatient setting, but with today’s advanced technology many children may receive treatment in the home, day care center, school, physician’s office, or other community setting.

This chapter will discuss the key elements of, and guidelines for, care related to medication administration, IV therapy, and nutritional support in children. Child and parent education is emphasized. The chapter will focus on adapting and modifying medication administration and nursing procedures based on the child’s growth and development and providing these treatments using a family-centered, atraumatic approach. Refer back to [Chapter 8](#) for an overview of the important aspects of caring for a child who is to undergo a procedure.

At one time or another, every child will need to receive medication. As with adults, pediatric medication administration is a critical component of safe and effective nursing care. The pediatric nurse must adapt administration principles and techniques to meet the child's needs. Medication administration, regardless of the route, requires a solid knowledge base about the drug and its action. As with medication administration to any child, the nurse must adhere to the "rights" of medication administration (Box 13.1).

Differences in Pharmacodynamics and Pharmacokinetics

Although a drug's mechanism of action is the same in any individual, the physiologic immaturity of some body systems in a child can affect a drug's **pharmacodynamics** (behavior of the medication at the cellular level). As a result, the body may not respond to the drug as intended. The intended effect may be enhanced or diminished, necessitating a change in the dosage to ensure optimal effectiveness without increasing the child's risk for toxicity.

The child's age, weight, body surface area, and body composition also can affect the drug's **pharmacokinetics** (movement of drugs throughout the body via absorption, distribution, metabolism, and excretion). Drugs are administered to children via many of the same routes that are used for adults. However, this similarity ends once the drug is administered. During the absorption process, drugs move from the administration site into the bloodstream. In infants and young children, the absorption of orally administered medications is affected by slower gastric emptying, increased intestinal motility, a proportionately larger small intestine surface area, higher gastric pH, and decreased lipase and amylase secretion compared with adults. Intramuscular absorption in infants and young children is affected by the amount of muscle mass, muscle tone and perfusion, and vasomotor instability. Similarly, decreased perfusion alters subcutaneous absorption. Absorption by these routes is erratic and may be decreased. In contrast, topical absorption of medications is increased in infants and young children, which can result in adverse effects not seen in adults. Infants and young children have a greater body surface area, leading to increased absorption of topical medications. Absorption in infants is also increased due to greater permeability of the infant's skin.

BOX 13.1

EIGHT RIGHTS OF PEDIATRIC MEDICATION ADMINISTRATION

Right Medication

- Check order and expiration dates.
- Know action of medication and potential side effects (use pharmacy, drug formulary).
- Ensure that the medication provided is the medication that is ordered.

Right Patient

- Confirm child identity since children may deny their identity in attempt to avoid an unpleasant situation, play in another child's bed, or remove ID bracelet.
- Confirm identity each time medication is given.
- Verify child's name with caregiver to provide additional verification.

Right Time

- Give within 20 to 30 minutes of the ordered time.
- For a medication given on an as-needed (PRN) basis, know when it was last given and how much was given during the past 24 hours.

Right Route of Administration

- Check ordered route and ensure this is the most effective and safest route for this child; clarify any order that is confusing or unclear.
- Give the medication by the route ordered. If there is a need to change route, always check with prescriber (e.g., if a child is vomiting and has an order for an oral medication, the medication may need to be given via the IV or rectal route).

Right Dose

- Calculate the recommended dose according to child's weight and double-check your calculations.
- Always question the pharmacist and/or prescriber if the ordered dose falls outside the recommended dose range.

- Unusually large or small volumes or dosages should always be verified.

Right Documentation

- Record administration of the medication on the appropriate paper or computerized form according to agency policy.
- Ensure that all medications administered and refused are documented.

Right to Be Educated

- Provide simple explanations to the child based on his or her level of understanding.
- Explain to the parents or caregiver about the medication to be given and what to expect from it.
- Use a positive, firm approach with the child. **Right to Refuse**
- Provide explanations to the child and parents to clarify any misconceptions or relieve fears.
- Reinforce the rationale for medication use.
- Respect the child's or parents' option to refuse.

The distribution (movement of a drug from the blood to interstitial spaces and then into cells) of medications is also altered in infants and young children. Medication distribution in children is affected by:

- Higher percentage of body water than adults
- More rapid extracellular fluid exchange
- Decreased body fat
- Liver immaturity, altering first-pass elimination
- Decreased amounts of plasma proteins available for drug binding
- Immature blood-brain barrier, especially in neonates, allowing permeation by certain medications

Metabolism of medications in children is altered because of differences in hepatic enzyme production and the child's increased metabolic rate. **Biotransformation** (the alteration of chemical structures from their original form, which allows for the eventual excretion of the substance) is affected by the same variations affecting distribution in children. In addition, the immaturity of the kidneys until the age of 1 to 2 years affects renal blood flow, glomerular filtration, and active tubular secretion. This results in a longer half-life and increases the potential for toxicity of drugs primarily excreted by the kidneys.

Developmental Issues and Concerns

Children are constantly growing and developing. The specific psychosocial, cognitive, physical, and motor developmental levels of children are important. Nurses need a solid understanding of growth and development to ensure safe administration of medications to children. [Table 13.1](#) details some growth and development issues related to administering medications to children. Always give developmentally appropriate, truthful explanations before administering medications to children, including:

- Why the drug is needed
- What the child will experience
- What is expected of the child
- How the parents can participate and support their child

Refer to [Chapters 3](#) through [7](#) for further information about growth and developmental issues.

The child's past experiences with taking medications and the approaches that may have been used will often affect how the child reacts. Always approach children positively; let your manner convey the belief that they can accomplish this needed behavior. Never label the child as "bad" if he or she did not fully cooperate in taking medication. When medications must be administered with a needle (intramuscularly or subcutaneously), assure the child that this method is not a consequence of the child's behavior. Help parents to work through the feelings of frustration that may result from the child's refusal to cooperate with medication administration. Provide parents with facts about growth and developmental issues and children's fears and anxiety related to medication administration. Model alternative ways for the parents to deal with undesirable behavior.

Take Note!

Always administer medications promptly, assist the child in holding still using a comforting position for the child, and reward positive behavior.

Determination of Correct Dose

Administering the correct dose is a key component of medication administration. Incorrect dosing is the most commonly reported medication error in the pediatric population (American Academy of Pediatrics, 2007). Many drug references list recommended pediatric dosages, and nurses are responsible for checking doses to ensure that they are appropriate for the child. Two common methods for determining pediatric doses are based on the unit of drug per kilogram of body weight or body surface area (BSA).

Dose Determination by Body Weight

The most common method for calculating pediatric medication doses is based on body weight. The recommended dosage is usually expressed as the amount of drug to be given over a 24-hour period (mg/kg/day) or as a single dose (mg/kg/dose). Differentiate between the 24-hour dosage and the single dose. Use these guidelines to determine the correct dose by body weight:

1. Weigh the child.
2. If the child's weight is in pounds, convert it to kilograms (divide the child's weight in pounds by 2.2).
3. Check a drug reference for the safe dose range (for example, 10 to 20 mg/kg of body weight).
4. Calculate the low safe dose (Box 13.2).
5. Calculate the high safe dose (Box 13.2).
6. Determine if the dose ordered is within this range.

The pediatric dosage should not exceed the minimum recommended adult dosage. Generally, once a child or adolescent weighs 50 kg or greater, the adult dose is frequently prescribed (Bowden & Greenberg, 2008). However, it remains important to always verify that the dose does not exceed the recommended adult dose.

| Stage of Development | Issue/Concern | Nursing Interventions |
|----------------------|---|---|
| Infant | Development of trust, which is fostered by consistent care; development of stranger anxiety later in infancy | Involve parents in medication administration to reduce stress for infant. Ensure that parents hold and comfort infant during intervention. |
| Toddler | Development of autonomy with displays of negativism; rituals, routines, and choices necessary to maintain some sense of control | Follow routines and rituals from home in giving medications if these are safe and positive approaches. Involve parents in medication administration. Offer simple choices (e.g., "Do you want Mom or me to give you your medicine?"). Allow child to touch or handle equipment as appropriate. |
| Preschooler | Development of initiative, which is fostered when they sense they are helping | Provide an opportunity to play with the equipment and respond positively to explanations and comforting. Provide choices that are possible and keep them simple (e.g., "Do you want juice or water with your medication?" or "Which medication do you want to take first?"). Do not ask, "Will you take your medicine now?" Involve parents in medication administration. Be aware that giving suppositories is particularly upsetting to this age group because of their fears of bodily intrusion and mutilation. |
| School-aged child | Development of industry, benefiting from being a part of their care; generally very cooperative | Explain to child in simple terms the purpose of the medication. Seek their assistance, such as putting pills in cup or opening the packet, and allow a broader range of choices. Establish a reward system to enhance their cooperation if necessary. |
| Adolescent | Development of identity, benefiting from much more control over their care | Approach in same manner as adults, with respect and sensitivity to their needs. Maintain the adolescent's privacy as much as possible. |

Dose Determination by Body Surface Area

Calculating the dosage based on BSA takes into account the child's metabolic rate and growth. It is commonly used for chemotherapeutic agents. Some recommended medication doses may read "mg/BSA/dose." To determine the dose using BSA, you will need to know the child's height and weight, which will be plotted on a nomogram (Fig. 13.1). A nomogram is a graph divided into three columns: height (left column), surface area (middle column), and weight (right column).

Use these guidelines to determine BSA:

1. Measure the child's height.
2. Determine the child's weight.
3. Using the nomogram, draw a line to connect the height measurement in the left column and the weight measurement in the right column.
4. Determine the point where this line intersects the line in the surface area column. This is the BSA, expressed in meters squared (m²).

Once you have determined the BSA, use the recommended dosage range to calculate the safe dosage.

Oral Administration

Medications to be given via the oral route are supplied in many forms, including liquids (elixirs, syrups, or suspensions), powders, tablets, and capsules. Generally, children younger than the age of 5 to 6 are at risk for aspiration because they have difficulty swallowing tablets or capsules. Therefore, if a tablet or capsule is the only oral form available, it needs to be crushed or opened and mixed with a pleasant-tasting liquid or a small amount (generally no more than a tablespoon) of a nonessential food such as applesauce. However, never crush or open an enteric-coated or time-release tablet or capsule. The crushed tablet or inside of a capsule may taste bitter, so never mix it with formula or other essential foods. Otherwise, the child may associate the bitter taste with the food and later refuse to eat it.

BOX 13.2

DOSAGE CALCULATION USING BODY WEIGHT

After converting the child's weight in pounds to kilograms and checking the safe dose range:

- Calculate the low safe dose range (e.g., 10 to 20 mg/kg and the child weighs 30 kg):
 - Set up a proportion using the low safe dose range $10 \text{ mg}/1 \text{ kg} = x \text{ mg}/30 \text{ kg}$
 - Solve for x by cross-multiplying:

$$1 \times x = 10 \times 30$$

$$x = 300 \text{ mg}$$
- Calculate the high safe dose range:
 - Set up a proportion using the high safe dose range $20 \text{ mg}/1 \text{ kg} = x \text{ mg}/30 \text{ kg}$
 - Solve for x by cross-multiplying:

$$1 \times x = 20 \times 30$$

$$x = 600$$
- Compare the safe dose range (for this example, 300 to 600 mg) with the ordered dose. If the dose falls within the range, the dose is safe. If the dose falls outside the range, notify the prescriber.

FIGURE 13.1 A nomogram to determine body surface area.

Take Note!

Certain drug formulations should not be crushed. Before crushing a pill or opening a capsule, always check that this will not alter the intended effects of the drug.

Liquid medications, primarily suspensions, may be less concentrated at the top of the bottle than at the bottom of the bottle. Always shake the liquid to ensure even drug distribution. The key to administering liquid forms of oral medications is to use calibrated equipment such as a medicine cup, spoon, plastic oral syringe, or dropper (Fig 13.2).

Take Note!

Use the medicine cup or syringe with proper calibration instead of household cups or measuring spoons, since they are not calibrated and may deliver an incorrect dose of medication.

If a dropper is packaged with a certain medication, never use it to administer another medication, since the drop size may vary from one dropper to another. If using a syringe for oral administration, only use the type intended for oral medications, not one designed for parenteral administration. When using a dropper or oral syringe (without a needle) for infants or young children, direct the liquid toward the posterior side of the mouth. Give the drug slowly in small amounts (0.2 to 0.5 mL) and allow the child to swallow before more medication is placed in the mouth (Fig 13.3). A nipple without the bottle attached is sometimes used to administer medication to infants. Place the medication directly in the nipple and keep the nipple filled with medication as the infant sucks so no air is taken in while the infant takes the medication. Always place the infant or young child upright (at least a 45-degree angle) to avoid aspiration. The toddler or young preschooler may enjoy using the oral syringe to squirt the medicine into his or her

mouth. Older children can take oral medication from a medicine cup or measured medicine spoon.

FIGURE 13.2 Devices used to administer oral medications to children.

FIGURE 13.3 Position the infant or young child for safe medication administration.

Take Note!

Never force an oral medication into a child's mouth or pinch the child's nose. Doing so increases the risk for aspiration and interferes with the development of a trusting relationship.

As children adapt to swallowing tablets or capsules, administration is similar to that of adults. When helping the younger child learn how to swallow medication, the tablet or capsule can be placed at the back of the tongue or in a small amount of food such as ice cream or applesauce. Always tell children if there is medicine in the food; otherwise, they may not trust you.

BOX 13.3

GUIDELINES FOR ADMINISTERING MEDICATIONS VIA GASTROSTOMY OR JEJUNOSTOMY TUBES

- Verify correct placement (refer to [Box 13.4](#)).
- Give liquid medications directly into the tube. Draw appropriate amount into syringe and clear air.
- Mix powdered medications well with warm water first.
- If medication is in pill form, verify it is OK to crush. Then, crush tablets and mix with warm water to prevent tube occlusion.
- Open up capsules and mix the contents with warm water to dissolve the contents and prevent tube occlusion. Label each syringe appropriately.
- Flush the tube with water after administering medications to ensure that the entire amount of medication has been given and to

prevent tube occlusion.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and Cincinnati Children's Hospital Medical Center. (2009). *Abdominal and digestive home care*. Retrieved January 23, 2010, from <http://www.cincinnatichildrens.org/health/info/abdomen/home/g-tube-care.htm>

When the child has a nasogastric, orogastric, nasojejunal, nasoduodenal, **gastrostomy** (opening into the stomach), or jejunostomy tube, oral medications may be given via these devices. The tube allows for the medication to be placed directly into the stomach or small intestine area. Be aware that not all medications can be placed directly into the duodenum or jejunum. Medication for administration via a tube must be supplied in a liquid form, or a crushed tablet or opened capsule can be mixed with a liquid (Box 13.3). Always check tube placement prior to administering the medication. After administration, flush the tube to maintain patency.

Rectal Administration

Rectal medications are typically supplied in the form of suppositories. The rectal route is not a preferred route for medication administration in children because the drug's absorption may be erratic and unpredictable and the method is invasive. The rectal route can be extremely upsetting to the toddler and preschooler because of age-related fears, and may be embarrassing to the school-age child or adolescent. However, the rectal route may be used when the child is vomiting or receiving nothing by mouth (NPO). Use age-appropriate explanations and reassurance. Helping the child to maintain the correct position may be necessary to ensure proper insertion and safety of rectal suppositories.

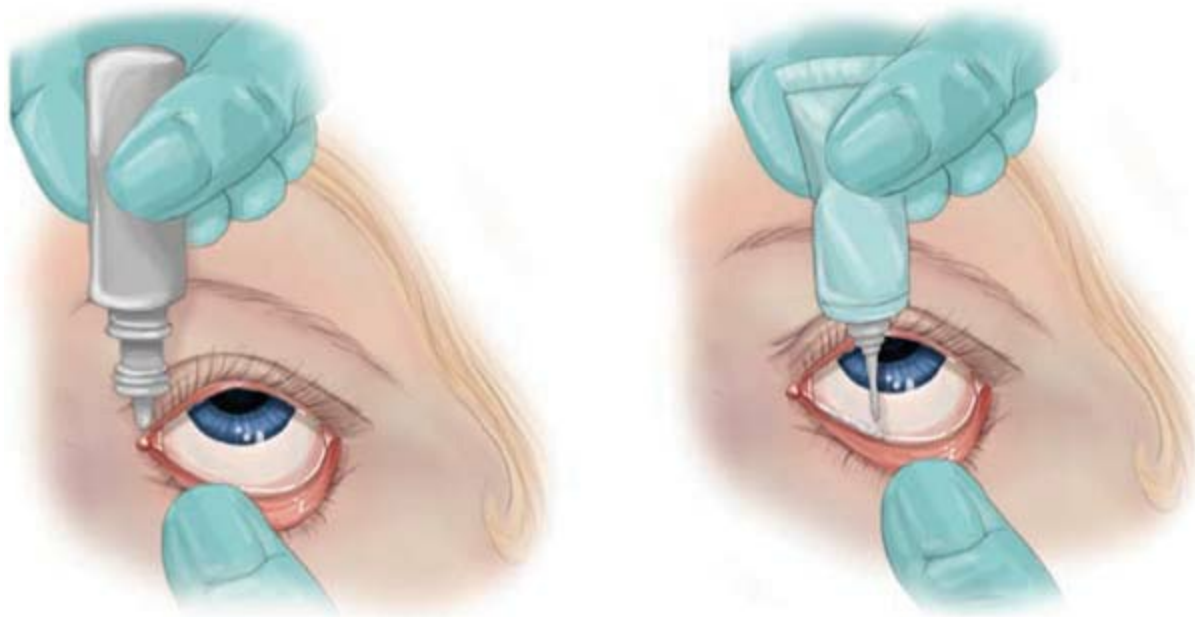

FIGURE 13.4 Administering eye medication: gently press the lower lid down and have the child look up as the medication is instilled into the lower conjunctival sac.

Lubricate the suppository well with a water-soluble lubricant. With the child in the side-lying position, insert the suppository into the rectum quickly but gently. Wear gloves or use a finger cot to insert the suppository. Insert the suppository above the anal sphincter. For an infant or child younger than the age of 3, use the fifth finger for insertion. For an older child, use the index finger. To prevent expulsion of the suppository, hold the buttocks together for several minutes or until the child loses the urge to defecate. If the child has a bowel movement within 10 to 30 minutes after administration of the medication, examine the stool for the presence of the suppository. If it is observed, notify the physician or nurse practitioner to determine if the drug needs to be administered again.

Ophthalmic Administration

Ophthalmic medications are typically supplied in the form of drops or ointment. Many children have a fear of having anything placed in their eyes. Therefore, provide an age-appropriate explanation to gain their cooperation. Also, have the child keep his or her eyes closed until you are ready to administer the medication. Ensure that the medication is at room temperature, as chilled medication may be uncomfortable to the child. Proper positioning of the child is necessary to control the child's head, keep the child's hands from interfering, and prevent injury to the eye. Attempt to administer the medication when the child is not crying to ensure that the medication reaches its intended target area.

Wash hands thoroughly and don gloves. Place the child in the supine position, slightly hyperextending the neck with the head lower than the body so the medication will be dispersed over the cornea. Rest the heel of your hand on the child's forehead to stabilize it. Retract the lower eyelid and place the medication in the conjunctival sac; maintain sterile technique by being careful not to touch the tip of the tube or dropper to the sac. For eye drops, place the prescribed number of drops into the lower conjunctival sac (Fig. 13.4). For ointment, apply the medication in a thin ribbon from the inner canthus outward without touching the eye or eyelashes. If the child is old enough to cooperate, instruct the child to gently close the eyes to allow the medication to be dispersed.

If a child is uncooperative, he or she may need to be immobilized in order to administer the eye drops. Alternatively, one or two drops on the inner canthus of the closed eye can be administered while the child is lying supine. Then instruct the child to open his or her eyes and the drops will enter the eye. Wipe any excess medication from the skin. Punctal occlusion after application is also important to slow systemic absorption and ensure the medicine stays in the eye.

Children often require ophthalmic medications at home. Parents or caregivers need instruction about how to administer this type of medication. [Teaching Guidelines 13.1](#) provides information on administering eye drops and eye ointments.

Teaching Guidelines 13.1

APPLYING EYE MEDICATIONS

- Wash your hands with soap and water. Dry them thoroughly using paper towels or a clean cloth.
- Allow the eye drops or ointment to come to room temperature (if the medication was stored in the refrigerator). If necessary, warm the eye drops or ointment tube in the palm of your hand. Keep the cap on to avoid any spillage. Make sure medication is well mixed if needed.
- Remove the cap, placing it on a dry, clean surface.
- For young children (3 years or younger), obtain assistance to keep their arms and fingers away during the procedure. If doing this procedure alone, wrap the child in a towel or blanket, keeping the arms inside. If you are applying eye drops, it may be easiest if you are standing or sitting behind the child, looking over the back of the child's head as he or she reclines. If you are applying an eye ointment, it may be easiest to face the child directly.
- Using one hand, hold the child's forehead in place while raising the eyelid with your thumb.
- With your other hand, hold the eye drop bottle or ointment tube above the eye, using an extended finger against the child's cheek, forehead, or nose to steady your hand.
- Gently squeeze the eye drop bottle, dispensing the proper number of drops, or gently squeeze the ointment tube, dispensing a small trail (about 2 cm) of ointment into the gap between the lower portion of the eye and bottom eyelid.
- Make sure the tip of the bottle or tube does not make contact with the eye or any other surface.
- For eye drops, gently press your finger against the inside corner where the eye meets the nose for about 1 minute, blocking the tears and medication from exiting through the tear duct. This will help the eye retain more of the medication. If the child is old enough, he or she may be able to do this unassisted.
- For ointment, have the child close his or her eye and not rub the area.
- Ask the child not to blink or squeeze the eye shut more than normal, as this may wash away the medication prematurely.
- Gently dab away any tears or medication on the face with a clean tissue.
- If necessary, clean the tip of the bottle or tube with a clean tissue and recap.
- Wash your hands again and dry them thoroughly.

Retrieved January 20, 2010, from <http://www.pgca.org/ointment.htm>

Otic Administration

Medications for otic administration are typically in the form of ear drops. This route of administration can be upsetting to the child because he or she cannot see what is happening. The child often receives otic drugs for an earache, and he or she may fear that the ear drops will increase the pain. Explain the procedure to the younger child in terms that he or she can understand to help allay these fears. Gain the older child's cooperation by explaining the purpose of the medication and the procedure for administration.

Reinforce the need for the child to keep the head still. Younger children may require assistance to do so. Be sure that the ear

drops are at room temperature. If necessary, roll the container between the palms of your hands to help warm the drops. Using cold ear drops can cause pain and possibly vertigo when they reach the eardrum (Bowden & Greenberg, 2008).

Place the child in a supine or side-lying position with the affected ear exposed (Fig. 13.5). Pull the pinna downward and back in children younger than age 3 and upward and back in older children. Instill the medication using a dropper. Then have the child remain in the same position for several minutes to ensure that the medication stays in the ear canal. Massage the area anterior to the affected ear to promote passage of the medication into the ear canal. If necessary, place a piece of cotton or a cotton ball loosely in the ear canal to prevent the medication from leaking.

Nasal Administration

Nasally administered medications are typically drops and sprays. Administering nose drops to infants and young children may be difficult, and additional help may be needed to help maintain the child's position. For nose drops, position the child supine with the head hyperextended to ensure that the drops will flow back into the nares. A pillow or folded towel can be used to facilitate this hyperextension. Place the tip of the dropper just at or inside the nasal opening, taking care not to touch the nares with the dropper (Fig. 13.6). Doing so might stimulate the child to sneeze. Although the nasal membranes are not sterile, the drop solution is, and sneezing would contaminate the dropper, leading to contamination of the drop solution when the dropper is returned to the bottle. Once the drops are instilled, maintain the child's head in hyperextension for at least 1 minute to ensure that the drops have come in contact with the nasal membranes.

FIGURE 13.5 Administering ear drops. (A) For the child younger than 3 years of age, the nurse pulls the pinna of the ear down and back. (B) For a child older than age 3 years, the nurse pulls the pinna of the affected ear up and back.

FIGURE 13.6 Administering nose drops. Tilt the head down and back to instill nose drops.

For nasal sprays, position the child upright and place the tip of the spray bottle just inside the nasal opening and tilted toward the back. Squeeze the container, providing just enough force for the spray to be expelled from the container. Using too great a force can push the spray solution and secretions into the sinuses or eustachian tube.

Take Note!

In young infants, instill the medication in one naris at a time, since they are obligate nose breathers.

Intramuscular Administration

Intramuscular (IM) administration delivers medication to the muscle. In children, this method of medication administration is used infrequently because it is painful and children often lack adequate muscle mass for medication absorption. However, IM administration is used to administer certain medications, such as many immunizations.

Muscle development and the amount of fluid to be injected determine IM injection sites in children. Needle size (gauge and length) is determined by the size of the muscle and the viscosity of the medication. For example, more viscous medications often require a larger-gauge needle. In addition, the needle must be long enough to ensure that the medication reaches the muscle.

The preferred injection site for infants is the vastus lateralis muscle (Immunization Action Coalition, 2010). The dorsogluteal site, often used in adults, is not recommended in children younger than 5 years of age (Bowden & Greenberg, 2008). The muscle has not fully developed and the sciatic nerve occupies a larger portion of this area in the young child.

Take Note!

Some experts no longer recommend use of the dorsogluteal site at any age due to the risk of damaging the sciatic nerve (Aschenbrenner & Venable, 2008).

The deltoid muscle is used as an IM injection site in children older than 3 years of age and may be used in toddlers if the muscle mass is sufficient (Immunization Action Coalition, 2010). [Figure 13.7](#) illustrates IM injection sites.

Select the needle size and gauge based on the size of the child's muscle. The goal is to use the smallest length and gauge that will deposit the medication in the muscle. [Table 13.2](#) provides general guidelines for solution amount, needle size, and needle gauge when administering IM medications.

Insert the needle into the skin at a 90-degree angle. Aspirating and, if no blood was present, injecting the medication was the traditional procedure. However, recent research has shown decreased discomfort and no associated complications with rapid injection of intramuscular immunizations without aspiration (Centers for Disease Control and Prevention, 2010). In addition, there are no large blood vessels present in the currently recommended injection sites, the vastus lateralis and deltoid muscles (Kroger, Sumaya, Pickering, & Atkinson, 2011). Therefore, the Centers for Disease Control and Prevention (CDC) and the Advisory Committee on Immunization Practices (ACIP) no longer recommend aspiration before injection (Centers for Disease Control and Prevention, 2010; Kroger et al., 2011).

Subcutaneous and Intradermal Administration

Subcutaneous (SQ) administration distributes medication into the fatty layers of the body. It is used primarily for insulin administration, heparin, and certain immunizations, such as the MMR. The amount of subcutaneous tissue differs among individuals. Therefore, when selecting a site and needle size, choose the most appropriate based on adequacy and condition of the subcutaneous tissue and the frequency and duration of the therapy. The preferred sites for SQ administration include the anterior thigh, lateral upper arms, and abdomen (Bowden & Greenberg, 2008; Immunization Action Coalition, 2010). Use a 3/8- or 5/8-inch, 23- to 25-gauge needle. Pinch up the skin with the nondominant hand to isolate the tissue from the muscle. Insert the needle at a 45- to 90-degree angle, release the skin if pinched, and inject the medication slowly.

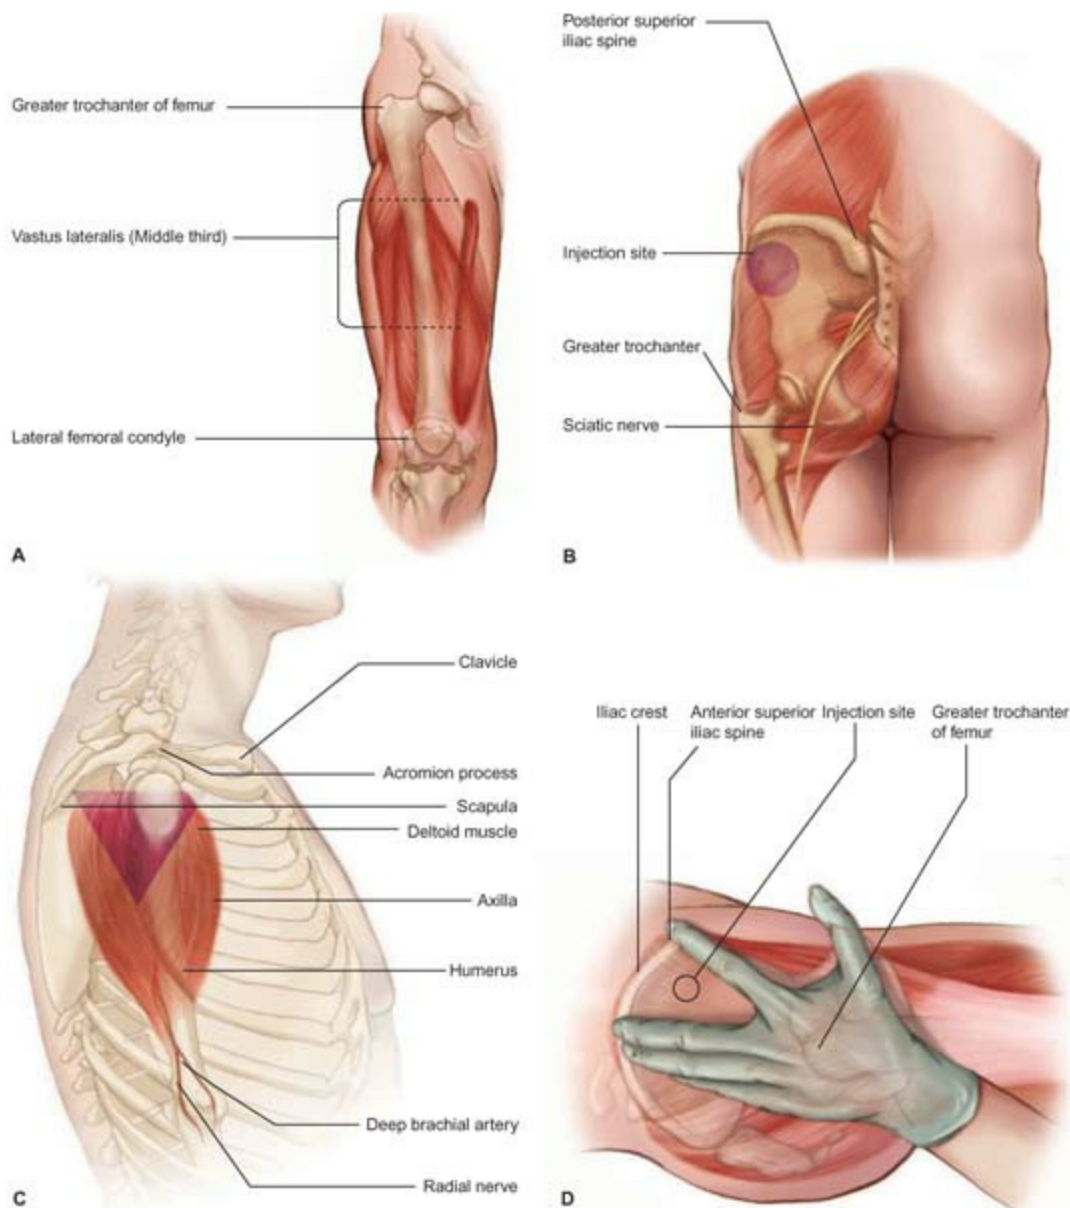

FIGURE 13.7 Locating intramuscular injection sites. **(A)** Vastus lateralis: identify the greater trochanter and the lateral femoral condyle; inject in middle third and anterior lateral aspect. **(B)** Dorsogluteal: place hand on iliac crest and locate the posterosuperior iliac spine; inject in the outer quadrant formed when an imaginary line is drawn between the trochanter and the iliac spine. **(C)** Deltoid: locate the lateral side of the humerus, one to two finger widths below the acromion process. Inject into upper third of muscle. **(D)** Ventrogluteal: place palm of left hand on right greater trochanter so index finger points toward anterosuperior iliac spine, spread middle finger to form a V, and inject in the middle of the V.

TABLE 13.2 GUIDELINES FOR SOLUTION AMOUNT, NEEDLE LENGTH, AND NEEDLE GAUGE FOR IM INJECTIONS^a

| | Solution Amount | | | | Length | Gauge |
|-------------|------------------|-----------------|--|-----------------|---------------------------|-------|
| | Vastus Lateralis | Deltoid | Ventrogluteal | Dorsogluteal | | |
| Infant | 0.5 mL | Not recommended | Not recommended until 7 months; then 0.5 mL. | Not recommended | $\frac{5}{8}$ to 1 inch | 22–25 |
| Toddler | 0.5–1 mL | 0.5 mL | 1 mL | Not recommended | $\frac{5}{8}$ to 1 inch | 22–25 |
| Preschooler | 1 mL | 0.5 mL | 1.5 mL | Not recommended | $\frac{5}{8}$ to 1 inch | 22–25 |
| School age | 1.5–2 mL | 0.5–1 mL | 1.5–2 mL | 1.5–2 mL | $\frac{5}{8}$ to 1.5 inch | 22–25 |

^aNeedle size and site need to be individualized based on the size of the muscle, amount of adipose tissue, and amount of solution to be administered.

Adapted from Centers for Disease Control and Prevention. (2010). *Vaccine administration guidelines*. Retrieved May 23, 2011, from http://www.cdc.gov/vaccines/pubs/pinkbook/downloads/appendices/D/vacc_admin.pdf; Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and Immunization Action Coalition. (2010). *How to administer intramuscular (IM) and how to administer subcutaneous (SC) injections*. Retrieved May 22, 2011, from <http://www.immunize.org/catg.d/p2020.pdf>

Intradermal (ID) administration deposits medication just under the epidermis. The forearm is the usual site for administration. ID administration is used primarily for tuberculosis screening and allergy testing. A 1-mL syringe with a 5/8-inch, 25- or 27-gauge needle is commonly used to administer the medication. Insert the needle, with the bevel up, beneath the skin at a 5- to 15-degree angle. Keep the fingers and thumb resting on the sides of the syringe to ensure the proper angle.

Intravenous Administration

Intravenous (IV) medication administration is commonly used with children, especially when a rapid response to a drug is desired or when absorption via other routes is difficult due to the child's illness or condition. In some cases, the IV route is the only effective method for administering a medication. Use of the IV route requires that the child have an IV device inserted, peripherally or centrally. Although insertion of this device is invasive and traumatic for the child, IV medication administration is considered to be less traumatic when compared to the trauma associated with multiple injections. Unfortunately, the veins of a child are small and easily irritated.

Most medications given by the IV route must be given at a specified rate and diluted properly to prevent overdose or toxicity due to the rapid onset of action that occurs with this route. Therefore, when administering medications via the IV route, knowledge of the drug, the amount of drug to be administered, the minimum dilution of the drug, the type of solution for dilution or infusion, the compatibility of various solutions and medications, the length of time for infusion, and the rate of infusion is required. Careful maintenance of the IV site is required to prevent complications.

The primary method for IV medication administration is a syringe pump. This method provides a highly precise rate of infusion. [Nursing Procedure 13.1](#) gives the steps for administering medication via a syringe pump.

If a pump is unavailable, the medication may be administered via a volume control device. The medication is added to the device with a specified amount of compatible fluid and then infused at the ordered rate.

Direct IV push medication typically is reserved for emergency situations and when therapeutic blood levels must be reached quickly to achieve the desired effect. Direct IV push administration requires that the drug be diluted appropriately and given at a specified rate, such as over 2 to 3 minutes. Care must be taken to prevent fluid overload, which may occur due to flushing needed to maintain IV patency and prevent drug incompatibilities, and from the administration of multiple drug therapies.

Providing Atraumatic Care

When administering any medication, including oral medications, use the principles of atraumatic care (see [Chapter 8](#) for more information). Children can experience stress and fear or upset when they must take medications. The child may become upset or stressed when he or she must be secured snugly or positioned to minimize movement. The child may experience further discomfort if the medication has an unpleasant taste or results in pain, such as with an injection.

NURSING PROCEDURE 13.1

Administering Medication via a Syringe Pump

Purpose: To provide accurate and safe administration of IV medication

1. Verify the medication order.
2. Gather the medication and necessary equipment and supplies.
3. Wash hands and put on gloves.
4. Attach the syringe pump tubing to the medication syringe and purge air from the tubing by gently filling the tubing with medication from the syringe.
5. Insert the syringe into the pump according to the manufacturer's directions.
6. Clean the appropriate port on the child's IV access device or tubing, flush the device or tubing if appropriate (e.g., an intermittent infusion device [saline lock or heparin lock]), and attach the syringe tubing to the IV tubing or device.
7. Set the infusion rate on the pump as ordered.
8. When the medication infusion is completed, flush the syringe pump tubing to deliver any medication remaining in the tubing, according to institution protocol.
9. Document the procedure and the child's response to it.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins.

Atraumatic Care

Encourage the child to participate in care and provide the child with developmentally appropriate options, such as which fluid to drink with the medication or which flavor of ice pop to suck on before or after the administration (see Table 13.1).

To decrease discomfort and pain for the child who is to receive an injection, apply a topical anesthetic such as EMLA (eutectic mixture of local anesthetic) cream or vapocoolant spray to the site before injection (Kroger et al., 2011) (see [Chapter 14](#) for additional information).

Ensuring that the child doesn't move is essential to prevent injury when administering an injection. When administering an injection to a young child, at least two adults should hold him or her; this may also be necessary to help an older child to remain still.

Atraumatic Care

Use positions that are comforting to the child, such as therapeutic hugging, during injections. Have the child sit on the caregiver's lap with the caregiver holding the child's arms and legs to his or her body. Refer to [Chapter 8, Figure 8.1](#). After administration, encourage the parents or caregivers to hold and cuddle the child and offer praise.

Educating the Child and Parents

Teaching the child and parents or caregivers about medication administration is key. Many medications are given in the home, making the parents or caregivers the persons responsible for administration. They need to know what medications they are giving and why, how to give them, and what to expect from the drug, including adverse effects. Caregivers and parents often incorrectly dose over-the-counter medications and prescription medications or fail to complete prescribed orders (Broselow, Luten, & Schuman, 2008a). Therefore, ensure thorough instruction, including frequency of administration, when the next dose is due, and length of time the medication is to be given. Emphasize the importance of completing the prescribed dose. Demonstrate use with an actual syringe if possible, encourage return demonstration of medication administration, advise against the use of home measuring devices (such as a spoon), and emphasize the importance of always using the calibrated dispensing device that was given with the medication. If the medication is to be given via injection, parents and caregivers need to learn how to administer the injection properly. Encourage questions or concerns from parents or caregivers. See [Evidence-Based Practice 13.1](#).

EVIDENCE-BASED PRACTICE 13.1

DOES A PICTOGRAM-BASED HEALTH LITERACY INTERVENTION DECREASE LIQUID MEDICATION ADMINISTRATION ERRORS BY CAREGIVERS OF YOUNG

CHILDREN?

Research suggests that caregivers of young children make frequent mistakes when administering medication at home, including improper dosing and not following medication regimens correctly. Need for liquid medications, availability of varying concentrations of pediatric medications, and variation in dosing instruments all can contribute to medication errors at home. Good communication from health care providers is essential in ensuring proper medication administration at home. Complex medication regimens; the use of different units of measure such as milliliters, teaspoons, and tablespoons; and communication issues can contribute to confusion of the caregiver and lead to errors in medication administration at home. Parents or caregivers with language barriers, low literacy levels, and low socioeconomic status appear to be at higher risk.

STUDY

A randomized controlled trial was performed at an urban public hospital pediatric emergency department. A randomized sample of parents and caregivers of children aged 30 days to 8 years, who were prescribed liquid medications, was divided into a group to receive the pictogram-based intervention and a group to receive standard care (the control group). The pictogram intervention consisted of education that used plain language, pictogram-based medication, and patient-specific instruction sheets in both English and Spanish. The instruction sheets included the medication name, indication, dose, dose frequency, length of treatment, preparation, and storage. A medication log was also included for the caregivers. Research staff also demonstrated dosing with a standardized instrument and parents then demonstrated back to the research staff how they would give the medication (referred to as “teach-back”). The pictogram instruction sheet and a standard dosing instrument were given to each caregiver in the intervention group to take home. The intervention took 1.5 to 3 minutes to complete. More information about the specific intervention can be obtained at <http://helpix.med.nyu.edu/> (NYU Langone Medical Center, 2009). The parents or caregivers were assessed before the intervention and then by phone or in person, 1 day after for daily dose medication and 3 to 5 days after for as-needed medications, after the emergency room visit.

Findings

The pictogram intervention significantly improved caregiver dosing accuracy and adherence to medication. Increased knowledge of dosing frequency was higher in the intervention group regarding daily dose medication. Correct medication preparation, such as to shake or not, was also higher in the intervention group. The intervention group was significantly more likely to use a standardized dosing instrument compared to the control group.

Nursing Implications

Nurses should consider the use of pictogram instruction sheets when discharging a child with home medications, especially if medication instructions are complex or the caregiver has a language barrier or low literacy levels. Nurses should demonstrate how to give home medications and utilize the method of teachback in order to improve caregiver dosing accuracy at home. Nurses should ensure caregivers are given a standardized dosing instrument to use at home to administer medications.

Adapted from Yin, H. S., Dreyer, B. P., van Schaick, L., Foltin, G. L., Dinglas, C., & Mendelsohn, A. L. (2008). Randomized controlled trial of a pictogram-based intervention to reduce liquid medication dosing errors and improve adherence among caregivers of young children. *Archives of Pediatrics and Adolescent Medicine*, 162(9), 814-822.

Parents and caregivers commonly need suggestions about the best ways to administer the medication to their child. Provide them with tips for administration, such as mixing unpleasant-tasting medications with applesauce or yogurt or offering a favorite liquid as a chaser. Also teach the parents how to properly measure the amount of drug to be given. [Teaching Guidelines 13.2](#) gives pointers about oral medication administration. Refer to [Chapter 8](#) for further information on teaching children and families about medication administration.

Teaching Guidelines 13.2

ADMINISTERING ORAL MEDICATIONS

- Be firm when telling your child that it is time for his or her medication. State, “It’s time for your medicine” instead of asking, “Will you take your medicine?” or “Can you take your medicine for me?”
- Allow your child to choose an appropriate liquid to help swallow the medication or drink after taking it. Limit the choices to two

or three.

- Never bribe or threaten your child to take his or her medication.
- Never refer to the medication as “candy.”
- Be honest about the taste of the medication. If necessary, mix it with another food such as applesauce, yogurt, or syrup to help mask the taste.
- Do not mix the medication with formula or baby food.
- Always check with your physician or nurse practitioner and pharmacy about opening capsules or crushing tablets and mixing them with food. Some medications should not be opened or crushed.
- If you are giving a liquid using an oral syringe or dropper, place the medication slowly along the inside of the cheek. Never squirt the medication forcibly to the back of the child’s throat. It may cause the child to gag and spit out the medication or aspirate it into his or her lungs.
- Always praise the child after taking the medication and provide comfort and cuddling.

Preventing Medication Errors

The incidence of potentially harmful medication errors may be three times as high in pediatrics compared to adults (The Joint Commission, 2008). This can be related to weight-based dosing calculations, fractional dosing, and the need for the use of decimal points. Children are also more susceptible because many drugs used in pediatrics are formulated and packaged for adults and lack U.S. Food and Drug Administration (FDA) approval and dosing guidelines for children. Children, especially the very young, are less able to physiologically tolerate medication errors and are often unable to communicate if an adverse reaction is occurring (The Joint Commission, 2008).

The need for safety takes on even greater importance due to the physiologic, psychological, and cognitive differences inherent in children. Confirming the child’s identity and double-checking the dosage before administration of any medication are two critical safeguards that play a major role in preventing medication errors. Other ways to prevent medication errors include the following:

- Confirm the children’s weight is accurate.
- Always weigh children in kilograms.
- Double-check medication calculations; utilize another health care provider when possible, especially for high-risk medications.
- If a dose seems unusually small or large, verify the order.
- Utilize medication ordering and dispensing systems if available.
- Always report medication errors or near-miss errors to help prevent future mistakes.
- Utilize the Joint Commission’s official “Do Not Use” list (link to this list is provided on http://www.jointcommission.org/assets/1/18/Official_Do_Not_Use_List_6_111.PDF).

Take Note!

If a parent, caregiver, or child questions whether a medication should be given, listen attentively, answer their questions, and double-check the order.

INTRAVENOUS THERAPY

IV access provides a route for the administration of medications and fluids. It is commonly used for children because it is the quickest, and often the most effective, method of administration. As with adults, numerous sites and various devices and equipment may be used to provide IV therapy over a short or long period of time. When administering IV therapy, safety is crucial. The nurse must have a solid knowledge base about the fluids or medications to be given as well as a thorough understanding of the child's physical and emotional development. Venipuncture can be a terrifying and painful experience for children and their families. Nurses play a crucial role in providing support and education to the child and family before, during, and after the procedure (refer to [Chapter 8](#) for additional information related to provision of atraumatic care with procedures).

Sites

IV therapy may be administered via a peripheral vein or a central vein. Peripheral IV therapy sites commonly include the hands, feet, and forearms ([Fig. 13.8](#)). In neonates and young infants, the scalp veins may be used (O'Grady et al., 2011). The scalp veins are easily visualized, being covered only by a thin layer of subcutaneous tissue. These veins do not have valves, so the device may be inserted in either direction, although the preference would be in the direction of blood flow. However, use of a scalp vein requires that that area of the infant's head be cleared of hair to enhance visualization. In addition, use of the scalp veins can be frightening to parents, who may think the fluid is infusing into the infant's brain. Thus, scalp veins are usually used only if attempts at other sites have been unsuccessful (Bergvall & Sawyer, 2009). When used, ensure appropriate education of the parents prior to insertion and, if shaving the child's hair is needed, inquire if parents would like to keep the child's hair.

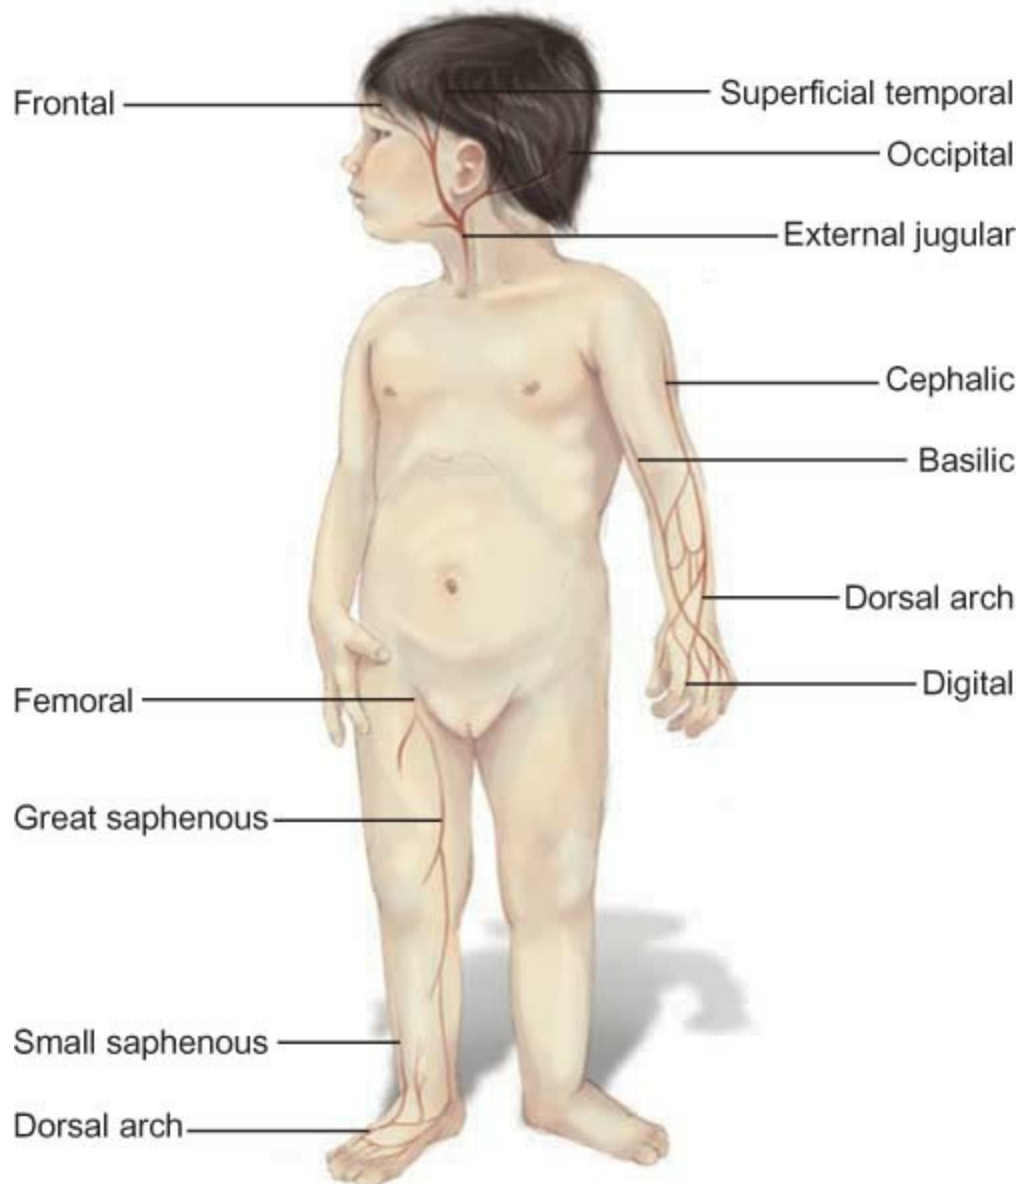

FIGURE 13.8 Preferred peripheral sites for intravenous insertion.

Take Note!

When selecting an IV site in an extremity, always choose the most distal site. Doing so prevents injury to the veins superior to the site and allows additional access sites should complications develop in the most distal site.

Central IV therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or the vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. The device is inserted surgically or percutaneously and exits the body typically in the chest area, just below the clavicle. A device can be inserted via a peripheral vein, such as the median, cephalic, or basilic vein, and then threaded into the superior vena cava.

Equipment

The choice of equipment is determined by the solution or medication to be administered, the duration of the therapy, the age and developmental level of the child, the child's status, and the condition of his or her veins. Various types of IV devices are commercially available. In addition, different types of tubing and infusion control devices may be necessary.

Peripheral Access Devices

Devices used for peripheral venous access in a child include over-the-needle catheters or winged-infusion sets, commonly referred to as “butterflies” or scalp vein needles. These devices are inserted into the vein and then connected to the IV solution via tubing to provide a continuous infusion of fluid. These devices can also be inserted for intermittent use if the child does not require a continuous fluid infusion. Typically, the hub of the device is capped or plugged to allow intermittent access, such as for administering medications or obtaining blood specimens. When used in this manner, these devices are termed peripheral intermittent infusion devices or saline or heparin locks.

Needle size on the device also varies. Typically, the needle ranges from 21 to 25 gauge, depending on the child's size. The rule of thumb is to use the smallest-gauge catheter with the shortest length possible to prevent traumatizing the child's fragile veins. Typically, peripheral IV devices are used for short-term therapy, usually averaging 3 to 5 days (O'Grady et al., 2011). Midline catheters are also available, and the CDC recommends the use of midline catheters if therapy is to exceed 6 days (O'Grady et al., 2011). These catheters are longer than peripheral catheters and can stay in for 2 to 4 weeks (Cook, 2007; Moureau, Bagnall-Trick, Nichols, & Moureau, 2007). They are seated deep in the cephalic or basilic veins, but the tip does not extend past the axilla.

Central Access Devices

Numerous devices for central venous access are available. The type chosen depends on several factors, including the duration of the therapy, the child's diagnosis, the risks to the child from insertion, and the ability of the child and family to care for the device. The device may have one or multiple lumens. Although central venous access devices can be used short term, the majority are used for moderate- to long-term therapy.

Central venous access devices are indicated when the child lacks suitable peripheral access, requires IV fluid or medication for more than 3 to 5 days, or is to receive specific treatments, such as the administration of highly concentrated solutions or irritating drugs that require rapid dilution (Cook, 2007; Moureau et al., 2007). Child preference is also a consideration. Central venous access is advantageous because it provides vascular access without the need for multiple IV starts, thus decreasing discomfort and fear. However, central venous access devices are associated with complications such as infection at the site, sepsis due to the direct access to the central circulation, and thrombosis due to partial occlusion of the vessel. Typically, a chest radiograph is performed after a central venous access device is inserted to verify proper placement. No fluids are administered until correct placement is confirmed. [Table 13.3](#) describes the major types of central venous access devices.

Infusion Control Devices

Infants and young children are at increased risk for fluid volume overload compared with adults. Also, malfunction at the IV insertion site, such as infiltration, may result in much greater injury than a similar incident would cause in an adult. Therefore, IV fluids must be carefully administered and monitored. To ensure accurate fluid administration, infusion control devices such as infusion pumps, syringe pumps, and volume control sets may be used.

Infusion pumps used for children are similar to those used for adults. Typically, the IV solution bag is attached to a calibrated volume control set that has been filled with a specified amount of IV solution ([Fig. 13.9](#)). The fluid chamber holds a maximum of 100 to 150 mL of fluid that can be infused over a specified period of time as ordered. Usually, a maximum of a 2-hour infusion amount in

the chamber avoids accidental fluid overload in the pediatric population. This chamber can be filled every 1 to 2 hours so only small amounts of ordered quantities of fluid can infuse and the child is protected from receiving too much fluid volume. In addition, syringe pumps may be used to deliver fluid and medications to children. These pumps can be programmed to deliver minute amounts of fluid over controlled periods of time (see discussion on p. 388 for additional information about syringe pumps).

| Device | Description |
|--|--|
| Nontunneled central venous catheter (CVC) | Usually used short term One or more lumens Surgical or percutaneous insertion most commonly via the subclavian, internal jugular, or femoral vein with the tip of the catheter at the top of the superior vena cava just above the right atrium Useful for emergency situations Catheter sutured in place at the exit site |
| Peripherally inserted central catheter (PICC) | Short- to moderate-term therapy Insertion via a peripheral vein such as antecubital, basilic, cephalic, or medial antecubital vein Catheter typically threaded into superior vena cava; distal tip terminates in the superior vena cava, inferior vena cava, or proximal right atrium. Insertion via saphenous vein with tip terminating in inferior vena cava above the diaphragm for infants Single or multiple lumens PICC insertion requires additional training and advanced skill. |
| Tunneled central venous catheter (e.g., Groshong, Hickman/Broviac) | Usually for long-term use Catheter inserted by a physician via small incision in jugular or subclavian vein and tunneled in the subcutaneous tissue under the skin Initially sutured in place to stabilize position; sutures removed after approximately 1 to 2 weeks when cuff on catheter attaches to subcutaneous tissue Single or multiple lumens Some have valves that prevent backflow of blood and air entrance. |
| Implanted ports (e.g., Port-a-Cath, Infus-a-Port, Mediport) | Surgically inserted by a physician Stainless steel port with a polyurethane or silicone catheter attached Catheter tip lying in subclavian or jugular vein; port implanted under skin in a subcutaneous pocket, usually on the upper chest wall Port covered completely by skin and visible only as a slight bulging on the chest; possibly more appealing to the older child and adolescent because there are no visible parts or dressings Access to port via a specially angled, noncoring needle (Huber needle) Site preparation and pain relief measures necessary before accessing the port |

Adapted from Cook, L. S. (2007). Choosing the right intravascular catheter. *Home Healthcare Nurse, 25*(8), 523–531, and Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins.

Inserting Peripheral IV Access Devices

Peripheral IV devices are used for most IV therapies. Prior to insertion, review the child’s diagnosis and medical history for information that may affect therapy, such as site selection or insertion. For example, a child who has a history of chronic illness may have heightened fears and anxieties related to insertion due to his or her previous experiences or difficulty in accessing IV sites. Typically, the nondominant extremity should be used for insertion, but this may not be possible in certain situations, such as if a right-handed child has a cast on his left arm.

Check the orders for the prescribed therapy. Determine the purpose and length of the IV therapy and the type of fluid or medication that is to be administered. This information aids in selecting the best device and insertion site. For example, the device needs to be of an adequate gauge to allow the solution or medication to infuse into the vein while at the same time allowing enough blood flow around the device to promote dilution of the infusion.

Establish rapport with the child and parents. Inform them about IV therapy and what to expect. Be honest with the child. Explain that the venipuncture will hurt but only for a short time. Provide the child with a time frame that he or she can understand, such as the time it takes to brush his or her teeth or eat a snack.

FIGURE 13.9 Volume control infusion device.

Atraumatic Care

Use therapeutic play to assist the child in preparation and coping for the procedure (see Chapter 11 for more information).

Insertion of an IV therapy device is traumatic. Follow the principles of atraumatic care, including the following:

- Gather all equipment needed before approaching the child.
- If possible, select a site using hand veins rather than wrist or upper arm veins to reduce the risk of phlebitis. Avoid using lower extremity veins and areas of joint flexion if possible because these are associated with an increased risk of thrombophlebitis and other complications (Alexander, Corrigan, Gorski, Hankins, & Perucca, 2010; Cook, 2007).
- Ensure adequate pain relief using pharmacologic and nonpharmacologic methods prior to insertion of the device (see Chapter 14 for more information about management of pain related to procedures).
- Allow the antiseptic used to prepare the site to dry completely before attempting insertion.
- Use a barrier such as gauze or a washcloth or the sleeve of the child's gown under the tourniquet to avoid pinching or damaging the skin.
- If the child's veins are difficult to locate, use a device to transilluminate the vein (utilizes a bright light, which illuminates the vein's size and direction of travel).
- Make only two attempts to gain access; if you are unsuccessful after two attempts, allow another individual two attempts to access a site. If still unsuccessful, evaluate the need for insertion of another device.

Take Note!

Some facilities have policies in place allowing only one stick per nurse with a maximum of two sticks; then the doctor needs to be notified unless the situation is an emergency.

- Encourage parental participation as appropriate in helping to position the child or to provide comfort positioning, such as therapeutic hugging.
- Coordinate care with other departments such as the laboratory for blood specimen collection to minimize the number of venipunctures for the child.
- Secure the IV line using a minimal amount of tape or transparent dressing.
- Protect the site from bumping by using a security device such as the IV house dressing (see Fig. 13.10).

IV Fluid Administration

Administering IV fluids to an infant or child requires close attention to the child’s fluid status. Typically, the amount of fluid to be administered in a day (24 hours) is determined by the child’s weight (in kilograms) using the following formula:

100 mL per kg of body weight for the first 10 kg

50 mL per kg of body weight for the next 10 kg

20 mL per kg of body weight for the remainder of body weight in kilograms

| TABLE 13.4 INTRAVENOUS MAINTENANCE FLUID CALCULATIONS BY BODY WEIGHT | |
|--|--|
| <10 kg in weight | 100 mL per kg of weight = # mL for 24 hours Example: A child weighs 7.4 kg. $7.4 \times 100 = 740$ mL (daily requirement) $740/24 = 30.8$ or 31 mL/hour |
| 11–20 kg in weight | 100 mL per kg of weight for the first 10 kg + 50 mL/kg for the next 10 kg = # mL for 24 hours Example: A child weighs 16 kg. $(10 \times 100 = 1,000)$ plus $(6 \times 50 = 300)$ Total = 1,300 mL (daily requirement) $1,300/24 = 54$ mL/hour |
| >20 kg in weight | 100 mL/kg for the first 10 kg + 50 mL/kg for the next 10 kg + 20 mL/kg for each kg > 20 kg = # mL for 24 hours Example: A child weighs 30 kg. $(10 \times 100 = 1,000)$ plus $(10 \times 50 = 500)$ plus $(10 \times 20 = 200)$ Total = 1,700 mL (daily requirement) $1,700/24 = 70.8$ or 71 mL/hr |

Table 13.4 gives examples of calculating a child’s fluid requirements using body weight. Once the 24-hour total fluid requirement is determined, this amount is divided by 24 hours to arrive at the correct hourly rate of infusion.

Maintaining IV Fluid Therapy

Throughout the course of therapy, monitor the fluid infusion rate and volume closely, as often as every hour. If a volume control set is used to administer the IV infusion, fill the device with the allotted amount of fluid that the child is to receive in 1 hour. Doing so prevents inadvertent administration of too much fluid. Never assume that just because an infusion pump is in use, the infusion is being administered without problems. Pumps can malfunction. The tubing can become blocked, or the IV device can move out of the vein lumen. Not enough fluid, fluid overload, or infiltration of the solution into the tissues can occur.

In addition to monitoring the fluid infusion, closely monitor the child’s output. Expected urine output for children and adolescents is 1.0 to 2.0 mL/kg/hour.

Take Note!

When measuring the output of an infant or child who is not toilet trained or who is incontinent, weigh the diaper to determine the output. Remember that 1 gram of weight is equal to 1 mL of fluid.

Flushing the IV line when the device is used intermittently may be necessary to maintain patency, such as before and/or after medication is administered and after obtaining blood specimens. However, there is much debate as to how often flushing should be done and the best flush solution to use, heparin or saline (Hepzibha, 2010; Pryce, 2009; Tripathi, Kaushik, & Singh, 2008). Saline

has been found to be more compatible with the numerous solutions and medications administered intravenously, and is less expensive and less irritating to the vein. In addition, using saline lessens the incidence of pain and phlebitis. Heparin is expensive and incompatible with numerous medications and solutions, and it can affect clotting time, depending on the concentration of the flush solution used. Evidence appears to support the use of normal saline flush with catheters larger than 22 gauge, but more studies are needed to determine the effectiveness of normal saline flushes with catheters smaller than 22 gauge (Alexander et al., 2010). Additional research is also needed to determine the volume and concentration of the flush solution and interval for flushing. Always follow your agency's policy for flushing IV lines.

If the child is receiving IV therapy via a central venous access device, provide site care using sterile technique and flush the device according to agency policy. Note the exit site for the device and inspect it frequently for signs of infection. If the device has multiple lumens, label each lumen with its use (i.e., blood specimen, medication, or fluid). Always check the compatibilities of solutions and medications being given simultaneously.

Take Note!

When flushing or administering medications through a peripherally inserted central catheter (PICC) line, follow the manufacturer's recommended syringe size, because PICC lines are fragile. Using a larger-volume syringe (i.e., 5 mL or larger) exerts less pressure on the PICC, thereby reducing the risk of complications (Bowden & Greenberg, 2008).

Preventing Complications

IV therapy is an invasive procedure that is associated with numerous complications. Strict aseptic technique is necessary when inserting the device and caring for the site. Adherence to standard precautions is key. Inspect the insertion site every 1 to 2 hours for inflammation or **infiltration** (inadvertent infusion of a nonirritant solution or medication into the surrounding tissue). Note signs of inflammation such as warmth, redness, induration, or tender skin. Check closely for signs of infiltration such as cool, blanched, or puffy skin. Use of a transparent dressing or IV house dressing provides easy access for assessing the IV insertion site. These types of dressings also help to prevent movement of the catheter hub, thus minimizing the risk of mechanical irritation, dislodgement, and complications such as phlebitis or infection (see [Fig. 13.10](#)).

Typically in adults, an IV site is changed every 72 to 96 hours and at any time when the integrity of the system has been compromised or contamination is suspected (O'Grady et al., 2011). However, with children, the 72- to 96-hour time frame may need to be adjusted to minimize the child's exposure to the repeated trauma of insertion. Current recommendations include replacement in children only when clinically indicated (O'Grady et al., 2011). Follow the agency's policies and procedures related to site changes. Consider an alternative route for fluid and medication administration or the insertion of an alternative IV device, such as a PICC line. Catheter-related bloodstream infections often can occur with the use of central venous lines. These infections result in increased morbidity and health care costs (O'Grady et al., 2011). Prevention is paramount. Nurses need to practice proper hand hygiene, use maximal barrier protection during insertion, assess the site frequently, provide proper site care using strict sterile technique, and ensure the child's central venous catheter is removed as soon as it is no longer needed. In children it is important also to prevent the child from touching and playing with the central venous line site or dressing. Replace administration sets per agency policy.

FIGURE 13.10 (A) Intravenous (IV) house over the IV site on a child's hand. (B) IV house over the site on an infant's foot.

Administration sets or IV tubing should be changed at least every 96 hours (other than those used for blood, blood products, and lipids) (National Guideline Clearinghouse, 2008). Ensure proper disinfecting of all catheter hubs, needleless connectors, and injection ports prior to accessing them to minimize contamination.

Take Note!

Chlorhexidine-impregnated sponge (Biopatch) dressings may be used to help prevent infection in children older than 2 months of age (O'Grady et al., 2011). Always follow agency or institution policy and procedures regarding site care.

Discontinuing the IV Device

Prepare the child for removal of the IV device in much the same manner as for insertion. Many children may fear the removal of the device to the same extent that they feared its insertion. Explain what is to occur and enlist the child's help in the removal.

Atraumatic Care

If appropriate, allow the child to assist in removing the tape or dressing. This gives the child a sense of control over the situation and also encourages his or her cooperation.

In addition, practice atraumatic care by doing the following:

- Use water or adhesive remover to help loosen the tape.
- If a transparent dressing is in place, gently lift off the dressing by pulling up opposite corners using a motion parallel to the skin surface.
- Avoid using scissors to cut the tape, but if cutting the tape is necessary, be sure that the child's fingers are clear of the tape and scissors.
- Turn off the infusion solution and pump.
- Once all tape and dressings are removed, gently slide the IV device out using a motion opposite to that used for the insertion.
- Apply pressure to the site with a dry gauze dressing and then cover with a small adhesive bandage. If possible, allow the child to choose the bandage.

Take Note!

If the IV site was in the arm at or near the antecubital space, do not have the child bend his or her arm after removal of the device. Doing so increases the risk of hematoma formation (Johnson, 2007).

PROVIDING NUTRITIONAL SUPPORT

Adequate nutrition is important for all individuals but especially for children. During the growing years the quality of a child's nutrition affects his or her overall health and development. The presence of a chronic illness, disease, or trauma can increase the child's nutritional demands; if the child cannot meet these even with oral supplementation, other measures may be necessary to provide nutritional support. Such measures may include **enteral nutrition** (delivery of nutrition into the gastrointestinal tract via a tube) and **par enteral nutrition** (IV delivery of nutritional substances). The nutritional plan is determined by the child's age, developmental level, and health status.

Enteral Nutrition

Enteral nutrition, commonly called tube feedings, involves the insertion of a tube so that feedings can be delivered directly into the child's gastrointestinal tract. The tube may be inserted via the nose or mouth or through an opening in the abdominal area, with the tube ending in the stomach or small intestine. Nasogastric or orogastric through tube feedings, a tube from the nose to the stomach or from the mouth to the stomach, respectively, are commonly referred to as **gavage feedings**. Nasoduodenal or nasojejunal feedings involve a tube that is inserted through the nose and ends in either the duodenum or jejunum. Gastrostomy feedings involve the insertion of a gastrostomy tube through an opening in the abdominal wall and into the stomach. Jejunostomy feedings are similar to gastrostomy feedings except that the tube lies in the jejunum.

Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot ingest enough nutrients orally. The child may be unconscious or have a severely debilitating condition that interferes with his or her ability to consume adequate food and fluids. Other conditions that may warrant the use of enteral nutrition include:

- Failure to thrive
- Inability to suck or tiring easily during sucking
- Abnormalities of the throat or esophagus
- Swallowing difficulties or risk for aspiration
- Respiratory distress
- Metabolic conditions
- Severe gastroesophageal reflux disease (GERD) Surgery
- Severe trauma

Enteral feedings may be given via nasogastric, orogastric, nasojejunal, nasoduodenal, gastrostomy, or jejunostomy tubes ([Fig. 13.11](#)). [Table 13.5](#) provides additional information about these types of feeding tubes. Enteral feedings costs less, are associated with fewer complications, and are considered safer than parenteral feedings. However, tube misplacement is a serious complication.

FIGURE 13.11 (A) Gastrostomy tube. (B) Low-profile (button) gastrostomy tube. The filled balloon keeps the tube in place inside the stomach.

Take Note!

Small-diameter feeding tubes, though more comfortable, may easily become dislodged if the child coughs vigorously or vomits (Bowden & Greenberg, 2008; Florida State Hospital, 2009).

Inserting a Nasogastric or Orogastric Feeding Tube

Tubes for gavage feeding can be inserted via the nose or mouth. For infants, who are obligate nose breathers, insertion via the mouth may be appropriate. Oral insertion also promotes sucking in the infant. For the older child, nasal insertion is usually the preferred method. If the tube is to remain in place, the nose also is considered to be more comfortable. [Nursing Procedure 13.2](#) gives the steps for inserting a gavage feeding tube.

DETERMINING TUBING LENGTH FOR INSERTION

Traditionally, morphologic methods, measuring from the nose to ear to midxiphoid to umbilicus or just nose to ear to midxiphoid, have been used to determine tube length for insertion. Recent research has shown that this way of measurement frequently underestimates the tube length (Cincinnati Children's Hospital Medical Center, 2009a). Improving the accuracy of predicting tube length will lead to an increase in successful nasogastric tube placements, and therefore improved outcomes and decreased health care costs.

TABLE 13.5

TYPES OF ENTERAL FEEDING TUBES

| Type of Tube | Indication | Nursing Implications |
|--|---|---|
| Nasogastric (inserted via the nose into the stomach) Orogastric (inserted via the mouth into the stomach) | Short-term enteral feeding Orogastric usually limited to young infants only | <ul style="list-style-type: none"> • Long-term use or repeated insertion causes irritation and discomfort. • Silicone and polyurethane tubes are very flexible and more comfortable; they require a stylet or guidewire for insertion. • Length of long-term use varies according to the type of tube used and the institution protocol. Periodically a nasogastric tube is removed and reinserted via the opposite nostril to prevent pressure on the nasal mucosa. • Maintaining orogastric placement between feedings can be difficult due to oral secretions. |
| Nasoduodenal (inserted via the nose to the duodenum) or nasojejunal (inserted via the nose to the jejunum) | Short-term enteral feeding. Indicated if child has trouble digesting food, cannot use his or her gastrointestinal tract secondary to congenital anomalies or surgery, or is at risk for or has a history of severe reflux or aspiration | <ul style="list-style-type: none"> • Silicone and polyurethane tubes with weighted tip allow tube to pass from pylorus into small intestines. • Agency may require special training in order to place at bedside; may also be performed in radiology • Length of use same as nasogastric or orogastric tubes |
| Gastrostomy (surgically inserted through the abdominal wall into the stomach) Jejunostomy (surgically inserted through the abdominal wall into the jejunum) | Long-term enteral feeding or when esophageal atresia or stricture is present Jejunostomy tubes are indicated when gastric feeding is not tolerated. | <ul style="list-style-type: none"> • The inner section of the tube is below the skin surface with the tip located in the stomach or jejunum (may be balloon, winged, or mushroom shaped). The outer section appears above the skin surface at the insertion site and has an opening or feeding port to which the feeding solution is attached. • Low-profile gastrostomy device (gastrostomy button) is flush with the abdominal surface. The flip-top opening is anchored by a dome that fits against the stomach wall. Less conspicuous, it allows the child to be more active and mobile. • After initial insertion, the tube length is measured from the insertion site to the far end of the tube and recorded. This measurement is checked at least daily to ensure that the tube has not moved. • There are many different devices available. For any gastrostomy or jejunostomy tube, the type and size of tube inserted as well as the amount required to fill the balloon if present should be known. |

According to the Agency for Healthcare Research and Quality's National Guideline Clearinghouse (2009), determining tubing length for insertion of a nasogastric tube using age-related height-based methods versus the traditional morphologic, nose-ear-midxiphoid-umbilicus method is more accurate for children younger than 8 years 4 months, but not including neonates:

- In children between ages 2 weeks and 28 months tube insertion length is determined by $17.6 + 0.197(\text{height in centimeters})$.
- In children between ages 28 months and 8 years 4 months tube insertion length is determined by $21.1 + 0.197(\text{height in centimeters})$ (National Guideline Clearinghouse, 2009).

Continue to use traditional morphologic methods in neonates, children older than 8 years 4 months, and children with short stature, or if unable to obtain an accurate height (National Guideline Clearinghouse, 2009).

NURSING PROCEDURE 13.2

Inserting a Gavage Feeding Tube

Purpose: To provide a means for delivering nutrition to the child's functioning gastrointestinal tract

1. Verify the order for gavage feeding.
2. Explain the procedure to the child and parents using appropriate language geared to the child's development level.
3. Gather the necessary equipment; remove formula for feeding from refrigerator if appropriate and allow it to come to room temperature.
4. Wash hands and put on gloves.
5. Inspect the child's nose and mouth for deformities that may interfere with passage of the tube.
6. Position the infant supine with the head slightly elevated and with the neck slightly hyperextended so that the nose is pointed

upward. If necessary, place a rolled towel or blanket under the neck to help in maintaining this position. Assist the older child to a sitting position if appropriate. Alternatively, have the parent or another person hold the child to promote comfort and reassurance. Enlist the aid of additional persons, such as a parent or other health care team member, to assist in maintaining the child's position.

7. Determine the tubing length for insertion: measure from the tip of the nose to the earlobe to the middle of the area between the xiphoid process and umbilicus. Also refer to [p. 395](#). Mark this measurement on the tube with an indelible pen or with a piece of tape.

8. Lubricate the tube with a generous amount of sterile water (many small-bore feeding tubes have a water-activated lubricant) or water-soluble lubricant to promote passage of the tube and minimize trauma to the child's mucosa.
9. Insert the tube into one of the nares or the mouth. Direct a nasally inserted tube straight back toward the occiput; direct an orally inserted tube toward the back of the throat.
10. Advance the tube slowly to the designated length; encourage the child (if capable) to swallow frequently to assist with advancing the tube.
11. Watch for signs of distress, such as gasping, coughing, or cyanosis, indicating that the tube is in the airway. If these signs develop, withdraw the tube and allow the child to rest before attempting reinsertion.
12. Temporarily secure tube, remove stylet if applicable, and check for proper placement of the tube. Refer to [Box 13.4](#).
13. Document the type of tube inserted; length of tubing inserted; measurement of external tubing length, from nares to end of tube, after insertion; and confirmation of placement.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins.

CHECKING TUBE PLACEMENT

Once the gavage feeding tube is inserted, checking for placement is essential. Tube placement must be confirmed each time the tube is inserted and before each use. Radiologic confirmation of tube placement is considered the most accurate method, but the risks associated with repeated radiation exposure, high costs, and the impractical nature of obtaining a radiograph before feeding tube use make it unrealistic. Several methods have been proposed as reliable for checking tube placement, but no single method has been shown to be consistently accurate for continually assessing tube placement.

Take Note!

Instilling air into the tube and then auscultating for the sound is no longer considered a viable method for checking tube placement. Air instilled into a tube that is positioned above the gastroesophageal sphincter can still be auscultated as air in the stomach, thereby giving a false-positive result. Gastric auscultation alone results in a 60% to 80% reliability. When using both aspirate and nonaspirate verification methods (refer to [Box 13.4](#)), accuracy increases to 97% to 99% (National Guideline Clearinghouse, 2009).

Research has suggested using measurements of bilirubin, trypsin, and pepsin levels and CO₂ monitoring to enhance assessment of tube placement, but no methods are available for bedside testing of these levels.

Refer to [Box 13.4](#) for methods to verify feeding tube placement. However, keep in mind that even with these methods, tube malpositioning can occur. Therefore, nurses need to be vigilant in checking for tube placement using the recommended methods and be cautious and proactive if there is any suspicion that the tube may be misplaced.

Take Note!

If bedside methods are conflicting or the child is high risk, such as children with swallowing problems, children with altered levels of consciousness, or children in the intensive care unit, radiologic verification is recommended (National Guideline Clearinghouse, 2009).

If the gavage feeding tube is to remain in place, secure it to the child's cheek. Do not tape the tube to the child's forehead, because this could lead to irritation and pressure on, and possible breakdown of, the nasal mucosa. Also measure the length of the tube extending from the nose or mouth to the end and record this information. Double-check this measurement before administering each intermittent tube feeding to verify that the feeding tube is in the proper position. Once the position of the gavage feeding tube is confirmed, the feeding solution or medication can be administered.

Remember Lily, the 9-month-old infant diagnosed with failure to thrive who is to receive gavage feedings with a nasogastric tube? What equipment will be needed, and what steps will you take to complete the procedure?

Administering Enteral Feedings

Enteral feedings can be given continuously or intermittently, regardless of the type of tube used. Intermittent feedings are commonly called **bolus feedings**. With a bolus feeding, a specified amount of feeding solution is given at specific intervals, usually over a short period of time such as 15 to 30 minutes. Given via a syringe, feeding bag, or infusion pump, bolus feedings most closely resemble regular meals. Continuous feedings are given at a slower rate over a longer period of time. In some cases, the feeding may be given during the night so that the child can be free to move about and participate in activities during the day. For continuous feedings, an enteral feeding pump is used to administer the solution at a prescribed rate.

Checking for tube placement is a priority before administering any intermittent tube feeding and periodically during continuous tube feedings, regardless of the type of tube being used. (Refer to [Box 13.4](#).) For gastrostomy and jejunostomy tubes, ensure that the calibration, if present, has not changed. Measure the length of the tube daily from the exit site on the stomach to the end of the tube. Assess the abdomen for distension and bowel sounds (Springhouse, 2007). Also, measure the gastric **residual** (the amount remaining in the stomach; indicates gastric emptying time) by aspirating the gastric contents with a syringe, measuring it, and then replacing the contents. Check the residuals periodically, according to the facility's policy, such as every 4 to 6 hours, and before each intermittent feeding. If the residual volume exceeds the amount specified by the physician's order, hold the feeding and notify the physician or nurse practitioner.

Begin the feeding by placing the child in a supine position with the head and shoulders elevated approximately 30 degrees so that the feeding will remain in the stomach area (Springhouse, 2007). Flush the tube with a small amount of water to clear it and prevent occlusion. This is not necessary for a gavage feeding if the tube is being inserted each time a feeding is given. Ensure that the feeding solution is at room temperature. Administer the feeding per the facility's policy.

Feeding solutions may be placed into the barrel of a syringe or into a feeding bag attached to the feeding tube and allowed to flow by gravity. The rate of flow for gravity-assisted feedings can be increased or decreased by raising or lowering the feeding solution container, respectively. Typically, intermittent feedings last from 15 to 30 minutes. A feeding bag also may be attached to a pump to control the rate of flow. Monitor the child's tolerance to the feeding.

BOX 13.4

METHODS FOR VERIFICATION OF FEEDING TUBE PLACEMENT

- Obtain radiographic confirmation of proper tube placement after initial placement.
- After initial confirmation, document pH of aspirate; document insertion distance and external length of tube in the chart. Mark and document the tube's exit site from the nose or mouth.
- Use bedside techniques at regular intervals to determine proper tube positioning.
 - Measuring pH
 - Gastric secretions have a pH less than 5. Small intestine secretions will usually have a pH greater than 6, but this does not reliably predict proper tube placement. A pH greater than 6 can occur with respiratory or esophageal placement, with proper tube placement (gastric or intestinal) when feedings are given continuously, or if the child is receiving acid-inhibiting medications. Therefore, if the pH is greater than 5, additional assessment is warranted.
 - Observing appearance of fluid aspirated from tube
 - Gastric secretions are usually grassy green or clear and colorless and can have off-white or tan mucous shreds. It may also be brown tinged if blood is present.
 - Intestinal secretions are often bile stained, light golden yellow to brownish green. They tend to be thicker and more translucent than gastric secretions.
 - Respiratory secretions can be white, yellow, straw colored, or clear.
 - Instill air into the tube and then auscultate for the sound (gastric auscultation).
 - Check external markings on tube and external tube length (tube remaining from nares to end of tube) to determine if the tube seems to have migrated or been misplaced.
- Continually assess for signs indicative of feeding tube misplacement, such as unexplained gagging, vomiting, or coughing; signs and symptoms of respiratory distress; and decreased oxygen saturations.
- If bedside techniques reveal conflicting results or the child is high risk, radiologic confirmation is recommended.
- Review routine chest and abdominal radiographs (if obtained) to double-check correct tube position.

Always follow agencies' policy and procedures.

Once the feeding is complete, but before the formula completely empties from the container, flush the tube with water. As the water leaves the syringe or tubing, clamp the tube to prevent air from entering the stomach. Then disconnect the syringe or tube-feeding bag from the tube.

Take Note!

If the child vomits during the feeding, stop the feeding immediately and turn the child onto his or her side or sit him or her up.

If the child has a gastrostomy button, open the cap and connect an adaptor or insert extension tubing through the one-way valve. This allows access to the gastric conduit. The feeding solution container is connected to the extension tubing or adaptor and the feeding is given as described previously. After the feeding is completed, the extension tubing or adaptor is flushed with water and the flip-top opening is closed.

Burp the infant during and after any type of tube feeding in the same manner as for an infant who is bottle- or breast-fed. Also, position the child on his or her right side with the head slightly elevated, approximately 30 degrees, for about 1 hour after the feeding to facilitate gastric emptying and reduce the risk of aspiration and regurgitation. Some children have a difficult time with gas and burping on their own after tube placement. Venting, which helps relieve gas, may be ordered by the physician or nurse practitioner. It removes excess air and can be helpful if the child is bloated or the abdomen is distended. Use a catheter-tip syringe with the plunger removed and attach to the end of the tube. Hold the syringe above the child's stomach for a few minutes. Once the air or gas is removed, allow any stomach contents or formula to flow back into the stomach.

Weigh the child daily throughout enteral nutrition therapy to determine the effectiveness of the therapy.

Providing Skin and Insertion Site Care

Skin around the gastrostomy or jejunostomy insertion site may become irritated from movement of the tube, moisture, leakage of stomach or intestinal contents, or the adhesive device holding the tube in place. Keeping the skin clean and dry is important and will help prevent most of these problems.

The skin around a gastrostomy or jejunostomy tube requires cleaning at least once a day. Routine site care includes gentle cleansing with sterile water or saline for newly placed tubes, or for established tubes, soap and water followed by rinsing or cleaning with water alone. To clean under an external disc or bumper, a cottontipped applicator may be used. Diluted hydrogen peroxide may be necessary to clean crusted drainage off the skin, tube, or disc (Cincinnati Children's Hospital Medical Center, 2008). During insertion site care, rotate the gastrostomy tube or button a quarter-turn to prevent skin adherence and irritation. Always follow agency or institution policies and procedures.

Take Note!

Do not rotate a jejunal tube because it can cause kinking (Bowden & Greenberg, 2008).

Assess the insertion site and condition of the surrounding skin for signs and symptoms of infection, such as erythema, induration, foul drainage, or pain. A small amount of clear or tan drainage is normal. If any drainage is present, a dressing can be placed. Use a presplit 2 X 2 gauze and place it loosely around the site. Change this dressing when it is soiled. If no drainage is present, do not place a dressing as it can cause undue pressure and trap moisture, leading to skin irritation.

Preventing movement of the tube also helps reduce skin irritation. Check the volume of the balloon with a balloon-tipped device about once or twice a week and reinflate the balloon to the initial volume if needed. The tube should be able to move slightly in and out of the child's stomach. The plastic disc should be snug against the skin but not tight enough to cause pressure. Tube stabilization methods help prevent the tube from moving around and sliding further into the stomach or jejunum. Stabilize the tube by pulling gently on the tubing and sliding the stabilizer bar or disc snugly against the abdomen.

Take Note!

Rotate sites where the tube is secured to the abdomen to prevent tension on the stoma or skin breakdown.

Measure and record the length of the tube from the exit site of the abdominal wall to the end of the tube. All future measurements should be the same unless the tube length is changed. For tubes without a stabilizer bar or disc or for additional stabilization needs,

several other methods may be used, including cut baby bottle nipples, taping methods, and commercially available stabilizers (see [Fig. 13.12](#)). It is always important to follow agency policy.

Take Note!

When using the nipple method, make sure to cut several holes in the base of the nipple to allow air circulation and site assessment.

Promoting Growth and Development

Some children receive all of their nutritional needs through tube feedings, whereas other children use tube feedings as a supplement to eating by mouth. Feeding time is a special time for infants and children. Occasionally, babies who are fed solely through an enteral feeding tube may forget or lose the desire to eat by mouth. Use a pacifier to help avoid this, allowing the infant to associate the nipple in his or her mouth with a feeding (Sexton & Natale, 2009). The sucking motion will also exercise the jaw and promote the flow of the feedings. The saliva produced during sucking aids in digestion. Combined with holding the infant and cuddling, rocking, and talking to him or her, this promotes a more normal feeding time.

Talking with children, playing music, or reading a story promotes an active feeding time. At home, encourage parents to include the feeding as a part of regular family mealtime together to provide socialization for the child. Allow the child to participate in the feedings by gathering supplies and administering the actual feeding so that the child may experience independence and adaptation. If the child also eats food by mouth, feed him or her by mouth first and then administer the tube feeding. During tube feedings in bed, make sure the head of the bed is elevated at least 30 degrees to help prevent vomiting and aspiration (Springhouse, 2007).

Children with feeding tubes should be allowed as normal a routine as possible. For example, they can crawl, walk, and jump just like children of the same age and developmental level. However, in some cases, contact sports such as football, hockey, and wrestling should be avoided because of the higher risk of injury. Securing the tubing under the child's clothing will prevent it from becoming accidentally dislodged and prevent the child from pulling and playing with it. Using one-piece outfits, an Ace wrap, or stretchy gauze to cover the tube can help protect it.

Educating the Child and Family

Educate children receiving enteral feedings and their parents thoroughly about this method of nutritional support. Reinforce the reason for the therapy and provide the child and parents with opportunities to verbalize their concerns and ask questions. Ensure that the parents understand the risks and benefits of the therapy and the expected duration.

Provide the child, if developmentally appropriate, and parents with opportunities to participate in the feeding sessions. This helps allay some of their fears and anxieties and promotes a sense of control over the situation. They will also gain valuable practice in learning the skill should the feedings be required at home. [Teaching Guidelines 13.3](#) identifies important topics to include in the teaching plan for a child receiving enteral nutrition at home. Troubleshooting problems at home is an important topic to cover. Refer to [Teaching Guidelines 13.4](#). Education also involves helping the family develop appropriate coping strategies to adapt, solve problems, and access the support and services they will need after discharge.

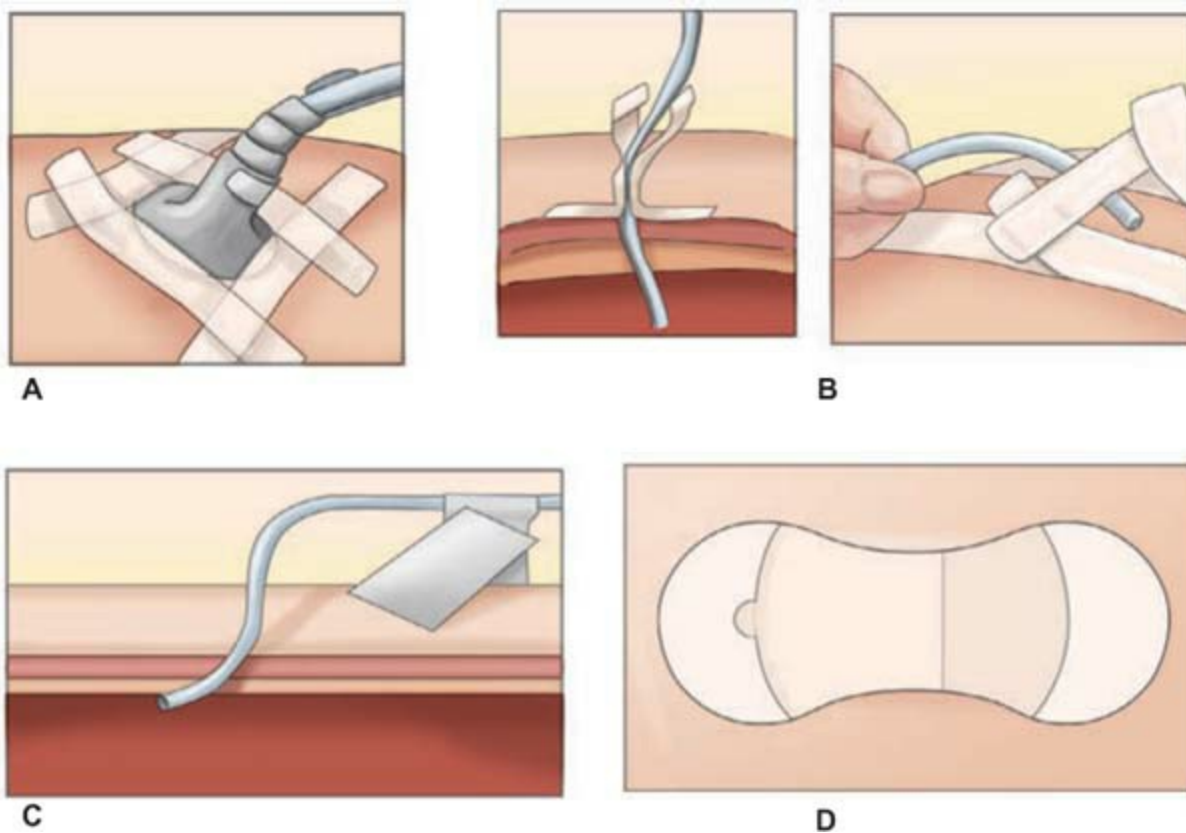

FIGURE 13.12 Methods to stabilize a gastrostomy tube include (A) the nipple method, (B) taping methods, (C) the tension loop method, and (D) commercially available stabilizing devices (GripLok® pictured here).

Teaching Guidelines 13.3

TOPICS TO BE COVERED FOR HOME ENTERAL NUTRITION

- Type and size of tube
- Type of nutritional support
- Rationale for therapy
- Expected results from therapy
- Duration of therapy
- Frequency of feedings
- Feeding solution and equipment
- Tube insertion technique (if appropriate)
- Methods to check for correct placement
- Steps for administering the feeding (and medication if ordered)
- Procedure for flushing tube
- Procedure for venting the tube, if appropriate
- Frequency of weighing the child
- Signs and symptoms of complications and when to notify physician or nurse practitioner
- Troubleshooting problems, such as clogging of the tube or dislodgement (see [Teaching Guidelines 13.4](#))
- Daily tube care (e.g., cleaning the site, rotating tube)
- Site assessment
- Technique for reinsertion/replacement of tube as appropriate
- Equipment suppliers
- Resources for support
- Follow-up visits and referrals

Teaching Guidelines 13.4

TROUBLESHOOTING COMPLICATIONS AT HOME

- If a tube becomes clogged, instruct caregivers to slowly push warm water into the tube. Amount and size of syringe will vary based on child's size and facility policy. Repeat if necessary. Instruct caregivers to never use an object or put anything into the tube. They should call the doctor or nurse if they are unable to unclog the tube. Declogging medications may be prescribed.
- If a tube is inadvertently removed, instruct the care-giver to cover the site with a small clean dressing tape, then to call the physician or nurse immediately; the tube needs to be replaced as soon as possible or the tract will close. Some institutions may instruct the family on how to replace the tube once the tube is more than 6 weeks old and has formed an established G-tube tract.
- If the site is red or irritated, instruct caregivers to continue with routine cleaning and call the physician. An antibiotic or skin barrier cream may be ordered. Assess for leakage and try to minimize if possible. Ensure tube is stabilized and secure and not dangling.
- If the tube is leaking, the caregiver needs to keep the dressing clean and dry. More frequent venting may help and the physician should be notified.

Always teach following the instructions per agency policy and procedure regarding home care.

Adapted from Bowden, V. R., & Greenberg, C. S. (2008). *Pediatric nursing procedures*. Philadelphia: Lippincott Williams & Wilkins; and Cincinnati Children's Hospital Medical Center. (2009). *Abdominal and digestive home care*. Retrieved January 23, 2010, from <http://www.cincinnatichildrens.org/health/info/abdomen/home/g-tube-care.htm>

Remember Lily from the beginning of the chapter? She is to be discharged home after having a gastrostomy tube inserted to continue feedings at home.

What teaching is needed for her family prior to discharge?

Parenteral Nutrition

Nutritional support can be administered IV through a peripheral or central venous catheter. The concentration and components of the solution determine the type of parenteral nutrition. Parenteral nutrition given via a central venous access device is termed **total parenteral nutrition (TPN)**. [Comparison Chart 13.1](#) gives information about peripheral and central parenteral nutrition.

Administering TPN

Typically, the physician or nurse practitioner determines the concentration and components of the TPN solution based on a thorough assessment of the child's status, including the results of laboratory testing. This information is used as a baseline for evaluating the effectiveness of therapy.

The solution is prepared under sterile conditions in the pharmacy. For TPN, a central venous access device is inserted and secured, if one is not already in place. Use specialized tubing with an inline filter (to prevent small microparticles from entering the circulation).

TPN solutions may be refrigerated until they are to be used. Once started, a single solution of TPN should hang for no longer than 24 hours (Springhouse, 2007). The infusion of the solution is initiated at a slow rate that is gradually increased as ordered based on how the child tolerates the therapy. TPN solutions are highly concentrated glucose solutions that can cause hyperglycemia if given too rapidly. Use of an infusion pump is essential to control the rate of infusion. Fat emulsions are administered periodically to meet the child's need for essential fatty acids. These solutions are given as a piggyback solution into the TPN line, but below the inline filter.

Throughout TPN therapy, be vigilant in monitoring the infusion rate, and report any changes in the infusion rate to the physician or nurse practitioner immediately. Adjustments may be made to the rate, but only as ordered by the physician or nurse practitioner. The infusion rate should never be adjusted more than 10% higher or lower than the current rate (Weinstein, 2006).

Initially, check blood glucose levels frequently, such as every 4 to 6 hours, to evaluate for hyperglycemia. These levels can be obtained with a bedside glucose meter. Minimize the trauma and discomfort associated with frequent invasive procedures by using the principles of atraumatic care. If blood glucose levels are elevated, subcutaneous administration of insulin may be needed. Once the

child's glucose levels stabilize, the frequency of blood glucose level determinations decreases, such as every 8 to 12 hours, based on the facility's policy.

COMPARISON CHART 13.1

PERIPHERAL PARENTERAL NUTRITION VERSUS TOTAL PARENTERAL NUTRITION

| | Peripheral Parenteral Nutrition | Total Parenteral Nutrition |
|------------------------|---|--|
| <i>Indications/use</i> | Primarily supplemental Short-term use to supply additional calories and nutrients | Provides all nutrients to meet child's needs Enough calories supplied to maintain a positive nitrogen balance ^a |
| <i>Route</i> | Peripheral vein | Central venous access to allow rapid dilution of hypertonic solution |
| <i>Child's status</i> | Nutritional status usually within acceptable parameters Oral intake decreased or absent | Child with a nonfunctioning gastrointestinal (GI) tract, such as a congenital or acquired GI disorder Severe failure to thrive Multisystem trauma or organ involvement Preterm newborns |
| <i>Components</i> | Fluid, electrolytes, and carbohydrates (dextrose); usually no protein or fats Carbohydrate concentration usually limited to 10% ^a | Highly concentrated solution of carbohydrates, electrolytes, vitamins, and minerals Lipid emulsion to supply need for essential fatty acids Total nutrient admixture (TNA) with components of TPN plus lipids and other additives in one container |

^aWeinstein, S. M. (2006). *Plumer's principles and practice of intravenous therapy* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

Take Note!

If for any reason the TPN infusion is interrupted or stops, be prepared to begin an infusion of a 5% to 10% dextrose solution at the same infusion rate as the TPN (Bowden & Greenberg, 2008). This helps to prevent rebound hypoglycemia that may occur due to the increased insulin secretion by the child's body in response to the use of the highly concentrated TPN solution.

Perform catheter site care, tubing and filter changes, and dressing changes according to the facility's policy. Inspect the insertion site closely for signs of infection. Also monitor the child's vital signs, daily weights, and intake and output closely for changes. In addition, review laboratory test results, which can aid in early detection of problems, such as infection or electrolyte excesses or deficits.

TPN can be administered continuously over a 24-hour period, or after initiation it may be given on a cyclic basis, such as over a 12-hour period during the night. When administering cycled TPN, the solution is infused at half the prescribed rate for the first and last hour to prevent hyper- and hypoglycemia.

Preventing Complications

Nurses play a key role in minimizing the risk for complications related to use of central venous access devices and TPN. [Box 13.5](#) describes these complications. Key measures to reduce the risk of complications include the following:

- Monitor the child's vital signs closely for changes.
- Adhere to strict aseptic technique when caring for the catheter and administering TPN.
- Ensure that the system remains a closed system at all times. Secure all connections and clamp the catheter or have the child perform the Valsalva maneuver during tubing and cap changes.
- Use occlusive dressings. Chlorhexidine-impregnated sponge (Biopatch) dressings may be used to help prevent infection. Always follow agency or institution policy and procedures.
- Adhere to agency policy for flushing of the catheter and maintaining catheter patency.
- Assess intake and output frequently.
- Monitor blood glucose levels and obtain laboratory tests as ordered to evaluate for changes in fluid and electrolytes.

Take Note!

Never administer any medication, blood, or other solution through the TPN lumen. Doing so increases the risk for contamination of the system and subsequent infection (Springhouse, 2007).

COMPLICATIONS THAT CAN OCCUR WITH CENTRAL VENOUS ACCESS DEVICES AND TOTAL PARENTERAL NUTRITION (TPN)

- Air embolism from inadvertent entry of air into the system during tubing or cap changes or accidental disconnection
- Cardiac tamponade due to catheter advancement with movement of the arm, neck, or shoulder
- Catheter occlusion from the development of a fibrin sheath or thrombus at the catheter tip, malpositioning or kinking, or the deposition of precipitates or a blood clot
- Venous thrombosis from injury to the vessel wall during insertion or movement of the catheter after insertion or from chemical irritation due to administration of concentrated solutions, vesicants, and other medications through the catheter
- Hyperglycemia, typically with too rapid an infusion of TPN
- Hypoglycemia, which may occur with rapid cessation
- Dehydration as the child's body attempts to rid itself of excess glucose through renal excretion
- Electrolyte imbalance (particularly potassium, sodium, calcium, magnesium, and phosphorus)
- Infection at the skin insertion site, along the catheter pathway, or in the bloodstream. Organisms can arise from the skin, hands of caregivers, or other areas such as wound drainage, droplets from the lungs, or urine. For example, connection sites can be contaminated during tubing or dressing changes.

Promoting Growth and Development

Meals are a time for meeting nutritional needs as well as a time for love, comfort, support, and socialization. TPN meets the child's nutritional needs, but the child's need for love and support also must be met. Implement measures similar to those for children receiving enteral nutrition (see discussion earlier in this chapter). Also provide opportunities for holding and cuddling the child. Allow the older child to participate in activities that can help to occupy the time associated with meals. Encourage the child and parents to participate in the care to promote a sense of independence as well as a sense of control over the situation.

Educating the Child and Family

Children who require long-term TPN therapy may receive TPN in the home. Administering TPN at home requires thorough education of the child and parents. This teaching can occur in the health care agency or in the child's home. The amount of information to be taught can be overwhelming, so ensure that ample time is available. Allow time for questions and concerns. Offer emotional support and guidance whenever necessary.

Provide written and verbal instructions about the care involved. Have the child (if appropriate) and parents demonstrate the care needed, including care of the central venous access device. Review with them the measures for obtaining, storing, and handling the solutions and supplies. Develop plans for troubleshooting problems with devices and equipment, and give instructions on how to recognize and treat complications. Also teach them about danger signs and symptoms that require immediate notification. Be sure they have the name and number of a contact person in case of emergency situations.

Initiate the appropriate referrals for support. Specialized home care infusion services are available for follow-up in the home. In addition, social services can be helpful in providing assistance with finances, health insurance reimbursement, scheduling, transportation, emotional support, and community resources.

KEY CONCEPTS

- The "eight rights" of pediatric medication administration are the right drug, right dose, right route, right time, right patient, right documentation, right to be educated, and right to refuse.
- The physiologic immaturity of some body systems in children can affect a drug's pharmacodynamics, leading to differences in the body's response to the drug and thus enhancing or diminishing the drug's effects. The child's age, weight, body surface area, and body composition can affect the drug's pharmacokinetics.
- The two most common methods for determining pediatric drug doses involve the use of the child's body weight and body surface area.
- Children younger than the age of 5 to 6 are at risk for aspiration when receiving tablets or capsules because they have difficulty swallowing them; liquids may be more appropriate. When administering oral medications to children, always tell them whether a medication is being mixed with food.
- Medication administration via the rectal route is not preferred because the drug's absorption may be erratic and unpredictable and

children find this route extremely upsetting or embarrassing.

- When administering otic medications, pull the pinna downward and back if the child is younger than age 3, and up and back for older children.
- Intramuscular administration is used infrequently in children because it is painful and children often lack the adequate muscle mass. When used with infants, the preferred site is the vastus lateralis muscle.
- Administration of medication via the IV route is common with children, especially when a rapid response to the drug is desired or when absorption via other routes is difficult or impossible. The primary method for IV medication administration is via a syringe pump.
- Preferred sites for peripheral IV therapy include the veins of the hands, feet, and forearms. The scalp vein may be used in infants but only if attempts at other sites have been unsuccessful. The rule of thumb for insertion of any peripheral devices is to use the smallest-gauge catheter for the shortest length of time possible to prevent trauma to the child's fragile veins.
- Central venous therapy usually is administered through a large vein, such as the subclavian, femoral, or jugular vein or vena cava. The tip of the device lies in the superior vena cava just at the entrance to the right atrium. Devices include single- or multiple-lumen short- and long-term catheters, peripherally inserted central catheters, tunneled catheters, and vascular access ports.
- Monitoring intake and output is important when a child is receiving IV therapy. Site inspection, proper care of the site, and proper dressing changes are key to preventing complications.
- Nutritional support can be administered enterally via a nasogastric or orogastric tube (gavage feeding) or via a gastrostomy or jejunostomy device or administered parenterally through a peripheral or central venous access device.
- Enteral nutrition is indicated for children who have a functioning gastrointestinal tract but cannot consume adequate amounts of nutrients orally.
- Prior to any enteral feeding, placement of the feeding tube must be confirmed. The gold standard for confirming placement is with a radiograph. At the bedside, checking the color and pH of the aspirate is used to confirm placement.
- Children receiving TPN require close monitoring of the infusion rate and volume, intake and output, vital signs, and blood glucose levels. Strict aseptic technique is necessary when caring for the central venous access site and TPN infusion.

MULTIPLE CHOICE QUESTIONS

1. A nurse is preparing to administer an intramuscular injection to an infant. What is the most appropriate site for this injection?
 - a. Deltoid muscle
 - b. Vastus lateralis
 - c. Dorsogluteal
 - d. Rectus femoris
2. A 3-year-old child is to receive a medication that is supplied as an enteric-coated tablet. What is the best nursing action?
 - a. Crush the tablet and mix it with applesauce.
 - b. Dissolve the medication in the child's milk.
 - c. Place a pill in the posterior part of the pharynx and tell the child to swallow.
 - d. Check with the prescriber to see if an alternative form can be used.
3. The nurse is caring for an infant who weighs 8.2 kg and is NPO and receiving IV fluid therapy. What rate does the nurse calculate as meeting the child's daily fluid requirements?
 - a. 82 mL per hour
 - b. 41 mL per hour
 - c. 34 mL per hour
 - d. 22 mL per hour
4. When administering ear drops to a 2-year-old, which action would be most appropriate?
 - a. Tell the child that the drops are to treat his infection.
 - b. Pull the pinna of the child's ear down and back.
 - c. Have the child turn his head to the opposite side after giving the drops.
 - d. Massage the child's forehead to facilitate absorption of the medication.

CRITICAL THINKING EXERCISES

1. When reviewing the medical record of a child, the nurse notes that the ordered dose of medication is different from the recommended dose. How should the nurse proceed?
2. While caring for a 5-year-old child who is receiving IV fluid therapy at a rate of 100 mL per hour, the nurse notes that the infusion is running slowly. The insertion site appears slightly reddened and swollen. What should the nurse do next?
3. A school-aged child is to be discharged, continuing TPN therapy at home. The child lives with his parents and two younger siblings. How would the nurse prepare this child and family for discharge? How could the nurse promote growth and development for this child during TPN therapy?

STUDY ACTIVITIES

1. Review the medical records of several children who are on a pediatric unit in your agency. Note the type of medication, route ordered, and what specific interventions are needed for each child related to the medication administration and developmental age of the child, include atraumatic care interventions. Compile a list of the most commonly used routes.
2. Interview several parents about their experiences in giving medications to their children. From these interviews, develop a teaching sheet that provides tips to facilitate oral medication administration to children.
3. Create a chart that compares and contrasts the subcutaneous, intramuscular, and intravenous methods of medication administration. Include examples of medications given via these routes, onset of action, appropriate sites, and necessary safety measures for each.
4. An infant is to receive intermittent gavage feedings via a nasogastric tube every 6 hours. The feeding tube was inserted with a previous feeding and remains in place. The nurse is preparing to administer the next scheduled feeding. Place the events in the proper sequence.
 - _____ a. Check the placement of the feeding tube.

- _____ b. Position the infant on his right side with the head of the bed slightly elevated.
- _____ c. Allow the feeding to come to room temperature.
- _____ d. Flush the tube with water.
- _____ e. Clamp the tube to prevent air from entering the stomach.
- _____ f. Pour the solution into the barrel of the syringe.

Pain Management in Children

Words of Wisdom All of our children in pain deserve as much comfort as we can give.

KEY TERMS

acute pain
 chronic pain
 drug tolerance
 epidural analgesia
 moderate sedation
 neuromodulators
 neuropathic pain
 nociceptive
 pain
 nociceptors
 pain
 pain threshold
 patient-controlled analgesia (PCA)
 physical dependence
 somatic pain
 transduction
 visceral pain

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Identify the major physiologic events associated with the perception of pain.
2. Discuss the factors that influence the pain response.
3. Identify the developmental considerations of the effects and management of pain in the infant, toddler, preschooler, school-age child, and adolescent.

4. Explain the principles of pain assessment as they relate to children.
5. Understand the use of the various pain rating scales and physiologic monitoring for children.
6. Establish a nursing care plan for children related to management of pain, including pharmacologic and nonpharmacologic techniques and strategies.

Aiden Russell is a 6-year-old on the pediatric unit admitted for a wound infection. He requires BID dressing changes. In report you are told that Aiden cries and fights during the dressing change but otherwise seems to be playing and not experiencing much pain. The nurse reporting off duty states, “Aiden’s mother keeps requesting pain medication for Aiden. She states he’s complaining of pain most of the time. I’m not sure if I believe her: when I see Aiden, he’s playing Nintendo games or watching television and seems to be fine. I’ve tried to hold off on his pain medication as long as I can.”

Pain is a highly individualized, subjective experience that can affect any person of any age. It is a complex phenomenon that involves multiple components and is influenced by myriad factors. **Pain** is defined by the International Association for the Study of Pain as “an unpleasant sensory and emotional experience that is associated with actual or potential tissue damage” (International Association for the Study of Pain, 2007). Another definition of pain that is commonly used defines pain as whatever the person says it is, existing whenever the person says it does—that is, pain is present when the person says that it is (Ferrell, 2005; McCaffery, 1968; McCaffery & Pasero, 2011). The person experiencing the pain is the only one who can identify pain and know what the pain is like.

Pain is a universal experience. Pain affects adults and children of all ages, even preterm infants. Pain can result from numerous causes, including disease processes, injuries, procedures, and surgical interventions. In 1995 the American Pain Society (1995) labeled it “the fifth vital sign.” The American Pain Society’s goal was to encourage health care professionals to assess pain every time that temperature, pulse, respirations, and blood pressure are assessed and to institute measures to manage the pain.

Unlike adults, however, children may lack the verbal capacity to describe their pain accurately. In addition, many caregivers and health care providers have misconceptions about pain in children, it is difficult to assess the complex nature of the pain experience, and limited resources and research are available related to pain relief strategies for children. Therefore, pain is a major source of distress for children and their families as well as for health care providers.

If left unmanaged, pain in children can lead to serious physical and emotional consequences, such as increased oxygen consumption and alterations in blood glucose metabolism. In addition, the experience of untreated pain early in life may lead to long-term physiologic and psychological consequences for the child (Bowden & Greenberg, 2008). For example, inadequately controlled pain can have long-lasting negative outcomes such as increased distress during later procedures, nonadherence to treatment regimens, inactivity, prolonged bed rest, and the development of chronic pain. Detrimental effects on the course of the disease itself may also be seen with untreated pain. Preterm infants, due to long hospitalizations and numerous painful and invasive procedures, are often at greater risk for experiencing memories of pain (American Academy of Pediatrics, 2010).

All these factors make pain management a critical element in the plan of care for children. Treating pain reduces anxiety during procedures and decreases the need for physical restraints, reduces anxiety regarding subsequent procedures, and prevents short- and long-term consequences of inadequately treated pain, particularly in newborns (Cohen & Baxter, 2008; Kennedy, Luhmann, & Zempsky, 2008). Pain management in children has improved, but underestimation and inadequate management still remain a problem (Bowden & Greenberg, 2008). Various national health associations have issued position papers and guidelines related to the need to treat pain and suffering in children. Effective pain management involves initial pain assessment, therapeutic interventions, and reassessment for all children in any health care setting.

This chapter describes the pain experience in children, including the types of pain, factors influencing pain, and common fallacies and myths associated with pain in children. The nursing process is applied to provide an overview of the care for a child in pain. Various pain management strategies are described, including nonpharmacologic and pharmacologic interventions and measures to address procedure-related and chronic pain.

PHYSIOLOGY OF PAIN

The sensation of pain is a complex phenomenon that involves a sequence of physiologic events in the nervous system. These events are transduction, transmission, perception, and modulation.

Transduction

Peripheral nerve fibers extend from the spinal cord to various locations in and throughout the body's tissues, such as skin, joints, bones, and membranes covering the internal organs. At the end of these fibers are specialized receptors, called **nociceptors**, which become activated when they are exposed to noxious stimuli. The noxious stimuli can be mechanical, chemical, or thermal. Mechanical stimuli may include intense pressure to an area, a strong muscular contraction, or extensive pressure due to muscular overstretching. Chemical stimulation may involve the release of mediators, such as histamine, prostaglandins, leukotrienes, or bradykinin, as a response to tissue trauma, ischemia, or inflammation. Thermal stimuli typically involve extremes of heat and cold. This process of nociceptor activation is called **transduction**.

Transmission

When nociceptors are activated by noxious stimuli, the stimuli are converted to electrical impulses that are relayed along the peripheral nerves to the spinal cord and brain. Specialized afferent nerve fibers are responsible for moving the electrical impulse along. Myelinated A-delta fibers are large fibers that conduct the impulse at very rapid rates. The pain transmitted by these fibers is often referred to as fast pain, most commonly associated with mechanical or thermal stimuli (Porth & Matfin, 2009). Pain also is transmitted by unmyelinated small C fibers. These fibers transmit the impulse slowly and are often activated by chemical stimuli or continued mechanical or thermal stimuli (Porth & Matfin, 2009). These fibers carry the impulse to the spinal cord via the dorsal horn. Neurotransmitters are released to facilitate the transmission process to the brain.

Several theories have been proposed in an attempt to explain the process of pain transmission. The best known of these is the gate-control theory. According to this theory, the dorsal horn of the spinal cord contains interneuronal or interconnecting fibers. Large-diameter faster fibers carry nonnociceptive, tactile information, while small nerve fibers carry nociceptive or pain signals. Large fibers, when stimulated, close the gate or pathway to the brain, thereby inhibiting or blocking the transmission of the pain impulse. Subsequently, the impulse does not reach the brain, where it would be interpreted as pain. This theory helps explain why some nonpharmacologic therapies, such as massage and pressure, are effective in reducing pain (Porth & Matfin, 2009).

Perception

Once in the dorsal horn of the spinal cord, the nerve fibers divide and then cross to the opposite side and rise upward to the thalamus. The thalamus responds quickly and sends a message to the somatosensory cortex of the brain, where the impulse is interpreted as the physical sensation of pain. The impulses carried by the fast A-delta fibers lead to the perception of sharp, stabbing localized pain that also commonly involves a reflex response to withdraw from the stimulus. The impulses carried by the slow C fibers lead to the perception of diffuse, dull, burning or aching pain. The point at which the person first feels the lowest intensity of the painful stimulus is termed the **pain threshold**. In addition to sending a message to the cerebral cortex, the thalamus also sends a message to the limbic system, where the sensation is interpreted emotionally, and to the brain stem centers, where autonomic nervous system responses begin.

Modulation

Research has identified substances called **neuromodulators** that appear to modify the pain sensation. These substances have been found to change a person's perception of pain. Examples of these neuromodulators include serotonin, endorphins, enkephalins, and dynorphins.

Pain perception can be modified peripherally or centrally. In the peripheral nerve fibers, chemical substances are released that either stimulate the nerve fibers or sensitize them. Peripheral sensitization allows the nerve fibers to react to a stimulus that is of lower intensity than would be needed to cause pain. As a result, the person perceives more pain. Actions that block or inhibit the release of these substances can lead to a decrease in pain perception.

FIGURE 14.1 Physiology of pain. (7) Exposure to thermal noxious stimuli results in activation of nociception (transduction). (2) Impulses are relayed along the peripheral nerves to the spinal cord through the dorsal horn (transmission). (3, 4) This results in the individual feeling the sensation of pain (perception). (5) Neurons in the brain stem send signals back down to the dorsal horn, and these fibers release substances such as endorphins, which can inhibit painful impulses in the dorsal horn (modulation). These neurotransmitters are taken back by the body, therefore limiting the analgesic value.

Modification of pain perception can occur centrally in the spinal cord at the dorsal horn. Substances released by the excited interneurons can potentiate the pain sensation. Other neurochemicals, through their binding to specific receptors, can inhibit the perception of pain. [Figure 14.1](#) illustrates the physiology of pain.

TYPES OF PAIN

Many different systems can be used to classify pain. Most commonly, pain is classified based on its duration, etiology, or source or location.

Classification by Duration

Pain is classified by duration as acute or chronic.

Acute Pain

Acute pain is defined as pain that is associated with a rapid onset of varying intensity. It usually indicates tissue damage and resolves with healing of the injury. Acute pain reflects stimulation of nociceptors and serves a protective function (i.e., alerting the person to a problem). Examples of causes of acute pain include trauma, invasive procedures, acute illnesses such as sore throat or appendicitis, and surgery. This type of pain generally lasts a few days.

Take Note!

Children often experience pain associated with various procedures done in health care settings. This type of pain is usually short in duration. Preparation of the child and family will help to decrease fears or anxiety. Depending on the type of procedure and the child's age, cognitive level, and temperament, various techniques and methods can be used. Advocating for atraumatic care and adhering to its guidelines will help to minimize procedure-related pain.

Chronic Pain

Chronic pain is defined as pain that continues past the expected point of healing for injured tissue. It provides no protective function. It may be continuous or intermittent, with and without periods of exacerbation or remission. It often interferes with sleep and performance of activities of daily living. It can result in loss of appetite and depression. Thus, chronic pain impairs a person's ability to function. In contrast to acute pain, environmental and psychological factors influence behaviors associated with chronic pain. In children, chronic, recurrent pain is most commonly associated with abdominal pain, nonspecific headache, limb pain, or chest pain. Some conditions, such as sickle cell disease and migraines, have characteristics of both acute and chronic pain (Porth & Matfin, 2009). Children with chronic pain may not exhibit the same physical or emotional responses as seen with acute pain. As pain becomes prolonged and continuous, the autonomic nervous system response tends to diminish.

Classification by Etiology

Pain can be classified by etiology as nociceptive or neuropathic.

Nociceptive Pain

Nociceptive pain reflects pain due to noxious stimuli that damages normal tissues or has the potential to do so if the pain is prolonged. The pain perceived often correlates closely with the degree or intensity of the stimulus and the extent of real or possible tissue damage. With nociceptive pain, nervous system functioning is intact. Reports of nociceptive pain vary depending on the location of the nociceptors being stimulated. Nociceptive pain ranges from sharp or burning, to dull, aching, or cramping, and to deep aching or sharp stabbing. Examples of conditions that result in nociceptive pain include chemical burns, sunburn, cuts, appendicitis, and bladder distention.

Neuropathic Pain

Neuropathic pain is pain due to malfunctioning of the peripheral or central nervous system. It may be continuous or intermittent and is commonly described as burning, tingling, shooting, squeezing, or spasm-like pain. Examples of neuropathic pain include posttraumatic and postsurgical peripheral nerve injuries, pain after spinal cord injury, metabolic neuropathies, phantom limb pain after amputation, and poststroke pain.

Classification by Source or Location

Pain also may be classified by the source or location of the area involved. It can be somatic pain (superficial and deep) or visceral pain. These classifications typically indicate nociceptive pain.

Somatic Pain

Somatic pain refers to pain that develops in the tissues. It can be further divided into two groups—superficial and deep. Superficial somatic pain, often called cutaneous pain, involves stimulation of nociceptors in the skin, subcutaneous tissue, or mucous membranes. Typically the pain is well localized and described as a sharp, pricking, or burning sensation. Superficial somatic pain may be due to external mechanical, chemical, or thermal injury or skin disorders. Tenderness commonly is present.

Deep somatic pain typically involves the muscles, tendons, joints, fasciae, and bones. It can be localized or diffuse and is usually described as dull, aching, or cramping. Deep somatic pain may be due to strain from overuse or direct injury, ischemia, and inflammation. Tenderness and reflex spasm may be present. Additionally, the person may exhibit sympathetic nervous system activation such as tachycardia, hypertension, tachypnea, diaphoresis, pallor, and pupillary dilation.

Visceral Pain

Visceral pain is pain that develops within organs such as the heart, lungs, gastrointestinal tract, pancreas, liver, gallbladder, kidneys, or bladder. It is often produced by disease. It usually is diffuse and poorly localized and is described as a deep ache or sharp stabbing sensation that may be referred to other areas. Visceral pain may be due to distention of the organ, organ muscular spasm, contraction, pulling, ischemia, or inflammation. Tenderness, nausea, vomiting, and diaphoresis may be present.

FACTORS INFLUENCING PAIN

Children, like adults, experience neurologic events that result in the perception of pain. However, research has found that environmental and psychological factors may exert a greater influence on the child's perception of pain (McGrath & Hillier, 2003). Certain factors such as age, gender, cognitive level, temperament, previous pain experiences, and family and cultural background cannot be changed. However, situational factors involving behavioral, cognitive, and emotional aspects can be modified. These situation-specific factors that affect the child's pain experience include "what the child and parents understand, what they and the health care staff do and how the child and parents feel. Certain situational factors can intensify pain and distress, whereas others can eventually trigger pain episodes, prolong pain-related disability or maintain the repeated pain episodes in recurrent pain syndrome" (McGrath, 2005, p. 437).

Age and Gender

Research has demonstrated that the nervous system structures needed for pain impulse transmission and perception are present by the 23rd week of gestation (Blount, Piira, Cohen, & Cheng, 2006). Therefore, children of any age, including preterm newborns, are capable of experiencing pain (Finley, Franck, Grunau, & von Baeyer, 2005). Early on, children can interpret pain as an unpleasant sensation, but this interpretation is based on their comparison with other sensations. As they get older, they learn to use words to describe their pain more fully.

Gender and sex also may play a role in a child's perception of pain, but research has failed to yield concrete evidence supporting it (Hurley & Adams, 2008). It has been suggested that boys and girls differ in how they perceive and cope with pain and respond to analgesics. This may be influenced by various factors including genetics, hormones, family, and culture. Further research is warranted in this area to allow for more focused care in pain management.

Cognitive Level

Cognitive level is a key factor affecting a child's pain perception and response and usually goes hand in hand with the child's age. Cognitive level typically increases with age, thereby influencing the child's understanding of the pain and its impact and his or her choices for coping strategies. In addition, as the child's cognitive level increases, his or her ability to communicate information about pain increases. However, this increased understanding and ability to communicate with advancing age may not apply to the child experiencing developmental delays. For example, a developmentally delayed school-aged child or adolescent may have the cognitive level of a toddler or preschooler. Health care providers need to be cognizant of this difference when caring for the child in pain. Numerous research studies have revealed that young children often describe pain in concrete terms, whereas older children use more abstract terms that involve both physical and psychological components (McGrath, 2005).

Temperament

Literature suggests that temperament plays a role in predicting distress and pain levels in a child during painful events (Ranger & Campbell, 2008). For example, a child with a "difficult temperament" is more likely to have an increased distress response to pain. Nurses can personalize interventions in the clinical environment and during the pain experience to better fit the child's temperament and other personality traits of the child and family.

Previous Pain Experiences

A child identifies pain based on his or her experiences with pain in the past. The number of episodes of pain, the type of pain, the severity or intensity of the previous pain experience, the effectiveness of treatment of pain, and how the child responded all affect how the child will perceive and respond to the current experience. Research suggests that severe pain experiences in the neonate or young infant can lead to sensory disturbances and altered pain responses lasting into adulthood (Hatfield, Chang, Bittle, Deluca, & Polomano, 2011). Previous pain experiences with inadequate pain control may lead to increased distress during future painful procedures. For example, research studies have demonstrated that neonates who had undergone painful procedures such as circumcision and heel lancing showed a stronger negative response to routine immunizations and venipuncture weeks to months later (Kennedy et al., 2008).

Family and Culture

The child's cultural and family background will influence how he or she will express and manage pain. Some cultures transmit the

standard of accepting pain stoically; others allow outward expression. The parents have a strong influence on the child's ability to cope. For example, if a parent reacts to the child's pain in a positive manner and offers comfort measures, the child may have an easier time coping. If the parent shows anger or disapproval, the pain experience may be intensified for the child.

Situational Factors

Situational factors involve factors or elements that interact with the child and his or her current situation involving the experience of pain. These factors are highly variable and dependent on the specific situation. Situational factors result from the context in which the child is experiencing pain and include cognitive, which is what the child understands and believes about the pain experience; behavioral, which is how the child and family react and what they do about the pain experience; and emotional, which is how the child and family feels about the pain experience (Crowell, 2009). Due to children's limited experience with pain, situational factors may affect them more than adults (McGrath, 2005). A thorough pain assessment must include assessment for situational factors that may exacerbate pain. Examples of situational factors include:

- Child's lack of understanding of the source of pain
- Child's lack of ability to use coping mechanisms or pain-relieving strategies to decrease pain
- Stress and anxiety in anticipation of pain Child's lack of control of cause of pain
- Child's lack of ability to understand what to expect from potentially painful experiences
- Increased anxiety exhibited by the family
- Overly protective behaviors exhibited by the family
- Presence of emotions such as fear, anxiety, frustration, distress, underlying anxiety, and depression (Crowell, 2009; McGrath, 2005; McGrath & Hillier, 2003)

DEVELOPMENTAL CONSIDERATIONS

Since children of various developmental ages respond differently to pain and perceive pain in different ways, it is important to review developmental considerations. Refer to [Chapters 3](#) through [7](#) for a more complete understanding of childhood development. Nurses must understand how children of various ages respond to painful stimuli and what behaviors may be expected based on their developmental level. By understanding these developmental considerations, the nurse can appropriately assess the child's pain and provide effective interventions.

Infants

Research has demonstrated that infants, including preterm infants, experience pain and can distinguish pain from other tactile experiences (Weissman, Arano-vitch, Blazer, & Zimmer, 2009). Much of this research focuses on pain related to invasive procedures, such as heel sticks and intravenous catheter insertion. Research suggests that neonates, especially preterm infants, actually experience pain at a greater intensity than older-age children and adults (American Medical Association, 2010; Codipietro, Ceccarelli, & Ponzone, 2008). The belief is related to the immaturity of the inhibitory mechanisms that develop higher in the central nervous system at a later time during fetal development. These mechanisms are more complex and do not become functional until later in gestation.

In preterm and term newborns, behavioral and physiologic indicators are used for determining pain. Behavioral indicators include facial expression, such as brow contracting and chin quivering; body movements; and crying (American Academy of Pediatrics, 2010; Henry, Haubold, & Dobrzykowski, 2004). Physiologic signs include changes in heart rate, respiratory rate, blood pressure, oxygen saturation levels, intracranial pressure, and vagal tone, palmar sweating, and an increase in plasma cortisol or catecholamine levels (American Academy of Pediatrics, 2010; Henry et al., 2004).

In the younger infant, facial expression is the most common response to pain ([Fig. 14.2](#)). The brows may be lowered and drawn together, with the eyes tightly closed. The mouth is open, often forming a square. The body may be stiff, and thrashing may be seen. When the area is stimulated, the infant may demonstrate a generalized reflex withdrawal. The infant may exhibit a high-pitched, shrill cry.

FIGURE 14.2 In the younger infant, facial expression is the most common response to pain.

The older infant often displays similar behavioral manifestations of pain. The older infant may display an angry facial expression, but the eyes are open. He or she often demonstrates a definite withdrawal response when the area is stimulated. The older infant cries loudly and tries to push away the stimulus that is causing the pain. Other manifestations include irritability, restless sleeping, and poor feeding.

Take Note!

Although an infant usually exhibits typical behaviors indicating pain, absence of these manifestations does not indicate a lack of a pain; the response to pain is highly variable (Ranger, Johnston, & Anand, 2007; Weissman, Aranovitch, Blazer, & Zimmer, 2009).

Infants also demonstrate physiologic responses to pain. These may include:

- Increased heart rate, usually averaging approximately 10 beats per minute; possibly bradycardia in preterm newborns
- Decreased vagal tone
- Decreased oxygen saturation
- Palmar or plantar sweating (as measured by skin conductivity testing); not reliable in infants before 37 weeks' gestation

Toddlers

Toddlers can react to painless procedures as intensely as painful ones, with intense emotional upset and physical resistance or aggression. They may bite, hit, scream, or kick. Other behaviors may include being very quiet, pointing to where it hurt, or saying such words as “owww.” Facial grimacing and teeth clenching may be noted. They may also react with fear and try to hide or leave the room. They often have limited vocabularies, so it may be difficult for them to express pain. It is important to ask about and encourage the child to verbalize his or her pain. Ensure the use of words the toddler understands, such as “owie” or “boo-boo.” Toddlers may demonstrate regressive behaviors, such as clinging to the parent or crying loudly.

Take Note!

Children do not use the word “pain” until around the age of 6. By 2.5 years they spontaneously will use the word “hurt” (von Baeyer, 2006).

Preschoolers

Preschoolers may become quiet or try to withdraw and hide in response to actual or perceived pain. For example, the child may say he or she needs to go to the bathroom or needs to get something from another room. Because of their magical type of thinking, preschoolers may believe pain is a punishment for misbehaving or having bad thoughts. Preschoolers may not verbally report their pain, thinking that pain is something to be expected or that the adults are aware of their pain. They can tell someone where it hurts and can use various tools to describe the severity of pain. However, because they may have limited experience with pain, they may have difficulty distinguishing between types of pain (sharp or dull), describing the intensity of the pain, and determining whether the pain is worse or better.

School-Age Children

School-age children can usually communicate the type, location, and severity of pain. Children older than the age of 8 years can use specific words, such as “sharp as a knife,” “burning,” or “pulling” to describe their pain. However, they may deny pain in an attempt to appear brave or to avoid further pain related to a procedure or intervention. They may be more concerned with their fear about the illness and its effects rather than the pain. They also may fear being embarrassed by acting-out behaviors in response to pain, such as screaming or thrashing. Thus, a typical response might be to withdraw by staring at the television. Other behaviors that may indicate pain in a school-age child include muscular rigidity, such as clenching the fists, stiffening the body, closing the eyes, wrinkling the forehead, or gritting the teeth.

Adolescents

Adolescents may be concerned primarily about body image and fear losing control over their behavior. This may result in denial or refusal of medications. Their mood and what they think is expected of them will also affect their response to pain. Adolescents often ask numerous questions and pay close attention to how others respond to them. Fearing that their behavior may be viewed as

juvenile, they may attempt to remain stoic and not exhibit any emotion. Subtle changes such as increased muscle tension with clenched fists and teeth, rapid breathing, and guarding the affected body part may occur. They may also show lack of interest in everyday activities or a decreased ability to concentrate.

COMMON FALLACIES AND MYTHS ABOUT PAIN IN CHILDREN

In general, children respond to pain based on the type of pain, the extent of pain, and their age and developmental level. Table 14.1 highlights some common myths and misconceptions related to pain in children. Because of these myths, children have been medicated less than adults with a similar diagnosis, leading to inadequate pain management.

| Myth or Misconception | Fact |
|---|--|
| Newborns do not feel pain. | Newborns, including preterm newborns, do feel pain. The neurologic and hormonal systems needed for the transmission of painful stimuli are sufficiently developed. |
| Exposure to pain at an early age has little to no effect on the child. | Prolonged or severe pain can lead to increased newborn morbidity. Infants who have experienced pain during the neonatal period respond differently to subsequent painful events. ^a |
| Infants and small children have little memory of pain. | Repeated exposure to painful procedures and events can have long-term consequences. Memories of pain may be stored in the child's nervous system, influencing later reactions to painful stimuli. ^b |
| The intensity of a child's behavioral reaction indicates the intensity of the child's pain. | Numerous factors affect a child's response to pain. Each child is an individual, with his or her own set of responses. |
| A child who is sleeping or playing is not in pain. | Sleep or play may be a coping strategy for the child in pain. Sleep may reflect exhaustion of the child who is coping with pain. |
| Children are truthful when they are asked if they are experiencing pain. | Often children deny pain to avoid a painful situation or procedure, embarrassment, or loss of control. Children may assume that others know how they are feeling and thus will not verbalize their complaints. |
| Children learn to adapt to pain and painful procedures. | Repeated exposure to pain or painful procedures can result in an increase in behavioral manifestations. |
| Children experience more adverse effects of narcotic analgesics than adults do. | The risk of adverse effects of narcotic analgesics is the same for children as for adults. |
| Children are more prone to addiction to narcotic analgesics. | Addiction to narcotics when used to treat children's pain is very rare. ^c |

NURSING PROCESS OVERVIEW FOR THE CHILD IN PAIN

Nursing care of the child with pain includes nursing assessment, nursing diagnosis, planning, interventions, and evaluation. Each step of this process must be individualized for each child. A general understanding of the physiology of pain, factors that influence pain, and effective pain management techniques can help to individualize the child's plan of care.

Assessment

Assessment of pain in children consists of both subjective and objective data collection. The acronym **QUESTT** is an excellent way to remember the key principles of pain assessment (Baker & Wong, 1987):

- **Question** the child.
- **Use** a reliable and valid pain scale.
- **Evaluate** the child's behavior and physiologic changes to establish a baseline and determine the effectiveness of the intervention. The child's behavior and motor activity may include irritability and protection as well as withdrawal of the affected painful area.
- **Secure** the parent's involvement.
- **Take** the cause of pain into account when intervening.
- **Take** action.

Take Note!

Children do experience pain! Pain management techniques work just as well with children as they do with adults.

Health History

When assessing pain in children, tailor the assessment to the child's developmental level and ask questions geared to the child's cognitive ability. During the health history, determine the child's previous exposure to pain, if any, and how the child responded. This information will provide clues about how the child copes and his

or her current response. Attempt to determine what word the child uses to denote pain. Some children may not understand the term “pain” but do understand terms such as “ouchie” or “boo-boo.”

The health history also includes questioning the parents about their cultural beliefs related to pain and their child’s usual responses. This information aids in planning developmentally and culturally appropriate family-centered care.

QUESTIONING THE CHILD

When questioning the child, phrase the questions in a manner that the child will be able to understand based on his or her developmental level. Some input from the child’s family may be helpful in determining where best to focus the questions.

Ask the child what pain means to him or her. Use words that the child may comprehend more easily, such as “hurt,” “boo-boo,” or “ouch,” as appropriate. Inquire about similar experiences in the past and how he or she responded. Determine whether the child let others know that he or she was hurting and how this message was conveyed (e.g., crying, acting out, or pointing to the hurting area).

Review the history of the pain and various influences such as cultural aspects, caregiver attitudes or expectations, previous experiences, and any education or teaching related to pain management. Continue to formulate questions to ascertain the following:

- Location, quality, severity, and onset of the pain, as well as the circumstances in which the child experiences the pain. Have the child point to the area where it hurts or identify the location on a diagram or doll.
- Conditions, if any, that preceded the onset of pain and the conditions that followed the onset of pain
- Any associated symptoms, such as weight loss, fever, vomiting, or diarrhea, which may indicate a current illness
- Any recent trauma, including any interventions that were used in an attempt to relieve the pain

Continue the health history by inquiring about what the child wants others, including the nurse, to do when the child hurts. Conversely, ask the child what he or she doesn’t want others to do. Finally, question the child about measures that seem to be most effective in relieving the pain. Ask if there is anything special the child wants to tell the nurse, such as a special pain relief technique or a specific comfort object.

If the child is experiencing chronic or recurrent pain, suggest the child and family record information in a symptom diary. Explain that this will be helpful in identifying the best ways to manage the pain.

QUESTIONING THE PARENTS

Parents play a key role in assessing pain in children. Often it is the parents who provide information about the child’s current and past experiences with pain. In addition, parents can provide information about how the child exhibits and responds to pain. Parents may be aware of subtle changes in the child’s behavior that may precede the pain, occur with the pain, or indicate relief of pain. Including the parents in this process helps create a positive experience for all involved and promotes feelings of control over the situation.

The questions posed to the parents are similar in focus to those posed to the child. However, more detailed information may be obtained from the parents because they are usually able to describe events more fully or in greater detail due to their higher cognitive level. Parents typically know their child best.

Take Note!

Parents may assume that nurses have greater expertise when it comes to assessing their child’s pain and taking appropriate action. Thus, they may not always report when they notice changes suggesting that their child is uncomfortable. Emphasize the important role that parents play in reporting any changes in their child so that pain relief measures can be instituted as soon as possible.

When questioning the parents, use the following examples as a guide for assessing the child’s pain: Has your child ever been in pain before? If so, what was the cause of the pain? How long did he or she have the pain? Where was the pain located? How did your child react to the pain? What did you do to lessen the pain?

- Did your child let you know that he or she was in pain? Did he or she tell you or did you notice something?
- Are there any special signs that let you know that your child is hurting? If so, what are they?
- Is there anything that your child does or that you do when he or she is hurting that helps relieve the pain?
- Does one thing work better than another when your child is hurting?
- Is there any special information that you want to tell me about your child?

USING PAIN RATING SCALES

Various pain assessment, or pain rating, scales are available. These scales allow the child to report his or her pain, and the pain level is quantified. These standardized rating scales provide a greater alignment between the child’s pain and the nurse’s assessment of the severity of the pain. Self-report measures should be used in conjunction with observation and discussion with the child and family, especially in children younger than age 5 or in children with cognitive impairments (American Academy of Pediatrics and the American Pain Society, 2001). Some studies have found validity in self-report tools used in children as young as 3 years of age, while others have found inconsistent findings when they are used in children younger than 5 years of age (Besenski, For-syth, & von Baeyer, 2007). Therefore, it is important to assess young children’s ability to perform self-report tasks rather than rely solely on their chronological age (Besenski et al., 2007).

Many health care facilities have specific policies and procedures related to pain assessment, including the frequency of assessment, the rating tool to use, and nursing interventions to be instituted based on the rating. For example, many facilities require assessment of the child using a specific tool with documentation at least once a shift and 30 minutes to 1 hour after a non-pharmacologic or pharmacologic pain relief intervention. This process provides a more objective method to determine whether the pain is increasing or decreasing and whether pain relief methods are effective.

Take Note!

Typically, different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Regardless of the tool used, nurses need to be consistent in using the same tool so that appropriate comparisons can be made and effective interventions can be planned and implemented. Using the most appropriate tool consistently allows the most accurate assessment of the child’s pain.

FACES Pain Rating Scale. The FACES pain rating scale (Fig 14.3) is a self-report tool that can be used by children as young as 3 or 4 years of age (Oakes, 2011). The scale consists of six illustrations of faces arranged horizontally with expressions ranging from smiling (indicating no hurt) to crying with frowning (indicating hurts worst). Under each face is a short description such as “hurts little bit” and a number. The number scale can be 0, 1, 2, 3, 4, and 5 or 0, 2, 4, 6, 8, and 10. The nurse explains the words associated with each face to the child. Then the nurse asks the child to select the facial expression that best describes the level of pain he or she is feeling. The nurse then documents the number corresponding to the word description and face (Hockenberry & Wilson, 2009).

Oucher Pain Rating Scale. The Oucher pain rating scale is similar to the FACES scale in that it uses facial expressions to indicate increasing degrees of hurt. However, instead of illustrations, six photographs are used: “no hurt” is placed at the bottom of the arrangement and “most hurt” at the top. Alongside the photos is a scale ranging from 0 to 10 that corresponds to the facial expressions in the photographs (Fig 14.4). After explaining the photos and numeric scale, the child is asked to point to the number that best describes his or her level of pain (Beyer, Denyes, & Villarruel, 1992).

This scale is useful for self-reporting of pain in children between 3 and 13 years of age (Oakes, 2011). Three different scales have been developed for use with Caucasian, Hispanic, and African American children (Cohen et al., 2008).

Poker Chip Tool. The poker chip tool, also known as the pieces of hurt tool, is a self-reporting pain assessment tool that uses four red poker chips to quantify the child’s level of pain (von Baeyer, 2006). The chips are arranged in a horizontal line on a surface in front of the child. Starting with the chip closest to the child’s left side, the nurse points to the chip and explains that the first chip means a little hurt, the next chip means more hurt, the third chip means more hurt, and the fourth chip means the worst hurt ever. Then the nurse asks the child how many “pieces of hurt” he or she is having (Fig 14.5). If the child is not experiencing any pain, typically the child will state that he or she isn’t having any. When the child identifies the number of “pieces of hurt,” the nurse follows up by asking the child to tell the nurse more about his or her hurt (Hester, 1979).

The poker chip tool is useful for assessing pain in children who are 3 to 4 years of age or older (Cohen et al., 2008; Stinson, Kavanagh, Yamada, Gill, & Stevens, 2006). Children may view this assessment tool as a game since it involves poker chips. However, the nurse needs to ensure that the child has the cognitive ability to distinguish the numbers.

Word-Graphic Rating Scale. The word-graphic rating scale is a self-reporting scale that consists of a line with descriptors underneath: no pain, little pain, medium pain, large pain, and worst possible pain (Fig 14.6). The nurse explains the line and descriptors to the child. Then the child is asked to make a vertical mark on the horizontal line at the point that best describes the child’s level of pain. The nurse uses a ruler to measure the distance from the “no pain” starting point to the area marked by the child.

Take Note!

Toddlers and preschoolers may not be used to being asked questions by strangers, and may not understand quantitative ratings or estimation. Preschoolers will often construct an answer even if they do not understand the question. They also will often use extremes of scales, such as no pain or the worst pain (von Baeyer, 2006).

Visual Analog and Numeric Scales. Visual analog and numeric scales involve a horizontal or vertical line with marked endpoints. With a visual analog scale, the endpoints are identified as no pain and worst pain. A numeric scale typically has endpoints of 0 and 10, reflecting no pain and worst pain, respectively (Fig 14.7). The nurse explains the scale to the child. With the visual analog scale, the child makes a line that best describes the level of pain. The nurse then measures the distance from the “no pain” endpoint to the child’s mark and records this as the pain score. With the numeric scale, the nurse asks the child to pick the number that best describes his or her level of pain.

The visual analog scale can be used in children 7 years or older (Oakes, 2011). The numeric scale can be used with children 8 years or older (von Baeyer, 2006). Even though a younger child may be able to count and give numbers on the scale, they have not yet developed an understanding of the quantitative significance of the numbers.

Adolescent Pediatric Pain Tool. The Adolescent Pediatric Pain Tool is a self-report type of tool useful for older children, usually between 8 and 17 years of age (Bowden & Greenberg, 2008). The tool involves three aspects of assessment. In the first assessment the child identifies the location of the pain on two illustrations of the body—front and back views (Fig 14.8).

The child is instructed to color the areas where he or she is hurting. The child is also instructed to color the area as big or as small as how much he or she is hurting. For example, if the hurt is mild or moderate, the child would color a moderate area of the location; if the pain is severe, he or she would color a much larger area. The second portion of the tool involves a scale that ranges from “no pain” to “worst possible pain.” The nurse instructs the child to identify the severity of his or her pain. The third assessment is a list of words that may be used to describe pain, such as throbbing, pounding, stabbing, or sharp. The nurse asks the child to point to or circle the words that describe the current pain. Children with limited reading skills or vocabulary may have difficulty with some of the words listed to describe pain. Work with the child and encourage the parents to help the child understand the various descriptive words. Parental participation fosters control over the situation and gives the parents some insight into what their child is experiencing (Crandall & Savedra, 2005).

Physical Examination

Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure.

OBSERVE FOR MANIFESTATIONS OF PAIN

Observe for physical signs and symptoms of pain, keeping in mind the child’s developmental level. Look for facial expressions of discomfort, grimacing, or crying. Be alert for movements that may suggest pain. For example, an infant or toddler may pull on the ear when experiencing ear pain. The child may move the head from side to side, suggesting head pain. Typically, children with abdominal pain will lie on one side and draw their knees up to the abdomen. Inspect the child’s gait: a limp or avoidance of weight bearing may suggest leg pain. Immobility, guarding of a particular body area, or refusal to move an area may be observed. Inspect the skin for flushing or diaphoresis, possible indicators of pain. Also monitor vital signs for changes. Pulse or heart rate, respiratory rate, and blood pressure may increase. Other physiologic parameters that suggest pain may include elevated intracranial pressure and pulmonary vascular resistance and decreased oxygen saturation levels.

Take Note!

The body responds to acute pain via the sympathetic nervous system, leading to stimulation and a subsequent increase in vital signs. However, if the child has persistent or chronic pain, the body adapts and these changes may be less noticeable (Bowden & Greenberg, 2008; Oakes, 2011).

The child also may exhibit behavioral changes indicating pain. Be alert for irritability and restlessness. Watch for clenching of teeth or fists, body stiffening, or increased muscle tension. Note any changes in the child's behavior. For example, a child who previously was talkative and playful may become quiet and almost withdrawn in response to pain. Remember, a child in pain may sleep or play in order to cope with the pain. In addition, pay close attention to the child's cultural background and how these beliefs may be affecting the behavioral response to pain.

Each child is an individual with unique responses to pain, so the nurse must ensure that observations of behavior do indeed reflect the child's pain level. To help ensure the accuracy of observations, several physiologic and behavioral assessment tools have been developed to help quantify the observations.

USING PHYSIOLOGIC AND BEHAVIORAL PAIN ASSESSMENT TOOLS

Use of physiologic and behavioral pain assessment tools allows measurement of specific parameters and changes that would indicate that the child is experiencing pain. These measurements aid in determining the intensity of the pain experience. Along with the self-report pain rating scales, measurement of these changes allows the nurse to objectively assess pain and the effectiveness of pain management measures.

Neonatal Infant Pain Scale. The Neonatal Infant Pain Scale (NIPS) is a behavioral assessment tool that is useful for measuring pain in preterm and full-term neonates (Lawrence et al., 1993). Six parameters are measured: facial expression, cry, breathing patterns, arms, legs, and state of arousal (Table 14.2). Each parameter except for cry is scored as a 0 or 1; cry is scored as 0, 1, or 2. The scores are then totaled and the maximum score that can be achieved is 7. A higher score indicates increased pain. This scale does not include any physiologic parameters; therefore, it may not detect early pain in neonates who are too ill to respond, who are receiving paralyzing agents, or who are premature (Hand, Noble, Geiss, Wozniak, & Hall, 2010). In these cases, a falsely low score may be produced.

Riley Infant Pain Scale. The Riley Infant Pain Scale (RIPS) is a behavioral assessment tool useful for infants who lack verbal ability (Schade, Joyce, Gerkensmeyer, & Keck, 1996). Like NIPS, RIPS measures six parameters: facial expression, body movement, sleep, verbal or vocal ability, consolability, and response to movements and touch (Table 14.3). Each parameter is scored as 0, 1, 2, or 3. The score is then totaled and the maximum score that can be achieved is 18. The higher the total score, the more intense the pain.

Pain Observation Scale for Young Children. The Pain Observation Scale for Young Children (POCIS) is a behavioral assessment tool designed for use in children between 1 and 4 years of age (Boelenvander Loo, Scheffer, de Haan, & de Groot, 1999). This tool measures seven parameters: facial expression, cry, breathing, torso, arms and fingers, legs and toes, and state of arousal (Table 14.4). Each parameter is scored as 0 or 1; the maximum score achievable is 7. The higher the score, the greater the pain being experienced by the child. This measurement is recorded as the pain score. The word-graphic rating scale is useful for children between 4 and 17 years old.

CRIES Scale for Neonatal Postoperative Pain Assessment. The CRIES scale is a behavioral assessment tool that also includes measures of physiologic parameters (Krechel & Bildner, 1995). It was developed to quantify postoperative pain in the newborn. The tool also may be used to monitor the infant's progress over time during recovery or after interventions. The tool assesses five parameters: cry, oxygen required for saturation levels less than 95%, increased vital signs, facial expression, and sleeplessness (Table 14.5). Each parameter is scored as 0, 1, or 2 and then totaled. As with other assessment tools, the higher the score, the greater the infant's pain.

FLACC Behavioral Scale for Postoperative Pain in Young Children. The FLACC behavioral scale is a behavioral assessment tool that is useful in assessing a child's pain when the child cannot report accurately his or her level of pain (Merkel, Voepel-Lewis, Shayevitz, & Malviya, 1997). It has been demonstrated to be a reliable tool for children from age 2 months to 7 years of age (Oakes, 2011). This tool measures five parameters: facial expression, legs, activity, cry, and consolability (Table 14.6). Observe the child with the legs and body uncovered. If the child is awake, observe him or her for 2 to 5 minutes; if sleeping, observe the child for 5 minutes or longer. Each parameter is scored as 0, 1, or 2. The scores are totaled, with a maximum achievable score of 10. As with other assessment tools, the higher the score, the greater the pain.

Nursing Diagnoses, Goals, Interventions, and Evaluation

After assessing the child, the nurse identifies appropriate nursing diagnoses. The most commonly identified nursing diagnosis would be acute or chronic pain. However, the related factors and defining characteristics can vary widely. Nursing diagnoses will focus on the effects of pain on the child, for example, the stress incurred as a result of the pain or the fear or anxiety associated with the pain or events causing the pain. Moreover, pain can affect physiologic functions, such as sleep, nutrition, mobility, and elimination. Examples of common nursing diagnoses may include:

- Acute pain related to repeated need for invasive procedures, surgical experience, recent trauma, or infection
- Chronic pain related to prolonged illness or injury, effects of cancer on surrounding tissues, or treatment-related effects
- Fear related to the unknown, separation from family, anticipation of invasive procedures, or effects of treatment
- Anxiety related to the stress and uncertainty of the situation
- Deficient knowledge related to current condition and appropriate methods for managing pain
- Sleep deprivation related to inability to manage pain effectively
- Impaired mobility related to increased episodes of pain
- Risk for constipation related to potential adverse effects of narcotic analgesic agents

When caring for a child experiencing pain, the ultimate goal is that the child will be free of pain as evidenced by participation in age-appropriate activities of daily living and vital signs within age-appropriate parameters. However, at times, this may be unrealistic, especially if the child is experiencing chronic pain. Therefore, a more appropriate goal would be that the child reports that his or her pain has decreased to a tolerable level. Pain assessment tools can be used to quantify the amount by which the child's pain has decreased. For example, if the child has rated the pain as 7 out of 10, a realistic goal might be that the child reports a pain rating of no more than 4 out of 10. Additional goals would reflect improvement or resolution of the identified problem. For example, a short-term goal for a child experiencing disturbed sleep due to the pain might be that the child sleeps for a minimum of 4 consecutive hours through the night. A long-term goal might be that the child sleeps for 7 to 8 hours undisturbed through the night.

Various interventions can be used for pain management. These interventions include nonpharmacologic and pharmacologic measures. A guiding principle when caring for the child experiencing pain is the provision of atraumatic care (see [Chapter 8](#) for more information). For example, cognitive and behavioral approaches are appropriate for pain management, including pain management related to procedures. In addition to nonpharmacologic measures, pharmacologic measures are appropriate for pain management. For example, apply a topical anesthetic cream to a site early enough before a venipuncture that it becomes effective. Another idea is to use an intermittent infusion device to obtain multiple blood specimen samples rather than performing repeated venipunctures. In addition, it is a good idea to consider the use of sedation for more painful procedures.

Throughout the child's care, be sure to discuss specific goals and interventions with the child and family as appropriate. Include the family in developing appropriate interventions so they can continue to support the child. Education of the child and family about interventions, including various therapies, is key. Ongoing assessment is needed to determine the effectiveness of the pain relief measures in achieving the desired goals.

Atraumatic Care

Play therapy may be helpful in allowing the child to express his or her feelings and adapt to the stressors of the current situation.

[Nursing Care Plan 14.1](#) can be used as a guide in planning nursing care for the child experiencing pain. The nursing care plan should be individualized based on the child's symptoms and needs. Specific information related to pain management and the nurse's role will be discussed later in the chapter.

When you enter Aiden's room, he is crying and says his leg hurts. What will be your initial action? What will be your plan of care to manage Aiden's pain (refer to QUEST assessment)? How would you address the statements made by the nurse in report? What approaches can you use to change staff behavior about pain management?

Wong-Baker FACES Pain Rating Scale

Instructions: Explain to the person that each face is for a person who feels happy because he has no pain (hurt) or sad because he has some or a lot of pain. **Face 0** is very happy because he doesn't hurt at all. **Face 1** hurts just a little bit. **Face 2** hurts a little more. **Face 3** hurts even more. **Face 4** hurts a whole lot. **Face 5** hurts as much as you can imagine, although you don't have to be crying to feel this bad. Ask the person to choose the face that best describes how he is feeling.

Thinking About Development

Kaylee Cooper is a 4-year-old female with a fractured femur. She has been in traction since arriving in the emergency room last night. When you enter her room at the beginning of your shift you note she is quiet and withdrawn. How will Kaylee's developmental stage affect the use of self-report? What special considerations must the nurse think about when using self-report of pain with Kaylee? What is the most appropriate pain rating scale to be used for Kaylee?

| Sensory | Affective | Evaluative | Temporal |
|---|--|--|--|
| Aching ("pain all over") | Awful ("cannot do anything") | Annoying ("cannot sleep") | Always ("pain always there") |
| Hurting ("pain all over") | Crying ("hurts so bad") | Bad ("cannot stop the hurting") | Comes and goes ("always pain") |
| Sore ("like a cut") | Frightening ("scared it won't stop") | Miserable ("cannot sleep or do stuff") | Comes on all of a sudden ("no warning") |
| Beating (procedural pain "spots") | Screaming (afraid of "going to the hospital") | Terrible ("don't like it") | Constant ("never goes away") |
| Pounding ("gets on your nerves") | Terrifying ("cannot sleep," "really tired," "not going to live") | Uncomfortable ("can't stay in one spot") | Continuous ("pain not going away") |
| Cutting ("hurts more than a cut") | Dozy ("don't know where I am") | Uncontrollable ("cannot stop it") | Forever ("never will go away") |
| Like a sharp knife ("stabbing and sharp") | | | Once in a while ("in a month sometimes pain; sometimes not") |
| Sharp (no meaning) | | | Sneaks up ("don't know when the pain will happen") |
| Stabbing (no meaning) | | | Sometimes ("goes away sometimes; sometimes not") |
| Cramping ("everywhere like a plane crash") | | | |
| Crushing (no meaning) | | | |
| Pressure ("pushing all over") | | | |
| Itching ("all over") | | | |
| Scratching ("helps sometimes") | | | |
| Shocking (pain "surprises" her) | | | |
| Splitting ("splitting in half" her body) | | | |
| Numb ("knows pain is there"/ procedural pain) | | | |
| Stiff ("cannot move") | | | |
| Swollen ("meds do not help") | | | |
| Tight ("cannot move") | | | |

| TABLE 14.6 FLACC BEHAVIORAL SCALE | | | |
|---|--|---|--|
| Category | Scoring | | |
| | 0 | 1 | 2 |
| Face | No particular expression or smile | Occasional grimace or frown, withdrawn, disinterested | Frequent to constant frown, clenched jaw, quivering chin |
| Legs | Normal position or relaxed | Uneasy, restless, tense | Kicking, or legs drawn up |
| Activity | Lying quietly, normal position, moves easily | Squirming, shifting back and forth, tense | Arched, rigid, or jerking |
| Cry | No cry (awake or asleep) | Moans or whimpers, occasional complaint | Crying steadily, screams or sobs, frequent complaints |
| Consolability | Content, relaxed | Reassured by occasional touching, hugging, or being talked to, distractible | Difficult to console or comfort |
| Each of the five categories is scored from 0 to 2, which results in a total score between 0 and 10. © 2002, The Regents of the University of Michigan. All rights reserved. | | | |

NURSING CARE PLAN 14.1

Overview for the Child in Pain

NURSING DIAGNOSIS: Acute pain related to need for invasive procedures, surgery, recent trauma, or infection as evidenced by pain rating scale, facial grimacing, crying, irritability, withdrawal activity, or changes in vital signs

Outcome Identification and Evaluation

Child will achieve adequate comfort level as evidenced by a decrease in rating number on a pain rating scale, quietness, calm resting behaviors, decrease in crying and irritability, and vital signs within acceptable parameters.

Interventions: Promoting Pain Relief

- Assess pain level using a developmentally appropriate pain rating tool *to establish a baseline.*
- Assess for verbal and nonverbal indicators of pain *to help determine child's pain level;* question parents about child's typical behaviors and previous experiences with pain *to determine factors that may be influencing child's response to pain.*
- Institute nonpharmacologic methods for pain control based on the child's age and cognitive level *to help decrease pain;* encourage parental participation in use of methods *to provide additional support and pain relief for the child.*
- Administer pharmacologic agents as ordered using the least traumatic route possible *to alter pain impulse transmission and minimize distress while promoting effective pain relief.*
- Explain the action of the drug and what the child should expect from the medication at a level that the child can understand *to promote trust and reduce fear while providing effective pain relief.*
- Give analgesics around the clock if pain is continuous and can be predicted *to maintain steady blood levels of the drug, thereby maximizing the drug's effect.*
- Perform atraumatic care at all times *to minimize the child's exposure to physical and psychological distress and pain.*
- Anticipate timing of procedures or situations that may lead to pain and provide appropriate analgesic therapy as ordered *to ensure that therapy is most effective at the time of the procedure.*
- Ensure that the child's environment is quiet and conducive to rest, dim the lights, and close the door or curtain *to reduce sensory overload that would increase the child's pain sensation.*
- Encourage the parents to stroke, touch, caress, and hold the child *to reduce discomfort and promote feelings of security.*

- Reassess the child's pain level after use of nonpharmacologic and pharmacologic methods *to determine effectiveness*; anticipate the need to modify or adapt nonpharmacologic methods or adjust analgesic dosage, route, or frequency *to promote maximum pain relief*.
- Perform nursing care activities after administering analgesic *to prevent exacerbating the child's pain*.
- Use diversional activities, distraction, and play appropriate to the child's age and cognitive level *to promote additional pain relief*

NURSING DIAGNOSIS: Anxiety related to stress and uncertainty of the situation, unknown cause of pain, lack of familiarity with procedures, testing, and health care facility, and painful procedures, as evidenced by crying, irritability, withdrawal, stoic or aggressive behaviors

Outcome Identification and Evaluation

Child and family will demonstrate a decrease in anxiety level as evidenced by age-appropriate positive coping behaviors, verbalization of feelings, playing out of feelings, child and family cooperation with plan of care, and absence of signs and symptoms associated with escalating anxiety.

Interventions: *Minimizing Anxiety*

- Assess child's and parents' understanding of the situation, including their understanding of what may be causing the pain and the reasons for the procedures and testing, *to provide baseline information about the child's and parents' knowledge and possible clues to anxiety*.
- Spend time with the child and parents discussing what they think might be happening, encouraging the child and parents to talk openly about their feelings, *to facilitate continued expressions and communication*. Allow time for questions and answer questions honestly *to establish rapport and build trust*.
- Approach the child and family in a calm, relaxed manner *to foster trust and communication and decrease anxiety*.
- Allow the child options related to interventions as much as possible, such as fluid to drink or snack to eat, extremity to use for venipuncture (right or left), color of bandage, or holding tape or dressing, *to foster feelings of control*.
- Provide atraumatic care *to reduce exposure to distress, which would exacerbate the child's anxiety level*.
- Explain any procedures, tests, or activities at a level the child can understand *to reduce fear of the unknown*.
- Incorporate aspects of the child's routine at home as much as possible *to reduce feelings of separation and promote feelings of normalcy*.
- Ensure consistency in care *to facilitate trust and acceptance*.
- Encourage parents in the use of comfort measures such as stroking, cuddling, holding, and rocking *to promote feelings of security and minimize stress*.
- Provide positive reinforcement for choices, participation in activities, and use of appropriate coping methods *to foster self-esteem*.
- Encourage the child's participation in play (unstructured and therapeutic play as needed) *to promote expression of feelings and fears*.

NURSING DIAGNOSIS: Deficient knowledge related to current condition and appropriate methods for managing pain as evidenced by crying, irritability, pushing away, questions and verbalizations about pain and relief methods

Outcome Identification and Evaluation

Child and parents will demonstrate adequate knowledge about the child's current condition and use of pain relief methods as evidenced by statements about the cause of the child's pain, demonstration of chosen nonpharmacologic relief methods, use of pharmacologic agents, and statements related to signs and symptoms of increased and decreased pain.

Intervention: *Providing Child and Family Teaching*

- Assess the child's and parents' knowledge and understanding of the child's current condition and current pain level *to establish a baseline for teaching*.
- Provide time for the child and parents to ask questions; answer questions honestly and in terms they can understand *to promote learning*.
- Explain in simplified terms how the child's condition is associated with pain or the rationale for procedures needed that may contribute *to pain to promote understanding and foster trust*.
- Teach in short sessions *to prevent overloading the child and parents with information*.
- Provide reinforcement and rewards *to help facilitate the teaching/learning process*.
- Use multiple modes of learning, such as written information, verbal instruction, demonstrations, and media when possible, *to facilitate learning and retention of information*.
- Instruct the parents and child as appropriate in nonpharmacologic methods for pain relief; encourage practice and participation by parents in methods chosen *to foster independence and use of method when necessary*.
- Teach the child as appropriate and parents about pharmacologic methods for pain relief; review specific information about the drug to be used, including action, duration, administration, possible adverse effects, and care necessary when the drug is used, *to promote learning*; have the child and parents report back information or demonstrate administration *to evaluate effectiveness of teaching*.
- Provide parents with written information about pain relief methods for use at home if indicated *to allow for reference at a later date*.

NURSING DIAGNOSIS: Sleep deprivation related to inability to manage pain effectively as evidenced by frequent waking by child during night, signs and symptoms of pain including irritability and restlessness, statements about being tired, pain rating scale

Outcome Identification and Evaluation

Child will exhibit increased ability to sleep during the night as evidenced by increasing periods of calm and restfulness (initially starting at 2 hours and gradually increasing to 7 to 8 hours), decreased pain level on pain rating scale, and statements of decreased fatigue.

Intervention: *Promoting Sleep and Rest*

- Assist the child in using nonpharmacologic methods of pain relief, such as imagery, distraction, and muscle relaxation, *to promote relaxation*.
- Administer pharmacologic pain relief as ordered *to minimize pain interfering with sleep*; anticipate a change in drug therapy if pain relief is inadequate.
- Cluster nursing care activities *to minimize energy expenditure and disruptions in the child's ability to rest*.
- Help the child with a nighttime routine similar to one he or she uses at home *to promote feelings of security*.
- Offer the child a back rub, warm bath, or warm liquids; reading a story; or listening to music *to facilitate relaxation*; provide stroking, hugging, cuddling, rocking, and light touch *to promote a sense of security and calm*.
- Dim the lights and close the curtain or door to the room *to provide a quiet, restful environment*.
- Ensure round-the-clock pain relief for the child through the night *to minimize the risk of pain*.

Outcome Identification and Evaluation

Child will remain free of any injury related to signs and symptoms of adverse effects of analgesic therapy as evidenced by respiratory rate appropriate for age and no complaints of gastrointestinal (GI) upset, dizziness, or sedation or episodes of constipation, nausea, vomiting, or pruritus.

Intervention: Promoting Safety

- Ensure that the child's call light is within reach *to allow for notification of health care personnel should problems arise.*
- Administer analgesic exactly as prescribed *to reduce the risk of error and development of adverse effects.*
- Assess the child's respiratory status closely for changes *to allow for early detection of respiratory depression.*
- If an opioid analgesic is being given, have naloxone readily available *to reverse the action of the narcotic if respiratory depression occurs.*
- Monitor appetite and assess bowel sounds for changes; note any abdominal distention or decreased bowel sounds, *which would suggest decreased peristalsis.*
- Ensure adequate fluid and fiber intake *to reduce risk of constipation.*
- Offer small frequent meals and give medication with food *to minimize risk of GI upset.*
- Assess for nausea and vomiting; if necessary, withhold food and fluids *to rest the GI tract and administer antiemetics until nausea and vomiting resolve.*
- Instruct the child to remain in bed after receiving analgesic, raise crib or side rails as appropriate, and instruct the child and parents to have someone accompany the child to the bathroom if allowed *to reduce the risk of falls from sedation.*
- Assess for complaints of itching and observe for rash or reddened areas; if pruritus occurs, urge the child not to scratch and expect to administer antihistamine as ordered *to reduce pruritus.*
- Provide the child with distraction to assist in helping *to reduce effects of pruritus.*

MANAGEMENT OF PAIN

Management of pain begins with assessment of the child's comfort level. If pain or the potential for pain, such as during an invasive procedure, is identified, steps must be taken to minimize or treat the pain. Three general principles guide pain management in children:

1. Individualize interventions based on the amount of pain experienced and the child's characteristics, such as developmental level, temperament, previous pain experience, and coping strategies.
2. Use nonpharmacologic and pharmacologic approaches to ease or eliminate the pain.
3. Teach the child and family about pain relief interventions and techniques and discuss with the child and family expectations of pain management.

Specific strategies for pain management include nonpharmacologic interventions such as relaxation, distraction, and guided imagery and pharmacologic interventions such as analgesics, patient-controlled analgesia, local analgesia, epidural analgesia, and moderate sedation.

Nonpharmacologic Management

Various techniques may be available to assist in managing mild pain in children or to augment the effectiveness of medications for moderate or severe pain. Many of these nonpharmacologic techniques assist children in coping with pain and give them an opportunity to feel a sense of mastery or control over the situation. Two types of techniques are behavioral-cognitive strategies and biophysical strategies. It is important to involve the parents in the process when using these techniques.

Behavioral-Cognitive Strategies

Behavioral-cognitive strategies for pain management involve measures that require the child to focus on a specific area rather than the pain. These strategies help to change the interpretation of the painful stimuli, reducing pain perception or making pain more tolerable. In addition, these strategies help to decrease negative attitudes, thoughts, and anxieties, thereby improving the child's coping mechanisms. Typically, these interventions work well with older children, but younger children also benefit from these techniques if they are adapted to the child's age and developmental level. Common behavioral-cognitive strategies include relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk.

RELAXATION

Relaxation aids in reducing muscle tension and anxiety. A wide variety of techniques can be used. Relaxation can be as simple as holding an infant or young child closely while stroking the child or speaking in a soft soothing manner, or having the child inhale and exhale slowly using rhythmically controlled deep breathing. It also can involve more sophisticated techniques such as progressive relaxation. With this technique the child is asked to focus on one area of the body and let that body part go limp. Then in an organized fashion, usually working from the toes to the head or vice versa, the child is asked to focus on another body part, making it go limp. Eventually the exercises work through all body areas, leading to relaxation of the entire body.

DISTRACTION

Distraction involves having the child focus on another stimulus, thereby attempting to shield him or her from pain. Research has shown distraction to be a statistically and clinically significant intervention in reducing pain. In addition, it is time and cost efficient to use (MacLaren & Cohen, 2007).

This technique does not eliminate the pain but does help to make it more tolerable. Various methods can be used for distraction, including:

- Counting
- Repeating specific phrases or words, such as "ouch"
- Listening to music or singing
- Playing games, including computer and video games
- Blowing bubbles or blowing pinwheels or party favors
- Listening to favorite stories (Fig. 14.9)
- Watching cartoons, television shows, or movies
- Visiting with friends
- Humor

Humor has been demonstrated to be an effective distracting technique for pain management. However, make sure that the

technique is age appropriate and be sure to determine what or who will make the child laugh. If possible, allow the child and his or her family to choose the materials that they consider humorous.

The type of distraction used depends on the age of the child. For example, a younger child may enjoy blowing pinwheels and blowing bubbles. He or she also will enjoy listening to favorite stories or books. Older children may enjoy computer or video games, listening to favorite music, or visiting with friends. See [Evidence-Based Practice 14.1](#).

FIGURE 14.9 A child using distraction for pain management.

EVIDENCE-BASED PRACTICE 14.1

WHAT ARE THE EFFECTS OF DISTRACTION ON PAIN, FEAR, AND DISTRESS DURING VENOUS PORT ACCESS AND VENIPUNCTURE IN CHILDREN WITH CANCER?

Children with cancer undergo multiple procedures, and many describe these procedures as the most distressing part of their disease. Distraction can decrease procedural pain, distress, and fear by redirecting the child from threatening to nonthreatening stimuli, resulting in a therapeutic benefit.

STUDY

This study used an intervention-comparison group design in a large university-affiliated pediatric medical center. A convenience sample of 50 children with cancer, from 5 to 18 years old, was randomly assigned to either a comparison or an intervention group. Two oncology nurses performed all port access or venipunctures per institutional guidelines. Both groups received standard care with the intervention group also using a self-selected distracter from a pool of five choices, which were chosen based on recommendations in the literature (*Spy: Super Challenger* book, bubbles, music, VR glasses that allow the child to watch a video in 3-D and listen to music in stereo sound, and Nintendo Gameboy).

Findings

The pain and fear scores were lower in the intervention group, although the difference was not statistically significant. Fear and distress scores were significantly improved from during to after the procedure in the intervention versus the comparison group. Forty-six percent of those in the intervention group stated the current poke was “better” or “much better” than their last one, compared to 39% in the comparison group. Fifty-nine percent of parents in the intervention group, compared to 16% in the comparison group, felt this venous access or venipuncture was better than the last one. Ninety-one percent of those children in the intervention group stated that the distracter helped and they would use it again. All of the parents (100%) reported the distracter was effective and they would encourage their child to use it again.

Nursing Implications

Nurses need to encourage distraction strategies as they have been shown to positively enhance procedure outcomes. The nurse needs to facilitate and encourage parent participation in the use of distraction strategies.

Adapted from Windich-Biermeier, A., Sjoberg, I., Dale, J. C., Eshelman, D., & Guzzetta, C. E. (2007). Effects of distraction on pain, fear, and distress during venous port access and venipuncture in children and adolescents with cancer. 0(1), 8-19.

IMAGERY

Imagery involves the use of the imagination to create a mental image. This mental image usually is a positive, pleasurable image, but it need not be real. The child is encouraged to include details and sensations that are associated with the image, such as specific descriptions of the image, colors, sounds, feelings, and smells. In some instances, the child may write down or record the image on a tape or compact disc. When pain occurs, the child is encouraged to create the mental image or read or listen to the description.

BIOFEEDBACK

Biofeedback involves having the child gain an awareness of his or her body functions and learn ways to modify them voluntarily. The child usually is taught specific skills about how to modify body functions using an apparatus that measures pain-related changes in muscle tone or physiologic data, such as blood pressure or pulse rate. This teaching usually is performed by a specialized health care provider and occurs over several sessions, in advance of the pain experience. With practice, the child learns to control the changes without the apparatus. This technique can be used by older children, such as adolescents, who can concentrate for longer periods of time.

THOUGHT STOPPING

Thought stopping involves substituting a pleasurable or positive thought for the painful experience. Examples of positive thoughts might be, "It's only for a short time" or "It's important so I get better." The negative component of the pain is not ignored or suppressed; rather, it is transformed into something positive. Thought stopping also can involve the use of short, positive phrases. For example, the child may repeat "quick stick, feel better go home soon" when he or she anticipates pain or experiences pain.

Thought stopping is a useful method for reducing anxiety before and during events associated with pain. Children can be taught to use this technique any time they experience anxiety related to a painful experience. Doing so helps to promote the child's sense of control over the situation.

POSITIVE SELF-TALK

Positive self-talk is similar to thought stopping in that it involves the use of positive statements. With positive self-talk the child is taught to say positive statements when he or she is experiencing pain. For example, the child may be taught to say, "I will feel better and be able to go home and play with my friends."

Take Note!

Studies have shown hypnosis to be consistently effective in decreasing pain and anxiety in children during procedures involving acute pain (Evans, Tsao, & Zelter, 2008).

Biophysical Interventions

Biophysical interventions focus on interfering with the transmission of pain impulses reaching the brain. The interventions involve some type of cutaneous stimulation near the site of the pain. This stimulation decreases the ability of the A-delta and C fibers to transmit pain impulses. Examples of biophysical interventions include application of heat and cold, massage and pressure, and transcutaneous electrical nerve stimulation (TENS).

SUCKING AND SUCROSE

Sucking is a behavior from which infants derive satisfaction. Therefore, nonnutritive sucking (e.g., sucking a pacifier) can be used to reduce pain behaviors in neonates undergoing painful procedures. In addition, infants show reduced pain behaviors after ingestion of sucrose or other sweet-tasting solutions such as glucose during single-event procedures, such as heel lancing (Stevens, Yamada, & Ohlsson, 2010). Optimal dosing for sucrose needs further research and caution must be used in extremely low-birthweight infants and infants with unstable blood glucose levels.

Atraumatic Care

Breastfeeding is also a noninvasive, natural, and feasible way to use sucking to reduce pain in infants.

HEAT AND COLD APPLICATIONS

Heat and cold applications alter physiologic mechanisms associated with pain. Cold results in vasoconstriction and alters capillary permeability, leading to a decrease in edema at the site of the injury. Due to vasoconstriction, blood flow is reduced and the release of pain-producing substances such as histamine and serotonin also is decreased. Moreover, transmission of painful stimuli via peripheral nerve fibers is decreased.

Heat results in vasodilation and increases blood flow to the area. It also leads to a decrease in nociceptive stimulation and removal of chemical substances that can stimulate nociceptive fibers. The increase in blood flow alters capillary permeability, leading to a reduction in swelling and pressure on nociceptive nerve fibers. Heat may also trigger the release of endogenous opioids, which mediate the pain response.

MASSAGE AND PRESSURE

Massage and pressure, like other biophysical interventions, are believed to inhibit stimulation of the A-delta and C fibers. These methods are helpful in relaxing muscles and reducing tension. In addition, these techniques can aid in distracting the child. Massage can be as simple as rubbing a body part or pressing on an area such as an injection site for about 10 seconds. It can also be more involved, requiring the use of another person to perform the massage. Lotion or ointment can be used during the massage and may provide a comforting effect. Contralateral pressure or massage (i.e., of the opposite area) may be used, especially if the area of pain cannot be accessed or if the affected area is too painful to touch.

A more formal method of pressure application is acupressure. In acupressure the fingertip, the thumb, or a blunt instrument is used to apply gentle, firm pressure to specifically designated sites to control pain. The pressure may be applied in one motion followed by releasing, in a circular motion for several minutes and then releasing or with a vibrating motion using the fingertips. The motion of applying and then releasing pressure is thought to facilitate the release of endogenous endorphins and enkephalins. The techniques of pressure and massage are easy to learn and use and can be taught to children and parents.

The Nurse's Role in Nonpharmacologic Pain Intervention

The nurse plays a major role in teaching the child and family about nonpharmacologic pain interventions. Help the child and family choose the most appropriate and most effective methods and ensure that the child and parents use the method before pain occurs as well as before the pain increases. [Teaching Guidelines 14.1](#) lists some helpful instructions for the parents and child about nonpharmacologic pain management.

Teaching Guidelines 14.1

TEACHING TO MANAGE PAIN WITHOUT DRUGS

- Review the methods available and choose the method(s) that your child and you find best for your situation.
- Learn to identify the ways in which your child shows pain or demonstrates he or she is anxious about the possibility of pain. For example, does he or she get restless, make a face, or get flushed in the face?
- Begin using the technique chosen before your child experiences pain or when your child first indicates he or she is anxious about, or beginning to experience, pain.
- Practice the technique with your child and encourage the child to use the technique when he or she feels anxious about pain or anticipates that a procedure or experience will be painful.
- Perform the technique with your child. For example, take the deep breath in and out or blow bubbles with him or her; listen to the music or play the computer game with your child.
- Avoid using terms such as “hurt” or “pain” that suggest or cause your child to expect pain.
- Use descriptive terms like “pushing,” “pulling,” “pinching,” or “heat.”
- Avoid overly descriptive or judgmental statements such as, “This will really hurt a lot” or “This will be terrible.”
- Stay with your child as much as possible; speak softly and gently stroke or cuddle your child.
- Offer praise, positive reinforcement, hugs, and support for using the technique even when it was not effective.

It is also important to assist the child and parents when using the technique in order to make sure that they are using the technique correctly. Offer suggestions for modifications or adaptations as necessary.

Parents are important components of the pain management program. Give them the option to stay with the child, or let them know that someone else will support the child if they opt not to stay. Offer simple, concrete ways to assist and help the child to manage pain. Many of the nonpharmacologic techniques can be done by parents, and children may respond better if their parents demonstrate the technique and encourage them to use it. Invite parents to participate in decisions as well as act as a coach to their child during procedures. Prepare the parents and explain the most appropriate pain management approaches and strategies. Discuss the type and amount of pain expected as well as the potential complications associated with pain management approaches. Ask how the parent predicts the child will react to a painful situation. Finally, offer techniques and strategies to the parents as they act as the coach during these situations.

Take Note!

Although parents want to help their children and some are able to act as coaches, the response of the child to pain and stress and to their parents' distraction interventions is highly variable. Some children appear to be soothed by their parents' distraction actions; others appear to become distressed. Be alert to factors that may influence the child's response, including age, sex, diagnosis, ethnicity, previous experience, temperament, anxiety, and coping style. Also be aware of parental factors, including ethnicity, sex, previous experience, belief in the helpfulness of the intervention, parenting style, and parental anxiety (McCarthy & Kleiber, 2006).

Pharmacologic Management

Pharmacologic interventions involve the administration of drugs for pain relief. Administration may occur using a wide variety of methods. The selection of the method is determined by the drug being administered; the child's status; the type, intensity, and location of the pain; and any factors that may be influencing the child's pain. Research overwhelmingly supports the appropriate use of analgesics to reduce pain perception in children.

Medications Used for Pain Management

Analgesics (medications for pain relief) typically fall into one of two categories—nonopioid analgesics and opioid analgesics. Anesthetics also may be used. Drugs such as sedatives and hypnotics may be used as adjuvant medications to help minimize anxiety or provide or assist with pain relief when typical analgesics are ineffective.

NONOPIOID ANALGESICS

Nonopioid analgesics include acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen, ketorolac, naproxen, indomethacin, diclofenac, and piroxicam ([Drug Guide 14.1](#)). These agents may be used to treat mild to moderate pain, often for conditions such as arthritis; joint, bone, and muscle pain; headache; dental pain; and menstrual pain. Acetaminophen, probably the most widely known nonopioid analgesic, and ibuprofen are also commonly used to treat fever in children.

Take Note!

Aspirin should not be used in children for analgesic and antipyretic purposes because of the high risk of Reye syndrome.

According to the World Health Organization's (WHO's) pain ladder, acetaminophen and NSAIDs are first-line agents for the treatment of pain (WHO, 2010). Although this ladder was developed for the relief of cancer pain, it can be applied to any child experiencing pain of increasing intensity.

Nonopioid agents are typically administered orally or rectally. In some cases, such as with postoperative pain, they may be administered intravenously as a continuous infusion or as bolus doses. Administration via intramuscular injection is not recommended because the injection can cause significant pain and the onset of pain relief is not increased.

Adverse effects commonly associated with these agents include gastrointestinal irritation, blood clotting problems, and renal dysfunction. However, research has demonstrated that children experience only mild gastrointestinal upset and negligible effects on a healthy, well-functioning renal system. Blood clotting problems arise primarily when these agents are given perioperatively before primary hemostasis has occurred (Maunukela & Olkkola, 2003). Nonopioids are relatively safe, have few incompatibilities with other medications, and do not depress the central nervous system. Unfortunately, they exhibit a ceiling effect for analgesia. That is, after a certain level, they do not provide increasing pain relief even when administered at increased doses. As a result, they may be combined with opioids for more effective pain relief.

| Drug | Actions/Indications | Nursing Implications |
|---|--|---|
| Acetaminophen (Tylenol) | <p>Possible inhibition of cyclooxygenase in the central nervous system</p> <p>Direct action on hypothalamic heat-regulating center</p> <p>Mild to moderate pain, fever; arthritis, musculoskeletal pain, headache</p> | <ul style="list-style-type: none"> Administer orally or rectally. Do not exceed five doses of drug in 24 hours. Caution parents to read labels of other over-the-counter (OTC) drugs carefully; some may contain acetaminophen and if given in conjunction may lead to overdose. |
| Ibuprofen (Motrin, Advil) | <p>Inhibition of prostaglandin synthesis</p> <p>Mild to moderate pain, fever, treatment of inflammatory diseases</p> | <ul style="list-style-type: none"> Administer orally. Give with food or after meals if GI upset occurs. Assess for easy bruising, bleeding gums, or frank or occult blood in urine or stool. Monitor for nausea, vomiting, GI upset, diarrhea or constipation, dizziness, or drowsiness. Caution parents to read labels of OTC medications closely; some may contain ibuprofen or other NSAIDs and if given in conjunction may lead to overdose. |
| Other NSAIDs: ketorolac (Toradol), diclofenac (Voltaren), indomethacin (Indocin), naproxen (Naprosyn, Aleve) | <p>Inhibition of prostaglandin synthesis</p> <p>Moderate to severe pain</p> | <ul style="list-style-type: none"> Administer oral form with food or after meals if GI upset occurs. Monitor for headache, dizziness, nausea, vomiting, constipation, or diarrhea. Assess for signs and symptoms of bleeding, such as bruising, epistaxis, gingival bleeding, or frank or occult blood in urine or stool. Ketorolac: may also be given IV or IM. In children ages 2 to 16 years, recommended as single dose only Naproxen: also available in combination products (caution parents to read OTC labels carefully) Indomethacin: when administering IV, report oliguria or anuria. Didofenac: may also be given rectally |
| Opioid agents: morphine, codeine, fentanyl (Sublimaze, Duragesic), hydromorphone (Dilaudid), oxycodone (OxyContin), Methadone | <p>Opioid agonist acting primarily at μ-receptor sites (morphine, codeine, fentanyl, hydromorphone, oxycodone, methadone)</p> <p>Moderate to severe acute and chronic pain</p> <p>Morphine: intractable pain, preoperative sedation</p> <p>Codeine: also suppresses cough reflex</p> <p>Fentanyl: pain associated with short procedures such as bone marrow aspiration, fracture reductions, suturing</p> | <ul style="list-style-type: none"> Assess respiratory status frequently, noting any decrease in ventilatory rate or changes in breathing patterns; have naloxone readily available in case of respiratory depression (particularly morphine, fentanyl, hydromorphone). Monitor for sedation, dizziness, lethargy, or confusion. Educate parents and child that the drug may make the child sleepy, drowsy, or lightheaded. Institute safety measures to prevent injury to the child. Assess bowel sounds for decreased peristalsis; observe for abdominal distention. Ensure adequate fiber intake and administer stool softeners as prescribed to minimize risk for constipation. Monitor urine output for changes and report. Morphine: may cause itching, particularly facial Codeine: may cause nausea, vomiting, abdominal pain. IV administration results in apnea and severe hypotension. Most commonly administered orally in combination with acetaminophen Fentanyl: observe for chest wall rigidity, which can occur with rapid IV infusion. Oxycodone is the opioid component of Tylox and Percocet. |
| Mixed opioid agonist-antagonist: pentazocine (Talwin), butorphanol (Stadol), nalbuphine (Nubain) | <p>Pentazocine: antagonist at μ-receptor sites, agonist at κ-receptor sites.</p> <p>Butorphanol: high affinity for κ-receptor sites, minimal affinity for σ-receptor sites. Nalbuphine: partial agonist at κ-receptor sites, antagonist at μ-receptor sites</p> <p>Moderate to severe pain</p> <p>Relief of migraine headache (butorphanol)</p> <p>Preoperative analgesia (nalbuphine)</p> | <ul style="list-style-type: none"> Monitor the child for sedation. Educate child and parents that the drug may make the child sleepy, drowsy, or lightheaded. Institute safety measures to prevent injury to the child. Pentazocine, butorphanol: monitor for diaphoresis, dizziness. Assess for tachycardia and hypertension. Butorphanol is given intranasally for migraine headaches. |

GI, gastrointestinal.

(2010). *Lexi-comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-comp, Inc.

OPIOID ANALGESICS

Opioid analgesics are typically used for moderate to severe pain. They are classified as either agonists (when they act as the neurotransmitter at the receptor site) or antagonists (when they block the action at the receptor site). Opioid agents that act as agonists include morphine, codeine, fentanyl, meperidine, hydromorphone, oxycodone, and hydrocodone. Opioids that act as mixed agonists-antagonists include pentazocine, butorphanol, and nalbuphine (see [Drug Guide 14.1](#)). Opioids can be administered orally,

rectally, intramuscularly, or intravenously. In addition, some agents such as fentanyl can be administered transdermally or transmucosally. Morphine is considered the “gold standard” for all opioid agonists; it is the drug to which all other opioids are compared and is usually the drug of choice for severe pain (Oakes, 2011).

Opioid agonists, such as morphine, are associated with numerous adverse effects, resulting primarily from their depressant action on the central nervous system.

Take Note!

When administering parenteral or epidural opioids, always have naloxone (Narcan) readily available to reverse the opioid's effects should respiratory depression occur

Opioids stimulate the chemoreceptor trigger zone (CTZ), leading to nausea and vomiting. Moreover, **drug tolerance** (increased dosage required for the same pain relief previously achieved with a lower dose) and **physical dependence** (need for continued administration of the drug to prevent withdrawal symptoms) are commonly noted when opioids are given repeatedly. [Drug Guide 14.1](#) gives additional information related to the opioid analgesics.

Take Note!

Drug tolerance occurs when increasing doses are required to manage the pain. Physical dependence can occur after as few as 5 days of continuous use of the drug; symptoms of withdrawal begin if it is suddenly stopped (Oakes, 2011).

Mixed agonist-antagonists are associated with less respiratory depression than agonists. Unfortunately, like NSAIDs, this group also has a ceiling effect, leading to inadequate pain relief even with increased dosages. When this occurs, increasing the dosage of the mixed agonist-antagonist or combining it with an agonist provides no additional pain relief.

Take Note!

Meperidine (Demerol), an opioid agonist, is not recommended as a first-choice agent for pain relief in children. Meperidine's metabolite, normeperidine, is associated with the development of restlessness, irritability, twitching, agitation, tremors, and, most importantly, seizures (American Medical Association, 2010). Normeperidine is a central nervous stimulant and its adverse effects cannot be reversed by an opioid antagonist such as naloxone (Kim, 2009).

ADJUVANT DRUGS

Adjuvant drugs are drugs that are used to promote more effective pain relief, either alone or in combination with nonopioids or opioids. Their primary indication is for diagnoses other than pain. These agents are not classified as analgesics but may provide a coanalgesic effect or may treat side effects. Benzodiazepines, such as diazepam and midazolam, help to relieve anxiety. Midazolam also produces amnesia. Anticonvulsants, such as carbamazepine, and tricyclic antidepressants, such as amitriptyline and nortriptyline, are used to treat neuropathic pain.

LOCAL ANESTHETICS

Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. However, local anesthetics such as lidocaine historically were not used in children because these drugs need to be injected. The belief was that children feared needles and use of a local anesthetic subjected the child to two needlesticks instead of one. Advances in technology have led to the development of improved methods of delivery such as topical ointments and iontophoresis for administration of local anesthetics, thereby promoting atraumatic care. (For a more detailed discussion, see the next section on drug administration methods and later in the chapter on the nurse's role in managing procedure-related pain.)

Drug Administration Methods

With any medication administered for pain management, the timing of administration is vital. Timing depends on the type of pain. For continuous pain, the current recommendation is to administer analgesia around the clock at scheduled intervals to achieve the necessary effect (Oakes, 2011). Scheduled dosing has been associated with decreased pain intensity ratings for children (Paice, Noskin, Vanagunas, & Shott, 2005; Sutters et al., 2010). As-needed or PRN dosing is not recommended for continuous pain. This method can lead to inadequate pain relief because of the delay before the drug reaches its peak effectiveness, and as a result the child continues to experience pain, possibly necessitating a higher dose of analgesic to achieve relief. This then places the child at risk for overmedication and toxic effects.

For pain that can be predicted or considered temporary, such as with a procedure, analgesia is administered so that the peak action of the drug matches the time of the painful event.

There are various methods for administering pain medications to children. The preferred methods are the oral, rectal, intravenous, topical, or local nerve block routes. Epidural administration and moderate sedation also can be used.

ORAL METHOD

The oral method is often preferred because it is simple, easy, and convenient. The medication may be in the form of a pill, capsule, tablet, syrup, or elixir. Oral administration provides relatively steady blood levels of the drug when administered as a scheduled dose. Effectiveness typically occurs 1 to 2 hours after administration. As soon as possible, switch the child to oral dosing from parenteral dosing. However, keep in mind that higher doses of the oral medication may be needed to achieve the same effect.

RECTAL METHOD

The rectal method may be used when the child cannot take the medication orally, such as when he or she has difficulty swallowing or is experiencing nausea and vomiting. It is a viable alternative for drug administration. Some analgesics are available in suppository form. For others that are not, the drug can be compounded into a suppository form. The absorption rate varies with rectal administration, and children may find insertion of a suppository uncomfortable and embarrassing (Bowden & Greenberg, 2008).

INTRAVENOUS METHOD

Intravenous analgesia administration is the method of choice in emergency situations and when pain is severe and quick relief is needed. With intravenous administration, the drug usually takes effect within 5 minutes. Intravenous administration can be accomplished with bolus injections or continuous infusions. Continuous infusions may be preferred over bolus doses because steady blood levels are more easily maintained, thereby enhancing the drug's effect in relieving pain. Typically, opioids such as morphine, hydromorphone, and fentanyl are used due to their short half-life and decreased risk for toxicity.

PATIENT-CONTROLLED ANALGESIA

In **patient-controlled analgesia (PCA)**, a computerized pump is programmed to deliver an infusion of analgesics via a catheter inserted intravenously, epidurally, or subcutaneously. The analgesic may be given as a continuous infusion, as a continuous infusion supplemented by patient-delivered bolus doses, or as patient-delivered bolus doses only. Typically the child presses a button to administer a bolus dose. The pump has a lockout function that is preset with the dose and time interval. If the child presses the button before the preset time, he or she will not receive an overdose of medication. By delivering small, frequent doses of opioids, the child can experience pain relief without the effects of oversedation. The child also experiences a sense of control over the pain experience.

Both the Institute for Safe Medical Practices (ISMP) and the Joint Commission have identified infants and young children as not being good candidates for PCA usage (D'Arcy, 2007). However, PCA has been used successfully in children as young as 5 or 6 years old (D'Arcy, 2007). It is essential to assess each child individually and consider his or her developmental level and psychosocial factors in determining appropriate PCA use. The child must have the necessary intellect, manual dexterity, and strength to operate the device.

PCA has been used to control postoperative pain and the pain associated with trauma, cancer, and sickle cell crisis. It can be used in acute care settings or in the home. Most commonly, morphine, hydromorphone, and fentanyl are the drugs used with PCA. The dosage is based on the child's response. Dosages for infusions depend on the child's age, the opioid used, and the type of pain. A commonly used range for morphine infusion to treat postoperative pain ranges from 0.01 to 0.04 mg/kg/hour. Higher dosage ranges have been used to treat the pain associated with sickle cell crisis and cancer.

Serious adverse events, such as oversedation, respiratory depression, and even death, can occur when family members, caregivers, or clinicians who are not authorized administer PCA doses "by proxy" (D'Arcy, 2007; The Joint Commission, 2004). The ISMP recommends developing specific criteria in any situation where authorized agent-activated PCA is being used (D'Arcy, 2007). Proper education and instruction are crucial in any situation where someone other than the child may be administering PCA doses. Thorough assessment is necessary to ensure the child's pain is neither undertreated nor overtreated. To ensure safety with PCA use, each institution must have policies and procedures in place, appropriate education of health care staff, quality control measures, and quality machines.

LOCAL ANESTHETIC APPLICATION

A local anesthetic may sometimes be used to alleviate the pain associated with procedures such as venipuncture, injections, wound repair, lumbar puncture, or accessing of implanted ports. Local anesthesia is a type of regional analgesia that blocks or numbs specific nerves in a region of the body. Medications called local anesthetics include topical forms, such as creams, agents delivered by

iontophoresis, vapocoolants, and skin refrigerants, and injectable forms.

Topical Forms. A common choice for effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections for up to 24 hours after the injection. However, it requires a 60- to 90-minute application time to intact skin using an occlusive dressing for superficial procedures and up to 2 to 3 hours for deeper, more invasive procedures (Box 14.1). EMLA is approved for use in infants 37 weeks' gestation or older. Maximum dosage and maximum area of application are based on the child's weight. Parents can be taught how to apply the EMLA at home in preparation for a procedure (Fig. 14.10). Sometimes EMLA is not used due to the expense and the time needed to allow the drug to act. New approaches to EMLA delivery have been developed. Examples include other drug formulations and a patch delivery with a heat-activated system (Synera) that enhances the delivery of lidocaine and prilocaine. Synera is labeled for children older than 3 years of age and needs to be applied only 20 to 30 minutes before the procedure.

BOX 14.1

APPLYING EMLA

Follow these guidelines when applying EMLA:

- Explain the purpose of the medication to the child and parents, reinforcing that it will help the pain go away.
- Check the scheduled time for the procedure; plan to apply the cream 60 minutes before a superficial procedure such as a heel stick or venipuncture or 2 to 3 hours before a deeper procedure such as a lumbar puncture or bone marrow aspiration.
- Place a thick layer of the cream on the skin at the intended site of the procedure, making sure that the area where the cream is being applied is free of any breaks. Do not rub the cream in once it is applied to the skin.
- Cover the site with a transparent dressing such as Tegaderm or Op-site and secure it so that the dressing is occlusive. Alternatively, use plastic film wrap and tape the edges to secure the dressing.
- Instruct the child not to touch the dressing once it is secured. If necessary, cover the occlusive dressing with a protection device or a loosely applied gauze or elastic bandage.
- After the allotted time, remove the occlusive dressing and wipe the cream from the skin. Inspect the skin for a change in color (blanching or redness), which indicates that the medication has penetrated the skin adequately.
- Verify that sensation is absent by lightly tapping or scratching the area. Use this technique also to demonstrate to the child that the anesthetic is effective. If sensation is present, reapply the cream.
- Prepare the child for the procedure. Assess the child's pain after the procedure to evaluate for pain and to differentiate pain from fear and anxiety.

Take Note!

EMLA is used with caution in children younger than 3 months and other susceptible persons because it may be associated with methemoglobinemia (Oakes, 2011; Zempsky, 2008). It is contraindicated in children who have congenital or idiopathic methemoglobinemia (OpenAnesthesia.org, 2011). It must be used cautiously in those younger than age 12 months who are receiving methemoglobin-inducing agents, such as sulfonamides, phenytoin, phenobarbital, and acetaminophen. Use of these agents in combination with EMLA increases the child's risk for methemoglobinemia, a condition that could lead to cyanosis and hypoxemia (OpenAnesthesia.org, 2011).

FIGURE 14.10 A parent applies EMLA cream to the child at home in preparation for a procedure.

TAC (tetracaine, epinephrine, cocaine) and LET (lidocaine, epinephrine, tetracaine) are other examples of topical anesthetics. These are commonly used for lacerations that require suturing. The agent is applied directly to the wound with a cotton ball or swab for 20 to 30 minutes until the area is numb. These methods are not used in children with known sensitivity to any of these medications.

Lidocaine can also be dispersed in liposomes to allow for transcutaneous delivery (liposomal lidocaine). Over-the-counter LMX4 (lidocaine 4%), formerly called ELA-Max, is massaged into the skin without the use of an occlusive dressing. Anesthesia to the area is reached in 15 to 30 minutes and lasts about 60 minutes. Recent studies suggest that the analgesic effect may be equal to that of EMLA with the advantage of a shorter onset (American Medical Association, 2010). Research has shown that liposomal lidocaine 4% cream was highly effective in reducing the pain associated with intravenous cannulation (Zempsky, 2008). The researchers cited a short onset of action (30 minutes) and minimal vascular effects as benefits. They found that the liposomal encapsulation protects the anesthetic from being metabolized too quickly (Zempsky, 2008). Study results have shown higher intravenous cannulation success rates, less pain, shorter total procedure time, and minor dermal changes among children (Taddio, Soin, Schuh, Koren, & Scolnik, 2005).

Needle-free powder lidocaine (Zingo) is another topical analgesic. It is labeled for use in children 3 to 18 years of age. It is a single-use, prefilled disposable system that provides analgesia in 1 to 3 minutes. Studies have shown it to be safe and well tolerated with a rapid onset and significant reduction in needlestick pain (Zempsky et al., 2008).

Another choice for local anesthesia is iontophoresis. Iontophoretic lidocaine (Numby Stuff) provides a deeper analgesia in a shorter duration (approximately 10 to 25 minutes) and is used over intact skin. A mild electrical current from a small battery-powered generator and two iontophoretic drug-delivery electrodes push drug molecules (lidocaine HCl 2% with epinephrine 1:100,000) into the skin. A mild tingling sensation may be felt during drug delivery, with an increase in tingling noted with higher currents. This type of local anesthesia is not recommended for use in children who have a history of allergy or sensitivity to these drugs, in children who have electrically sensitive equipment such as a pacemaker, or in children who have damaged skin or scar tissue.

Vapocoolant spray, another type of local analgesia, can be sprayed onto the skin or administered using a cotton ball soaked in liquid. The depth of anesthesia is not known, but it appears to provide immediate pain control. It is inexpensive and requires no waiting time. The effect lasts for approximately 1 to 2 minutes. Studies have found it to be an effective analgesic for short-duration procedures (American Medical Association, 2010).

Injectable Forms. Injectable forms of lidocaine or procaine can be administered subcutaneously or intradermally around the procedural area approximately 5 to 10 minutes before the procedure. Common problems with this form of anesthetic include the pain

associated with the subcutaneous injection and some burning associated with lidocaine administration, as well as blanching of the skin.

Take Note!

The burning that lidocaine causes on injection may be diminished by buffering lidocaine with sodium bicarbonate, using 10 parts lidocaine and 1 part sodium bicarbonate (1 mL of 1% to 2% lidocaine and 0.1 mL of 8.4% sodium bicarbonate). Then inject 0.1 mL or less of the solution intradermally at the site of venipuncture. Anesthetic action is almost immediate. The solution is stable for only approximately 1 week if not refrigerated.

EPIDURAL ANALGESIA

For **epidural analgesia**, a catheter is inserted in the epidural space at L1-L2, L3-L4, or L4-L5. The drug, usually fentanyl or morphine, diffuses into the cerebrospinal fluid and crosses the duramater to the spinal cord. Then it binds with the opioid receptors located at the dorsal horn. The drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule), a continuous infusion, or PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic such as bupivacaine.

Epidural analgesia is typically used postoperatively, providing analgesia to the lower body for approximately 12 to 14 hours. The small amount of medication used with this type of analgesia causes less sedation, thereby allowing the child to participate more actively in postoperative care activities. This type of analgesia also is effective for children undergoing upper or lower abdominal surgeries because it controls localized intense pain, somatic pain, and visceral pain.

When epidural analgesia is being administered, additional narcotic analgesics are not given in order to prevent complications such as respiratory depression, pruritus, nausea, vomiting, and urinary retention.

Take Note!

Respiratory depression, although rare when epidural analgesia is used, is always a possibility. When it does occur, it usually occurs gradually over a period of several hours after the medication is initiated. This allows adequate time for early detection and prompt intervention.

Constant assessment is essential because insertion of an epidural catheter and epidural analgesia can lead to infection at the site of the insertion, epidural hematoma, arachnoiditis, neuritis, or spinal headache (rare) due to a cerebrospinal fluid leak and respiratory depression. Frequent assessment, typically every 1 to 2 hours, of heart rate, respiratory rate, and depth of sedation, and every 2 to 4 hours of blood pressure, pain level, and motor function, is imperative (Oakes, 2011). Assessing for adverse reactions such as nausea and vomiting and pruritus, checking the tubing and catheter site, and ensuring the occlusive dressing is intact are all important nursing interventions. The dermatome, which is the area of the body associated with supply by a particular nerve, that innervates the diaphragm can become suppressed during continuous epidural analgesia, resulting in respiratory depression. It is important to assess the child's sensory level frequently. Using cool water or an alcohol pad, bilaterally touch the child's body every 2 to 3 cm. The level where the child states he or she feels the temperature change is the level of anesthesia. (Refer to [Figure 14.11](#) for dermatome levels.)

MODERATE (CONSCIOUS) SEDATION

Moderate sedation used to be labeled conscious sedation, but the term "conscious" has been replaced since it can be misleading (Krauss & Green, 2006). It is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so the child has the ability to maintain a patent airway and respond to physical or verbal stimulation. This procedure requires adherence to specific protocols, and many regulatory bodies, such as the Joint Commission, and societies, including the American Academy of Pediatrics, American Society of Anesthesiologists, and American College of Emergency Physicians, have published standards and guidelines to improve patient safety and outcomes (Krauss & Green, 2006). The depressed state is obtained by using various agents such as morphine, fentanyl, midazolam, chloral hydrate, or diazepam and other adjuvants such as pentobarbital. Midazolam and fentanyl often are the drugs of choice for moderate sedation because they act quickly, last only a short time, and are available in oral and intravenous formulations ([Box 14.2](#)). Midazolam provides only sedative effects and no analgesia; therefore, it is commonly administered with an opioid.

FIGURE 14.11 The level of anesthesia should not go higher than T4, the nipple line, in children.

Take Note!

The combination of meperidine (Demerol), promethazine (Phenergan), and chlorpromazine (Thorazine), commonly called DPT, is no longer recommended because it has been shown to cause excessive depression of the central nervous system, extrapyramidal reactions, and prolonged recovery times (Buck, 2010; American Academy of Pediatrics, 1995). In addition, the combination must be administered intramuscularly, which causes the child to experience more pain.

BOX 14.2

ORAL FORMS OF MIDAZOLAM AND FENTANYL

Two of the most commonly used agents for moderate sedation are midazolam and fentanyl. Each of these is available in an oral form, which promotes atraumatic care.

Oral Midazolam Syrup

- Clear purplish-red cherry-flavored syrup
- Syrup containing 2 mg/mL
- Recommended dosage: 0.25 to 0.5 mg/kg to a maximum dose of 20 mg
- Action usually within 10 to 20 minutes
- Major adverse effects: respiratory depression and arrest

Fentanyl Oralet

- Oral transmucosal formulation

- Candy-type lozenge on a plastic holder
- Available in 200, 300, and 400 mcg
- Recommended dose: 5 to 15 mcg/kg
- Not recommended for use in children weighing less than 15 kg
- Onset of action in about 15 minutes of sucking lozenge; duration of action approximately 1 hour

Take Note!

Studies have found a high rate of complications, mainly vomiting and pruritus with transmucosal fentanyl, therefore limiting its usefulness (Klein et al., 2002).

Moderate sedation is used for procedures that are painful and stressful. For example, moderate sedation is suggested instead of restraints, especially for toddlers and preschool children who are undergoing frightening or invasive procedures and who are manifesting extreme anxiety and behavioral upset. Other indications include situations involving:

- Evidence that the child is experiencing a heightened stress reaction (e.g., attempting to flee, crying inconsolably, or flailing)
- Verbalization by the child that he or she is frightened and does not want to be touched
- Inability to remain immobilized, such as during laceration repair or computed tomography
- Any procedure that is painful and fear provoking

The route of administering the medications for sedation should follow the guidelines of atraumatic care. Oral, topical, or an existing intravenous route should be used. Personnel administering moderate sedation must be specially trained, and emergency equipment and medications must be readily available.

The Nurse's Role in Pharmacologic Pain Management

The nurse plays a major role in providing pharmacologic pain relief. As with any medication, the nurse is responsible for adhering to the rights of medication administration—right drug, right dose, right route, right time, and right patient. In addition, the nurse also adheres to three additional rights—the right of the child and parents to be educated, the right of the child to refuse the medication, and the right documentation. The nurse also must have a solid knowledge base about the medications used for pain relief. This knowledge includes information about the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects). Refer to [Chapter 13](#) for further information.

Assessment is crucial when pharmacologic pain interventions are used. An initial assessment of pain provides a baseline from which options for relief can be chosen. Factors that can affect the choice of analgesic, such as the child's age, pain intensity, physiologic status, or previous experiences with pain, also need to be considered. The nurse acts as an advocate for the child and the family to ensure that the most appropriate pharmacologic agent is chosen for the situation.

Assessment is ongoing once the agent is administered. Monitor physiologic parameters such as level of consciousness, vital signs, oxygen saturation levels, and urinary output for changes that might indicate an adverse reaction to the agent. More intensive monitoring is needed when agents are administered intravenously or epidurally or by moderate sedation. For example, if the child is receiving moderate sedation, interventions include:

- Ensuring that emergency equipment is readily available
- Maintaining a patent airway
- Monitoring the child's level of consciousness and responsiveness
- Assessing the child's vital signs (especially pulse rate, heart rate, blood pressure, and respiratory rate)
- Monitoring oxygen saturation levels

Typically, a specially trained health care provider is specifically designated to perform these activities during the administration of the sedation. Afterwards, the nurse is responsible for ongoing monitoring of the child's status.

| TABLE 14.7 INTERVENTIONS FOR COMMON OPIOID-INDUCED ADVERSE EFFECTS | |
|--|--|
| Adverse Effect | Nursing Interventions |
| Constipation | Encourage fluid intake unless contraindicated. Ensure intake of high-fiber foods, including fruits, if allowed. Encourage activity, including ambulation if possible. Obtain order for stool softener. Administer laxative as ordered. |
| Pruritus | Apply cool compresses and lotions. Administer antihistamine as ordered. |
| Nausea and vomiting | Inform child and parents that these symptoms usually subside in 1 to 2 days. Encourage small frequent meals with bland foods. Administer antiemetic if ordered. |

Monitor the child closely for evidence of adverse effects. [Table 14.7](#) describes the interventions useful for responding to these adverse effects. Be alert for signs and symptoms of respiratory depression secondary to opioid administration. Have an opioid antagonist such as naloxone (Narcan) and the benzodiazepine antagonist flumazenil (Romazicon) readily available should the child experience respiratory depression.

In addition to assessing physiologic parameters, assess the child's and parents' emotional status before and after the agent is administered. For example, increased anxiety and fear may necessitate a change in method of administration, such as topical application instead of an intradermal injection of a local anesthetic. Use nonpharmacologic methods to help lessen anxiety, thereby promoting more effective relief from the drug.

Nurses also are responsible for ensuring that the child and parents are adequately prepared for the use of the pharmacologic agent. Teach the child and parents about the drug, why it is being used, its intended effects, and possible adverse effects, tailoring the teaching to the child's cognitive level. Provide opportunities for the child and parents to ask questions, offering support and guidance throughout the experience. Provide a demonstration or use visual aids so that the child and parents know exactly what to expect. Encourage the use of play to help the child express fears and anxieties related to the administration.

Management of Procedure-Related Pain

One of the most common causes of pain in children is procedure-related pain. The procedure may be minor, such as an intramuscular injection, heel stick, or venipuncture, or it may be more involved, such as lumbar puncture, bone marrow aspiration, or wound care. Regardless, pain is real for children and painful procedures are often extremely distressing to them. Variables that affect pain include the intensity or length of the procedure and the skill of the health care provider performing the procedure.

The Nurse's Role in Managing Procedure-Related Pain

Through the use of behavioral and pharmacologic approaches, nurses can significantly reduce the pain and distress of procedures. Use the guiding principles of atraumatic care, which include the following:

- Use topical EMLA, iontophoretic lidocaine, vapocoolant spray, or buffered lidocaine at the intended site of a skin or vessel puncture.
- Incorporate the use of nonpharmacologic strategies for pain relief in conjunction with pharmacologic methods.
- Prepare the child and parents ahead of time about the procedure and then keep all equipment out of site until it is ready to be used.
- Use therapeutic hugging (see [Chapter 8](#)) to secure the child.
- Use the smallest-gauge needle possible or an automated lancet device to puncture the skin.
- Use an intermittent infusion device or peripherally inserted central catheter (PICC) if multiple or repeated blood samples are necessary. Coordinate care so that several tests can be performed from one sample if possible.
- Opt for venipuncture in newborns instead of heel sticks if the amount of blood needed would require much squeezing.
- Use kangaroo care (skin-to-skin contact) for newborns before and after heel stick.
- Provide nonnutritive sucking, with sucrose solution, if appropriate; pacifier; or breastfeeding for newborns several minutes before the procedure.

Take Note!

Individualize interventions based on the painfulness of the procedure and the child's developmental age and personality. Use behavioral-cognitive approaches and pharmacologic interventions. For example, encouraging the school-age child to assist during painful procedures in age-appropriate ways may actually help ease some of the pain related to a heightened state of anxiety, or at least assist the child in coping with the situation. Always use appropriate pharmacologic treatment especially for the first procedure to provide as painless an experience as possible for the child.

Nursing care for the child with procedure-related pain includes the child as well as the parents. Be sure to prepare them for the procedure using an appropriate developmental approach. Promote environmental comfort, too. Ensure that the child's privacy is maintained and that the lighting is adequate for the procedure but not so bright as to cause the child discomfort.

Painful procedures performed in the child's room can lead to an association of pain or fear with the room or bed. Many hospitals have a special treatment room where procedures can be performed. These rooms are usually equipped with many activities, toys, and decorations to help distract the child. The use of a treatment room may not be feasible or desirable in all situations or for all procedures. The ultimate goal is to do what is best for the child; therefore, the nurse needs to consider the needs of the child, the demands of the procedures, and the conditions that would facilitate the best outcome.

Unless contraindicated, encourage the parents to be present before, during, and after the procedure to provide comforting support to the child. Also encourage the child and parents to use nonpharmacologic methods to help maximize pain relief and reduce anxiety. For example, nonpharmacologic methods that are helpful for the toddler and preschooler may include positioning the child on the lap and hugging the child, distracting the child with toys or interactive books, and blowing bubbles.

Play therapy can be useful when preparing children for painful procedures. Encourage children to make decisions about their care related to pain management if their condition or procedure allows. It is also helpful to anticipate and recognize painful situations and provide pain medication before the actual procedure to ensure comfort. Many nonpharmacologic strategies can be enhanced and better implemented with the help of the child life specialist or play therapist, who have specialized training in these techniques.

Recall Aiden from the beginning of the chapter. What are some interventions that may be helpful prior to, during, and after his dressing change?

Management of Chronic Pain

Typically, pain in children is acute pain, but chronic pain is a significant problem in the pediatric population. Historically, chronic pain was defined by the duration of the pain, such as longer than 3 to 6 months. However, research has identified elements associated with chronic pain as occurring much earlier in time (American Pain Society, 2001). Currently, chronic pain is identified as the complex interplay of biological, psychological, and environmental factors (American Pain Society, 2001). According to the American Pain Society (2001), children with chronic pain and their families experience significant emotional and social consequences from the pain and disability; also, the experience of chronic pain in childhood may predispose the individual to chronic pain in adulthood.

The Nurse's Role in Managing Chronic Pain

The nurse's role in managing chronic pain in children is similar to that for the child experiencing acute pain or procedure-related pain. Assessment of the child's pain is key and should include a history of the present problem. Questions should focus on the onset of the pain; its intensity, duration, and location; and any factors that alleviate or exacerbate it. In addition, it is important to question the child and parents about the impact of the pain on the child's daily life, such as sleep, play, eating, school, and interactions with peers, other family members, and friends. Also address the impact of the child's chronic pain on the family's life.

Another key area of assessment is determining how the pain affects the child's and family's level of stress. Areas to address include the child's and parents' feelings of hopelessness, anxiety, and depression. Also question the child and parents about what they think has caused the pain and how they have coped with it. In addition, ascertain what methods the child and parents have used to alleviate the pain and the success of these methods. Inquire about any home remedies or alternative therapies that may have been used.

Review past physical examination findings for clues to the underlying problem. Observe the child's overall appearance, gait, and posture. Assess the child's cognitive level and emotional response, especially related to the experience of pain. Expect to complete a neurologic examination and observe for muscle spasms, trigger points, and increased sensitivity to light touch. Abnormal body postures assumed by the child due to chronic pain may result in the development of secondary pain in the muscles and fascia. When children tense their muscles due to fear of examination, somatic pain may occur.

Various nonpharmacologic and pharmacologic strategies are used to manage chronic pain. Often multiple strategies are combined

to address pain relief as well as the pain's impact on other areas, such as sleep or school functioning. When pharmacologic agents are used, the oral form is the method of choice. As with any pain management strategy, education of the child and family is paramount. A referral to a pediatric pain specialist may be needed if the child's pain is not controlled effectively.

KEY CONCEPTS

- Pain is a highly individualized subjective experience affecting persons of any age. It is a universal experience and is considered the fifth vital sign.
- Pain management is a critical element in a child's plan of care because children may lack the verbal capacity to describe their pain experience; caregivers and health care providers often have misconceptions about pain; assessment of the complex nature of the pain experience is difficult; if left unmanaged, pain in children can lead to serious physical and emotional consequences; and available resources and research related to pain relief strategies in children are limited.
- The sensation of pain involves a sequence of physiologic events: transduction, transmission, perception, and modulation.
- Pain can be classified by duration as acute or chronic, by etiology as nociceptive or neuropathic, or by source or location as somatic or visceral.
- Factors influencing a child's perception of pain include age and gender, cognitive level, temperament, previous pain experiences, and family and cultural background, all of which cannot be changed. Situational factors involve behavioral, cognitive, and emotional aspects and can be changed.
- Infants, including preterm infants, experience pain. Behavioral and physiologic indicators are used to assess pain. Toddlers commonly react with intense emotional upset and physical resistance or aggression. Preschoolers may feel that pain is a punishment for misbehaving or having bad thoughts. School-age children can communicate the type, location, and severity of pain but may deny having pain to appear brave or avoid further pain. Adolescents, with their focus on body image and fear of loss of control, often ask numerous questions and may attempt to remain stoic to avoid being viewed as childish.
- Assessment of pain in children includes both subjective and objective data. Nurses need to tailor the assessment to the child's developmental level and ask appropriate questions geared to the child's cognitive level. Parental questioning during the health history also is important.
- Self-report pain rating scales are valuable assessment tools that allow the child's level of pain to be quantified. Examples include the FACES pain rating scale, the Oucher pain rating scale, the poker chip tool, the word-graphic rating scale, visual analog and numeric scales, and the Adolescent Pediatric Pain Tool.
- Different pain rating scales are appropriate for different developmental levels. However, children may regress when in pain, so a simpler tool may be needed to make sure that the child understands what is being asked. Consistency in using the same tool is essential so that appropriate comparisons can be made and effective interventions can be planned and implemented.
- Physical examination of the child for pain primarily involves the skills of observation and inspection. These skills are used to assess for physiologic and behavioral changes that indicate pain. Auscultation also may be used to assess for changes in vital signs, specifically heart rate and blood pressure. Physiologic and behavioral pain assessment tools, such as the Neonatal Infant Pain Scale, Riley Infant Pain Scale, Pain Observation Scale for Young Children, CRIES Scale for Neonatal Postoperative Pain Assessment, and FLACC Behavioral Scale for Postoperative Pain in Young Children, measure specific parameters and changes that would indicate that the child is in pain.
- Nonpharmacologic pain management strategies aim to assist children in coping with pain and to give them a sense of mastery or control over the situation. These strategies may be categorized as behavioral-cognitive, in which the child focuses on a specific area or aspect rather than the pain (e.g., relaxation, distraction, imagery, biofeedback, thought stopping, and positive self-talk), or biophysical, in which the focus is on interfering with the transmission of pain impulses reaching the brain (e.g., heat and cold applications, massage and pressure).
- The nurse plays a major role in teaching the child and family about available nonpharmacologic pain interventions, helping them choose the most appropriate and most effective methods, and ensuring that the child and parents use the method before the pain occurs as well as before it increases.
- Pharmacologic interventions involve the administration of drugs for pain relief, most commonly nonopioids and opioid analgesics. The selection of the method is determined by the drug being administered; the child's status; the type, intensity, and location of the pain; and any factors that may be influencing the child's pain. The preferred methods for administering analgesics include the oral, rectal, intravenous, or local nerve block routes; epidural administration; and moderate sedation.
- Nonopioid analgesics used to treat mild to moderate pain include acetaminophen and NSAIDs such as ibuprofen, ketorolac, naproxen, and, less commonly, indomethacin, diclofenac, and piroxicam.
- Morphine is considered the "gold standard" for all opioid agonists; it is the drug to which all other opioids are compared and is

usually the drug of choice for severe pain (Oakes, 2011).

- Local anesthetics are commonly used to provide analgesia for procedures. They are effective in providing successful pain relief with only minimal risk of systemic adverse effects. The first choice for the most effective, painless local anesthesia is EMLA (eutectic mixture of local anesthetics [lidocaine and prilocaine]). It achieves anesthesia to a depth of 2 to 4 mm, so it reduces pain of phlebotomy, venous cannulation, and intramuscular injections up to 24 hours after injection.
- Epidural analgesia involves the insertion of a catheter into the epidural space through which drugs can be administered as bolus injections (a one-time bolus or on an intermittent schedule), as a continuous infusion, or as PCA. Usually an opioid, such as morphine, fentanyl, or hydromorphone, is given in conjunction with a long-acting local anesthetic, such as bupivacaine.
- Moderate sedation is a medically controlled state of depressed consciousness that allows protective reflexes to be maintained so the child has the ability to maintain a patent airway and respond to physical or verbal stimulation.
- When providing pharmacologic pain relief, the nurse must adhere to the five rights of medication administration and have a solid knowledge base about the medications used for pain relief and the drug's pharmacokinetics (absorption, distribution, metabolism, and excretion) and pharmacodynamics (mechanism of action, including adverse effects). Initial and ongoing assessment is crucial.
- The principles of atraumatic care guide nursing interventions for providing pain relief, especially for procedure-related pain.
- Chronic pain in children can significantly affect the child's daily life and activities as well as the family's life.

CHAPTER WORKSHEET

MULTIPLE CHOICE QUESTIONS

1. The nurse is preparing to assess the pain of a 3-year-old child who had surgery the day before. Which pain assessment method would be most appropriate for the nurse to use?
 - a. FACES pain rating scale and poker chip tool
 - b. FACES pain rating scale, observation of the child, and parent report
 - c. Asking the parents to rate their child's pain using the word-graphic rating scale
 - d. Visual analog scale

2. When developing the plan of care for a child in pain, the nurse identifies appropriate strategies aimed at modifying which factors influencing pain?
 - a. Gender
 - b. Cognitive level
 - c. Previous pain experiences
 - d. Anticipatory anxiety
3. An adolescent who is a competitive swimmer comes to the emergency department complaining of localized aching pain in his shoulder. He states, "I've been practicing really hard and long to get myself ready for my meet this weekend." The area is tender to the touch. The nurse determines that the adolescent is most likely experiencing which type of pain?
 - a. Cutaneous pain
 - b. Deep somatic pain
 - c. Visceral pain
 - d. Neuropathic pain
4. After teaching a child's parents about the different methods of distraction that can be used for pain management, which statement by the parents indicates a need for additional teaching?
 - a. "We'll have her focus on her hand and count each finger slowly."
 - b. "We'll read some of her favorite stories to her."
 - c. "We'll have her imagine that she's at the beach this summer."
 - d. "She likes to play video games, so we'll bring in some from home."
5. A child is scheduled for a bone marrow aspiration at 4 p.m. The nurse would plan to apply EMLA cream to the intended site at which time?
 - a. 1:30 p.m.
 - b. 3:00 p.m.
 - c. 3:30 p.m.
 - d. 4:00 p.m.

CRITICAL THINKING EXERCISES

1. The nurse asks a 12-year-old girl if she is having pain. She denies pain, even though she is lying on her left side holding her abdomen with her knees flexed up to it. What might be some underlying factors leading the child to deny her pain? How would the nurse go about assessing this child's pain?
2. The nurse comes into the room of a 6-year-old who is sleeping. His mother states, "He's asleep, so he's not in pain." How should the nurse respond?
3. A child who is receiving ibuprofen is experiencing increased pain. The dosage of ibuprofen is increased but is no longer effective in providing adequate pain relief. What is occurring? What would be most likely to happen next?

STUDY ACTIVITIES

1. Interview nurses who work on a pediatric unit about their experiences with managing pain in children. Ask them how they assess pain in children and the major methods they use to assist the children in managing their pain.
2. Interview families of children with chronic illnesses who deal with pain. Ask the parents how they assess their children's pain level and what methods they have used in assisting their children in managing pain.
3. Compare and contrast the drugs fentanyl and midazolam when used for moderate sedation in terms of onset of action, duration, primary effects, and antidotes.
4. A child is receiving epidural analgesia with morphine. The nurse would be alert for which of the following adverse effects? Select all that apply.
 - a. Respiratory depression
 - b. Pruritus
 - c. Constipation
 - d. Vomiting
 - e. Amnesia
 - f. Hematoma

Nursing Care of the Child With a Health Disorder

Nursing Care of the Child With an Infectious or Communicable Disorder

Words of Wisdom

Complete and lasting freedom from infectious disease remains a dream, but one worth fighting a hard battle for.

KEY TERMS

antibody
antigen
chain of infection
communicability
endogenous pyrogens
exanthem
fomite
pathogen
phagocytosis

Learning Objectives

Upon completion of the chapter, you will be able to:

1. Discuss anatomic and physiologic differences in children versus adults in relation to the infectious process.
2. Identify nursing interventions related to common laboratory and diagnostic tests used in the diagnosis and management of infectious conditions.
3. Identify appropriate nursing assessments and interventions related to medications and treatments for childhood infectious and communicable disorders.
4. Distinguish various infectious illnesses occurring in childhood.
5. Devise an individualized nursing care plan for the child with an infectious or communicable disorder.
6. Develop child/family teaching plans for the child with an infectious or communicable disorder.

Mrs. Goldberg brings her son Samuel, 3 months old, to the clinic. He presents with a history of fever and nasal congestion. His mother tells you, “He’s been very irritable and crying more than usual.”

Infectious and communicable diseases are one of the leading causes of death worldwide. As the world has become increasingly connected, infectious diseases have presented new challenges. Children are particularly vulnerable to these types of illnesses. Their immune systems are still developing and their natural curiosity, especially in infants and toddlers, leads to wide-range handling of objects and surfaces coupled with a tendency to place their hands and objects in their mouths without washing first. Infectious diseases in children can range in severity from mild with few or no symptoms to serious illness, such as damage to organs, and even death. Infectious and communicable diseases include bacterial infections (e.g., sepsis), viral infections (e.g., viral exanthems and rabies), zoonotic infections, vector-borne infections, parasitic and helminthic infections (e.g., round-worm and pediculosis capitis [head lice]), and sexually transmitted infections (e.g., chlamydia and gonorrhea).

There has been a dramatic decrease in the incidence and severity of infectious and communicable diseases since the advent of vaccines, antibiotics, antiviral drugs, and antitoxins (Global Health Council, 2011). Some diseases have been effectively controlled, but the vast majority will not be eliminated. New diseases emerge and old diseases are reappearing, sometimes in a drug-resistant form. The Centers for Disease Control and Prevention (CDC) tracks certain infectious diseases. This list of nationally reportable diseases is revised periodically to add new pathogens or remove diseases as their incidence declines. Reporting by each state to the CDC is voluntary. Therefore, slight variations exist from state to state. [Box 15.1](#) lists nationally reportable diseases.

BOX 15.1

NATIONALLY NOTIFIABLE DISEASES

- Botulism
- *Chlamydia trachomatis*
- Diphtheria
- Ehrlichiosis
- Gonorrhea
- Hepatitis A, B, and C
- Influenza (pediatric mortality)
- Lyme disease
- Malaria
- Measles
- *Meningococcus* Mumps Pertussis
- Poliomyelitis, paralytic
- Q fever
- Rabies
- Rocky Mountain spotted fever (spotted fever rickettsiosis)
- Rubella
- Streptococcal disease, invasive group A
- Syphilis
- Tetanus
- Tuberculosis
- Varicella (morbidity)
- Varicella (deaths only)

For a complete list of nationally notifiable diseases in the United States, go to http://www.cdc.gov/osels/ph_surveillance/nndss/phs/infdis2011.htm

Nurses, particularly those working in schools, child care centers, and outpatient settings, are often the first to see the signs of infectious or communicable diseases in children. These signs are often vague at first (e.g., a sore throat or rash). Therefore, nurses must have accurate assessment skills and be familiar with the signs and symptoms of common childhood infectious diseases so that they can provide prompt recognition, treatment, guidance, and support to families. Identifying the infectious agent is of primary importance to prevent further spread.

Many infectious diseases can be prevented through simple and inexpensive methods such as hand washing, adequate immunization, proper handling and preparation of food, and judicious antibiotic use. Nurses play a key role in educating parents and the community on ways to prevent infectious and communicable diseases.

| Objective | Nursing Significance |
|---|---|
| Reduce, eliminate, or maintain elimination of cases of vaccine-preventable diseases. Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children. | <ul style="list-style-type: none"><li data-bbox="836 138 1154 285">• Educate children and their families on the importance of proper immunizations.<li data-bbox="836 306 1154 411">• Assess immunization status at every healthy encounter.<li data-bbox="836 432 1154 541">• Provide families with a written record of immunizations given. |

Healthy People Objectives based on data from <http://www.healthypeople.gov>.

INFECTIOUS PROCESS

Infection occurs when an organism enters the body and multiplies, causing damage to the tissues and cells. The body's response to this damage due to infection or injury is inflammation. The body delivers fluid, blood, and nutrients to the area of infection or injury and attempts to eliminate the pathogens and repair the tissues. The body does this through vascular and cellular reactions. The vascular response is an initial period of vasoconstriction followed by vasodilatation. This vasodilatation allows for the increase of fluids, blood, and nutrients to the area.

The cellular response involves the arrival of white blood cells (WBCs) to the area. WBCs are the body's defense against infection or injury. The types of WBCs are neutrophils, basophils, eosinophils, lymphocytes, and monocytes. Elevations in certain portions of the WBC count reflect different processes occurring in the body, such as infection, allergic reaction, or leukemia. Table 15.1 explains the function of each type of WBC. Each type is generally present in a balanced state; the types are reported as a percentage of the total WBC count or as the number per certain volume of blood.

| Type of White Blood Cell | Function |
|--|--|
| Granulocytes <ul style="list-style-type: none">• Neutrophils (polymorphonuclear leukocytes or PMNs, segs)• Eosinophils• Basophils | Phagocytic cells <ul style="list-style-type: none">• First line of defense upon invasion of bacteria, fungus, cell debris, and other foreign substances• Respond to allergic disorders and parasitic infections• Respond to allergic disorders and hypersensitivity reactions; used to study chronic inflammation |
| Lymphocytes (B lymphocytes, T lymphocytes, and natural killer cells) | Main source of producing an immune response; respond to viral infections (measles, rubella, chickenpox, infectious mononucleosis); tumors |
| Monocytes | Second line of defense; respond to larger and more severe infections than neutrophils by phagocytosis; leukemias and lymphomas; chronic inflammation |

Adapted from Fischbach, F. T., & Dunning III, M. B. (2009). *A manual of laboratory and diagnostic tests* (8th ed., pp. 74–85). Philadelphia: Lippincott Williams & Wilkins; and Caspard, K. J. (2009). Blood cells and the hematopoietic system. In C. M. Porth & G. Matfin (Eds.), *Pathophysiology: Concepts of altered health states* (8th ed., pp. 254–261). Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins.

WBCs use **phagocytosis** to ingest and destroy the **pathogen**. If bacteria escape the action of phagocytosis, they enter the bloodstream and lymph system and the immune system is activated. With activation of the immune system, B lymphocytes (humoral immunity) and T lymphocytes (cell-mediated immunity) are matured and activated. B and T cells recognize and attack infectious pathogens. B cells, which mature in the bone marrow, produce specific antibodies to a specific offending **antigen** (a substance that the body recognizes as foreign). T cells, which mature in the thymus, attack the antigen directly. Once B and T cells have been exposed to an antigen, some cells will remember the antigen. Therefore, if the particular antigen invades again, the body will act more quickly. A third type of lymphocyte, natural killer cells are a part of the innate immune system and function to destroy foreign material present.

Fever

Infection or inflammation caused by bacteria, viruses, or other pathogens stimulates the release of **endogenous pyrogens** (interleukins, tumor necrosis factor, and interferon). The pyrogens act on the hypothalamus, where they trigger prostaglandin production and increase the body's temperature set point. This triggers the cold response, resulting in shivering, vasoconstriction, and a decrease in peripheral perfusion to help decrease heat loss and allow the body's temperature to rise to the new set point. Fever, defined as a temperature greater than 38°C (100.4°F), then occurs. Box 15.2 gives specific temperature parameters for fever based on what route is used for measurement.

Antipyretics are often used to lower fever and increase comfort. They decrease the temperature set point by inhibiting the production of prostaglandins. As a result, sweating and vasodilation occur and there is heat loss and a drop in temperature.

It is important to distinguish between fever and hyperthermia. Hyperthermia occurs when normal thermoregulation fails, resulting in an unregulated rise in core temperature. Hyperthermia may occur if the central nervous system of the child becomes impaired by disease, drugs, and abnormalities of heat production or thermal stressors, such as being left in a hot automobile or exertional heat stroke. In the absence of hyperthermia and in the normally neurologic child, the body does not allow fever to rise to lethal levels. The body actually produces a natural antipyretic, called cryogen. If there is no hyperthermic insult, it is rare to see a child's temperature

rise above 41.4°C (106°F) (Crocetti & Serwint, 2005).

BOX 15.2

DEFINITION OF FEVER BY MEASUREMENT ROUTE

- Oral: >37.5°C (99.5°F)
- Rectal: >38°C (100.4°F)
- Axillary: >37.3°C (99.1°F)
- Tympanic: >38°C (100.4°F)

| Stage | Explanation |
|---------------|---|
| Incubation | Time from entrance of pathogen into the body to appearance of first symptoms; during this time, pathogens grow and multiply |
| Prodrome | Time from onset of nonspecific symptoms such as fever, malaise, and fatigue to more specific symptoms |
| Illness | Time during which child demonstrates signs and symptoms specific to an infection type |
| Convalescence | Time when acute symptoms of illness disappear |

Stages of Infectious Disease

Infectious diseases follow a similar pattern. They progress through certain stages (Table 15.2) in which **communicability** (ability to spread to others) can be predicted. It is important for nurses to understand these stages to help control and manage infectious diseases.

Chain of Infection

The **chain of infection** is the process by which an organism is spread. Behaviors of infants and young children, mainly pertaining to hygiene, increase their risk for infection by promoting the chain of infection. Poor hygiene habits, including lack of hand washing, placing toys and hands in the mouth, drooling, and leaking diapers, all can contribute to the spread of infection and communicable diseases. Table 15.3 reviews the chain of infection and nursing implications related to it.

Preventing the Spread of Infection

Nurses play a key role in breaking the chain of infection and preventing the spread of diseases. It is important to follow infection control and prevention practices. It is also very important to educate parents and children on the measures they can take to prevent the spread of infection.

Take Note!

Frequent hand washing is the most important way to prevent the spread of infection.

Isolation precautions help nurses break the chain of infection and provide strategies to prevent the spread of pathogens among hospitalized children. Guidelines can be found on the CDC website (<http://www.cdc.gov/hicpac/2007IP/2007isolationPrecautions.html>). Additional guidelines are available from various infection control societies and regulatory agencies such as the Occupational Safety and Health Administration (OSHA). The Joint Commission has also developed infection control standards. This leads to an array of complex guidelines that all health professionals need to be familiar with.

The Hospital Infection Control Practices Advisory Committee (HICPAC) has presented guidelines for hospitalized children that include two tiers (Siegel, Rhinehart, Jackson, Chiarello, and the Healthcare Infection Control Practices Advisory Committee, 2007). Tier 1 is standard precautions, which are designed for the care of all children in the hospital regardless of their diagnosis. Tier 2 is transmission-based precautions, designed for children who are known, or suspected, to be infected with epidemiologically important

pathogens. These pathogens can be spread by air-borne, droplet, or contact transmission. **Box 15.3** gives an overview of standard and transmission-based precautions.

Take Note!

Hand hygiene includes both hand washing with soap and water and the use of alcohol-based products (gels, rinses, foams) that do not require water. If there is no visible soiling of the hands, approved alcohol-based products are preferred because of their superior microbicidal activity, reduced drying of the skin, and convenience (World Health Organization, 2009).

When caring for children, these guidelines may need to be modified. For instance, diaper changing is routine in the pediatric setting. Since it does not usually soil hands, it is not mandatory to wear gloves (except if gloves are required due to transmission-based precautions). According to the standard precaution guidelines, single rooms are required for those who are incontinent and cannot control bodily excretions. Since the majority of young children are incontinent, obviously this guideline is inappropriate in the pediatric setting. Pediatric units often have common rooms, such as playrooms and schoolrooms. Children placed on transmission-based isolation are not allowed to leave their rooms and therefore are not allowed to use these common rooms.

| Chain Link | Explanation | Nursing Implications |
|-----------------------|--|--|
| Infectious agent | Any agent capable of causing infection; examples: bacteria, viruses, rickettsiae, protozoa, and fungi | <ul style="list-style-type: none"> Control or eliminate infectious agents through: <ul style="list-style-type: none"> Hand washing Wearing gloves Cleaning, disinfecting, or sterilizing equipment |
| Reservoir | A place where the pathogen can thrive and reproduce; examples: human body, animals, insects, food, water, inanimate objects (e.g., stethoscopes) | <ul style="list-style-type: none"> Control or eliminate reservoirs. Control sources of body fluids, drainage, or solutions that may harbor pathogens. Follow institutional guidelines for disposing of infectious wastes. Provide proper wound care, change dressings or bandages when soiled. Assist children to carry out appropriate skin and oral care. Keep linens clean and dry. |
| Portal of exit | A way for the pathogen to exit the reservoir; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract | <ul style="list-style-type: none"> Control portals of exit and educate children and families. Cover mouth and nose when sneezing or coughing. Avoid talking, coughing, or sneezing over open wounds or sterile fields. Use personal protective equipment. |
| Modes of transmission | <p>Direct transmission: body-to-body contact</p> <p>Indirect transmission: transferred by fomite or vector; spread by droplet or air-borne transmission</p> | <ul style="list-style-type: none"> Wash hands before and after child contact, invasive procedures, or touching open wounds. Use personal protective equipment when necessary. Urge children and family to wash hands frequently, especially before eating or handling food, after eliminating, and after touching infectious material. |
| Portal of entry | A way for the pathogen to enter the host; examples: skin and mucous membranes, respiratory tract, urinary tract, gastrointestinal tract, reproductive tract | <ul style="list-style-type: none"> Use proper sterile technique during invasive procedures. Provide appropriate wound care. Dispose of needles and sharps in puncture-resistant containers. Provide all children with their own personal care items. |
| Susceptible host | Any person who cannot resist the pathogen | <ul style="list-style-type: none"> Protect susceptible host by promoting normal body defenses against infection. Maintain integrity of the child's skin and mucous membranes. Protect normal defenses by regular bathing and oral care, adequate fluid intake and nutrition, and proper immunization. |

Normal immune function is an amazing protective response by the body. It involves complex responses including phagocytosis, humoral immunity, cellular immunity, and activation of the complement system. Blood and lymph are responsible for transporting the agents of the immune system. Due to the immature responses of the immune system, infants and young children are more susceptible to infection. The newborn displays a decreased inflammatory response to invading organisms, contributing to an increased risk for infection. Cellular immunity is generally functional at birth, and humoral immunity occurs when the body encounters and then develops immunity to new diseases. Since the infant has had limited exposure to disease and is losing the passive immunity acquired from maternal antibodies, the risk of infection is higher. Young children continue to have an increased risk for infection and communicable disorders because disease protection from immunizations is not complete. (Refer to [Chapter 9](#) for further details.)

BOX 15.3

STANDARD PRECAUTIONS AND ISOLATION PRECAUTIONS

Standard Precautions (Tier One)

- Apply to all children
- Apply to all body fluids, secretions, and excretions except sweat, nonintact skin, and mucous membranes
- Designed to reduce the risk of transmission of microorganisms from recognized and unrecognized sources
- Techniques include:
 - Proper hand hygiene
 - Use of gloves (clean or sterile) when touching blood, body fluids, secretions or excretions, and contaminated items
 - Masks, eye protection, and face shields when patient care may include splashing or sprays of blood, body fluid secretions, or excretions, and during bronchoscopy, endotracheal intubation, and open suctioning of the respiratory tract
 - Fluid-resistant nonsterile gowns, to protect skin and clothing, when patient care may include splashing or sprays of blood, body fluid secretions, or excretions
 - Patient care equipment handled in a manner that prevents skin or mucous membrane exposure and contamination of clothing
 - All used linen is considered contaminated and needs to be handled and disposed of appropriately.
 - Mouthpieces, resuscitation bags with one-way valves, and other ventilation devices should be readily available.
 - Cleaning and disinfecting noncritical surfaces in patient care areas
 - Respiratory hygiene/cough etiquette: applies to any person with signs of illness including cough, congestion, rhinorrhea, or increased respiratory secretions that is entering a health care facility. It includes education regarding covering the mouth/nose with a tissue; prompt disposal of used tissues, along with surgical masks used by a person who is coughing when appropriate; hand hygiene after contact with respiratory secretions; and separation, ideally greater than 3 feet, of persons with respiratory infections in common waiting areas when possible.
 - Safe injection practices: use of sterile single-use disposable needle. When possible use of single-dose vials; precautions used to prevent injury when using, cleaning, or disposing of needles and sharps
 - Use of masks for insertion of catheters or injection into the spinal or epidural space via lumbar puncture procedures

Transmission-Based Precautions (Tier Two)

Designed for children with known or suspected infection with pathogens for which additional precautions are warranted to interrupt transmission

Air-Borne

- Designed to reduce the risk of infectious agents transmitted by air-borne droplet nuclei or dust particles that may contain the infectious agent
- Examples of such illnesses include measles, varicella, and tuberculosis.
- Techniques include standard precautions as well as:
 - Room with negative air pressure ventilation, with air externally exhausted or high-efficiency particulate air filtered if recirculated; if unavailable, mask the child and place in private room with the door closed.
 - Wear a mask or respirator depending on specific recommendations based on disease, such as if infectious pulmonary tuberculosis is suspected or proven, wear a respiratory protective device, such as an N95 respirator, while in the child's room.
 - Susceptible health care personnel should not enter the room of children with measles or varicella zoster infections. Those with

proven immunity to these viruses need not wear a mask.

Droplet

- Intended to prevent transmission of pathogens spread through close respiratory or mucous membrane contact with respiratory secretions. Designed to reduce the risk of infectious agents transmitted by contact of the conjunctivae or the mucous membranes of the nose or mouth of a susceptible person with large-particle droplets containing pathogens generated from a person (generally through coughing, sneezing, talking, or procedures such as suctioning) who has a clinical disease or who is a carrier of the disease
- Examples of such illnesses include diphtheria, pertussis, streptococcal group A, influenza, mumps, rubella, and scarlet fever.
- Techniques include standard precautions as well as:
 - Private room (if unavailable, consider cohorting children with the same disease. If this is not possible, separation of at least 3 feet between other children and visitors should be maintained.)
 - Wear a mask if within 3 feet of the child.

Contact

- Most important and most common route of transmission of health care-associated infections
- Designed to reduce the risk of infectious agents transmitted by direct or indirect contact. Direct-contact transmission involves skin-to-skin contact and physical transfer of pathogens between a susceptible host and an infected or colonized person. Examples include patient care activities that involve physical contact such as turning and bathing. Direct-contact transmission also can occur between two children, where one serves as the source of infectious pathogen and the other as a susceptible host. Indirect-contact transmission involves contact of a susceptible host with a contaminated intermediate object, usually inanimate, in the child's environment.
- Examples of such illnesses include diphtheria,^a pediculosis, scabies, and multidrug-resistant bacteria.
- Techniques include standard precautions as well as:
 - Private room (if unavailable, consultation with infection control personnel is recommended. Consider cohorting children with the same disease. If this is not possible, separation of at least 3 feet between other children and visitors should be maintained.)
 - Gloves (clean or sterile) should be used at all times.
 - Proper hand hygiene after glove removal
 - Use gloves and gowns for all interactions that involve contact with the child or potentially contaminated areas. Don before entering and remove before leaving the child's room.

Prevention standards are applied in all health care settings and are modified to meet each setting's unique needs. Health care workers must practice within the specific institution's guidelines.

^aCertain infections require more than one precaution.

Adapted from Siegel, J. D., Rhinehart, E., Jackson, M., Chiarello, L., and the Healthcare Infection Control Practices Advisory Committee. (2007). *Guideline for isolation precautions: Preventing transmission of infectious agents in healthcare settings*. Retrieved on June 8, 2011, from <http://www.cdc.gov/hicpac/pdf/isolation/Isolation2007.pdf>

COMMON MEDICAL TREATMENTS

A variety of medications and other medical treatments are used to treat infectious disorders in children. Most of these treatments will require a physician's or nurse practitioner's order when the child is in the hospital. The most common treatments and medications are listed in [Common Medical Treatments 15.1](#) and [Drug Guide 15.1](#). The nurse caring for the child with an infectious disorder should be familiar with what the procedures are, how they work, and common nursing implications related to use of these modalities.

NURSING PROCESS OVERVIEW FOR THE CHILD WITH AN INFECTIOUS OR COMMUNICABLE DISORDER

Care of the child with an infectious or communicable disorder includes assessment, nursing diagnosis, planning, interventions, and evaluation. There are a number of general concepts related to the nursing process that may be applied to the care of children with infectious disorders. From a general understanding of the care involved for a child with an infectious disorder, the nurse can then individualize the care based on the child's specifics.

Remember Samuel, the 3-month-old with fever, congestion, and irritability? What additional health history and physical examination assessment information should you obtain?

Assessment

Assessment of the child with a communicable or infectious disorder includes health history, physical examination, and laboratory and diagnostic testing.

Health History

The health history consists of the past medical history, including the mother's pregnancy history; family history; and history of present illness (when the symptoms started and how they have progressed), as well as treatments used at home. The past medical history might be significant for lack of recommended immunizations, prematurity, maternal infection during pregnancy or labor, prolonged difficult delivery, or immunocompromise. Family history might be significant for lack of immunization or recent infectious or communicable disease. When eliciting the history of the present illness, inquire about the following:

- Any known exposure to infectious or communicable disease
- Immunization history
- History of having any common childhood communicable diseases
- Fever
- Sore throat
- Lethargy
- Malaise
- Poor feeding or decreased appetite
- Vomiting
- Diarrhea
- Cough
- Rash (in the older child ask for a description [i.e., Is it painful? Does it itch?])

Take Note!

Many childhood infections and communicable diseases involve a rash. Rashes can be difficult to identify. Therefore, it is important to obtain a thorough description and history from the caregiver.

Physical Examination

Physical examination of the child with an infectious disorder includes inspection, observation, and palpation.

INSPECTION AND OBSERVATION

Begin the physical examination with inspection and observation. Assess the child's skin, mouth, throat, and hair for lesions or wounds. Note the color, shape, and distribution of any lesions or wounds. Assess whether there is any exudate from the lesions or wounds. A thorough and accurate description is important to assist in identifying the rash and causative organism. Observe for scratching, restlessness, avoidance of the use of a body part, or guarding of a body part. Observe the child's affect, energy level, and interaction with caregivers. Lethargy can indicate serious infection or sepsis. Observe if there is any discharge from the nose, cough, or respiratory difficulty.

Assess hydration status. Inspect the oral mucosa; dry and pale mucous membranes can indicate dehydration. Observe for other signs of dehydration, such as sunken eyes and no tears with crying.

Assessment of vital signs can provide more information about the child's condition. Elevated temperature can indicate infection. Often tachypnea and tachycardia accompany fever. Hypotension may also occur, but it is usually a late sign with sepsis.

Take Note!

Neonates may not present with fever; some may be hypothermic (Anderson-Berry, Bellig, & Ohning, 2010).

PALPATION

Palpate the skin to assess temperature, moisture, texture, and turgor. In a child with an infectious or communicable disease, the skin may be warm and moist due to fever. Turgor may be decreased secondary to dehydration. In infants, palpate the fontanel; if they are sunken, the infant may be dehydrated. Palpate the rash to determine if it is raised or flat. A thorough picture of the presenting rash can help identify the child's illness. Palpate the lymph nodes and note any that are swollen

and tender.

Laboratory and Diagnostic Testing

Common Laboratory and Diagnostic Tests 15.1 discusses the tests used most commonly when communicable disorders are suspected. The tests can assist the physician or nurse practitioner in diagnosing the disorder and/or be used as guidelines in determining ongoing treatment. Laboratory or nonnursing personnel obtain some of the tests, while the nurse might obtain others. In either instance the nurse should be familiar with how the tests are obtained, what they are used for, and normal versus abnormal results. This knowledge will also be necessary when providing child and family education related to the testing.

OBTAINING BLOOD SPECIMENS

Giving a blood specimen may be very frightening to children because of the fear of needles, pain, and blood loss. Provide atraumatic care when performing venipunctures and other needlesticks in children (refer to [Chapter 8](#) for further information). Whether the laboratory technician or the nurse is drawing the blood, the procedure should be performed in an area other than the child's bed, such as the treatment room; the child's bed should be kept as a "safe" area. Provide teaching about the procedure based on the child's developmental level and readiness to learn. In infants and younger children, additional assistance with positioning and restraint will be needed to perform the procedure safely and to ensure proper collection. Use a topical anesthetic cream or gel, refrigerant spray, or iontophoresis before venipuncture. In young infants, administer oral sucrose beginning 1 to 2 minutes before the procedure and throughout the course of the venipuncture (Hatfield, Chang, Bittle, Deluca, & Polomano, 2011). Refer to [Chapter 14](#) for additional information about decreasing venipuncture-related pain in infants and children.

The usual sites for obtaining blood specimens via venipuncture are the superficial veins of the dorsal surface of the hand or the antecubital fossa, although other locations may also be used. In specific situations, the jugular or femoral vein may be used; in this case either the physician or nurse practitioner will perform the venipuncture.

Capillary puncture of the child's fingertip, the great toe, or the infant's heel may also be used to obtain blood specimens. Fingertip puncture is similar to that in the adult, directed to the sides of the fingertip. Great toe puncture is performed in the same way. Capillary heel puncture must be performed in the proper location to avoid striking the medial plantar artery or periosteum (see [Nursing Procedure 15.1](#)). Automatic lancet devices can be used to deliver a more precise puncture depth (Folk, 2007).

A traumatic Care

The young infant will benefit from the use of oral sucrose via pacifier before and during the capillary puncture (Hatfield et al, 2011).

Occasionally, blood samples may be obtained from an artery rather than a vein or capillary. Blood gases in particular are usually obtained by arterial puncture. Arterial puncture requires additional training and in many institutions is performed only by the respiratory therapist, physician, or nurse practitioner.

Children with indwelling venous access devices may be spared the trauma of puncture for blood specimens. Follow your institution's guidelines for withdrawing blood from peripherally inserted venous catheters or central venous catheters. The initial blood will be discarded to prevent contamination with intravenous fluids or medications such as heparin. The amount discarded depends on the size of the catheter, the weight of the child, and the institution's guidelines. After aspirating the specimen, flush the venous access device with normal saline to prevent clogging. The device may then be reconnected to the intravenous fluid or flushed according to the institution's protocol.

Nursing Diagnoses, Goals, Interventions, and Evaluations

After completing a thorough assessment, the nurse might identify several nursing diagnoses, including:

- Risk for imbalanced body temperature
- Impaired comfort
- Impaired skin integrity
- Risk for infection
- Deficient fluid volume
- Social isolation
- Deficient knowledge (specify)

After completing an assessment of Samuel, you note the following: rectal temperature of 39°C, poor sucking, and lethargy. Based on these assessment findings, what would your top three nursing diagnoses be for Samuel?

Nursing goals, interventions, and evaluation for the child with a communicable or infectious disorder are based on the nursing diagnoses. [Nursing Care Plan 15.1](#) provides a general guide for planning care for a child with an infectious or communicable disorder. Additional information about nursing management will be included later in the chapter as it relates to specific disorders.

Managing Fever

Fever in their children is one of the most common reasons parents seek medical attention (Sullivan, Far-rar, & the AAP's Section on Clinical Pharmacology and Therapeutics, and Committee on Drugs, 2011). Most infections or communicable diseases are accompanied by fever. Many parents have great concerns about fever. For example, they fear febrile seizures, neurologic complications, and a potential serious underlying disease. Many health care providers share these fears. This leads to the common recommendation to intervene and reduce fever. These fears and misconceptions about fever can lead to mismanagement of fever, such as inappropriate dosing of antipyretics, awakening the child during sleep to give antipyretics, or inappropriate use of nonpharmacologic treatments such as sponging the child with alcohol or cold water (Crocetti & Serwint, 2005; Sullivan et al., 2011).

It is important to educate parents that fever is a protective mechanism the body uses to fight infection. Evidence exists that an elevated body temperature actually enhances various components of the immune response (Crocetti & Serwint, 2005; Sullivan et al., 2011). Fever can slow the growth of bacteria and viruses and increase neutrophil production and T-cell proliferation (Crocetti & Serwint, 2005). Studies have shown that the use of antipyretics may prolong illness (Crocetti & Serwint, 2005; Sullivan et al., 2011). Another concern is that reducing fever may hide signs of serious bacterial illness (Crocetti & Serwint, 2005; Sullivan et al., 2011).

Take Note!

Infants younger than 3 months of age with a rectal temperature greater than 38°C should be seen by a physician or nurse practitioner. They are *considered* at risk for sepsis until proven otherwise due to their immature immune system and inability to localize or handle infection very well (Powell, 2007a).

In infants older than 3 months of age, fever less than 39°C usually does not require treatment (Powell, 2007b). Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits of decreasing fever are increasing comfort in the child and decreasing fluid requirements, which helps to prevent dehydration. Children with certain underlying conditions, such as cardiovascular disease or pulmonary disease, also benefit from treating fever because such treatment decreases demands on the body.

HOME MANAGEMENT OF FEVER

Fever is typically managed at home, so it is important to give guidance and instruction at well-child visits and review this information at subsequent visits. Written and video materials about fever management may be effective in increasing caregivers' knowledge. Parents can refer to the written instructions when needed (see [Teaching Guidelines 15.1](#)).

The use of acetaminophen or ibuprofen to reduce fever in children has been shown to be safe and effective when the appropriate dose is administered at the appropriate interval (Crocetti & Serwint, 2005). However, some studies have shown that ibuprofen is superior in reducing fever faster and lasts longer than acetaminophen (Walling, 2009).

Box 15.4 gives dosing recommendations for both medications.

Take Note!

Never give aspirin to children to reduce fever, due to the risk of Reye syndrome.

CAUTIONS ABOUT ACETAMINOPHEN USE

Acetaminophen is widely used and accepted, but toxic reactions can be seen in children (American Academy of Pediatrics, 2009). Causes of acetaminophen toxicity include overdosing or incorrect dosing due to failure to read and understand the label instructions, use of an incorrect measuring device or concentration, and coadministration with an over-the-counter fixed-dose combination medication (the parent may not recognize that it has acetaminophen in it).

Another factor that may cause acetaminophen toxicity is the controversial, but common, practice of alternating acetaminophen and ibuprofen to help reduce fever. Studies of the use of alternating acetaminophen with ibuprofen have had conflicting results (Walling, 2009). This practice can result in overdose or improper administration. It can be hard for parents to keep track of the time each medication is due. Parents may confuse which medication is given every 4 hours and which is given every 6 hours. They may exceed the recommended daily doses or may confuse the strength or dosage of the medicines. See [Evidence-Based Practice 15.1](#).

Managing Skin Rashes

Skin rashes accompany many infectious or communicable diseases. These rashes can be very uncomfortable and irritating for the child. Management often occurs at home, so it is important to educate parents on ways to relieve the discomfort and protect and maintain skin integrity. The physician may prescribe anti-pruritics, including oral medications or topical creams or ointments (see [Drug Guide 15.1](#)). Instruct parents on the importance of maintaining skin integrity to prevent infection or scarring. Teach parents to keep their child's fingernails short and hands clean. Explain the importance of discouraging scratching, and discuss distraction techniques they can use with the child. Cool compresses or cool baths can relieve itching. Encourage the child to press on rather than scratch the itchy area; this can relieve discomfort while maintaining skin integrity. Refer to [Chapter 24](#) for more information on managing skin rashes.

Based on your top three nursing diagnoses for Samuel, describe appropriate nursing interventions.

COMMON MEDICAL TREATMENTS 15.1

| Treatment | Explanation | Indications | Nursing Implications |
|-----------------|---|--|---|
| Hydration | Promoting proper fluid balance either orally or intravenously | Child who can't replace insensible loss due to fever, child who is vomiting or has diarrhea | <ul style="list-style-type: none"> Encourage oral fluids, if possible. Offer child preferred fluid; try popsicles or games to promote fluid intake. If administering IV fluids, ensure proper fluid and rate per order and assess IV site and fluid intake every hour. Maintain strict record of intake and output. |
| Fever reduction | Reducing temperature by use of antipyretics or nonpharmacologic interventions | Febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever | <ul style="list-style-type: none"> Administer antipyretics, such as ibuprofen and acetaminophen. Avoid aspirin use in children and adolescents. Use nonpharmacologic interventions such as dressing lightly, removing blankets, use of a fan, tepid bath, and cooling blanket. Make sure that nonpharmacologic measures do not induce shivering or discomfort. If they do, they should be stopped immediately. |

IV, intravenous.

DRUG GUIDE 15.1 COMMON DRUGS FOR COMMUNICABLE DISORDERS

| Medication | Actions/Indications | Nursing Implications |
|---|---|---|
| Antibiotics | Kill and prevent the growth of bacteria Used for treatment of bacterial infections such as sepsis | <ul style="list-style-type: none"> Check for antibiotic allergies. Give as prescribed for the length of time prescribed. |
| Antivirals (e.g., acyclovir) | Kill and prevent the growth of viruses Used for treatment of viral infections such as herpes simplex 2 | <ul style="list-style-type: none"> Observe infusion site for signs of tissue damage. If administering topically, clean and dry area before application and wear gloves. Give as prescribed for the length of time prescribed. |
| Antipyretics (acetaminophen, ibuprofen) | Decrease the temperature set point (only in a child with a raised temperature) by inhibiting the production of prostaglandins, leading to heat loss (through vasodilation and sweating) and resulting in a reduction in fever Used to decrease temperature in the febrile child who is uncomfortable or who can't keep up with the increased metabolic demands associated with fever | <ul style="list-style-type: none"> Ensure proper dosing, concentration, and dosing interval. Avoid aspirin use in children and adolescents. Avoid ibuprofen use in children with a bleeding disorder. Assess fever and any related symptoms such as tachycardia, shivering, or diaphoresis. Properly educate caregivers on appropriate dosing, concentration, dosing interval, and use of accurate measuring device. |
| Antipruritics (usually antihistamines) | Given orally or topically to block the histamine reaction Used to relieve discomfort associated with itching | <ul style="list-style-type: none"> When applying topically, wear gloves. Do not apply to open wounds. Oral antihistamines may cause drowsiness. |

Adapted from Karch, A. (2010). 2010 *Lippincott's nursing drug guide*. Philadelphia: Wolters Kluwer Health/Lippincott Williams & Wilkins; and Taketokino, C. K., Hodding, J. H., & Kraus, D. M. (2010). *Lexi-Comp's Drug Reference Handbook: Pediatric & Neonatal Dosage Handbook* (18th ed.). Hudson, OH: Lexi-Comp, Inc.

COMMON LABORATORY AND DIAGNOSTIC TESTS 15.1

| Test | Explanation | Indications | Nursing Implications |
|---|--|---|---|
| Complete blood count (CBC) | Evaluate white blood cell count (particularly the percentage of individual white cells) | Detect the presence of inflammation, infection | <ul style="list-style-type: none"> Normal values vary according to age and gender. White blood cell count differential is helpful in differentiating source of infection. May be affected by myelosuppressive drugs |
| Erythrocyte sedimentation rate (ESR) | Nonspecific test used in conjunction with other tests to determine presence of infection or inflammation | Detect the presence of inflammation, infection | <ul style="list-style-type: none"> Send to laboratory immediately; specimens allowed to stand for longer than 2 hours may produce a falsely low result. |
| C-reactive protein (CRP) | Nonspecific test that measures a type of protein produced in the liver that is present during episodes of acute inflammation or infection Usually used to diagnose bacterial infections; does not consistently rise with viral infections | To detect the presence of infection, CRP is a more sensitive and rapidly responding indicator than ESR. | <ul style="list-style-type: none"> Presence of an intrauterine device may cause positive test results because of tissue inflammation. Exogenous hormones, such as oral contraceptives, may cause increased levels. Nonsteroidal anti-inflammatories, salicylates, and steroids may cause decreased levels. Fasting may be required. |
| Blood culture and sensitivity | Deliberate growing of microorganisms in a solid or liquid medium. Once it has grown, it is tested against various antibiotics to determine which antibiotics will kill it. | Detect the presence of bacteria or yeast, which may have spread from a certain site in the body into the bloodstream Determine which antibiotics the bacteria or yeast is sensitive to | <ul style="list-style-type: none"> Follow aseptic technique and hospital protocol to prevent contamination. Two cultures obtained from two different sites are preferred. Ideally obtain before administering antibiotics; if child is taking antibiotics, notify laboratory and draw specimen shortly before next dose. Deliver specimen to laboratory immediately (within 30 minutes). |
| Stool culture (including stool for ova and parasites [O&P]) | To determine if bacteria or parasite has infected the intestines | Detect pathogens, including parasites or overgrowth of normal flora in the bowel. Indicated for children with diarrhea, fever, or abdominal pain | <ul style="list-style-type: none"> Stool must be free of urine, water, and toilet paper. Do not retrieve out of toilet water. Deliver to laboratory immediately. Mineral oil, bismuth, and bismuth interfere with the detection of parasites; specimen collection should be delayed for 7 to 10 days. Often a minimum of three specimens on 3 separate days are required for adequate examination, since many parasites and worm eggs are shed intermittently. |

| | | | |
|----------------|--|--|--|
| Urine culture | Collection of urine to detect the presence of bacteria in the urine | Detect the presence of bacteria in the urine. Indicated for children with fever of unknown origin, dysuria, frequency, or urgency, or if urinalysis suggests infection | <ul style="list-style-type: none"> • Should be obtained by midstream clean-catch, catheterization, or suprapubic aspiration. Avoid contamination with stool, vaginal secretions, hands, or clothing. • Placing bags on the perineum is not acceptable due to high chance of contamination. • Obtain before antibiotics are administered. • Deliver to laboratory immediately or refrigerate. |
| Wound culture | Allows for microbial growth and identification of specific organism | Identification of specific organism | <ul style="list-style-type: none"> • Do not take from exudate or eschar. • Irrigate the wound with sterile saline if necessary. • Note sensitivities. • Specimens taken from wounds can harbor a variety of organisms. Pathogenicity depends of the quantity of organisms present. |
| Throat culture | Vigorous swabbing of the tonsillar area and posterior pharynx to detect the presence of invasive organisms | <p>Most reliable method of detecting group A streptococcal pharyngitis</p> <p>Will also detect <i>Bordetella pertussis</i>, <i>Corynebacterium diphtheriae</i></p> <p>May be performed in those with fever of unknown origin</p> | <ul style="list-style-type: none"> • Ensure specimen is of secretions in the pharyngeal or tonsillar area. Avoid touching tongue or lips with swab. • When performing on young children, have adult hold child in lap. • Health care worker needs to stabilize head by placing hand on the child's forehead. |

Adapted from Fischbach, F. T., & Dunning III, M. B. (2009). *A manual of laboratory and diagnostic tests* (8th ed.). Philadelphia: Lippincott Williams & Wilkins.

NURSING PROCEDURE 15.1

Capillary Heel Puncture

1. Choose the collection site and apply a commercial heel warmer or warm pack for several minutes prior to specimen collection.
2. Assemble equipment:
 - Gloves
 - Automatic lancet
 - Antiseptic wipe
 - Cotton ball or dry gauze
 - Capillary blood collection tube
 - Band-aid

3. Perform hand hygiene and don gloves. Remove the warm pack.
4. Cleanse the site with antiseptic prep pad and allow to dry.
5. Hold the dorsum of the foot with the nondominant hand; with the dominant hand, pierce the heel with the lancet. Place the extremity in the dependent position.
6. Wipe away the first drop of blood with the cotton ball or dry gauze.

7. Collect the blood specimen with a capillary specimen collection tube. Avoid squeezing the foot during specimen collection if possible, as it may contribute to hemolysis of the specimen.
8. Hold dry gauze over the site until bleeding stops, elevate extremity above the level of the heart, and then apply a Band-aid.

NURSING CARE PLAN 15.1

Overview for the Child With an Infectious or Communicable Disorder

NURSING DIAGNOSIS: Risk for imbalanced body temperature: fever related to infectious disease process as evidenced by rectal temperature greater than 38°C or 100.4°F

Outcome Identification and Evaluation

Child will maintain temperature within adaptive levels and be comfortable and remain hydrated. *Temperature will be 38°C or 100.4°F or less. Child will verbalize or exhibit signs of comfort during febrile episode; child will demonstrate adequate signs of hydration.*

Interventions: Managing Fever

- Assess temperature at least every 4 to 6 hours, 30 to 60 minutes after antipyretic is given and with any change in condition: *recognizing the pattern of fever may help identify source.*
- Use same site and device for temperature measurement to *reflect a more accurate trend in temperature, since different sites can result in significant differences in temperature reading.*
- Administer antipyretics per physician order when the child is experiencing discomfort or cannot keep up with the metabolic demands of the fever. *Fever is a protective response of the body to fight infection. Antipyretics provide symptomatic relief but do not change the course of the infection. The major benefits to decreasing fever are increasing comfort in the child and decreasing fluid requirements, helping to prevent dehydration.*
- Notify physician of temperature per institution or specific order guidelines: *increases in temperature may indicate worsening infection and relevant changes in condition.*
- Assess fluid intake and encourage oral intake or administer intravenous fluids per physician order: *increased metabolic rate and diaphoresis related to fever can cause fluid loss and lead to fluid volume deficit. Keep linens and clothing clean and dry: diaphoresis can leave clothing and linen soaked, increasing discomfort for the child.*
- Use of nonpharmacologic measures such as tepid bath and removal of clothing and blankets is controversial. If used, discontinue if shivering begins.

NURSING DIAGNOSIS: Impaired comfort related to infectious and/or inflammatory process as evidenced by hyperthermia, pruritus, rash or skin lesions, sore throat, or joint pain

Outcome Identification and Evaluation

Pain or discomfort will be reduced to level acceptable to child. *Child will verbalize absence or decrease of pain using a pain scale (FLACC, FACES, or linear pain scale), will verbalize decrease in uncomfortable sensations such as itching and aches; infants will exhibit decreased crying and ability to rest quietly.*

Interventions: Improving Comfort

- Assess pain and response to interventions frequently with use of pain scales or other pain measurement tools: *provides baseline of pain and allows for evaluation of effectiveness of interventions.*
- Administer analgesics and antipruritics as ordered to *relieve pain via interruption of central nervous system (CNS) pathways and to decrease discomfort related to itching.*
- Apply cool compresses to areas of pruritus or provide a cool bath to *decrease inflammation and soothe pruritus.*
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) to prevent injury to the skin, which leads to increased pain.
- Encourage child to press on rather than scratch the area of pruritus: *pressing on the area that itches can soothe the itching and prevent scratching, which can lead*

to skin injury.

- Provide fluids frequently and offer warm fluids such as soup or cold foods such as popsicles to ease the discomfort of a sore throat.
- Provide cool mist humidification to ease the discomfort of a sore throat.
- Dress the child in light clothing; restrictive clothing and diaphoresis can lead to increased pruritus.
- Use diversional activities and distraction appropriate to developmental level: distraction from pain can reduce the need for pharmacologic agents, and distraction from pruritus can minimize scratching.

NURSINGDIAGNOSIS: Impaired skin integrity related to mechanical trauma secondary to infectious disease process as evidenced by rash, pruritus, and scratching

Outcome Identification and Evaluation

Child will maintain or regain skin integrity. *Child will breakdown. Child or parent will be able to describe or and heal skin and proper care for any lesions.*

Interventions: Promoting Skin Integrity

- Monitor skin for color changes, temperature, redness, swelling, warmth, pain, signs of infection, or changes in rash lesions, distribution, or size to help identify problems early and allow for prevention of infection; can also provide information regarding the course of the illness.
- Encourage fluid intake and proper nutrition to promote wound healing.
- Keep child's fingernails short (use mitts, gloves, or socks over hands if necessary) to prevent injury to the skin, which leads to increased pain.
- Encourage child to press on rather than scratch the area of pruritus; pressing on the area that itches can soothe the itching and prevent scratching, which can lead to skin injury.
- Use antipruritics and topical ointments or creams as ordered to minimize scratching to prevent injury to skin; can aid in healing.

NURSINGDIAGNOSIS: Risk for infection related to insufficient knowledge regarding measures to avoid exposure to pathogens, increased environmental exposure to pathogens, transmission to others secondary to contagious organism or presence of infectious organisms

Outcome Identification and Evaluation

Child will exhibit no signs or symptoms of local or systemic infection. Child will not spread infection to others. *Symptoms of infection will decrease over time; others will remain free of infection. Child and family will demonstrate appropriate hygiene measures using proper technique, such as hand washing, to prevent the spread of infection.*

Interventions: Preventing and Controlling Infection

- Monitor vital signs: elevation in temperature may indicate infection.
- Monitor skin lesions for signs of local infection: redness, warmth, drainage, swelling, and pain at lesions can indicate infection.
- Maintain aseptic technique and practice good hand washing to prevent introduction of further infectious agents and prevent transmission to others.
- Administer antibiotics as prescribed to prevent or treat bacterial infection.
- Encourage nutritious diet and proper hydration according to child's preferences and ability to feed orally to assist body's natural defenses against infection.
- Isolate child as required based on transmission-based precautions to prevent nosocomial spread of infection.
- Teach child and family preventive measures such as good hand washing, covering mouth and nose with cough or sneeze, and proper disposal of used tissues to prevent nosocomial or community spread of infection.

NURSINGDIAGNOSIS: Fluid volume deficit, risk for, related to increased metabolic demands and insensible loss due to fever, vomiting, poor feeding or intake

Outcome Identification and Evaluation

Fluid volume will be maintained and balanced. *Oral is elastic, urine output is at least 1 to 2 ml/kg/hour.*

Interventions: Promoting Adequate Fluid Balance

- Administer IV fluids if ordered to maintain adequate hydration in children who are nothing by mouth (NPO), unable to tolerate oral intake, or unable to keep up with fluid losses.
- When oral intake is allowed and tolerated, encourage oral fluids to promote intake and maintain hydration.
- Assess for signs of adequate hydration such as pink and moist oral mucosa, elastic skin turgor, and adequate urine output to detect fluid imbalance.
- Monitor intake and output to identify fluid imbalance.
- Assess urine specific gravity, urine and serum electrolytes, blood urea nitrogen, creatinine, and osmolality and daily weights to monitor fluid status.

NURSING DIAGNOSIS: Social isolation related to required isolation from peers secondary to transmission-based precautions, as evidenced by disruption in usual play secondary to inability to leave hospital room, activity intolerance, and fatigue

Outcome Identification and Evaluation

Child will participate in stimulating activities. *Child is able to verbalize reason for isolation and length of isolation (if developmentally appropriate); child verbalizes interest in activities.*

Interventions: Preventing Social Isolation

- Explain reasons for transmission-based precautions and length of time: this helps increase understanding and decrease anxiety about isolation. Children sometimes mistake isolation as punishment. Explaining length of time gives child an endpoint he or she can work toward.
- Visit child frequently, at least every hour, and try to spend some uninterrupted time to play and allow child time to verbalize feelings about separation from others: helps establish a therapeutic relationship and demonstrates caring.
- Let child see caregiver's face before applying mask if appropriate to help child identify and relate to those caring for him or her and minimize anxiety about strangers and the unknown.
- Consult child life specialist to arrange for stimulating activities child enjoys: can help child to understand reasons for isolation.
- Contact volunteers to spend time with child, if appropriate: gives child attention and support, which will help child to cope and decrease stress.

NURSINGDIAGNOSIS: Knowledge deficit related to lack of information regarding medical condition, prognosis, and medical needs as evidenced by verbalization, questions, or actions demonstrating lack of understanding regarding child's condition or care

Outcome Identification and Evaluation

Child and family will verbalize accurate information and understanding about condition, prognosis, and medical needs. *Child and family demonstrate knowledge of condition and prognosis and medical needs, including possible causes, contributing factors, and treatment measures.*

Interventions: Providing Child and Family Teaching

- Assess child's and family's willingness to learn: *child and family must be willing to learn in order for teaching to be effective.*
- Provide family with time to adjust to diagnosis *to facilitate adjustment and ability to learn and participate in child's care.*
- Repeat information *to give family and child time to learn and understand.*
- Teach in short sessions: *many short sessions are more helpful than one long session.*
- Gear teaching to level of understanding of the child and family (depends on age of child, physical condition, memory) *to ensure understanding.*
- Provide reinforcement and rewards *to facilitate the teaching/learning process.*
- Use multiple modes of learning involving many senses (provide written, verbal, demonstration, and videos) when possible: *the child and family are more likely to retain information when it is presented in different ways using many senses.*

Teaching Guidelines 15.1

FEVER MANAGEMENT

- Fever is a sign of illness, not a disease; it is the body's weapon to fight infection.
- Diurnal variation may allow temperature changes as much as 1°C (1.8°F) over a 24-hour period, peaking in the evening.
- Antipyretics are used if the child demonstrates discomfort. Always check correct doses before administration. Never give aspirin or aspirin-containing products to a child younger than 19 years with a fever due to the risk of Reye syndrome
- In some children fever can be associated with a seizure or dehydration, but this will not lead to brain damage or death. Discuss the facts about febrile seizures (see [Chapter 16](#) for further information on febrile seizures).
- Watch for the signs and symptoms of dehydration; it is important to provide oral rehydration by increasing fluid intake.
- Dress the child lightly and avoid warm, binding clothing or blankets.
- The use of sponging with tepid water is controversial; if used, encourage the parent to give an antipyretic prior to sponging. Ensure the sponging does not produce shivering (which causes the body to produce heat and maintain the elevated set point), and reinforce the importance of using tepid water, not cold water or alcohol. Instruct the parent to stop if the child experiences discomfort.
- Call the provider for:
 - Any child younger than 3 months of age who has a rectal temperature above 38°C (100.4°F)
 - Any child who is lethargic or listless, regardless of temperature
 - Fever lasting more than 3 to 5 days
 - Fever greater than 40.6°C (105°F)
 - Any child who is immunocompromised by illness, such as cancer or HIV, will need further evaluation and treatment.

BOX 15.4

DOSE RECOMMENDATIONS FOR ACETAMINOPHEN AND IBUPROFEN

Acetaminophen, 10 to 15 mg/kg/dose

- No more than every 4 hours
- No more than five doses in a 24-hour period

Ibuprofen, 5 to 10 mg/kg/dose

- Only children older than 6 months of age
- No more than four doses in a 24-hour period

Adapted from Gal, P., & Reed, M. D. (2007). Medications. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & B. F. Stanton (Eds.), *Nelson's textbook of pediatrics* (18th ed., pp. 2955–2999). Philadelphia: Saunders.

Fever is one of the most common health concerns seen in pediatrics. Alternating acetaminophen and ibuprofen for fever reduction is a common practice, but there has been limited evidence on its safety or efficacy. It may be a harmful practice due to combined toxicity and potential parental confusion in timing and dosing.

STUDY

This study was a randomized, double-blinded, placebo-controlled trial. It evaluated the antipyretic efficacy of alternating acetaminophen with ibuprofen versus acetaminophen with a placebo. It also evaluated the safety of the two regimens along with caretaker perception of efficacy. Study participants were healthy children ages 6 months to 6 years presenting to a medical center with the chief complaint of fever.

Findings

A significant difference was seen in fever reduction in the alternating group versus the acetaminophen alone group at hours 4 and 5, but this difference diminished by hour 6. Administration, including dosing and interval, were undercontrolled conditions during this study; however, safety concerns remain. Parents, even without the confusion of alternating two medications, often over- or underdose these medications. No association of perception of efficacy by caregivers was found based on regimen used.

Nursing Implications

Although this study suggests improved fever reduction with alternating of acetaminophen and ibuprofen, safety concerns remain. Further research with larger sample sizes and longer follow-up are warranted. To alleviate some of the concerns that parents have with fever, nurses should consistently educate parents about why fever occurs and fever facts and myths.

Adapted from Kramer, L.C., Richards, P.A., Thompson, A.M., Harper, D.P., & Fairchok, M.P. (2008). Alternating antipyretics: Antipyretic efficacy of acetaminophen versus acetaminophen alternated with ibuprofen in children. *Clinical Pediatrics*, 47(9), 907–912.

SEPSIS

Sepsis is a systemic overresponse to infection resulting from bacteria (most common), fungi, viruses, or parasites. It can lead to septic shock, which results in hypotension, low blood flow, and multisystem organ failure. Septic shock is a medical emergency and children are usually admitted to an intensive care unit (see [Chapter 31](#)). The cause of sepsis may not be known, but common causative organisms in neonates include *Escherichia coli*, *Listeria monocytogenes*, group B *Streptococcus*, enteroviruses, and herpes simplex virus, and in older children include *Neisseria meningitidis*, *Streptococcus pneumoniae*, and *Staphylococcus aureus* (Enrione & Powell, 2007). Sepsis can affect any age group but is more common in neonates and young infants (Santhanam & Tolan Jr., 2011). Neonates and young infants have a higher susceptibility due to their immature immune system, inability to localize infections, and lack of immunoglobulin M (IgM), which is necessary to protect against bacterial infections.

The prognosis for sepsis is variable and depends on the child's age and the cause of the sepsis. The mortality rate ranges from 9% to 35% (Santhanam & Tolan Jr., 2011). Neonates are at highest risk for a poor outcome. Due to this high mortality rate, when an ill-appearing febrile neonate presents, a full workup is indicated (Powell, 2007b). Usually, admission to the hospital to rule out sepsis is the standard of practice.

Pathophysiology

Sepsis results in the systemic inflammatory response syndrome (SIRS) due to infection. The pathophysiology of sepsis is complex. It results from the effects of circulating bacterial products or toxins, mediated by cytokine release, occurring as a result of sustained bacteremia. The pathogens cause an overproduction of proinflammatory cytokines, previously termed endotoxins. These cytokines are responsible for the clinically observable effects of the sepsis. Impaired pulmonary, hepatic, or renal function may result from excessive cytokine release during the septic process.

Therapeutic Management

Therapeutic management of sepsis in infants, especially neonates, is more aggressive than for older children. Neonates and infants with sepsis or even suspected sepsis are treated in the hospital. The infant is admitted for close monitoring along with antibiotic therapy. Intravenous antibiotics are started immediately after the blood, urine, and cerebrospinal fluid cultures have been obtained. The length of therapy and the specific antibiotic used will be determined based on the source of the positive culture and the results of the culture and sensitivity. If final culture reports are negative and symptoms have subsided, antibiotics may be discontinued (usually after 72 hours of treatment). If the child is not responding to therapy and symptoms worsen, sepsis may be progressing to shock. Management of the child with septic shock is usually done in the intensive care unit.

Nursing Assessment

For a full description of the assessment phase of the nursing process, refer to [page 452](#). Assessment findings pertinent to sepsis are discussed below.

Health History

Elicit a description of the present illness and chief complaint. Signs of sepsis can vary with each child. Some common signs and symptoms reported during the health history might include:

- Child just does not look or act right
- Crying more than usual, inconsolable
- Fever
- Hypothermia (in neonates and those with severe disease)
- Lethargic and less interactive or playful
- Increased irritability
- Poor feeding or poor suck
- Rash (e.g., petechiae, ecchymosis, diffuse erythema)
- Difficulty breathing
- Nasal congestion
- Diarrhea
- Vomiting
- Decreased urine output

- Hypotonia
- Changes in mental status (confused, anxious, excited)
- Seizures
- Older child may complain of heart racing

Explore the child's current and past medical history for risk factors such as:

- Prematurity
- Lack of immunizations
- Immunocompromise
- Exposure to communicable pathogens

In neonates and young infants, seek pregnancy and labor risk factors such as:

- Premature rupture of membranes or prolonged rupture
- Difficult delivery
- Maternal infection or fever, including sexually transmitted infections
- Resuscitation and other invasive procedures
- Positive maternal group β -streptococcal vaginosis

Sepsis may occur in the hospitalized child. Assess for risk factors such as:

- Intensive care unit stay
- Presence of central line or other invasive lines or tubes
- Immunosuppression

Take Note!

Listen to the parents' descriptions of the neonate's or infant's behavior and appearance, as well as changes they have observed. Many times they are the first to notice when their child is not acting right, even before clinical signs of infection are seen.

Physical Examination

Perform a thorough physical examination of the infant or child with proven or suspected sepsis. Specific findings related to inspection and observation are noted below.

INSPECTION AND OBSERVATION

Observe the child's general appearance, color, level of arousal, and hydration status. The child with sepsis may appear lethargic and pale and show signs of dehydration. In neonates and infants, observe the quality of their cry and reaction to parental stimulation, noting weak cry, lack of smile or facial expression, or lack of responsiveness. Inspect the skin for petechiae or other skin lesions. Petechiae may indicate a serious bacterial infection (often *N. meningitidis*), and other skin lesion patterns may help identify the cause of the fever. Observe respiratory effort and rate. The infant or child with sepsis may demonstrate tachypnea and increased work of breathing, such as nasal flaring, grunting, and retractions.

Assess vital signs, noting abnormalities. Note elevation in temperature or hypothermia in the young infant. Note tachypnea or tachycardia in the child or apnea or bradycardia in the infant. Document blood pressure. Hypotension, especially when accompanied by signs of poor perfusion, can be a sign of worsening sepsis with progression to shock (refer to [Chapter 31](#)).

Laboratory and Diagnostic Tests

Symptoms of sepsis can be vague in infants. Therefore, laboratory tests play a crucial role in confirming or ruling out sepsis. Common laboratory and diagnostic studies ordered for the assessment of sepsis include:

- Complete blood count: WBC levels will be elevated; in severe cases they may be decreased (this is an ominous sign).
- C-reactive protein: elevated
- Blood culture: positive in septicemia, indicating bacteria is present in the blood
- Urine culture: may be positive, indicating presence of bacteria in the urine
- Cerebrospinal fluid analysis: may reveal increased WBCs and protein and low glucose
- Stool culture: may be positive for bacteria or other infectious organisms
- Culture of tubes, catheters, or shunts suspected to be infected: the fluid inside these tubes may be tested for bacteria.
- Chest radiograph: may reveal signs of pneumonia such as hyperinflation and patchy areas of atelectasis or infiltration

Nursing Management

Monitor the infant or child closely for changes in condition, especially the development of shock. Administer antibiotics as ordered. Refer to [Nursing Care Plan 15.1](#) for nursing diagnoses and related interventions. In addition to these interventions, it is important to prevent infection and provide education to the child and family.

Preventing Infection

Sepsis is a potentially life-threatening illness, and prevention is important. Hand washing is the most effective intervention against nosocomial infection. Nurses play a key role in minimizing environmental sources by cleaning equipment, disposing of soiled linens and dressings properly, and adhering to proper aseptic technique with all invasive procedures. Follow your institution's policies and use evidence-based practice guidelines for interventions such as invasive line dressing changes and intravenous tubing changes to reduce the risk of infection. Encourage immunization as recommended. To reduce group B streptococcus infection in neonates, screen pregnant woman. If the results are positive, administer intrapartum antibiotics.

Take Note!

There has been a dramatic reduction in invasive *Haemophilus influenzae* type B diseases since the widespread use of the Hib vaccine (Centers for Disease Control and Prevention, 2008b).

Educating the Child and Family

Early recognition of the signs of sepsis is essential in preventing morbidity and mortality. Educate parents about the significance of fever, especially in neonates and infants younger than 3 months old. Instruct parents to contact their physician or nurse practitioner if their infant or neonate has a fever. A physician or nurse practitioner should see any child with a fever accompanied by lethargy, poor responsiveness, or lack of facial expressions. Signs and symptoms of sepsis can be vague and vary from child to child. Encourage parents to contact their physician or nurse practitioner if they feel their febrile child is “just not acting right.”

BACTERIAL INFECTIONS

Bacteria are one-celled organisms that can live, grow, and reproduce. They exist everywhere. Most are completely harmless and some are very useful. Others can lead to disease either because they are in the wrong place in the body or they are designed to invade and cause disease in humans and animals. Children are at a high risk of developing bacterial infections, which can result in life-threatening illness. Fortunately, many bacterial diseases, such as diphtheria, pertussis, and tetanus, can be prevented by immunization (see [Chapter 9](#) for more information on immunizations).

Community-Acquired Methicillin-Resistant *Staphylococcus Aureus*

Community-acquired methicillin-resistant *Staphylococcus aureus* (CAMRSA) is a staphylococcal infection that is resistant to certain antibiotics. Methicillin-resistant *S. aureus* (MRSA) in the community is increasing in occurrence throughout the United States (Centers for Disease Control and Prevention, 2011a). These infections range from minor skin rashes to abscesses to serious, complicated, life-threatening infections. Serious and invasive infections, such as sepsis, necrotizing pneumonia, and osteomyelitis, often are secondary to a skin or soft tissue infection. The CDC and World Health Organization (WHO) have recognized MRSA as a major health threat (Hinckley & Allen, 2008). Prior to the early 1990s, MRSA was mainly considered a hospital-acquired infection. However, health care professionals began to identify MRSA in the community setting in seemingly healthy individuals, including children (Rose & Senita, 2009).

Transmission occurs through direct person-to-person contact, respiratory droplets, blood, or sharing personal items, such as hair brushes, towels, and sports equipment, and touching surfaces or items contaminated with MRSA. Clusters of MRSA have been found in day care centers and among athletic teams. Staphylococci are resistant to heat and drying and can be found on environmental surfaces months after contamination. Intact skin and mucous membranes, along with proper hand hygiene, are the best barriers to MRSA.

Nursing Assessment

In the child, skin and tissue infections are common infections caused by CAMRSA. Symptoms include a bump or skin area that is red, swollen, painful, and warm to touch. It may also include fever, fluctuance, and purulent drainage. The lesion may have appeared suddenly and be red and raised, resembling an insect bite. Necrotic areas may develop. Abscesses, especially abscessed hair follicles, and pimples are common presentations. Assessment needs to include a thorough past medical history to determine history of recurrent skin infections with or without complete resolution along with assessment for risk factors. Risk factors include playing contact sports; openings in the skin, such as abrasions and cuts; contact with contaminated items and surfaces; poor hygiene; and crowded living conditions (Hinckley & Allen, 2008).

Diagnosis is determined through culture. Diagnostic tests include incision and drainage (I&D), aspiration of the abscess, and culturing the fluid or tissue. Antimicrobial susceptibility along with culture is critical.

Nursing Management

Care of the child with CAMRSA will typically occur at home. Antibiotics with microbial susceptibility will often be prescribed. Comprehensive wound care, which may include I&D, may occur. Follow-up for reassessment is key. Child and family education is crucial. Include the following in the teaching plan:

- Educate the family on the importance of taking the antibiotics as directed and finishing all the medicine. Emphasize that this will help slow the creation of antimicrobial-resistant organisms.
- Teach the child and parents proper hand hygiene and hand washing.
- Discourage family members from sharing personal items.
- Explain the risk factors involved in transmission.
- Explain the importance of keeping cuts and scrapes cleaned and covered.
- Review the signs of MRSA and emphasize the importance of early recognition and treatment.

Scarlet Fever

Scarlet fever is an infection resulting from group A streptococci. It usually occurs with a group A streptococci throat infection (i.e., strep throat). However, in the case of scarlet fever, the bacteria produce a toxin that causes a rash. Not all children with a group A streptococci infection will develop the rash of scarlet fever. Only children who are infected with streptococci that produce pyrogenic

exotoxins and do not have antitoxin antibodies, making them sensitive to the bacterial toxin, will develop scarlet fever (Gerber, 2007). Scarlet fever is usually seen in children younger than 18 years of age, with the peak incidence between the ages of 4 and 8 years (Balentine & Lombardi, 2010). It is rare in children younger than 2 years old (Balentine & Lombardi, 2010). Transmission is through droplets and follows contact with respiratory tract secretions. Transmission is facilitated by the type of close contact that occurs in schools and child care centers. Food-borne outbreaks have occurred due to human contamination of food. After exposure, the incubation period is 2 to 5 days (Gerber, 2007). Communicability is highest during acute infection, and the child is no longer contagious 24 hours after the initiation of appropriate antimicrobial therapy (Gerber, 2007).

There has been a dramatic decrease in the mortality rate from scarlet fever due to antibiotic use, but complications such as rheumatic fever and glomerulonephritis can still occur (Balentine, & Lombardi, 2010; Gerber, 2007).

Nursing Assessment

Symptoms of scarlet fever begin abruptly. The health history may reveal a fever greater than 101°F, chills, body aches, loss of appetite, nausea, and vomiting. Inspect the pharynx, which is usually very red and swollen. The tonsils may have yellow or white specks of pus, and cervical lymph nodes may be swollen. Inspect the skin for the most striking symptom of scarlet fever, which is an erythematous rash appearing on the face, trunk, and extremities. The rash is typically absent from the palms and soles of the feet. It looks like a sunburn but feels like sandpaper (Fig. 15.1A). The rash lasts approximately 5 days and is followed by desquamation, typically on the fingers and toes. Early in the illness the tongue develops a thick coat with a strawberry appearance. The tongue will later lose the coating and become bright red (see Fig. 15.1B).

Diagnosis is made by identification of group A streptococcus on throat culture. Several rapid tests for group A streptococcal pharyngitis are available. The accuracy of these tests depends on the quality of the specimen. It is important that the secretions obtained are pharyngeal or tonsillar (see [Common Medical Treatments 15.1](#) for more information on throat cultures).

Nursing Management

Children with scarlet fever are usually cared for at home. Penicillin V is the antibiotic of choice. In those sensitive to penicillin, erythromycin may be used. Educate the family on the importance of taking the antibiotic as directed and finishing all the medicine.

Encourage fluid intake to maintain adequate hydration due to fever. Teach parents ways to provide comfort for the child. A cool mist humidifier can soothe the child's sore throat. Soft foods, warm liquids like soup, or cold foods like Popsicles may also be helpful. If the child is hospitalized, droplet precautions, along with standard precautions, are necessary.

Diphtheria

Diphtheria is caused by infection with *Corynebacterium diphtheriae* and may affect the nose, larynx, tonsils, or pharynx. Tonsillar and pharyngeal infections are the most common and will be the focus of this discussion. A pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate (Fig. 15.2). The neck becomes edematous and lymphadenopathy develops. The pseudomembrane causes airway obstruction and suffocation. Diphtheria is very rare in the United States but continues to infect people worldwide due to lack of routine immunization (Mayo Clinic Staff, 2011). Risk factors include children and adults who are unimmunized or underimmunized, living in crowded or unsanitary living conditions, having a compromised immune system, and traveling to developing countries where diphtheria remains endemic (Mayo Clinic Staff, 2011). Routine infant immunization can prevent the disease. Therapeutic management involves administration of antibiotics and antitoxin, as well as airway management.

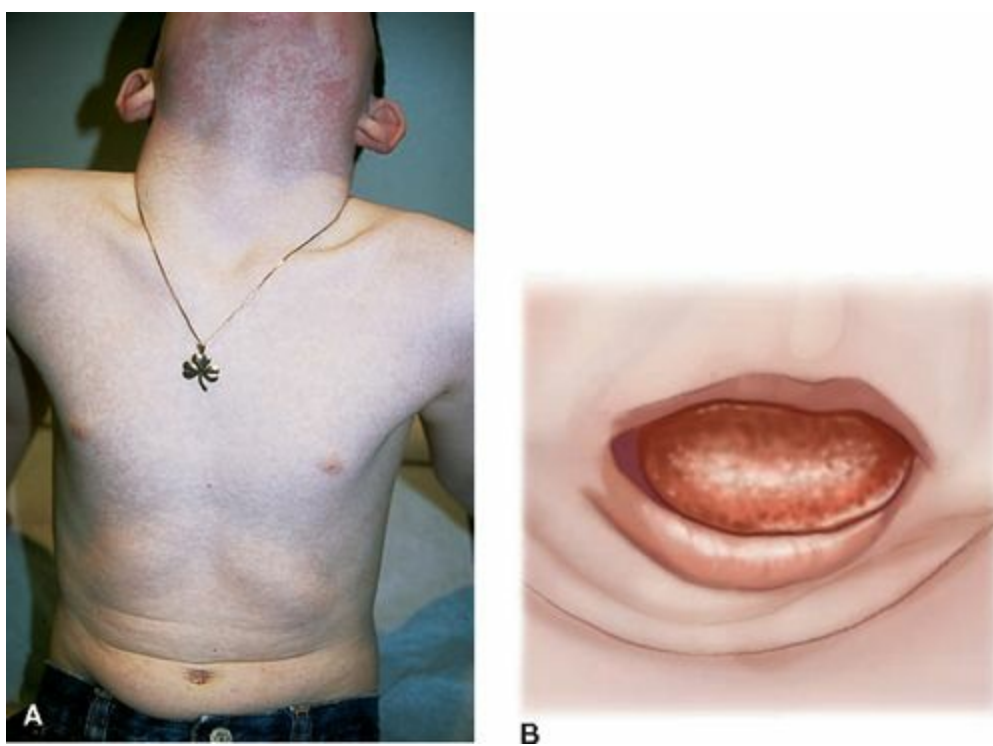

FIGURE 15.1 (A) Rash of scarlet fever. (B) Strawberry tongue.

FIGURE 15.2 In diphtheria a pseudomembrane forms over the pharynx, uvula, tonsils, and soft palate.

Nursing Assessment

Children at risk for diphtheria are those who are unimmunized. Note history of sore throat and fever, usually less than 38.9°C. As the pseudomembrane forms, swallowing becomes difficult and signs of airway obstruction become apparent. A specimen of the membrane may be cultured for *C. diphtheriae*.

Nursing Management

Close observation of respiratory status is of utmost importance. Administration of antibiotics and the antitoxin is critical to encourage sloughing of the membrane. The child should remain on strict droplet precautions in addition to standard precautions and should maintain bed rest.

Pertussis

Pertussis is an acute respiratory disorder characterized by paroxysmal cough (whooping cough) and copious secretions. The highest incidence is seen in children younger than 1 year of age, and children younger than 6 months of age are at greatest risk for severe disease and death (Centers for Disease Control and Prevention, 2010e). The disease is caused by *Bordetella pertussis*. The incubation period is 6 to 21 days, usually 7 to 10 days. Pertussis usually starts with 7 to 10 days of cold symptoms. The paroxysmal coughing spells then begin and can last 1 to 4 weeks. Convalescence occurs over the course of several weeks to months. Initially, immunization decreased the incidence of pertussis, but since the 1980s there has been a gradual increase (Centers for Disease Control and Prevention, 2011b). In recent years, there has been an increase in pertussis cases and reports of localized outbreaks, especially in adolescents and adults (Centers for Disease Control and Prevention, 2011b). Therefore, children older than 11 years of age and adults are now required to get one immunization booster of Tdap (tetanus, diphtheria, and pertussis) instead of Td (tetanus and diphtheria) (Centers for Disease Control and Prevention, 2011b, 2011c). Over the last several years an increased incidence of disease in children 7 to 10 years has been reported. The Advisory Committee on Immunization Practices (ACIP) revised their recommendations and currently recommends the use of Tdap in undervaccinated children aged 7 to 10 years (Centers for Disease Control and Prevention, 2010e, 2011c). Infants and young children continue to be required to get five doses of DTaP (diphtheria, tetanus, and pertussis) at 2 months, 4 months, 6 months, 15 to 18 months, and 4 to 6 years. Complications of pertussis include hypoxia, apnea, pneumonia, seizures, encephalopathy, and death.

Therapeutic Management

Therapeutic management of pertussis focuses on eradicating the bacterial infection and providing respiratory support. CDC guidelines recommend antimicrobial treatment (Centers for Disease Control and Prevention, 2011b). For infants older than 1 month of age, macrolide drugs, including erythromycin, clarithromycin, and azithromycin, are the drugs of choice (Centers for Disease Control and Prevention, 2005). For younger infants, azithromycin should be used and erythromycin and clarithromycin avoided (Centers for Disease Control and Prevention, 2005). An alternative to macrolides in children older than 2 months is trimethoprim-sulfamethoxazole (TMP-SMZ) (Centers for Disease Control and Prevention, 2005). A course of macrolide antibiotics is also recommended to treat symptomatic close contacts within 3 weeks of exposure (Centers for Disease Control and Prevention, 2005).

Nursing Assessment

The most important risk factor for the development of pertussis is lack of immunization. The history may reveal cold and cough symptoms, progressing to paroxysmal coughing spells. During the paroxysms, the child might cough 10 to 30 times in a row, followed by a whooping sound. This might be accompanied by redness in the face, progressive cyanosis, and protrusion of the tongue. Saliva, mucus, and tears flow from the mouth, nose, and eyes. Between the paroxysmal episodes, the child might rest well and appear relatively unaffected. Auscultate the lungs to assess air exchange. The diagnosis may be confirmed by a variety of laboratory tests accompanied by clinical history. Culture is considered the gold standard, but polymerase chain reaction (PCR) is used by some laboratories due to its increased sensitivity and faster results (Centers for Disease Control and Prevention, 2011b).

Nursing Management

Nursing care will focus on providing a high-humidity environment and frequent suctioning to mobilize secretions. Observe for signs of airway obstruction. Encourage fluids to keep secretions thin and maintain adequate hydration. Offer reassurance to the child and family; the coughing episodes can be very frightening. Droplet precautions along with standard precautions are necessary for the hospitalized child.

Tetanus

Tetanus is an acute, often fatal neurologic disease caused by the toxins produced by *Clostridium tetani*. Tetanus is rare in the United States but continues to be significant worldwide due to lack of routine immunization (Arnon, 2007). It is characterized by increased muscle tone and spasm. *C. tetani* spores can live anywhere but are found most commonly in soil, dust, and feces from humans or animals, such as sheep, cattle, chickens, dogs, cats, and rats. The spores can enter the body through a wound that is contaminated, through a burn, or by injecting contaminated street drugs. Once it enters the body, an anaerobic environment allows it to multiply and a poisonous toxin is released.

There are four forms of tetanus. Neonatal tetanus is the most common worldwide, affecting newborns in the first week of life secondary to an infected umbilical stump or unsterile surgical technique during circumcision (Arnon, 2007). Most women in the United

States have been immunized and will pass the immunity to their fetus. Along with proper hygiene during delivery and adequate cord care, this makes this type rare in the United States, but in underdeveloped countries it remains a significant problem (Centers for Disease Control and Prevention, 2011b). The second form is local tetanus. This rare form is characterized by local muscle spasms within the area of the wound. The third type is cephalic tetanus, which is associated with recurrent otitis media or head trauma. It is also rare and affects the cranial nerves, especially facial nerves. Generalized tetanus is the most common form and results in spasms that progress in a descending fashion beginning at the jaw. The most profoundly affected muscles are those of the neck and back.

In the United States the fatality rate associated with tetanus has declined and cases are rare, but 1 in 10 cases will result in death (Centers for Disease Control and Prevention, 2011i). The general incubation period is 3 to 21 days, with an average of 8 days. Recovery can be long and difficult, and children with tetanus may have to spend several weeks in the hospital in an intensive care setting. It has been suggested that the shorter the incubation period, the higher the risk of more severe illness and poorer prognosis. Complications associated with tetanus include breathing problems, fractures, elevated blood pressure, dysrhythmias, clotting in the blood vessels of the lung, pneumonia, and coma.

Therapeutic Management

Therapeutic management is directed toward supporting respiratory and cardiovascular function. Tetanus immunoglobulin may be given as well as the tetanus vaccine. Removal of the offending organism, by debridement of the wound, may occur, and intravenous antibiotics such as metronidazole may be initiated. In severe cases, the child may require intensive nursing care with mechanical ventilation.

Nursing Assessment

Note history of initial signs such as headache, spasms, crankiness, and cramping of the jaw (lockjaw), which are followed by difficulty swallowing and a stiff neck. Tetanus progresses in a descending fashion to other muscle groups, causing spasms of the neck, arms, legs, and stomach; seizures may result. Document the presence of fever along with an elevated blood pressure and tachycardia. Opisthotonos may be noted due to severe spasms of the neck and back. The spasms or muscle contractions in children may be strong enough to result in fractures. The diagnosis of tetanus is based on the clinical findings of the history and physical examination.

Nursing Management

Nursing management focuses on observing for signs of respiratory distress. Provide a quiet environment with reduced external stimuli to decrease the incidence of spasms. Appropriately manage pain. Encourage adequate nutrition and hydration. Administer sedatives and muscle relaxants as ordered to reduce the pain associated with the muscle spasms and to prevent seizures. Encourage the parents to stay with their child. The child's mental status is unaffected by the disease, and therefore he or she is aware of what is happening. Efforts need to be made to reduce the child's anxiety and to provide reassuring, sympathetic care to the child and family. Tetanus is not contagious from person to person; therefore, standard precautions are sufficient.

Tetanus is a preventable but potentially fatal disease. Education is essential regarding the importance of receiving this routine immunization (refer to [Chapter 9](#) for immunization schedule) as well as a booster every 10 years. Instructing parents on proper wound care can also help prevent tetanus. All wounds should be cleaned thoroughly and a proper antiseptic used. If a wound is deep and contamination is suspected, the child should be seen by a physician or nurse practitioner. If it has been more than 5 years since the last tetanus dose, a booster may be needed. This can help to neutralize the poison and prevent it from entering the nervous system.

VIRAL INFECTIONS

Viruses are very small particles that infect cells. They cannot multiply on their own and require a living host, such as humans, animals, or plants. They can reproduce only by invading and taking over the host cells. Young children are highly sensitive to viruses; their resistance is low and exposure is high. Viruses are hard to destroy without damaging or killing the living cells they infect. Therefore, drugs are not used to control them. However, many viral diseases can be prevented by immunization, such as measles, rubella, varicella, mumps, and poliomyelitis (see [Chapter 9](#) for more information on immunizations).

Viral Exanthems

Many viral infections of the skin in childhood are called viral exanthems. **Exanthem** means rash or skin eruption. Viral exanthems of childhood often present with a distinct rash pattern that assists in the diagnosis of the virus. [Table 15.4](#) discusses common childhood exanthems. Immunizations have led to a decrease in the incidence of certain viral exanthems, such as measles, rubella, and varicella.

Typically, children with viral exanthems are cared for at home, but there are times when a child may be hospitalized or may develop the disease while being hospitalized. Appropriate transmission-based precautions must be taken. Therapeutic management of the viral exanthems focuses on fever management and relief of discomfort.

Nursing Assessment

Obtain the history of the present illness, noting the onset of rash in relation to the onset of fever. Note accompanying symptoms such as respiratory complaints. Document known exposure to childhood diseases. Note immunization status. Inspect the skin for rash, noting the distribution, type, and extent of lesions. [Table 15.4](#) describes the rash as well as accompanying symptoms for each of the viral exanthems.

| TABLE 15.4 COMMON VIRAL EXANTHEMS OF CHILDHOOD | | | |
|---|--|--|---|
| Disease | Clinical Manifestations | Management/Complications | Nursing Implications |
| <p>Rubella (Ger man measles)</p> <ul style="list-style-type: none"> Caused by rubella virus Transmitted by direct or indirect contact with droplets, primarily by nasopharyngeal secretions, but also in blood, stool, and urine. Also transmitted from mother to fetus Peak incidence during late winter and early spring Incubation period: 14 to 21 days (usually 16 to 18) Communicable 7 days before to 7 days after onset of rash  <p>Rubella rash. (CDC. [1956]. Obtained at http://phil.cdc.gov/phil/details.asp)</p> | <ul style="list-style-type: none"> Lymphadenopathy (retroauricular, posterior cervical, postoccipital) 24 hours before the onset of the rash, lasting up to 1 week Rash begins on face and spreads quickly down the neck, trunk, and extremities; disappears in same order it spread, usually by third day. On the second day the rash may appear pinpoint. Desquamation is minimal. Mild pruritus Polyarthralgia and polyarthritis (rare in children but common in adolescents) | <ul style="list-style-type: none"> Usually mild and self-limiting Treatment is mainly supportive. Complications: encephalitis and thrombocytopenia (rare) Maternal rubella during pregnancy can result in miscarriage, fetal death, or congenital malformations. | <ul style="list-style-type: none"> Comfort measures such as antipyretics, antipruritics, and analgesics for joint pain Droplet precautions for the duration of the illness in the hospitalized child Avoid exposure to pregnant women. |
| <p>Rubeola (measles)</p> <ul style="list-style-type: none"> Caused by measles virus Transmitted by direct or indirect contact with droplets, primarily by nasopharyngeal secretions, but also blood and urine. Highly contagious Incubation period: 8 to 12 days Communicable 1 to 2 days before the onset of symptoms (3 to 5 days before onset of rash) until 4 to 6 days after rash has appeared  <p>Koplik spots. (CDC/Dr. Heinz F. Echten-wald. [1958]. Obtained at http://phil.cdc.gov/phil/details.asp)</p> | <ul style="list-style-type: none"> Prodromal phase: 2 to 4 days, consisting of fever, cough, coryza, conjunctivitis Followed by Koplik spots (bright red spots with blue white centers on mucous membranes, mainly buccal mucosa, look like tiny grains of white sand surrounded by red rings) Erythematous maculopapular rash appears 3 to 4 days after the onset of the prodromal phase. Rash gradually proceeds from head downward and outward. | <ul style="list-style-type: none"> Treatment is mainly supportive, including antipyretics, bed rest, and adequate fluid intake. Possible vitamin A supplementation in children 6 months to 2 years hospitalized for measles or its complications or those with immunodeficiency* Complications: otitis media, pneumonia, croup, and diarrhea common in young children; acute encephalitis | <ul style="list-style-type: none"> Comfort measures, such as antipyretics and antipruritics Clean eyes with warm, moist cloth to remove secretions. Cool mist humidification to alleviate coryza and cough Air-borne precautions until 4 days after onset of rash |

Varicella zoster (chickenpox)

- Caused by varicella zoster virus, human herpes virus 3
- Highly contagious. Transmitted by direct contact with infected persons' nasopharyngeal secretions or via air-borne spread, to a lesser degree by contact with unscabbed lesions. Also transmitted from mother to fetus
- Peak incidence late fall, winter, and spring
- Incubation period: 10 to 21 days, usually 14 to 16
- Communicable 1 to 2 days before onset of rash until all vesicles have crusted over (about 3 to 7 days after onset of rash)

Rubeola (CDC [1963]. Obtained at <http://phil.cdc.gov/phil/details.asp>)

- Prodromal symptoms (fever, malaise, anorexia, headache, mild abdominal pain) may be present 24 to 48 hours before the onset of the rash. In children, rash is often the first sign of disease
- Lesions often appear first on scalp, face, trunk, then extremities; initially intensely pruritic erythematous macules that evolve to papules and then form clear, fluid-filled vesicles
- Vesicles eventually erupt, and then lesions scab and crust. A variety of lesions are present at one time
- More severe in adolescents and adults than in young children

- Usually self-limiting; treatment is mainly supportive: fever reduction, antipruritics, and skin care to prevent infection of lesions
- Antiviral therapy and varicella zoster immune globulin may be used in those considered to be at high risk (immunocompromised, pregnant women, and newborns exposed to maternal varicella). Routine antiviral therapy is not recommended for the treatment of uncomplicated varicella infection in otherwise healthy children
- Complications: bacterial superinfection of skin lesions, thrombocytopenia, arthritis, hepatitis, cerebellar ataxia, encephalitis, meningitis, pneumonitis, glomerulonephritis, congenital infection, and life-threatening perinatal infection
- Lifelong latent infection occurs; reactivation results in herpes zoster (shingles), uncommon in childhood

- Comfort measures, such as antipyretics and antipruritics
- Air-borne and contact precautions in the hospitalized child for a minimum of 5 days after onset of rash and as long as vesicular lesions are present
- For those with exposure to susceptible persons, air-borne and contact precautions, from 8 to 21 days after exposure
- Children may return to school or child care once lesions have crusted

Exanthem subitum (*r. roseola infantum* or sixth disease)

- Caused by human herpes virus 6 (HHV-6); less frequently human herpes virus 7 (HHV-7)
- Transmission mode: little is known but suspected to be from saliva of infected person and enters the host through the oral, nasal, or conjunctival mucosa
- Peak incidence age 6 to 15 months
- Incubation period: 5 to 15 days, average of 10 days
- Communicability is unknown, but most likely contagious during febrile stage

Varicella (CDC/Dr. John Noble, Jr. [1968]. Obtained at <http://phil.cdc.gov/phil/details.asp>)

- Prodromal phase: usually asymptomatic but may include upper respiratory signs
- Clinical illness: high fever ranging from 37.9°C to 40°C (101°C to 106°F) for 3 to 5 days, resolves abruptly; rash appears 12 to 24 hours later, lasting about 1 to 3 days. Rash is pinkish-red, flat or raised spots that blanch when touched

- Course is generally benign
- In children who are uncomfortable or irritable or have a history of febrile seizures, antipyretics may be warranted
- Complications: HSV-6 may be responsible for some febrile seizures, encephalitis, and meningoencephalitis (rare)

- Comfort measures, such as antipyretics, antipruritics
- Standard precautions are sufficient in the hospitalized child

Erythema infectiosum (*f. fifth disease*)

- Caused by human parvovirus B19
- Transmitted by large droplet spread from nasopharyngeal viral shedding or percutaneous exposure to blood and blood products. Also transmitted from mother to fetus
- Peak incidence late winter and early spring
- Incubation period: 4 to 28 days, average 16 to 17 days
- Communicability is uncertain, but most children are no longer infectious by the time the rash appears and diagnosis is made, so isolation or exclusion from school, once the child is diagnosed, is unnecessary (those with aplastic crisis may be communicable up to 1 week after onset of symptoms and those who are immunosuppressed with chronic infection and severe anemia may be communicable for months to years)

Exanthem subitum (roseola infantum)

- Prodromal phase: mild symptoms, low-grade fever, headache, mild upper respiratory infection
- Characteristic rash occurs in three stages:
 - Begins with erythematous flushing often described as "slapped-cheek" appearance, often with circumoral pallor
 - Spreads to trunk
 - Moves peripherally, appearing as a maculopapular, lace-like appearance; often pruritic
- Palms and soles are usually spared. Rash fluctuates in intensity and will disappear and reappear with environmental changes such as exposure to sunlight
- Resolves spontaneously over 1 to 3 weeks
- Children with preexisting anemia may develop aplastic crisis (will have fever, malaise, myalgia, but usually no rash)

- Usually benign and self-limited; supportive treatment is all that is needed
- Blood transfusion may be necessary in children with aplastic crisis
- Complications: arthritis and arthralgia
- May result in fetal loss, hydrops fetalis in pregnant woman

- Comfort measures, such as antipyretics, antipruritics
- Droplet precautions are required in the hospitalized child
- Inform pregnant women (including health care workers) of the potential risks to the fetus and preventive measures to decrease these risks (strict infection control practices, not caring for those likely to be contagious). The CDC does not recommend routine exclusion from a workplace where an outbreak is occurring

Hand, foot, and mouth disease, or herpangina (if only mouth involvement)

- Caused by viruses belonging to enterovirus genus. Coxsackieviruses (especially A16) is the most common. Transmitted by direct contact with infected fecal, oral secretions; spread mostly through saliva
- Peak incidence during spring and summer, particularly in children who wear diapers (1- to 4-year-olds)
- Incubation period: 3 to 6 days
- Communicable from time of infection until fever resolves; virus is shed for several weeks after the infection begins.

Erythema infectiosum (fifth disease)

- High fever usually occurs first.
- Vesicles on tongue and oral mucosa erode to shallow ulcers; vesicles on hands and feet are football shaped, with erythematous rims
- Extensive mouth lesions may lead to anorexia, dehydration, and drooling.

- Usually mild and self-limiting, resolving within 1 week
- Treatment is mainly supportive.
- Complications: dehydration, meningitis, encephalitis, and pulmonary edema

- Standard precautions and good hand hygiene are necessary.
- Encourage oral fluids of preference, popsicles.
- Provide analgesics as needed.

Mason, W. H. (2007). Measles. In R. M. Kliegman, R. E. Behrman, H. B. Jenson, & E. F. Stanton (Eds.), *Nelson's textbook of pediatrics* (18th ed., pp. 1331–1336). Philadelphia: Saunders.

Nursing Management

Nursing management of viral exanthems focuses on fever reduction, relief of discomfort, and protection of skin integrity. Encourage hydration. Administer antipyretics and antipruritics as needed (refer to [Drug Guide 15.1](#)). Nonpharmacologic interventions to reduce fever, such as tepid sponging and cool compresses, may be used. Refer to [Nursing Care Plan 15.1](#) for additional information; care should be individualized based on the child's and family's response to the illness.

Take Note!

Trim the child's fingernails or cover hands with mitts, gloves, or socks (which work well with younger infants and children) if the rash itches to help prevent breaks in the skin, which can lead to discomfort and infection.

Mumps

Mumps, a contagious disease caused by Paramyxovirus, is characterized by fever and parotitis (inflammation and swelling of the parotid gland). Mumps is spread via contact with infected droplets. Infected individuals are contagious for 1 to 7 days prior to onset of symptoms and for 7 to 9 days after parotid swelling begins. About 50% of all infected postpubertal boys also develop orchitis (inflammation of the testicle) (Centers for Disease Control and Prevention, 2011b). Orchitis in prepubertal males is rare (Mason, 2007c). This may lead to some degree of testicular atrophy, but rarely sterility. In about 5% of females oophoritis (ovarian inflammation) occurs with no relationship to infertility (Centers for Disease Control and Prevention, 2011b). Complications of mumps include meningitis with or without encephalitis with seizures, pancreatitis, and auditory neuritis, which can result in deafness. Therapeutic management is supportive.

Since the recommendation of the two-dose MMR (measles, mumps, rubella) vaccine, the incidence of mumps has declined and made mumps a rare disease seen in the United States (Centers for Disease Control and Prevention, 2011b). The American Academy of Pediatrics (AAP) and the ACIP recommends immunization against mumps for all children (Centers for Disease Control and Prevention, 2010g). Current recommendations include first mumps immunization between 12 and 15 months of age, followed by a second vaccine between 4 and 6 years of age (Centers for Disease Control and Prevention, 2010g). According to the CDC (2010d), one dose of MMR prevents between 73% and 91% of cases and two doses prevent approximately 79% to 95% of cases (see [Chapter 9](#) for information on mumps vaccination).

FIGURE 15.3 Parotitis associated with mumps.

Nursing Assessment

Note history of exposure to infected individuals as well as immunization status. Determine history of low-grade fever and onset and progression of parotid swelling. History may also include malaise, anorexia, headache, and abdominal pain. The parotid swelling is easily observed as swelling of the neck either bilaterally or unilaterally (Fig. 15.3). In boys, note orchitis. The diagnosis is usually based on the history and clinical presentation, but serum may be tested for the presence of mumps IgG or IgM **antibody**.

Nursing Management

Nursing management of mumps is primarily supportive. Acetaminophen or ibuprofen is used for fever management, and occasionally narcotic analgesics are required for pain management. Oral fluids are encouraged to prevent dehydration. If orchitis is present, ice packs to the testicles and gentle testicular support may be helpful. Hospitalized children should be confined to respiratory isolation to prevent spread of the disease. Infected children are considered no longer contagious 9 days following onset of parotid swelling (Centers for Disease Control and Prevention, 2011b).

Take Note!

In recent years mumps outbreaks have occurred, mainly in settings where prolonged close contact with other people occurs, such as college campuses and camps. The mumps vaccine is not 100% effective, and mumps infection can occur in vaccinated individuals. During an outbreak it is essential to define the population at risk and transmission setting, identify and isolate suspected cases, and identify and vaccinate susceptible individuals (Centers for Disease Control and Prevention, 2010d).

ZOONOTIC INFECTIONS

Zoonotic infections are diseases caused by infectious agents that are transmitted directly or indirectly from animals to humans. Zoonotic infections are responsible for about 75% of emerging infectious diseases, with approximately 60% of all human pathogens originating from animals (Centers for Disease Prevention and Control, 2011j). Two infections are covered below. Refer to [Table 15.5](#) for other zoonotic infections.

Cat Scratch Disease

Cat scratch disease is a relatively common and occasionally serious disease caused by the bacteria *Bartonella henselae*. It occurs in both children and adults but is more common in children (Klein, 2009). Cats can carry the bacteria in their saliva. In 90% of cases the child has had a recent interaction with cats and often kittens (Klein, 2009). No evidence exists to support person-to-person transmission (Klein, 2009). *B. henselae* is transmitted between cats via the cat flea. The incubation period is 7 to 12 days, with lymphadenopathy appearing in 5 to 50 days. Therapeutic management is supportive and is aimed at management of symptoms. The disease itself is usually self-limited, resolving on its own in 2 to 4 months. If lymphadenopathy persists or if the child is immunocompromised, antibiotics may be needed. Painful, swollen nodes may be treated with needle aspiration to provide symptom relief.

Nursing Assessment

Note history of headaches, fever, anorexia, and fatigue. The history may also include interaction or rough play with cats or kittens, resulting in a scratch. Document the temperature, noting fever. Palpate for enlarged lymph nodes, noting their location. A skin papule or pustule may be present or reported at this site of the bite or scratch. Diagnostic tests are available to detect serum antibodies to antigens of *Bartonella* species.

Nursing Management

Administer antibiotics if ordered. No transmission-based isolation is required; standard precautions are sufficient. Educate the child and family about prevention and control measures. Teach children to avoid rough play with cats and kittens. Teach parents and children to immediately wash any bites or scratches with soap and running water. Explain that cats should never lick open wounds on the child. Control of fleas in cats is important to prevent the spread of *B. henselae*.

Rabies

Rabies is a preventable viral infection of the central nervous system. It is transmitted to other animals and humans through close contact with the saliva of a rabid animal, usually by a bite. The number of cases of rabies has steadily declined in the United States (Immunization Action Coalition, 2010). It is rare in the United States and Western Europe due to routine vaccination of domestic animals, such as dogs, and the availability of effective postexposure prophylaxis. Now most cases of rabies in these areas are due to wild animals such as raccoons, skunks, bats, and foxes (Immunization Action Coalition, 2010). Rabies continues to be a major health problem in other parts of the world, especially in areas where dogs are not controlled.

Most cases of rabies occur in children younger than 15 years of age, and most human deaths occur in Asia and Africa (World Health Organization, 2010). Children have an increased susceptibility to rabies due to their fearlessness around animals, eagerness to play with animals, shorter stature, and inability to protect themselves. The incubation period for rabies is extremely variable. Typically it is several weeks to months but can range from days to years (Immunization Action Coalition, 2010). The incubation period tends to be shorter in children. Once symptoms of rabies have developed, the prognosis is poor. Death usually occurs within days of the onset of symptoms. Prevention is of paramount importance, and eliminating infection in animal vectors is essential. Successful animal vaccination and animal control campaigns in the United States have led to a very low rate of human rabies cases. Rabies among dogs in the United States has been virtually eliminated (Immunization Action Coalition, 2010). Recently, rabies transmitted from other animals, especially raccoons and bats, has become a cause for concern (Immunization Action Coalition, 2010).

It is important to contact the local health department whenever there is an exposure, or suspected exposure, to rabies. Several factors need to be considered when deciding to provide postexposure prophylaxis, such as local epidemiology, type of animal involved, availability of the responsible animal for testing or quarantine, and the circumstances of the exposure, such as a provoked versus an unprovoked attack. In a previously unvaccinated child, postexposure prophylaxis should begin with a thorough cleansing of all wounds with soap and water or a virucidal agent, such as povidone-iodine solution. In the United States, concurrent use of passive

and active immunoprophylaxis is then recommended. It consists of a regimen of one dose of immune globulin and four doses of human rabies vaccine. Rabies immune globulin and the first dose of rabies vaccine should be given as soon as possible after exposure, ideally within 24 hours. Additional doses of rabies vaccine should be given on days 3, 7, and 14 after the first vaccination. Rabies immune globulin is infiltrated into and around the wound, with any remaining volume administered intramuscularly at a site distant from the vaccine inoculation. Human rabies vaccine is administered intramuscularly into the anterolateral thigh or deltoid, depending on the age and size of the child. Administration into the gluteus muscle should be avoided, since this site has been associated with vaccine failure (Rupprecht et al., 2010; Toltzis, 2007).

| TABLE 15.5 OTHER ZOONOTIC AND VECTOR-BORNE ILLNESSES | | | | |
|--|---|--|--|---|
| Disease | Causative Organism | Geographic Distribution | Vector of Transmission | Manifestations |
| Rat bite fever | <i>Streptobacillus moniliformis</i> <i>Spirillum minus</i> | Throughout United States Asia and Africa | Bite or scratch from infected rat, after handling a rat, or ingestion of food or water contaminated with rat excreta Historically found mostly in wild or laboratory rats but pet rats have been a source especially affecting young children | Abrupt fever, chills, headache, and myalgias 2 to 10 days after infection 2 to 4 days after onset of fever, maculopapular rash develops, mainly on palms and soles, that may evolve into petechiae, purpura, and vesicles. |
| <i>Escherichia coli</i> O157:H7 | <i>E. coli</i> | Worldwide | Ingestion of contaminated food or water or fecal-oral spread from an infected animal (children who touched animals at a farm, fair, or petting zoo) | Symptoms range from asymptomatic infection to mild diarrhea to hemorrhagic colitis Often visible blood is present in stool of children with diarrhea Complaints of abdominal pain and vomiting, fever is usually low grade or absent |
| West Nile virus | <i>Flavivirus</i> | Throughout United States with higher rates found in Great Plains and mountain regions; seasonal epidemic from summer to fall | Mosquito bites Rare cases spread through blood transfusions, transplants, and mother to baby during pregnancy and breastfeeding | Symptoms include febrile illness, meningitis, encephalitis, or acute flaccid paralysis. Children more likely to be asymptomatic or have milder form of disease than adults but children manifest as meningitis more often than adults ^a |
| Rickettsial pox | <i>Rickettsia akari</i> | Northeastern cities in United States, Europe and Asia, mainly urban settings | Mouse mite bite | <ul style="list-style-type: none"> • Bite becomes a papule, then pustule, then ulcerates and forms eschar at site. • Fever, local adenopathy, headache, myalgia, maculopapular rash that may become vesicular |

| | | | | |
|--------------------------------|---|--|---|---|
| Epidemic typhus | <i>Rickettsia prowazekii</i> | Africa, South America, Central America, Mexico, Asia, occasional cases seen in United States | Louse feces (typically from the body louse) that are rubbed into broken skin or mucous membranes Cases in United States associated with louse or flea of flying squirrel | <ul style="list-style-type: none"> • Abrupt onset of high fever, chills, and myalgia with severe headache and malaise • Rash appears 4 to 7 days after onset of symptoms, beginning on the trunk and spreading to the extremities. • Maculopapular rash becomes petechial or hemorrhagic, then develops brown pigmented areas. • Changes in mental status may occur. • Flying squirrel–related disease typically presents as a milder illness. |
| Endemic typhus (murine typhus) | <i>Rickettsia typhi</i> and <i>Rickettsia felis</i> | Worldwide, especially warm coastal ports. In United States, most prevalent in Texas, parts of California, and Hawaii | Rat flea or cat flea feces | <ul style="list-style-type: none"> • Headache, myalgia, and chills that slowly worsen • Fever for 10 to 14 days • Rash appears after 3 to 8 days; it is macular or maculopapular with sparse lesions and no hemorrhage. |
| Ehrlichiosis and anaplasmosis | Three pathogens: <i>Ehrlichia chaffeensis</i> , <i>Anaplasma phagocytophilum</i> , <i>Ehrlichia ewingii</i> | Mostly in southeastern and south-central United States | Tick | <ul style="list-style-type: none"> • Fever with clinical signs similar to Rocky Mountain spotted fever. Rash is less commonly associated. • May also present with leukopenia, anemia, and hepatitis |
| Q fever | <i>Coxiella burnetii</i> | Worldwide | Inhalation of infected aerosols, ingestion of contaminated dairy products | <ul style="list-style-type: none"> • Most cases are initially asymptomatic. Occurs in two forms: <ul style="list-style-type: none"> • Acute: follows initial exposure and presents with abrupt onset of fever, chills, weakness, headache, and loss of appetite • Chronic: occurs years after initial exposure and may present with endocarditis (in clients with underlying heart disease), hepatitis, or fever of unknown origin |

| | | | | |
|---|---|---|--|---|
| Malaria | <i>Plasmodium</i> (four species exist that infect humans: <i>P. falciparum</i> , <i>P. vivax</i> , <i>P. ovale</i> , <i>P. malariae</i>) | Endemic in tropical areas of the world Highest risk in sub-Saharan Africa, Papua New Guinea, the Solomon Islands, and Vanuatu Other areas of risk: Haiti and Indian subcontinent Cases in the United States are usually in travelers and immigrants returning from countries where malaria transmission occurs | Bite of <i>Anopheles</i> species of mosquito | <ul style="list-style-type: none"> • High fever with chills, rigors, sweats, and headache, which may be paroxysmal • Nausea, vomiting, diarrhea, cough, arthralgia, and abdominal and back pain may also occur. • Anemia and thrombocytopenia with pallor and jaundice may be seen. • May occur in a cyclic pattern, and depending on the species fever may occur every other day or every third day. |

Note the history of an animal bite, especially if it was unprovoked, and exposure to bats. Document history of early symptoms of rabies infection, which are nonspecific and flu-like, such as fever, headache, and general malaise. The child may complain of pain, pruritus, and paresthesia at the bite site. As the virus spreads to the central nervous system, encephalitis develops. The disease will have progressive neurologic manifestations, which may include insomnia, confusion, anxiety, changes in behavior, agitation or excitation, hallucinations, hypersalivation, dysphagia, and hydrophobia, which results from aspiration when swallowing liquid or saliva. In some cases progressive paralysis may be present. The child may have periods of lucidity alternating with these neurologic changes.

Laboratory testing may include hair and saliva specimens from which the virus may be isolated. Serum and cerebrospinal fluid can be tested for antibodies to the rabies virus. Direct fluorescent antibody testing can be done to diagnose rabies in a suspected animal. The test can only be done postmortem and requires brain tissue from the potentially rabid animal.

Nursing Management

Few people survive once symptomatic rabies infection develops. Intensive supportive care is required, but recovery is extremely rare. Therefore, it is vital to educate children and families about the importance of seeking medical care after any animal bite to prevent death from rabies infection. Also, teach children to avoid wild animals, stray animals, and any animal with unusual behavior. Teach children not to provoke or attempt to capture wild or stray animals.

Regardless of whether immunoprophylaxis is initiated, appropriate wound management is necessary in all victims of a bite from a potentially rabid animal. This includes a thorough cleansing of all wounds with soap and water. Irrigation of wounds for at least 10 minutes with a virucidal agent, such as povidone-iodine solution, is recommended (Toltzis, 2007).

When caring for a child requiring postexposure prophylaxis, provide support and education to the child and family. Due to the seriousness and urgency surrounding this disease and treatment, the child and family are often very frightened. Consider comfort measures, such as EMLA (eutectic mixture of local anesthetics) cream and positioning, when giving immunization.

VECTOR-BORNE INFECTIONS

Children are at a particular risk for contracting vector-borne diseases, which are diseases transmitted by ticks, mosquitoes, or other insect vectors (Table 15.5). Young children are unaware of the health risks around them and cannot take protective measures. Their immature immune system leads to a decreased capacity to resist vector-borne diseases. These diseases can be severe and even fatal, though most are treatable if identified early. Many times the child presents initially with nonspecific symptoms. Coupled with the fact that there are few definitive diagnostic tests available, this can lead to difficulty in promptly recognizing and treating these diseases.

Tick-borne diseases are common vector-borne illnesses in the United States. Two of the most common will be covered below.

Lyme Disease

Lyme disease, the most common reported vector-borne disease in the United States, is caused by the spirochete *Borrelia burgdorferi* (Centers for Disease Control and Prevention, 2011e). It is transmitted to humans via the bite of an infected black-legged (deer) tick. Ninety-five percent of reported Lyme disease cases occurred in 12 states, mainly in the northeast (Pennsylvania, New Jersey, New York, Massachusetts, Connecticut, Maryland, New Hampshire, Delaware, Maine, and Virginia) and the upper Midwest (Minnesota and Wisconsin) (Centers for Disease Control and Prevention, 2011g).

Most cases are seen between June and August (Centers for Disease Control and Prevention, 2011e). Lyme disease can affect any age group, but the incidence is highest among children between 5 and 10 years of age (Shapiro, 2007). The prognosis for recovery in children who are treated is excellent.

Therapeutic Management

In most cases Lyme disease can be cured by antibiotics, especially if they are started early in the illness. Doxycycline is the drug of choice for children older than 8 years (Shapiro, 2007). Because it can cause permanent discoloration of the teeth, children younger than 8 years should be treated with amoxicillin (Shapiro, 2007). For children allergic to penicillin, cefuroxime or erythromycin can be used. Duration of treatment is usually 14 to 28 days, depending on the stage of disease.

Nursing Assessment

The clinical signs of Lyme disease are divided into three stages—early localized, early disseminated, and late disease. Untreated children may progress through the three stages or may present with early disseminated or late disease without having any symptoms of the earlier stages. If children are treated in the early stage, it is uncommon to see them with late disease. Nursing assessment for Lyme disease includes an accurate health history as well as physical examination.

Health History

Explore the health history for a tick bite. Document onset of rash. In early localized disease, the rash usually occurs 7 to 14 days after the tick bite (though it can appear 3 to 32 days after the bite). In early disseminated disease, the rash usually begins 3 to 5 weeks after the tick bite. Note complaints of fever, malaise, mild neck stiffness, headache, fatigue, myalgia, and arthralgia or pain in the joints. In late disease, note recurrent arthritis of the large joints, such as the knees, beginning weeks to months after the tick bite. The child with late disease may or may not have a history of earlier stages of the disease, including erythema migrans.

Physical Examination

Observe for a rash. A ring-like rash at the site of the tick bite (erythema migrans) characterizes early local disease (Fig. 15.4). If untreated, the rash gradually expands and will remain for 1 to 2 weeks. Suspect early disseminated disease if multiple areas of erythema migrans are found. The multiple lesions are usually smaller than the primary lesions. Note cranial nerve palsies (especially cranial nerve VII), conjunctivitis, or signs of meningeal irritation, which occur in early disseminated disease.

Laboratory and Diagnostic Testing

Immunoglobulin-specific antibody tests may not be positive in the early stage of the disease but may be useful in the later stages. The CDC recommends a two-step test—a sensitive enzyme immunoassay (EIA) or immuno-fluorescent assay (IFA), if positive, followed by a Western immunoblot (Centers for Disease Control and Prevention, 2011g). If these are negative, no further testing is indicated.

FIGURE 15.4 Erythema migrans, a ring-like rash at the site of the tick bite, occurs in Lyme disease. (CDC/James Gathany. [2007]. Obtained at <http://phil.cdc.gov/phil/details.asp?pid=9875>)

Nursing Management

Administer antibiotics as ordered. In the hospitalized child, no transmission-based precautions are necessary. Educate the child and family on the importance of taking the antibiotic as directed and finishing all the medicine. Another important nursing function is educating the child, family, and community on prevention measures ([Box 15.5](#)). For infection to occur, typically the tick must be attached for 36 to 48 hours (Centers for Disease Control and Prevention, 2011e). Therefore, prompt removal of ticks is essential to the prevention of Lyme disease. [Teaching Guidelines 15.2](#) gives information on tick removal.

BOX 15.5

PREVENTION OF TICK-BORNE ILLNESSES

- Wear appropriate protective clothing when entering tick-infested areas. Clothing should fit tightly around wrists, waists, and ankles. Tuck pants into socks if possible.
- After leaving the area, check for ticks and remove them promptly.
- Insect repellent may provide temporary relief but may produce toxicity, especially in children, if used frequently or in large doses.

Teaching Guidelines 15.2

TICK REMOVAL

- Use fine-tipped tweezers.
- Protect fingers with a tissue, paper towel, or latex gloves.
- Grasp tick as close to the skin as possible and pull upward with steady, even pressure.
- Do not twist or jerk the tick.
- Once the tick is removed, clean site with soap and water and wash your hands.
- Save the tick for identification in case the child becomes sick. Place in a sealable plastic bag and put it in your freezer. Write date of bite on the bag.

Rocky Mountain Spotted Fever

Rocky Mountain spotted fever (RMSF) is the most severe and frequently reported rickettsial illness in the United States (Siberry & Dumler, 2007). RMSF is caused by the bacteria *Rickettsia rickettsii*. The American dog tick and Rocky Mountain wood tick are the primary vectors, although others have been implicated. RMSF can be fatal without prompt and appropriate treatment (Siberry & Dumler, 2007). Most cases occur between April and September (Siberry & Dumler, 2007).

RMSF occurs throughout the United States. Its name is derived from the fact that it was discovered in the Rocky Mountain region, though few cases are found there today. RMSF is more common in the coastal Atlantic states, but the highest incidence has been found in North Carolina and Oklahoma. It occurs in all age groups but most frequently in children, with the peak incidence in children younger than 10 years of age (Siberry & Dumler, 2007).

Complications of RMSF include noncardiogenic pulmonary edema, cerebral edema, and multiorgan damage. Long-term neurologic involvement, such as partial paralysis of the lower extremities, hearing loss, loss of bladder and bowel control, movement disorders, and language disorders, may be seen, especially in children with severe illness who require long hospital stays.

Therapeutic Management

The fatality rate from RMSF has decreased with the widespread use of antimicrobial therapy (Siberry & Dumler, 2007). However, delays in diagnosis and therapy are significant factors associated with severity of disease and death. In most cases RMSF resolves rapidly with appropriate antibiotic therapy, especially if it is started early. Treatments of choice are tetracyclines, such as doxycycline. Doxycycline and other tetracyclines are not normally used in children younger than 8 years due to the risk of teeth staining. However, due to the life-threatening nature of RMSF and the limited course of antibiotic therapy, the American Academy of Pediatrics Committee on Infectious Diseases revised its recommendations and has identified doxycycline as the drug of choice for treating presumed or confirmed RMSF in children of any age (Center for Disease Control and Prevention, 2010n). Length of treatment is 7 to 14 days (Center for Disease Control and Prevention, 2010n).

Nursing Assessment

Note history of early signs of RMSF, such as sudden onset of fever, headache, malaise, nausea and vomiting, muscle pain, and anorexia. The incubation period varies from 2 to 14 days, with the average being around 7 days after the tick bite. Late signs include a rash, usually seen 2 to 5 days after the onset of the fever, abdominal pain, joint pain, and diarrhea. Inspect the skin for a rash, which starts as small, pink, macular, nonitchy, blanch-able spots on the wrists, forearms, and ankles. The rash then spreads rapidly over the entire body, including the soles and palms. After several days the rash will appear red, spotted, and petechial or hemorrhagic (Fig. 15.5). Approximately 5% of children with RMSF do not have a rash (Siberry & Dumler, 2007). Laboratory findings may include a low leukocyte count, low or decreasing platelet count, and hyponatremia. Biopsy of the rash with immunofluorescent assay and serologic tests may also be used.

Nursing Management

Nursing management is similar to that for Lyme disease. Educate the family about completing the antibiotic course, preventing tick bites, and appropriate tick removal (refer to [Box 15.5](#) and [Teaching Guidelines 15.2](#)).

FIGURE 15.5 Rash associated with Rocky Mountain spotted fever.

Take Note!

Many folklore remedies exist for tick removal such as use of petroleum jelly or hot matches. These often do little to get the tick to detach and may actually irritate the tick and stimulate it to release more saliva or gut contents, therefore increasing the chance of disease. The goal of tick removal is to detach it as quickly as possible (Centers for Disease Control and Prevention, 2011h).

PARASITIC AND HELMINTHIC INFECTIONS

Parasites are organisms larger than yeast or bacteria that can cause infection. They live in or on a host. Parasites receive nourishment from the host without benefiting or killing the host. Parasites frequently seen in children are scabies and head lice. A helminth is a parasitic intestinal worm. Helminthic infections seen in children include pinworms, roundworms, and hookworms. Children are at an increased risk for parasitic or helminthic infections due to poor hygiene practices. For example, children typically are more careless about hand washing and they tend to put things in their mouths and share toys and objects with other children.

Nursing Assessment and Management

Parents are often embarrassed when they find out that their child has a parasitic or helminthic infection. Reassure them that these infections can occur in any child. Tables 15.6 and 15.7 give nursing assessment and management information related to specific common parasitic and helminthic infections in children.

Take Note!

The head louse is becoming increasingly resistant to pediculicides (Diamantis, Morrell, & Burkhart, 2009). This may lead parents to resort to home remedies, such as covering the head with real mayonnaise or Vaseline. Inform parents that these remedies have not been proven to be effective (Durani, 2011).

Consider This!

As the nurse in a pediatric clinic, you receive a call from a frantic mother. She tells you, “The school sent my daughter home and told me she has lice! We are clean people! I don’t understand how this could happen!” How would you address her concerns? Discuss the plan of care for this child. What education and interventions will be necessary to prevent the spread of pediculosis capitis?

| Infection/Causative Organism | Transmission | Clinical Manifestations | Diagnosis/Treatment | Isolation/Control Measures/Concerns |
|--|---|--|---|--|
| Pediculosis capitis (head lice) Caused by <i>Pediculus humanus capitis</i> (head louse) | Direct contact with hair of infested people, less commonly with personal belongings, such as combs and hats, of those infested. Incubation period from laying of eggs to hatching of nymph is 6 to 10 days; adult lice will appear 2 to 3 weeks later. | Extreme pruritus is the most common symptom. Adult eggs (nits) or lice may be seen, especially behind the ears and at the nape of the neck. | Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Treatment: washing hair with a pediculicide such as permethrin, pyrethrins, lindane, malathion. Careful instructions on proper use of any product should be given and strict adherence to application instructions encouraged. Retreatment is usually recommended depending on treatment used. Detection of living lice 24 hours after treatment suggests incorrect use, a very heavy infestation, reinfestation, or resistance to treatment. | Contact precautions After treatment check hair and combs and lice from hair shafts every 2 to 3 days to prevent reinfestation. Control measures: Household and other close contacts should be examined and if infested treated. Bedmates should be treated prophylactically. Head lice do not survive long once they have fallen off. Most children can be treated effectively without treating their clothing and bedding. But to help avoid reinfestation disinfection of clothing, headgear, pillowcases, towels, and other items used by the individual within the past 2 days by washing in hot water and drying on the hot cycle may be helpful. Dry-cleaning nonwashable items or simply sealing them in a plastic bag for 10 days is effective. Soaking combs and hairbrushes in pediculicide, shampoo, or hot water Lice infestation is not a sign of poor hygiene; all socioeconomic groups are affected. |
| Pediculosis pubis (pubic lice) Caused by <i>Phthirus pubis</i> | Transmission usually occurs through sexual contact; also can be through contaminated items such as towels. | Pruritus of anogenital area; other hairy areas of the body, including eyelashes, eyebrows, axilla, legs, and beard, can be affected. | Diagnosis by identification of eggs, nymph, and lice with the naked eye is possible; adult lice are rarely seen. Same as treatment with pediculicides to treat head lice Retreat 7 to 10 days later. To treat eyelashes and eyebrows: if only a few nits are present remove these with fingernails or a nit comb; if additional treatment is needed apply ophthalmic-grade petrolatum ointment (prescription). | Standard precautions Control measures similar to head lice All sexual contacts should be treated. Avoid sexual contact with partners until both they and their partners have been successfully treated and reevaluated. Evaluation for presence of other sexually transmitted infections if found on children, may be a sign of sexual exposure or abuse. |

Scabies
Caused by *Sarcoptes scabiei*

Scabies

Incubation period from laying of eggs to hatching of nymph is 3 to 4 days; adult lice will appear 2 to 4 weeks later.
Transmission usually occurs through prolonged, close personal contact.
Incubation period in those without previous exposure is 4 to 6 weeks. Usually no symptoms are present during this time but transmission to others can occur.
People who were previously infested can develop symptoms in 1 to 4 days.

Intense pruritus (especially at night) with presence of erythematous, papular rash with excoriations. The lesions are generally distributed but often are concentrated on the hands and feet and in body folds.
May be found on head and neck
In infants and young children and those who are immunocompromised, the rash may include vesicles, pustules, or nodules.

Diagnosis can be made by a history of itching (especially at night), classic rash, and reports of itching in household or sexual contacts.
Mites can be seen on microscopic examination of skin scrapings to confirm diagnosis.
Treatment: A scabicide, such as permethrin or lindane, should be applied to the entire body below the head. Treatment of infants and young children should include the head, neck, and body. The cream is left on for a specified time (usually 8 to 14 hours) depending on the type of scabicide.
Careful instructions on proper use of any product should be given and strict adherence to application instructions should be urged.
Itching may not subside for several weeks, even after successful treatment.

Contact precautions
Prophylactic therapy for household members and sexual contacts
Bedding and clothing used by infested person or household, sexual, or close contacts within 4 days before treatment should be laundered in hot water and dried on the hot cycle (mites do not survive more than 3 to 4 days without skin contact).
Avoid direct skin-to-skin contact with person or items used by those infested.
Room used by an infested person, especially if he or she had crusted scabies, should be thoroughly cleaned and vacuumed.

TABLE 15.7 COMMON HELMINTHIC INFECTIONS IN CHILDREN

| Infection/Causative Organism | Clinical Manifestations | Transmission | Diagnosis/Treatment | Isolation/Control Measures |
|---|--|--|--|---|
| Roundworm (ascariasis) Caused by <i>Ascaris lumbricoides</i> , common in temperate and tropical areas | Most people are asymptomatic, may demonstrate slower growth and weight gain. In more severe infections, loss of appetite, nausea, vomiting, and abdominal pain may be seen. Cough and difficulty breathing may be present as immature worms migrate through the lungs. In significant infestation, partial or complete intestinal obstruction may occur. The more worms, the worse the symptoms. | Human feces are the major source of infected eggs. Hand to mouth is the usual route of transmission. The eggs are swallowed due to unclean hands or contaminated food. They pass into the intestine; larvae then hatch, penetrate the intestinal wall, enter the circulatory system, and migrate to any body tissue. | Diagnosis: once female worms are in the intestine, eggs can be visualized by microscopic evaluation of the stool. Occasionally a worm may be coughed up and visualized or seen in vomit or stool. Treatment is with mebendazole, albendazole, or pyrantel pamoate. | <ul style="list-style-type: none"> Standard precautions are sufficient. Sanitary disposal of feces Proper hand hygiene |
| Hookworm Caused by <i>Ancylostoma duodenale</i> (roundworm) and <i>Necator americanus</i> (roundworm); common in rural areas (especially with unsanitary conditions) | Most often people are asymptomatic until significant worms are established. May see pruritic erythematous papular rash at entry site (referred to as ground itch) or pulmonary symptoms as the larvae migrate. One of the greatest concerns in chronic infection is anemia (microcytic hypochromic anemia) secondary to blood loss as the worms suck blood and juices from the intestines. This can lead to hypoproteinemia, edema, pica, and wasting. The infection may result in physical or intellectual disability in children. | Hookworms are found in soil and enter the host through pores, hair follicles, and even intact skin (hands and feet are major sites of entry). The maturing larvae travel through the circulatory system into the lungs and then up the bronchial tree and are swallowed with secretions. They then migrate into the intestinal tract and attach to the wall of the small intestines, where they feed and reproduce. Transmission via ingested soil has been seen with <i>Ancylostoma duodenale</i> only. | Diagnosis is made through microscopic examination of feces that reveals hookworm eggs. Treatment: albendazole, mebendazole, and pyrantel pamoate Iron supplementation and possible blood transfusion in severe cases | <ul style="list-style-type: none"> Standard precautions are sufficient. Proper sanitation and disposal of feces Treatment of all known infested people Screening of high-risk individuals Encourage the wearing of shoes and avoiding going barefoot |

Pinworm
Caused by *Enterobius vermicularis* (roundworm), found in temperate climates

Some people are asymptomatic. May cause anal itching (pruritus ani), especially at night. Other clinical findings may include restlessness and teeth grinding at night, weight loss, and enuresis.

Fecal-oral route directly, indirectly, or inadvertently by contaminated hands or shared toys, bedding, clothing, toilet seats. Incubation period is 1 to 2 months or longer.

Diagnosis is made when adult worms are visualized in the perianal region; they are best viewed when the child is sleeping. Very few ova are present in stool, so examination of stool is not recommended. Transparent tape pressed to perianal area and then viewed under a microscope may reveal eggs. Three consecutive specimens should be obtained when the child first awakens in the morning. Treatment of choice is mebendazole, pyrantel pamoate, and albendazole, usually single doses and repeated in 2 weeks. All family members should be treated since transmission from person to person is very easy.

Standard precautions are sufficient. Reinfection occurs easily. Infected people should bathe, preferably in a shower, in the morning, which will remove a large portion of the eggs. Frequent changing of underclothes and bedding. Personal hygiene measures such as keeping fingernails short, avoiding scratching of perianal area and nail biting. Good hand hygiene is the most effective preventive measure, especially after using the bathroom and before eating.

SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted infections (STIs), commonly called sexually transmitted diseases, are infectious diseases transmitted through sexual contact, including oral, vaginal, or anal intercourse. Certain infections can be transmitted in utero to the fetus or during childbirth to the newborn leading to miscarriage, stillbirth, ectopic pregnancy, pre-term delivery, birth defects, and illness of disease (March of Dimes, 2008). [Table 15.8](#) gives information on specific STIs and their effects on the fetus or newborn. [Chapter 26](#) provides information related to HIV.

STIs are a major health concern for adolescents. The rates of many STIs are highest in adolescents (Centers for Disease Control and Prevention, 2010h). It is estimated that one in four adolescent women in the United States has an STI (Holland-Hall, 2008). Adolescents are at a greater risk for developing STIs for a variety of reasons, including frequency of unprotected intercourse, being biologically more susceptible to infection, engaging in partnerships of limited duration, and possible difficulty accessing the health care system (Centers for Disease Control and Prevention, 2010h).

Detection of STIs in infants and children is an important warning sign of potential sexual abuse. Due to the serious implications that a diagnosis of an STI can have in children, only tests that have high specificities and that can isolate an organism should be used. Also, treatment for the child with a suspected STI may be delayed until a definitive diagnosis can be made.

Nursing Assessment

Many health care providers fail to assess sexual behavior and STI risks, to screen for asymptomatic infection during clinic visits, or to counsel adolescents on STI risk reduction. Nurses need to remember that they play a key role in the detection, prevention, and treatment of STIs in adolescents and children. All states allow adolescents to give consent to confidential STI testing and treatment. [Table 15.9](#) discusses common clinical manifestations of specific STIs in adolescents.

Nursing Management

Encourage the child or adolescent to complete the antibiotic prescription. Prevention of STIs among children and adolescents is critical. Health care providers have a unique opportunity to provide counseling and education in this setting. Adapt the style, content, and message to the child or adolescent's developmental level. Identify risk factors and risk behaviors and help the adolescent develop specific individualized actions for prevention. This conversation needs to be direct and nonjudgmental.

| STI | Effects on Fetus or Newborn |
|---------------------------------------|--|
| Chlamydia | Newborn can be infected during delivery. Eye infections (neonatal conjunctivitis), pneumonia, low birthweight, increased risk of premature rupture of the membranes (PROM), preterm birth, and stillbirth |
| Gonorrhea | Newborn can be infected during delivery. Increased risk of miscarriage, PROM, and preterm birth Rhinitis, vaginitis, urethritis, inflammation of sites of fetal monitoring Gonococcal ophthalmia neonatorum can lead to blindness and sepsis (including arthritis and meningitis). |
| Herpes type 2 (genital herpes) | Contamination can occur during birth. Newborn may develop skin or mouth sores. Intellectual disability, premature birth, low birthweight, blindness, death |
| Syphilis | Can be passed in utero Can result in fetal or infant death Congenital syphilis symptoms include skin ulcers, rashes, fever, weakened or hoarse cry, swollen liver and spleen, jaundice and anemia, and various deformations. |
| Trichomoniasis | Low birthweight, increased risk of PROM and preterm birth |
| Vener eal warts | May develop warts in throat (laryngeal papillomatosis); uncommon but life-threatening |

| Disease | Causative Organism | Transmission Mode | Diagnostic Testing and Recommended Screening for Sexually Active Adolescent | Female Symptoms | Male Symptoms | Recommended Treatment |
|--|---|---|--|--|--|---|
| <p>Chlamydia Curable STI Seen frequently among sexually active adolescents and young adults Sexually active adolescents should be screened at least annually.</p> | <i>Chlamydia trachomatis</i> (bacteria) | Vaginal, anal, and oral sex and by childbirth | <p>Culture fluid from urethral swabs in males or endocervical swabs for females Noninvasive, non-culture-based testing is available using nucleic acid amplification and testing from urine—single test can test for chlamydia and gonorrhea. Conjunctival secretions in neonates Females: screen annually. Males: screen high-risk adolescents.</p> | <p>May be asymptomatic Dysuria, urinary frequency Vaginal discharge (mucus or pus) Endocervicitis May lead to pelvic inflammatory disease, ectopic pregnancy, infertility Can cause inflammation of the rectum and conjunctiva Can infect the throat from oral sexual contact with an infected partner</p> | <p>May be asymptomatic Dysuria, urethral itching Penile discharge (mucus or pus) Urethral tingling May lead to epididymitis and sterility Can cause inflammation of the rectum and conjunctiva Can infect the throat from oral sexual contact with an infected partner</p> | <p>Azithromycin (Zithromax) Doxycycline (Vibramycin) Erythromycin (EES) Ofloxacin (Floxin) Sexual partners need evaluation, testing, and treatment also. Abstinence from sexual activity until therapy complete and symptoms no longer present. Retesting in 3 to 4 months to rule out recurrence</p> |
| <p>Gonorrhea Curable STI Adolescent often coinfected with <i>Chlamydia trachomatis</i></p> | <i>Neisseria gonorrhoeae</i> (bacteria) | Vaginal, anal, and oral sex and by childbirth | <p>Gram stain or culture directly for the bacterium or same noninvasive, non-culture-based test as chlamydia Females: screen annually. Male: screen high-risk adolescents.</p> | <p>May be asymptomatic or no recognizable symptoms until serious complications such as pelvic inflammatory disease Dysuria Urinary frequency Vaginal discharge (yellow and foul) Dyspareunia Endocervicitis Arthritis May lead to pelvic inflammatory disease, ectopic pregnancy, infertility Symptoms of rectal infection include discharge, anal itching, and occasional painful bowel movements with fresh blood.</p> | <p>Most produce symptoms, but can be asymptomatic Dysuria Penile discharge (pus) Arthritis May lead to epididymitis and sterility Symptoms of rectal infection include discharge, anal itching, and occasional painful bowel movements with fresh blood.</p> | <p>Usually a single dose of one of the following: Cefixime (Suprax) Ciprofloxacin (Cipro) Ceftriaxone (Rocephin) Ofloxacin (Floxin) Levofloxacin (Levaquin) No Floxin or Cipro if younger than 18 years or pregnant! Azithromycin (Zithromax) Doxycycline (Vibramycin) Usually will be treated for coinfection with chlamydia, so a combination is given (such as ceftriaxone and doxycycline) Sexual partners need evaluation, testing, and treatment also. Abstinence from sexual activity until therapy complete and symptoms no longer present. Quinolone therapy is not recommended due to emergence of quinolone-resistant strain.</p> |
